- Because the WAN adapter creates a point-to-point connection to the ISP, any address can be entered for the gateway

address. The gateway address of 0.0.0.0 is an example. 0.0.0.0 is reserved as the unspecified IP address.

**4. Increase the number of PPTP ports**
By default, only five PPTP ports are enabled for VPN connections. The number of PPTP ports is increased to 1,000. For more information, see Add PPTP or L2TP ports.

**5. Configure PPTP packet filters**
PPTP packet filters are configured on the WAN adapter that connects to the Internet. For more information, see Add PPTP Filters.

**Domain configuration**
For each employee that is allowed VPN remote access:

- The remote access permission on the dial-in properties of the user account is set to **Allow access**.
- The user account is added to the VPN_Users group.

**Remote access policy configuration**
To define the authentication and encryption settings for remote access VPN clients, the following remote access policy is created:

- Policy name: Remote Access VPN Clients
- Conditions:
    - **NAS-Port-Type** is set to **Virtual (VPN)**
    - **Tunnel-Type** is set to **Point-to-Point Tunneling Protocol**
    - **Windows-Groups** is set to *VPN_Users* (example)
    - **Called-Station-ID** is set to *157.54.130.1* (example)
- Permission is set to **Grant remote access permission**
- Profile settings:
    - **Authentication** tab: **Microsoft Encrypted Authentication version 2 (MS-CHAP v2)** is enabled.
    - **Encryption** tab: Clear all the options except **Strongest**.

### Notes

- The **Called-Station-ID** is set to the IP address of the Internet interface for the remote access server. Only tunnels initiated from the Internet are allowed. Tunnels initiated from the Electronic, Inc. intranet are not permitted. Electronic, Inc. users that require Internet access from the Electronic, Inc. intranet must go through the Electronic, Inc. proxy server (not shown), where Internet access is controlled and monitored.
- In the access-by-user administrative model, the remote access permission on the remote access policy has no effect on granting remote access permission. However, the network administrator for Electronic, Inc. set the remote access permission on the policy to **Grant remote access permission** so that an eventual transition to an access-by-policy administrative model does not require changing all the remote access permission settings on all of the configured remote access policies.

**PPTP-based remote access client configuration**
The New Connection wizard is used to create a VPN connection with the following settings:

- VPN connection type: PPTP
- Host name or IP address: vpn.electronic.microsoft.com

**Note**

# Centralized authentication by using IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Centralized authentication by using IAS**

To spread the load between dial-up and VPN-based remote access users, the network administrator of Electronic, Inc. decided to configure a separate VPN server. To centralize the authentication and accounting functions for both the remote access server and the VPN server, a computer running Internet Authentication Service (IAS) with the IP address of 172.31.248.9 functions as a RADIUS server.

The following illustration shows the configuration of the Electronic, Inc. network for IAS-based centralized authentication and accounting.

The IAS server has its own set of remote access polices. Rather than maintain two different sets of remote access policies, one set for the remote access server and one for the VPN server, both the remote access server and the VPN server are configured to use RADIUS authentication. Therefore, both the remote access server and the VPN server are configured as RADIUS clients to the IAS server. The IAS server provides remote access authentication, authorization, and accounting for both the remote access server and the VPN server.

**Remote access policy configuration**

Once the server running Routing and Remote Access is configured to use RADIUS authentication, the remote access policies stored on the remote access server are no longer used. Instead, the remote access policies stored on the IAS server are used. Therefore, the current set of remote access policies is copied to the IAS server.

For more information, see Copy the IAS configuration to another server.

**RADIUS configuration**

To configure RADIUS authentication and accounting, the network administrator for Electronic, Inc. configures the following:

- The IAS server is configured for two RADIUS clients: the dial-up remote access server and the VPN server. For more information, see Internet Authentication Service and Add RADIUS clients.
- The dial-up server running Routing and Remote Access is configured to use RADIUS authentication and accounting (at the IP address of 172.31.248.9) and a shared secret. For more information, see Use RADIUS authentication and Use RADIUS accounting.
- The VPN server running Routing and Remote Access is configured to use RADIUS authentication and accounting (at the IP address of 172.31.248.9) and a shared secret. For more information, see Use RADIUS authentication and Use RADIUS accounting.

**Note**

- The example companies, organizations, products, people and events depicted herein are fictitious. No association with any real company, organization, product, person or event is intended or should be inferred.

This section covers:

- Remote access RADIUS attributes
- Netsh commands for remote access
- Expressing an IP address range with a mask
- Pattern matching syntax
- Remote Access Troubleshooting tools

# Remote access RADIUS attributes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote access RADIUS attributes**

The following lists the RADIUS attributes that are supported by Routing and Remote Access for the various RADIUS packet types. For more information about these attributes, see RFC 2865, "Remote Authentication Dial-in User Service (RADIUS)" and RFC 2548, "Microsoft Vendor-specific RADIUS Attributes."

**Access-Request**

- User-Name (RADIUS attribute 1)

  A string value that contains the user principal name or the Windows NT name without the domain.

- User-Password (RADIUS attribute 2)

  A string value that contains the user password and is only sent if Password Authentication Protocol (PAP) is negotiated as the authentication protocol.

- CHAP-Password (RADIUS attribute 3)

  Contains the response value provided by the Challenge Handshake Authentication Protocol (CHAP) in response to the challenge.

- NAS_IP_Address (RADIUS attribute 4)

  Contains the IP address of the remote access server.

- NAS-Port (RADIUS attribute 5)

  Indicates the number of the port on the remote access server on which the incoming call was received.

- Service-Type (RADIUS attribute 6)

  The only value that is sent is "Framed" (2).

- Framed-Protocol (RADIUS attribute 7)

  The only value that is sent is "PPP" (1).

- Framed-MTU (RADIUS attribute 12)

  Used in conjunction with EAP authentication to notify the RADIUS server of the maximum transmission unit (MTU) negotiated with the client, so that the RADIUS server does not send EAP messages that cannot be delivered over the link.

- State (RADIUS attribute 24)

  The remote access server never sends this attribute in the initial Access-Request. If EAP is used as the authentication protocol and a State attribute is received in an Access-Challenge packet, that State attribute is returned unmodified in the next Access-Request packet sent.

- Called-Station-Id (RADIUS attribute 30)

  Telephone number on which the call was received. For virtual private network (VPN) connections, the IP address of the VPN server.

- Calling-Station-Id (RADIUS attribute 31)

  Telephone number on which the call was made. For virtual private network (VPN) connections, the IP address of the VPN client.

- NAS-Identifier (RADIUS attribute 32)

  The fully qualified domain name of the remote access server.

- CHAP-Challenge (RADIUS attribute 60)

  The challenge sent by the remote access server during CHAP authentication.

- NAS-Port-Type (RADIUS attribute 61)

  The only values sent are **Async (Modem)** (0), **ISDN Sync** (2), **ISDN Async V.120** (3), **ISDN Async V.110** (4), and **Virtual (VPN)** (5). Virtual port is used to indicate VPN connections.

- Tunnel-Type (RADIUS attribute 64)

  The only values sent are PPTP (1) and L2TP (3).

- Tunnel-Medium-Type (RADIUS attribute 65)

  The only value sent is IP (1).

- Tunnel-Client-EndPoint (RADIUS attribute 66) (PPTP only)

- Tunnel-Server-EndPoint (RADIUS attribute 67) (PPTP only)

- Connect-Info (RADIUS attribute 77)

  Contains whatever data TAPI returns about the call.

- EAP-Message (RADIUS attribute 79)

- Message Authenticator (RADIUS attribute 80)

  Always sent if EAP is used for authentication. Otherwise, it is configurable on the properties of the RADIUS server.

- MS-CHAP-Response (vendor type 1)

- MS-CHAP-CPW-2 (vendor type 4)

- MS-Chap-LM-Enc-Pw (vendor type 5)

- MS-CHAP-NT-Enc-PW (vendor type 6)

- MS-Ras-Vendor (vendor type 9)

- MS-Chap-Challenge (vendor type 11)

- MS-Ras-Version (vendor type 18)

**Access-Accept**

- Service-Type (RADIUS attribute 6)

  Only Framed (2) and Callback Framed (4) are accepted. If any other Service-Type is received, the call is dropped.

- Framed-Protocol (RADIUS attribute 7)

  Only PPP (1) is accepted. If any other Framed-Protocol is received, the call is dropped.

- Framed-IP-Address (RADIUS attribute 8)

  The only acceptable values are 0xFFFFFFFF (user selects address) and 0xFFFFFFFE (remote access server selects address). If any other Framed-IP-Address is received, the call is dropped.

- Framed-MTU (RADIUS attribute 12)

  Not used.

- Framed-Compression (RADIUS attribute 13)

  The only recognized values are None (0) and VJ TCP/IP header compression (1). All other values are ignored.

- Reply-Message (RADIUS attribute 18)

  Returned in CHAP, PAP, and MS-CHAP (both v1 and v2) Success packets and in the EAP Notification message.

- Framed-Route (RADIUS attribute 22)

- State (RADIUS attribute 24)

  Returned to the remote access server unchanged.

- Class (RADIUS attribute 25)

  Sent unchanged to accounting server in Accounting Start message.

- Session-Timeout (RADIUS attribute 27)

- Idle-Timeout (RADIUS attribute 28)

- Termination-Action (RADIUS attribute 29)

  Not used.

- Port-Limit (RADIUS attribute 62)

- EAP-Message (RADIUS attribute 79)

- Message Authenticator (RADIUS attribute 80)

  Only accepted if EAP is used for authentication.

- Acct-Interim-Interval (RADIUS attribute 85)

- MS-MPPE-Encryption-Policy (vendor type 7)

- MS-MPPE-Encryption-Types (vendor type 8)

- MS-CHAP-Domain (vendor type 10)
- MS-BAP-Usage (vendor type 13)
- MS-Link-Utilization-Threshold (vendor type 14)
- MS-Link-Drop-Time-Limit (vendor type 15)
- MS-Filter (vendor type 22)

**Access-Challenge**
The Access-Challenge is only used with EAP. Otherwise, the receipt of an Access-Challenge is treated as Access-Reject.

- State (RADIUS attribute 24)
- Session-Timeout (RADIUS attribute 27)
- EAP-Message (RADIUS attribute 79)
- Message Authenticator (RADIUS attribute 80)

**Accounting-Request**

- User-Name (RADIUS attribute 1)
- NAS_IP_Addresss (RADIUS attribute 4)
- NAS-Port (RADIUS attribute 5)
- Service-Type (RADIUS attribute 6)
- Framed-Protocol (RADIUS attribute 7)
- Framed-IP-Address (RADIUS attribute 8)
- Framed-MTU (RADIUS attribute 12)
- Framed-Compression (RADIUS attribute 13)
- Framed-Route (RADIUS attribute 22)
- Class (RADIUS attribute 25)
- Session-Timeout (RADIUS attribute 27)
- Idle-Timeout (RADIUS attribute 28)
- Termination-Action (RADIUS attribute 29)
- Called-Station-Id (RADIUS attribute 30)
- Calling-Station-Id (RADIUS attribute 31)
- NAS-Identifier (RADIUS attribute 32)

- NAS-Port-Type (RADIUS attribute 61)
- Port-Limit (RADIUS attribute 62)
- Tunnel-Type (RADIUS attribute 64)
- Tunnel-Medium-Type (RADIUS attribute 65)
- Tunnel-Client-EndPoint (RADIUS attribute 66)
- Tunnel-Server-EndPoint (RADIUS attribute 67)
- Connect-Info (RADIUS attribute 77)
- Acct-Status-Type (RADIUS attribute 40)

  "On" is sent when the Routing and Remote Access service is started. "Off" is sent if the Routing and Remote Access service is gracefully stopped. "Start" and "Stop" are sent at the beginning and end of a user connection. "Interim-Update" is sent at approximately the interval specified in the Acct-Interim-Interval attribute (some random jitter is applied) and only if the Acct-Interim-Interval attribute was returned in the Access-Accept message.

- Acct-Delay-Time (RADIUS attribute 41)

  Five seconds are added on every retransmission (regardless of the actual time between retransmissions).

- Acct-Input-Octets (RADIUS attribute 42)
- Acct-Output-Octets (RADIUS attribute 43)
- Acct-Session-Id (RADIUS attribute 44)
- Acct-Authentic (RADIUS attribute 45)
- Acct-Session-Time (RADIUS attribute 46)
- Acct-Input-Packets (RADIUS attribute 47)
- Acct-Output-Packets (RADIUS attribute 48)
- Acct-Termination-Cause (RADIUS attribute 49)

  The only values sent are 1 (User Request), 4 (Idle Timeout), 5 (Session Timeout), 6 (Admin Reset), and 8 (Port Error).

- Acct-Multi-Session-Id (RADIUS attribute 50)
- Acct-Link-Count (RADIUS attribute 51)
- MS-Ras-Vendor (vendor type 9)
- MS-CHAP-Domain (vendor type 10)
- MS-Ras-Version (vendor type 18)
- MS-Filter (vendor type 22)

# Netsh commands for remote access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh commands for remote access**

The following table lists the Netsh commands that you can type at a command prompt to administer a server running Routing and Remote Access. If there are multiple commands for a particular function, they are indicated by separating the individual commands with a slash (/). For example, the command **ras add/delete/show registeredserver** is actually three separate commands: **ras add registeredserver**, **ras delete registeredserver**, and **ras show registeredserver**.

When you type the command at the command prompt, precede each command with **netsh**. For the exact syntax of each command, type the command with the **?** option. For example, to receive command-line Help on the **netsh ras add registeredserver** command, type **netsh ras add registeredserver ?** at the command prompt.

| Command | Description |
|---|---|
| **ras add/delete/show registeredserver** | Configures or displays whether the specified remote access server computer is a member of the **RAS and IAS Servers** security group in the Active Directory directory service of the specified domain. |
| **ras show activeservers** | Displays current servers running Routing and Remote Access on your network. |
| **ras set/show authmode** | Configures or displays whether and when dial-in connections are authenticated. |
| **ras add/delete/show authtype** | Configures or displays the permitted authentication types. |
| **ras add/delete/show client** | Configures or displays currently connected remote access clients. |
| **ras add/delete/show link** | Configures or displays the configuration of software compression and link control protocol (LCP) extensions. |
| **ras add/delete/show multilink** | Configures or displays Multilink and Bandwidth Allocation Protocol (BAP) settings. |
| **ras set/show tracing** | Configures or displays tracing settings. |
| **ras set/show user** | Configures or displays remote access settings for user accounts. |
| **ras ip set access** | Configures whether IP traffic from remote access clients is forwarded to the networks to which the remote access server is connected. |
| **ras ip set addrassign** | Configures the method by which the remote access server assigns IP addresses to incoming connections. |
| **ras ip set addrreq** | Configures whether remote access clients or demand-dial routers can request their own IP addresses. |
| **ras ip show config** | Displays IP remote access configuration. |
| **ras ip set negotiation** | Configures whether IP is negotiated for remote access connections. |
| **ras ip delete pool** | Deletes the static IP address pool. |
| **ras ip add/delete range** | Adds or removes a range of addresses from the static IP address pool. |
| **ras appletalk set access** | Configures whether AppleTalk traffic from remote access clients is forwarded to the networks to which the remote access server is connected. |

| | |
|---|---|
| **ras appletalk show config** | Displays AppleTalk remote access configuration. |
| **ras appletalk set negotiation** | Configures whether AppleTalk is negotiated for remote access connections. |
| **ras aaaa set/show accounting** | Configures or displays the accounting provider. |
| **ras aaaa add/delete/set/show acctserver** | Configures or displays RADIUS accounting servers. |
| **ras aaaa set/show authentication** | Configures or displays the authentication provider. |
| **ras aaaa add/delete/set/show authserver** | Configures or displays RADIUS authentication servers. |

For more information about Netsh, see The Netsh Command-Line Utility.

# Expressing an IP address range with a mask

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Expressing an IP address range with a mask**

In some cases, Routing and Remote Access allows you to enter a range of IP addresses as a starting and ending range. For example, when creating a DHCP scope, you enter the IP address range as 10.0.0.1 through 10.0.0.199. In this case, a suitable range for an arbitrary number of required IP addresses is specified.

In other cases, Routing and Remote Access requires you to enter a range of IP addresses as an IP address and mask. In these cases, a range for an arbitrary number of required IP addresses cannot be specified due to the mathematical relationship between the IP address and the mask. When expressing an IP address range in this way, you must choose a base IP address and a mask.

- An IP address is a 32-bit number that is expressed as a series of 4 octets converted to base 10 and separated by the period character. This is commonly known as dotted decimal notation. The base IP address contains a series of bits that are fixed and a series of bits that are variable. The bits that are fixed must be a set of contiguous bits starting from the high order bit. The range of IP addresses formed from the base IP address is the set of addresses defined by all of the possible values of the variable bits.

- The mask is a 32-bit number (also expressed in dotted decimal notation) that is used to explicitly define which bits in the base IP address are fixed and which bits are variable. In the mask, a 1 bit is used to indicate a bit in the IP address that is fixed. A fixed bit cannot be used to express the range. A 0 bit in the mask is used to indicate a bit in the IP address that is variable.

Because the bits that are fixed in the base IP address must be contiguous from the high order bit, a mask must consist of a series of contiguous 1 bits that represent the fixed portion of the address followed by a series of contiguous 0 bits that represent the variable portion of the address.

The following table shows examples of valid masks.

| Subnet mask (binary) | Subnet mask (decimal) |
|---|---|
| 11111111 11111111 11110000 00000000 | 255.255.240.0 |
| 11111111 11111111 11111111 00000000 | 255.255.255.0 |
| 11111111 11111111 11111111 11100000 | 255.255.255.224 |

The following table shows examples of invalid masks.

| Subnet mask (binary) | Subnet mask (decimal) |
|---|---|
| 11111111 11111111 10110000 00000000 | 255.255.176.0 |
| 11111111 11111111 11110000 11110000 | 255.255.240.240 |
| 11111111 11111111 11111111 00000111 | 255.255.255.7 |

The base IP address, the mask, and the range of addresses are related to each other by a mathematical operation called a bit-wise logical AND. In a bit-wise logical AND, the 32 bits of an IP address are lined up with the 32 bits of the mask. For each bit, a logical AND is performed. In a logical AND, the result is a 1 if both bits being compared are a 1 and a 0 otherwise.

Because the variable bits in the mask are always 0, the bit-wise logical AND of any IP address in the range (including the base IP address) and the mask always produces the same result: the base IP address.

The base IP address cannot have a 1 where there is a 0 in the mask. A bit-wise logical AND of a 1 with a 0 always produces a 0. Therefore, a base IP address with a 1 where there is a 0 in the mask will, when a bit-wise logical AND is used with the mask, not produce the base IP address. This is the reason for the error message: "The network mask entered is not valid. The destination address cannot be more specific than the network mask."

The base IP address that contains a 1 where there is a 0 is more specific than the mask. A base IP address can be less specific than the mask, but not more specific.

The following table shows an example of a valid address range.

| | Binary | Decimal |
|---|---|---|
| **Base IP address** | 11000000 10101000 10011100 00000000 | 192.168.156.0 |
| **Mask** | 11111111 11111111 11111100 00000000 | 255.255.252.0 |

In this example, the first 22 bits are fixed and the last 10 bits are variable. Notice how the bit-wise logical AND of the base IP address and the mask produces the base IP address (192.168.156.0 AND 255.255.252.0 = 192.168.156.0).

The following table shows an example of a invalid address range.

| | Binary | Decimal |
|---|---|---|
| **Base IP address** | 11000000 10101000 00111001 00000000 | 192.168.57.0 |
| **Mask** | 11111111 11111111 11110000 00000000 | 255.255.240.0 |

In this example, there are two bits in the base IP address set to 1 that are not included in the mask. Notice how the bit-wise logical AND of the base IP address and the mask does not produce the base IP address (192.168.57.0 AND 255.255.240.0 = 192.168.48.0).

**Multicast scopes**

The base IP address and mask that you choose for multicast scopes depends on two factors:

1. The originating address space

   The originating address space is the original set of addresses from which a range is being defined. For example, when defining multicast scopes, the originating address space is from 239.0.0.0 through 239.254.255.255.

2. The number of addresses needed

   The following table lists the mask needed based on a required number of addresses.

| Number of addresses required | Number of fixed bits | Number of variable bits | Mask |
|---|---|---|---|
| 1-2 | 31 | 1 | 255.255.255.254 |
| 3-4 | 30 | 2 | 255.255.255.252 |
| 5-8 | 29 | 3 | 255.255.255.248 |
| 9-16 | 28 | 4 | 255.255.255.240 |
| 17-32 | 27 | 5 | 255.255.255.224 |
| 33-64 | 26 | 6 | 255.255.255.192 |
| 65-128 | 25 | 7 | 255.255.255.128 |
| 129-256 | 24 | 8 | 255.255.255.0 |
| 257-512 | 23 | 9 | 255.255.254.0 |
| 513-1,024 | 22 | 10 | 255.255.252.0 |
| 1,025-2,048 | 21 | 11 | 255.255.248.0 |
| 2,049-4,096 | 20 | 12 | 255.255.240.0 |

| | | | |
|---|---|---|---|
| 4,097-8,192 | 19 | 13 | 255.255.224.0 |
| 8,193-16,384 | 18 | 14 | 255.255.192.0 |
| 16,385-32,768 | 17 | 15 | 255.255.128.0 |
| 32,769-65,536 | 16 | 16 | 255.255.0.0 |
| 65,537-131,072 | 15 | 17 | 255.254.0.0 |
| 131,073-262,144 | 14 | 18 | 255.252.0.0 |
| 262,145-524,288 | 13 | 19 | 255.248.0.0 |
| 524,289-1,048,576 | 12 | 20 | 255.240.0.0 |
| 1,048,577-2,097,152 | 11 | 21 | 255.224.0.0 |
| 2,097,153-4,194,304 | 10 | 22 | 255.192.0.0 |
| 4,194,305-8,388,608 | 9 | 23 | 255.128.0.0 |
| 8,388,609-16,777,216 | 8 | 24 | 255.0.0.0 |

Based on the base IP address, the range is defined as follows:

- The first IP address in the range is the base IP address.
- The last IP address in the range is the address obtained by setting all the variable bits to a 1 and then expressing the result in dotted decimal notation.

The following table shows an example for a multicast scope.

| | **Decimal** | **Binary** |
|---|---|---|
| **IP address** | 239.0.64.0 | 11101111 00000000 01000000 00000000 |
| **Mask** | 255.255.192.0 | 11111111 11111111 11000000 00000000 |
| **First IP address** | 239.0.64.0 | 11101111 00000000 01000000 00000000 |
| **Last IP address** | 239.0.128.255 | 11101111 00000000 01111111 11111111 |

# Pattern matching syntax

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Pattern matching syntax**

Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition support regular expressions for pattern matching, which is widely used in UNIX environments. You can use this syntax to specify the conditions of remote access policy attributes and RADIUS realms, as specified in the following table.

| Character | Description | Example |
|---|---|---|
| \ | Marks the next character as a character to match. | /n/ matches the character "n". The sequence /\n/ matches a line feed or newline character. |
| ^ | Matches the beginning of the input or line. | |
| $ | Matches the end of the input or line. | |
| * | Matches the preceding character zero or more times. | /zo*/ matches either "z" or "zoo." |
| + | Matches the preceding character one or more times. | /zo+/ matches "zoo" but not "z." |
| ? | Matches the preceding character zero or one times. | /a?ve?/ matches the "ve" in "never." |
| . | Matches any single character except a newline character. | |
| **(** *pattern* **)** | Matches *pattern* and remembers the match. To match ( ) (parentheses), use "\(" or "\)". | |
| *x* **\|** *y* | Matches either *x* or *y*. | /z\|food?/ matches "zoo" or "food." |
| **{** *n* **}** | Matches exactly *n* times (*n* is a nonnegative integer). | /o{2}/ does not match the "o" in "Bob," but matches the first two instances of the letter o in "foooood." |
| **{** *n* **,}** | Matches at least *n* times (*n* is a nonnegative integer). | /o{2,}/ does not match the "o" in "Bob" but matches all of the instances of the letter o in "foooood." /o{1,}/ is equivalent to /o+/. |
| **{** *n* **,** *m* **}** | Matches at least *n* and at most *m* times (*m* and *n* are nonnegative integers). | /o{1,3}/ matches the first three instances of the letter o in "fooooood." |
| **[** *xyz* **]** | Matches any one of the enclosed characters (a character set). | /[abc]/ matches the "a" in "plain." |
| **[^** *xyz* **]** | Matches any characters that are not enclosed (a negative character set). | /[^abc]/ matches the "p" in "plain." |
| **\b** | Matches a word boundary (for example, a space). | /ea*r\b/ matches the "er" in "never early." |
| **\B** | Matches a nonword boundary. | /ea*r\B/ matches the "ear" in "never early." |
| **\d** | Matches a digit character (equivalent to [0-9]). | |
| **\D** | Matches a nondigit character (equivalent to [^0-9]). | |
| **\f** | Matches a form feed character. | |
| **\n** | Matches a line feed character. | |

| | | |
|---|---|---|
| **\r** | Matches a carriage return character. | |
| **\s** | Matches any white space character including space, tab, and form feed (equivalent to [ \f\n\r\t\v]). | |
| **\S** | Matches any non-white space character (equivalent to [^ \f\n\r\t\v]). | |
| **\t** | Matches a tab character. | |
| **\v** | Matches a vertical tab character. | |
| **\w** | Matches any word character, including underscore (equivalent to [A-Za-z0-9_]). | |
| **\W** | Matches any nonword character, excluding underscore (equivalent to [^A-Za-z0-9_]). | |
| **** *num* | Refers to remembered matches (?*num*, where *num* is a positive integer). For example, \1 replaces what is stored in the first remembered match. This option can be used only in the **Replace** text box when configuring attribute manipulation. | |
| **/** *n* **/** | Allows the insertion of ASCII codes into regular expressions (?*n*, where *n* is an octal, hexadecimal, or decimal escape value). | |

**Examples for remote access policy attributes**

The following examples describe the use of the pattern matching syntax to specify remote access policy attributes:

- To specify all phone numbers within the 899 area code, the syntax is:

  899.*

- To specify a range of all IP addresses that begin with 192.168.1, the syntax is:

  192\.168\.1\..+

**Examples for manipulation of the realm name in the User-Name attribute**

The following examples describe the use of the pattern matching syntax to manipulate realm names for the User-Name attribute, which is located on the **Attribute** tab in the properties of a connection request policy. For more information, see Configure attribute manipulation.

- To remove the realm portion of the User-Name attribute

  In the outsourced dial scenario, the Internet service provider (ISP) might require a realm name to route the authentication request. However, the IAS server might not recognize the realm name portion of the user name. Therefore, the realm name must be removed before it is forwarded to the IAS server.

  - **Find:** @microsoft\.com
  - **Replace:**

- To replace *user@example.microsoft.com* with *example.microsoft.com\user*

  - **Find:** (.*)@(.*)
  - **Replace:** $2\$1

- To replace *domain\user* with *specific_domain\user*

  - **Find:** (.*)\\(.*)

- **Replace:** *specific_domain*\$2

- To replace *user* with *user@specific_domain*

  - **Find:** $

  - **Replace:** *@specific_domain*

**Example for RADIUS message forwarding by a proxy server**
You can create routing rules that forward RADIUS messages with a specific realm name to a specific set of RADIUS servers when IAS is used as a RADIUS proxy. Following is a recommended syntax for routing requests based on realm name.

| NetBIOS name | Pattern |
|---|---|
| WCOAST | ^wcoast\\ |

In the following example, wcoast.microsoft.com is a unique user principal name (UPN) suffix for the DNS or Active Directory domain wcoast.microsoft.com. Using the supplied pattern, the IAS proxy can route messages based on domain NetBIOS name or UPN suffix.

| NetBIOS name | UPN suffix | Pattern |
|---|---|---|
| WCOAST | wcoast.microsoft.com | ^wcoast\\\|@wcoast\.microsoft\.com$ |

**Ping user-name**
Some RADIUS proxy servers and network access servers periodically send authentication and accounting requests (known as ping requests) to verify that the IAS server is present on the network. These ping requests include fictional user names. When IAS processes these requests, the event and accounting logs become filled with access reject records, making it more difficult to keep track of valid records.

When you configure a registry entry for **ping user-name**, IAS matches the registry entry value against the user name value in ping requests by other servers. A **ping user-name** registry entry specifies the fictional user name (or a user name pattern, with variables, that matches the fictional user name) sent by RADIUS proxy servers and network access servers. When IAS receives ping requests that match the **ping user-name** registry entry value, IAS rejects the authentication requests without processing the request. IAS does not record transactions involving the fictional user name in any log files, which makes the event log easier to interpret.

### Note

- **Ping user-name** is not installed by default. You must add **ping user-name** to the registry. You can add an entry to the registry using Registry Editor. For more information, see Registry Editor.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**Adding ping user-name to the registry**
**Ping user-name** can be added to the following registry key as a string value by a member of the local Administrators group:

**HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\IAS\Parameters**

| Name | Type | Data |
|---|---|---|
| ping user-name | REG_SZ | *User name* |

### Note

- To indicate more than one user name for a **ping user-name** value, enter a name pattern, such as a Domain Name

System (DNS) name including wildcard characters, in **Data**.

# Remote Access Troubleshooting tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting tools**
To help you gather information to troubleshoot problems with the remote access server, the following troubleshooting tools are available:

- Authentication and accounting logging. For more information see Logging.
- Event logging records errors, warnings, and events in the system event log.
- PPP logging creates a log file of the PPP control messages that are sent and received during a PPP connection.
- Tracing records the sequence of programming functions called during a process to a file. For more information, see Using tracing.
- Network Monitor captures traffic sent between a remote access server and dial-up client during the PPP connection process and during data transfer.
- Netsh commands for remote access configure and display remote access settings for a server running Routing and Remote Access. For more information, see Netsh commands for remote access (ras).

**Remote Access Diagnostics**
You can use the Remote Access diagnostic functions available in the Windows Server 2003 family to collect detailed logs and information about a remote access connection. Diagnostics can be set from the **Diagnostics** tab of the properties of the connection in the Network Connection folder, or you can run specific diagnostics by typing the **netsh ras diagnostics** command at the command line.

**Audit logging and Oakley logging for L2TP/IPSec connections**
You can use the Audit Logging feature to monitor IPSec-related events. This is the fastest and simplest method to troubleshoot unsuccessful L2TP/IPSec connections. You can also enable the Oakley log to record all ISAKMP main mode or quick mode negotiations. For more information, see IPSec troubleshooting tools.

**Event logging**
You can use event logging to record remote access server errors, warnings, and other detailed information in the system event log. You can enable event logging on the **Event Logging** tab on the properties of a remote access server. For more information, see View properties of the remote access server.

**PPP logging**
PPP logging records the series of programming functions and PPP control messages during a PPP connection and is a valuable source of troubleshooting information when you are troubleshooting the failure of a PPP connection. To enable PPP logging, select the **Enable Point-to-Point Protocol (PPP) logging** option on the **PPP** tab on the properties of a remote access server. For more information, see View properties of the remote access server.

The PPP log in Windows NT 4.0 has been replaced by the tracing function. To duplicate the PPP log, you need to enable file tracing for the PPP key. By default, the PPP log is stored as the ppp.log file in the *systemroot*\Tracing folder. For more information on tracing options, see Using tracing.

**Network Monitor**
Network Monitor can capture the network traffic between a dial-up networking client and the remote access server. By analyzing remote access traffic, you can find answers to remote access problems and possible solutions or workarounds. For more information, see Install and Configure Network Monitor.

### Note

- The proper interpretation of remote access traffic with Network Monitor requires an in-depth understanding of PPP and other protocols. You can save Network Monitor traces as files and send them to Microsoft Product Support Services for analysis.

# Remote Access Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Unable to establish a remote access connection.
- Unable to access resources beyond the remote access server.
- Callback is not working.
- Not sure how to configure the remote access server to make as well as receive remote access connections (dial out and dial in).

**Unable to establish a remote access connection.**
**Cause:** Your modem is not working properly.

**Solution:** Verify that your modem is working properly.

**See also:** Troubleshooting modems

**Cause:** The Routing and Remote Access service is not started on the remote access server.

**Solution:** Verify the state of the Routing and Remote Access service on the remote access server.

**See also:** Monitor the Routing and Remote Access service

**Cause:** Remote access is not enabled on the remote access server.

**Solution:** Enable remote access on the remote access server.

**See also:** Enable the remote access server

**Cause:** Dial-in, PPTP, or L2TP ports are not enabled for inbound remote access connections.

**Solution:** Enable PPTP, L2TP, or dial-in ports for inbound remote access connections, as needed.

**See also:** Configure ports for remote access

**Cause:** The LAN protocols being used by the remote access clients are not configured on the remote access server to allow remote access connections.

**Solution:** Verify that remote access connections are allowed on the **IP** or **AppleTalk** tabs on the properties of a server. If you do not have one or more of these tabs, then the corresponding network protocol is not installed on the server.

**See also:** View properties of the remote access server

**Cause:** All of the remote access ports on the remote access server are already being used by currently connected remote access clients or demand-dial routers.

**Solution:** You can verify whether all of the remote access ports on the remote access server are not already being used by clicking **Ports** in Routing and Remote Access. If all ports are busy, disconnect any inactive connections, or consider adding more ports.

**Cause:** The remote access client and the remote access server in conjunction with a remote access policy are not configured to use at least one common authentication method.

**Solution:** Configure the remote access client and the remote access server in conjunction with a remote access policy to use at least one common authentication method.

If a remote access client running Windows 95 is attempting a dial-up connection, verify that the remote access server is not

requiring only MS-CHAP v2 authentication. A remote access client running Windows 95 supports the use of MS-CHAP v2 over virtual private network (VPN) connections, not the use of MS-CHAP v2 over dial-up connections.

**Cause:** The remote access client and the remote access server in conjunction with a remote access policy are not configured to use at least one common encryption strength.

**Solution:** Configure the remote access client and the remote access server in conjunction with a remote access policy to use at least one common encryption strength.

**See also:** Configure encryption

**Cause:** The remote access connection does not have the appropriate permissions through dial-in properties of the user account and remote access policies.

**Solution:** Verify that the remote access connection has the appropriate permissions through dial-in properties of the user account and remote access policies.

In order for the connection to be established, the settings of the connection attempt must:

- Match all of the conditions of at least one remote access policy.
- Be granted remote access permission through the local user account (set to **Allow access**), or through the domain user account (set to **Control access through Remote Access Policy**) and the remote access permission of the matching remote access policy (set to **Grant remote access permission**).
- Match all the settings of the profile.
- Match all the settings of the dial-in properties of the user account.

**See also:** Introduction to remote access policies; Accepting a connection attempt

**Cause:** The settings of the remote access policy profile are in conflict with properties of the remote access server.

**Solution:** Verify that the settings of the remote access policy profile are not in conflict with properties of the remote access server.

The properties of the remote access policy profile and the properties of the remote access server both contain settings for:

- Multilink
- Bandwidth allocation protocol
- Authentication protocols

If the settings of the profile of the matching remote access policy are in conflict with the settings of the remote access server, the connection attempt is rejected. For example, if the matching remote access policy profile specifies that the EAP-TLS authentication protocol must be used and EAP is not enabled on the remote access server, the connection attempt is rejected.

**See also:** Enable authentication protocols; Configure authentication

**Cause:** The credentials of the remote access client (user name, password, and domain name) are incorrect and cannot be validated by the remote access server.

**Solution:** Verify that the credentials of the remote access client (user name, password, and domain name) are correct and can be validated by the remote access server.

**Cause:** There are not enough addresses in the static IP address pool.

**Solution:** If the remote access server is configured with a static IP address pool, verify that there are enough addresses in the pool. If all of the addresses in the static pool have been allocated to connected remote access clients, the remote access server is unable to allocate an IP address, and the connection attempt is rejected. Modify the static IP address pool if needed.

**See also:** Create a static IP address pool

**Cause:** The authentication provider of the remote access server is improperly configured.

**Solution:** Verify the configuration of the authentication provider. You can configure the remote access server to use either Windows Authentication or Remote Authentication Dial-In User Service (RADIUS) to authenticate the credentials of the remote access client.

**See also:** Use RADIUS authentication

**Cause:** The remote access server cannot access Active Directory.

**Solution:** For a remote access server that is a member server of a domain that is configured for Windows Authentication, verify that:

- The **RAS and IAS Servers** security group exists. If not, then create the group and set the group type to **Security** and the group scope to **Domain local**.

- The **RAS and IAS Servers** security group has Read permission to the **RAS and IAS Servers Access Check** object.

- The computer account of the remote access server computer is a member of the **RAS and IAS Servers** security group. You can use the **netsh ras show registeredserver** command to view the current registration. You can use the **netsh ras add registeredserver** command to register the server in a specified domain.

  If you add or remove the remote access server to the **RAS and IAS Servers** security group, the change does not take effect immediately (due to the way that Active Directory information is cached). For the change to take effect immediately, you need to restart the remote access server computer.

- The remote access server has joined the domain.

**See also:** Create a new group; Verify permissions for the RAS and IAS security group; Netsh commands for remote access

**Cause:** A remote access server running Windows NT 4.0 cannot validate connection requests.

**Solution:** If remote access clients are dialing in to a remote access server running Windows NT 4.0 that is a member of a Windows 2000 mixed domain, verify that the Everyone group is added to the Pre-Windows 2000 Compatible Access group with the **net localgroup "Pre-Windows 2000 Compatible Access"** command. If not, type **net localgroup "Pre-Windows 2000 Compatible Access" everyone /add** at the command prompt on a domain controller computer and then restart the domain controller computer.

**See also:** Member server in a domain

**Cause:** The Windows Fax service is enabled and your modem does not support adaptive answer.

**Solution:** If the Windows Fax service and the Routing and Remote Access service are sharing the same modem, verify that the modem supports adaptive answer. If the modem does not support adaptive answer, you must disable fax on the modem to receive incoming remote access connections.

**Cause:** You are using MS-CHAP v1 and a user password over 14 characters long.

**Solution:** Either use a different authentication protocol such as MS-CHAP v2 or change your password so that it is 14 characters or less.

**See also:** MS-CHAP; Enable authentication protocols

**Unable to access resources beyond the remote access server.**
**Cause:** For IP-based remote access clients, IP routing is not enabled.

**Solution:** Verify that IP routing is enabled on the **IP** tab on the properties of the server.

**See also:** View properties of the remote access server

**Cause:** For AppleTalk-based remote access clients, network access is not allowed.

**Solution:** Verify that network access is allowed on the **AppleTalk** tab on the properties of a server. If you do not have the AppleTalk tab, then AppleTalk is not installed on the server.

**See also:** View properties of the remote access server

**Cause:** A static IP address pool is configured but there are no routes back to the remote access clients.

**Solution:** If the remote access server is configured to use a static IP address pool, verify that the routes to the ranges of addresses of the static IP address pool are reachable by the hosts and routers of the intranet. If not, then IP routes consisting of the address ranges of the static IP address pool, as defined by the IP address and mask of each range, must be added to the routers of the intranet or the routing protocol of your routed infrastructure on the remote access server must be enabled. If the routes to the remote access client subnets are not present, remote access clients cannot receive traffic from locations on the intranet. A route for the network is implemented either through static routing entries or through a routing protocol, such as Open Shortest Path First (OSPF) or Routing Information Protocol (RIP). OSPF is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

If the remote access server is configured to use DHCP for IP address allocation and no DHCP server is available, the remote access server allocates addresses from the Automatic Private IP Addressing (APIPA) address range from 169.254.0.1 through 169.254.255.254. Allocating APIPA addresses for remote access clients works only if the network to which the remote access server is attached is also using APIPA addresses.

If the remote access server is using APIPA addresses when a DHCP server is available, verify that the proper adapter is selected from which to obtain DHCP-allocated IP addresses. By default, the remote access server randomly chooses the adapter to use to obtain IP addresses through DHCP. If there is more than one LAN adapter, then the Routing and Remote Access service may choose a LAN adapter for which there is no DHCP server available.

If the static IP address pool consists of ranges of IP addresses that are a subset of the range of IP addresses for the network to which the remote access server is attached, verify that the ranges of IP addresses of the static IP address pool are not assigned to other TCP/IP nodes, either through static configuration or through DHCP.

**See also:** Create a static IP address pool

**Cause:** Packet filters on the remote access policy profile are preventing the flow of IP traffic.

**Solution:** Verify that there are no configured TCP/IP packet filters on the profile properties of the remote access policies on the remote access server (or the RADIUS server if Internet Authentication Service is used) that are preventing the sending or receiving of TCP/IP traffic.

You can use remote access policies to configure TCP/IP input and output packet filters that control the exact nature of TCP/IP traffic allowed on the remote access connection. Verify that the profile TCP/IP packet filters are not preventing the flow of needed traffic.

**See also:** Configure IP options

**Callback is not working.**
**Cause:** Callback is improperly configured on the dial-in properties of the user account.

**Solution:** Verify the callback configuration on the dial-in properties of the user account.

**See also:** Configure caller ID and callback

**Cause:** **Link control protocol (LCP) extensions** is disabled on the **PPP** tab for the properties of the remote access server.

**Solution:** Enable **Link control protocol (LCP) extensions** on the **PPP** tab for the properties of the remote access server.

**See also:** View properties of the remote access server

**Cause:** Callback numbers may be truncated when a remote access server running Windows NT 4.0 requests dial-in properties of a user account in a Windows 2000 native or Windows Server 2003 domain.

**Solution:** Reconfigure callback numbers on the dial-in properties of the user account.

**See also:** Configure caller ID and callback

For more information on troubleshooting remote access VPN connections, see Troubleshooting remote access VPNs.

To reset Routing and Remote Access back to default values, see Reset the Routing and Remote Access service.

**Not sure how to configure the remote access server to make as well as receive remote access connections (dial out and dial in).**
**Cause:** The remote access server is either not configured as a remote access server (dial in) or not configured for demand-dial routing (dial out).

**Solution:** In the console tree, right-click the remote access server, and click **Properties**. On the **General** tab, make sure that both the **Router** and the **Remote access server** check boxes are selected, and make sure that the **LAN and demand-dial routing** option is selected under **Router**. If these options are not configured, configure them, and click **OK**. In the console tree, click **Network Interfaces** and make sure that you have configured demand-dial interfaces for dialing out to the servers or services to which you want to connect. If no demand-dial interfaces exist, right-click **Network Interfaces**, and click **New Demand-dial Interface**.

**See also:** Demand-dial routing; Routing over VPN connections; Overview of remote access

# Connection Manager Administration Kit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connection Manager Administration Kit**
Connection Manager is a versatile client dialer and connection software that you can customize by using the Connection Manager Administration Kit (CMAK) wizard.

- For an overview of CMAK and its audience, see Connection Manager Administration Kit Welcome.
- Before installing CMAK, see Before You Start: Understanding Connection Manager and the Administration Kit.
- To understand your customization options and how to select the options most appropriate to your needs and those of your users, see Phase One: Planning.
- For information on how to design and develop custom graphics, text, programs, and other elements to support your needs, see Phase Two: Developing Custom Elements.
- For information on how to create your service profiles using the CMAK wizard and advanced customization techniques, see Phase Three: Running the CMAK Wizard and Creating a Service Profile.
- For information on delivery options and methods, see Phase Four: Preparing for Integration, Delivery, and Installation.
- For information on testing and verifying your customizations, see Phase Five: Testing Your Deliverables.
- For problem-solving instructions and other support information, including answers to Frequently Asked Questions about Connection Manager and CMAK, see Phase Six: Supporting Your Customers.

# Connection Manager Administration Kit Welcome

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Welcome**
Before you run the Connection Manager Administration Kit (CMAK) wizard, you should plan and develop the Connection Manager custom elements that you want in your client dialer. Then, simply run the CMAK wizard, answering the questions and providing the information about your custom elements. The CMAK wizard then builds a service profile, which is a set of files which you distribute to your users so that they can easily install and run your custom version of Connection Manager.

**Audience**
The CMAK wizard and this documentation is designed for the network administrators, information officers, and other team members responsible for the design, development, testing, distribution, and support of connection software for the customers who connect to your Internet or network service.

**About this documentation**
The CMAK wizard provides defaults that support quick and easy creation of a basic Connection Manager service profile. If you want to use all of the defaults and do not want to take advantage of the many customizable elements, you probably do not need this documentation.

However, if you want a custom dialer that promotes your brand and supports more advanced functions, such as automatic phone book updates and support for virtual private networking, you need this documentation to help you effectively plan and implement your custom elements.

### Notes

- The information in this documentation is based on the assumption that you have already installed the CMAK software. For more information on evaluating Connection Manager, see the Microsoft Web site.

- You can display this documentation directly from the CMAK wizard by clicking **Help**. When you click **Help** in a pane of the CMAK wizard, the Help topic associated with that specific pane appears.

# Before You Start: Understanding Connection Manager and the Administration Kit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Before you start: Understanding Connection Manager and the Administration Kit**
Connection Manager provides a customized remote access client so your customers can connect to your service using connection features that you define. The Connection Manager Administration Kit (CMAK) wizard simplifies the customization process by providing a graphical interface that you use to specify custom elements for your service. It then builds your customized installation package for you. This section covers the information you need to know before starting the customization process:

- Connection Manager components and system requirements
- Connection Manager features
- Connection Manager user interface
- The Connection Manager Administration Kit Wizard
- The Connection Manager Administration Kit and the customization process
- Connection Point Services and Connection Manager

# Connection Manager components and system requirements

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connection Manager components and system requirements**
This section covers the system requirements for Connection Manager and its components.

Connection Manager requires at least 2 megabytes (MB) of free disk space and one of the following:

- Windows 95
- Windows 98
- Windows NT Workstation 4.0
- Windows 2000
- Windows Millennium Edition
- Windows XP
- Windows Server 2003 family
- Internet Explorer 4.01, 5.0, 5.5, or 6.0. Users do not have to have Internet Explorer set as their default browser or use the software.

Disk-space requirements for each system vary, based on the elements included in the service profile. For information on determining the size of the complete deliverable, see Planning for effective implementation.

For dial-up connections, Connection Manager also requires a 28.8 modem or faster connection. Connection Manager can automatically configure the modem. If you include Connection Manager in the service profile, the user's modem is configured as needed to support Connection Manager.

Connection Manager requires Transmission Control Protocol/Internet Protocol (TCP/IP) (for peer connections in a network), Telephony Application Programming Interface (TAPI) (for dialing support), and Point-to-Point Tunneling Protocol (PPTP) or Layer Two Tunneling Protocol (L2TP) (to establish a VPN connection), but when Connection Manager installs, it automatically installs the appropriate level of software on computers with operating systems that do not have the appropriate level. There are two exceptions. On Windows NT 4.0, the user must manually set up PPTP (in **Remote Access Setup**). For information that you can provide to your users on how to set up PPTP on Windows NT 4.0, see Providing user documentation. On Windows 95, Windows 98, Windows Millennium Edition, and Windows NT 4.0, users must install Microsoft L2TP/IPSec VPN Client in order to set up L2TP. For more information about Microsoft L2TP/IPSec VPN Client, see the Microsoft Web site .

If your service profile supports PPTP VPN connections, any users who are running Windows 95 on their computers must have the latest connection software installed on their computers to establish a VPN connection. For more information on this requirement, see Implementing VPN support. For information that you can provide to your users to update their connection software, see Providing user documentation.

**Notes**

- It is recommended that your clients install the latest service pack for their operating systems before installing a Connection Manager service profile.
- If your Connection Manager profile includes phone book downloads, your users must have a version of Internet Explorer installed on their computers, as noted above. Users do not have to have Internet Explorer set as their default browser or use the software.

# Connection Manager features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connection Manager features**

Connection Manager 1.3 provides support for local and remote connections to your service using a network of access points, such as those available worldwide through Internet service providers (ISPs). If your service requires secure connections over the Internet, you can use Connection Manager to establish virtual private network (VPN) connections to your service. Following are some of the features supported by Connection Manager 1.3.

**New features of Connection Manager 1.3**

Connection Manager provides the following new features:

- **VPN server selection** If you include a VPN file and configure VPN entries, your users will be able to choose what VPN server to use when making a connection.
- **Log files** Log files for a connection can be created, cleared, and viewed by the user.
- **Favorites** Users can define the properties of a connection, save these settings for future use, and pick the favorite to use from the Connection Manager user interface. For example, a user can configure location properties and dialing rules for connecting to the office from home and from a frequent business travel location, and then the user can choose between these two sets of settings when connecting.
- **Provide user name and password for the service profile** An administrator can pre-populate the User Name and Password fields of a Connection Manager profile for first-time or permanent use.
- **Terminal windows** Connection Manager 1.3 supports the use of a terminal window on all supported platforms except Windows NT 4.0.
- **Network Access Quarantine Control** Formerly a feature installed through the Windows Server 2003 Resource Kit Tools, the Remote Access Quarantine Server (RQS) and Remote Access Quarantine Client (RQC) components are available as part of Windows Server 2003 operating systems with Service Pack 1 installed. RQC is available as a pre-defined custom action in the Connection Manager Administration Kit wizard, although you will have to customize it to meet the needs of your individual network. For more information about Network Access Quarantine Control, see Related Topics.

**General connection support**

Connection Manager supports a variety of features that both simplify and enhance implementation of connection support for you and your users. Most of these features can be incorporated using the Connection Manager Administration Kit (CMAK) wizard:

| Feature | Support |
|---|---|
| Routing table updates | You can reconfigure user routing tables in order to better manage your network traffic and security. |
| Automatic proxy configuration | You can configure user proxy settings to ensure that the user has appropriate access to internal and external resources while connected to your service. |
| Branding | You can customize the graphics, icons, messages, Help, and phone book support in Connection Manager to provide an identity and support that are unique to your service or corporation. You can include custom logos, customer support, and phone book information to identify and represent your company. |

| | |
|---|---|
| Custom actions and monitored applications | You can incorporate custom functionality, including your own programs to enhance the connection experience for your users. These programs can be automatically run at various points during the connection process, such as when users log on or disconnect. Connection Manager also supports pre-connect and pre-tunnel actions. And you can set up monitored applications to automatically disconnect after the program ends. |
| Multiple user support for each service profile | You can provide support for users who share computers. User profiles allow two or more people to use the same computer and the same service profile. Credentials are maintained, based on the logon ID of the user, so users do not have to re-enter them for each connection. |
| Simplified distribution | Using the CMAK wizard to automatically build your service profile (the customized software required for your users to run Connection Manager), you create a self-installing executable file that can be distributed on compact disc or downloaded by your users. |
| Custom phone books | You can specify the phone books to be provided to your users. You can download your phone book to users and provide automatic phone book updates when your users log on. And to simplify maintenance, you can combine existing phone books by merging existing service profiles. |

**VPN connection support**

In addition to the support for basic dial-up connections, you can also use the CMAK wizard to incorporate support for VPN connections using a tunneling protocol to tunnel through a public network (such as when dialing into an ISP to access a corporate server). Connection Manager can create a VPN connection through a pre-existing dial-up session, local area network (LAN), or digital subscriber line (DSL).

| Feature | Support |
|---|---|
| VPN server selection | You can allow your users to choose a VPN server to use when connecting to your service. |
| Direct connections | If you specify support for VPN, you can provide support for direct connections (sometimes referred to as *always on* or *persistent* connections). Support for direct connections includes support for cable, asymmetric digital subscriber lines (ADSLs), and other types of direct connections. |
| Protocols | You can specify whether or not to support VPN, which enables your users to connect to your service using Point-to-Point Tunneling Protocol (PPTP) or, if running Windows 2000, Windows XP, or a member of the Windows Server 2003 family, Layer Two Tunneling Protocol (L2TP) with IPSec encryption as the tunneling protocol. These protocols enable improved security for direct and dial-up connections. |

**Note**

- You must build profiles on a server operating system that is designed for the same processor set as the client computers on which users will install the profile. For example, if you want to build a profile for users running Windows XP Professional x64 Edition, you must build that profile on a server that is running an x64-based version of Windows Server 2003.

# Connection Manager user interface

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connection Manager user interface**
The Connection Manager user interface consists of a logon dialog box and a set of property dialog boxes with which users can customize their connection settings. What users see depends largely on how you customize your service profile.

**Logon dialog box**
The logon dialog box is often the only Connection Manager screen your users see when they access your service. In this dialog box, users specify their credentials (such as user name and user password) so they can connect to your network servers. You can customize the service name, the graphic, support information, and many other elements of this dialog box. Users can customize this logon box if they configure favorite connection settings. If two or more favorites have been configured, the user can select between them from the logon dialog box.

**Properties dialog box**
The *ServiceProfileServiceName* **Properties** dialog box appears when a user clicks **Properties** in the logon dialog box.

### Note

- The title bar of this dialog box contains the service name of the service profile in front of the word **Properties**, but it is referred to as simply the **Properties** dialog box throughout this documentation.

**Properties, General tab**
On the **General** tab, users can specify the way their system connects to an Internet service provider to access your service:

- If the service profile that you provide supports virtual private network (VPN) connections, users can choose to use a direct connection that has already been established through the Internet or use a dial-up connection, and they can specify phone numbers and other information needed to establish the dial-up connection.

- If the service profile that you provide does not support VPN connections, users do not see the direct connections option, but they are still able to specify phone numbers and other information for their dial-up connections.

Using this tab, users specify the following information for dial-up connections:

- **The phone number to be dialed to establish a connection.** Users can type a number or click the **Phone Book** button to select a phone number.

  When users click the **Phone Book** button, they can select a Point of Presence (POP) from the list in the **Phone Book** dialog box. Only those access numbers that are supported by the selected service type, country (or region), and state (or province) appear in the list.

  Additional numbers appear in the **More access numbers** box only if you configure the phone book to support this second set of numbers (such as the phone numbers you specify as surcharge numbers when you use Connection Point Services to create your phone book). If the phone book has not been set up with additional access numbers for the selected geographic location, the box will be empty. If you specify in the Connection Manager Administration Kit (CMAK) wizard that custom text is to be displayed next to the **More access numbers** box, the text appears only when numbers are available for the selected geographic location.

- **Dialing rules for the dialing location.** If users click **Dialing Rules** on the **General** tab, they can specify information about the location from which they are currently dialing, such as calling card numbers and codes for accessing outside and long-distance lines, or information about other locations for future use.

- **The type of device to be used to connect to your service.** Only installed and available device types appear in the **Connect using** list.

- **Whether to save the settings on the General tab as a favorite for later use.** Users can name and save all the

current settings on the General tab and then select one of these favorite sets of settings from the Connection Manager logon dialog box.

**Properties, Internet Logon tab**

On the **Internet Logon** tab, the user types a user name and password to connect to the Internet for a VPN connection. This tab appears only if, in the CMAK wizard, you:

- Specify support for VPN connections, and
- Do not select the **Use the same user name and password for VPN and dial-up connections** check box.

**Properties, Options tab**

On the **Options** tab, users can change the connection defaults for establishing and keeping active connections. Users can change both the number of redial attempts that occur and the amount of idle time that elapses before Connection Manager ends the connection. Users can also choose whether to enable logging for this connection. If a log file has been created, users can choose to view or clear it.

**Properties, VPN tab**

On the **VPN** tab, users can choose a VPN server for the connection. This tab appears only if, in the CMAK wizard, you do each of the following three things:

- Specify support for VPN connections.
- Select the **Allow the user to choose a VPN server before connecting** check box.
- Include a VPN file with your service profile.

For more information, see Implementing VPN support and Incorporating VPN entries.

**Properties, Advanced tab**

On the **Advanced** tab, users can enable Internet Connection Sharing, Internet Connection Firewall, Windows Firewall, or any combination of these services for the connection. This tab only appears on computers running Windows XP or a member of the Windows Server 2003 family. Users who are not members of the Administrators group will not see this tab.

For more information, see Internet Connection Firewall and Connecting to the Internet in a home or small office network.

### Notes

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

**Additional screens**

Depending on how you customize the service profile, other screens appear during the connection process. For example, you can specify whether a license agreement appears when users install Connection Manager. You can also incorporate Help screens and other messages into the service profile.

# The Connection Manager Administration Kit Wizard

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The Connection Manager Administration Kit Wizard**
The Connection Manager Administration Kit (CMAK) wizard guides you through the process of building service profiles that exactly meet your business needs. Before you can build these profiles, you must install the CMAK wizard.

**New features in the CMAK wizard**
The CMAK wizard offers many new features, including some that help you do the following:

- provide routing table updates that apply only while clients are connected to your server ("split tunneling")
- Automatically configure Internet Explorer proxy settings for a client computer
- Enable clients to choose which virtual private network (VPN) server to use when they connect
- Include a pre-shared key for L2TP/IPSec authentication
- Encrypt a pre-shared key profile with a personal identification number (PIN) that the user must type in before the profile can be installed

Additionally, the CMAK wizard gives you greater customization and control when you build the service profile, including:

- More types of custom actions and full configuration of all custom actions from within the wizard
- An advanced customization pane in which you can edit .cms and .cmp files as the profile is built
- Improved interface and text throughout the wizard

**Differences from earlier versions of the CMAK wizard**
If you have used an earlier version of the CMAK wizard, you should be aware of the following issues:

- If you have upgraded your operating system, you might have to manually migrate some profile files.
- If you have manually edited the .inf file of a profile created with an earlier version of the CMAK wizard, you must reapply the edits to the .inf file if you change the profile with the current version of the CMAK wizard.
- You can no longer use the CMAK wizard to incorporate an animation in your service profile.
- If you add a program under the **[RunPostSetupCommandsSection]** of the .inf file of your profile, you must add the file as an additional file when you edit the profile with the CMAK wizard.

**Installing the CMAK wizard**
To install Connection Manager components, including the CMAK wizard, on a computer running a member of the Windows Server 2003 family:

1. Open the Windows Components wizard.
2. In **Components**, click **Management and Monitoring Tools** (but do not select or clear the check box), and then click **Details**.
3. Select the **Connection Manager Administration Kit** check box.
4. Click **OK**, click **Next**, and then click **Finish**.

**Notes**

- To open the Windows Components Wizard, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- Certain Windows components require configuration before they can be used. If you installed one or more of these components but did not configure them, when you click **Add/Remove Windows Components**, a list of components that need to be configured is displayed. To start the Windows Components Wizard, click **Components**.

To install the CMAK wizard on a computer running Windows XP Professional, you must install the Windows Server 2003 Administration Tools Pack. To install the Administration Tools Pack:

1. Insert the installation CD for a member of the Windows Server 2003 family into the CD-ROM drive of the computer running Windows XP Professional.

2. Click **Perform additional tasks**.

3. Click **Browse this CD**.

4. Double-click the I386 folder.

5. Double-click the Adminpk.msi file and follow the instructions on your screen.

**Starting the CMAK wizard**

To start the CMAK Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Connection Manager Administration Kit**.

# The Connection Manager Administration Kit and the customization process

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The Connection Manager Administration Kit and the customization process**

Connection Manager is *brandable*, which means that you can customize the installation package that you deliver to your customers so that Connection Manager reflects the identity of your organization. You determine which functions and features you want to include, and how Connection Manager will appear to your customers. You do this by using the Connection Manager Administration Kit (CMAK) wizard to build custom service profiles.

A service profile consists of all of the files needed by Connection Manager to run the installation file and then enable users to establish connections with your service. You can maximize or minimize the identification of your service or organization, depending on what you decide to include in a service profile. For example, you can include custom corporate logos or other graphics, custom icons, and your own online Help. You can also add monitored applications, specify actions to run before, during, and after a connection, and customize other features available in Connection Manager.

To customize the features and support provided in Connection Manager for your service, you can customize your service profile in two ways:

- **Run the CMAK wizard (required to build a service profile).**

  You can use the CMAK wizard to customize most features of Connection Manager at the same time that you build a service profile. For example, you can use the wizard to specify the name and graphics that your users see when running Connection Manager, whether virtual private network (VPN) connections to your service are available to your users, and whether your custom connect actions should run when a connection is established. How much you customize depends on your needs and those of your users. When you finish running the wizard, it automatically builds your customized service profile for you.

- **Use advanced customization techniques (optional).**

  In some instances, there may be features or functions that you want to customize that are not available through the wizard. To add these features or functions, you can use the **Advanced customization** pane to edit the .cms and .cmp files when you build a service profile. After the service profile has been built, you can manually edit any service profile file, but you must run the CMAK wizard again after editing the files in this way in order to incorporate your changes. For example, you can change case sensitivity for passwords by editing the value for the **PasswordHandling** key in the **Advanced Customization** pane.

  For more information, see Methods of editing service profile files.

Each service profile that you create includes the ready-to-use custom features that you specify in a complete, self-installing package so users can seamlessly connect to your service.

Although using the CMAK wizard to build your custom service profiles is simple, creating the custom elements requires careful planning and development. This guide covers the six phases of planning, development, and implementation:

| Phase | Tasks | Persons responsible |
|---|---|---|
| 1 | Decide and document which features to customize for Connection Manager. The information you need to complete these tasks is covered in Phase One: Planning. | Network administrator or technical lead |
| 2 | Design and develop a phone book and any other custom elements you want, such as graphics, text, and related programs, as needed. The information you need to complete these tasks is covered in Phase Two: Developing Custom Elements. | Technical support team |

| | | |
|---|---|---|
| 3 | Use the CMAK wizard to build each custom service profile, and then use advanced customization techniques, as appropriate, to complete the customization of each, as covered in Phase Three: Running the CMAK Wizard and Creating a Service Profile. | Technical lead or other member of technical support team |
| 4 | Verify distribution readiness, including addressing any integration requirements, as covered in Phase Four: Preparing for Integration, Delivery, and Installation. | Technical lead or other member of technical support team |
| 5 | Test your Connection Manager deliverables, including all custom elements, on all target platforms and operating systems, using the process and criteria covered in Phase Five: Testing Your Deliverables. | Testers or other members of technical support team |
| 6 | Provide effective troubleshooting and other support to your customers. Phase Six: Supporting Your Customers. | Customer support team |

# Connection Point Services and Connection Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connection Point Services and Connection Manager**
Connection Point Services (CPS) enables you to automatically distribute and update custom phone books. These phone books contain one or more Point of Presence (POP) entries, with each POP supplying a telephone number that provides dial-up access to an Internet access point. The phone books give users complete POP information, so when they travel they can connect to different Internet access points rather than being restricted to a single POP.

Without the ability to update phone books (a task CPS handles automatically), users would have to contact technical support to be informed of changes in POP information and to reconfigure their client dialer software.

CPS has two components:

- **Phone Book Administrator**, a tool used to create and maintain the phone book database and to publish new phone book information to the Phone Book Service.

- **Phone Book Service**, an Internet Information Services (IIS) extension. Phone Book Service automatically checks subscribers' or corporate employees' current phone books and, if necessary, downloads a phone book update.

CPS is available with the Windows Server 2003 family.

For information on setting up a phone book, see Providing phone book support. For more information on CPS, see Connection Point Services.

# Phase One: Planning

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Phase one: Planning**
The information in this section supports the planning that you need to do before you run the Connection Manager Administration Kit (CMAK) wizard to create the customized service profiles that you need:

- Security information for the Connection Manager Administration Kit. This section provides an overview of basic security considerations when you design and deploy your customized service profiles.

- Deciding what to customize. This section provides an overview of the Connection Manager features and functions that can be customized and included in your service profile.

- Planning for effective implementation. This information covers the factors that you should consider before starting the planning for an individual service profile, so you will understand how your decisions will impact the service-profile deliverables. It includes information on the impacts of integrating your service profile with another installation package or otherwise tailoring your delivery and installation methods.

- Creating profiles in multiple languages. This information covers the factors you should consider when designing a multinational or multilingual deployment of a service profile.

# Security information for the Connection Manager Administration Kit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security information for the Connection Manager Administration Kit**

You can increase the security of your remote access solution by using the Connection Manager Administration Kit (CMAK) wizard to customize and control the connection experience for your users. By customizing the connection, you can control how your users connect to your network, and you can simplify troubleshooting.

Before you create a profile, you should understand your remote access solution, including its security requirements and limitations. You can consider remote access security in three parts: securing servers, including remote access servers and the computers on which you store profiles; understanding and securing the computers on which users will install profiles; and designing, creating, and distributing the profile itself. For more information about securing servers, see Security information for remote access, Security issues for VPN, and Security.

When you design your service profile, you should consider the following:

- **Who can create or edit service profiles using the CMAK wizard**. A user must be a member of the Administrators group to install the CMAK wizard. A user must be a member of either the Administrators or the Power Users group to run the CMAK wizard.

- **Who can edit service profile files using a plain text editor**. Service profile files are plain text files that users can edit using a plain text editor, such as Notepad, instead of using the CMAK wizard. By using a plain text editor instead of the CMAK wizard, users do not need to be members of the Administrators or the Power Users group to edit or to delete these files. You can help prevent users from changing these files on the server by limiting access to the directories that contain service profile files. Recognize that, after you distribute the service profile, users can edit the service profile files on their own computers. For more information, see Methods of editing service profile files and Including Connection Manager in custom applications.

- **Which operating systems your users will use**. You should consider two things regarding the operating systems on your users' computers: the level of security inherent in the operating system itself, as well as the security features that you can configure for the operating system. Not all operating systems support all Connection Manager features. For example, Windows 98 does not support user certificates. Therefore, if you want to deploy a highly secure VPN solution, you might need to limit your deployment to users running Windows XP on hard disks formatted with NTFS.

  Depending on how your users have configured their computers, you might have these security considerations:

  - Whether the user's hard disk is formatted with FAT or NTFS. FAT systems are not as secure as NTFS systems.

  - What authentication and tunneling protocols are supported. Not all operating systems support all of the same protocols as the Windows Server 2003 family. For more information, see Dial-up networking clients and Virtual private networking clients.

  - Whether your users will install the profile for individual use only or for all users of that computer (Windows 2000, Windows XP, and the Windows Server 2003 family only). You should encourage your users to install the profile for individual use only so that only the user who installed the profile and members of the Administrators or System Operators groups can modify the service profile files. If a user installs a profile for all users, all users of that computer can modify or delete the service profile files.

  - Whether the profile allows users to save the password for the profile. You can hide the check box that allows users to save passwords by configuring the **HideRememberPassword** key. For Windows XP and the Windows Server 2003 family, you can configure the **GlobalCredentials** key to prevent users from saving a user name and password for any other users of that computer. This key prevents other users from using another user's credentials. The connection will close automatically if Fast User Switching is used.

- If necessary, you can create different service profiles for different operating systems, restricting access for users with less secure systems.

- **Whether your service profile will include a phone book or multiple phone books**. If your service profile will include one or more phone books, you will need to create the phone book with Phone Book Administrator (PBA), and you will need to include a Phone Book Service (PBS) server in your deployment. For more information, see Security information for Connection Point Services.

- **How you will distribute your service profile**. You can distribute your service profile in several ways, including on a Web site and on portable media such as floppy disks. Depending on what kind of service profile you create, you might want to consider how to control the distribution of your profile. For example, if you create a profile with a pre-shared key, you will want to limit distribution of the profile to authorized users, particularly if you do not encrypt the profile with a personal identification number (PIN). For more information about distributing service profiles, see Planning for effective implementation.

  For detailed information about deploying Connection Manager, see "Deploying Remote Access Clients Using Connection Manager" at the Microsoft Windows Resource Kits Web site.

# Deciding what to customize

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deciding what to customize**

You use the Connection Manager Administration Kit (CMAK) wizard to do most of the customization for a service profile. Before running the CMAK wizard, you need to decide what to customize and then provide the information and files needed to run the wizard and implement your decisions. To help prepare for creating a service profile, you can complete the planning worksheet that is available in the Microsoft Windows Server 2003 *Resource Kit*. For more information about Connection Manager, see "Deploying Remote Access Clients Using Connection Manager" at the Microsoft Windows Resource Kits Web site.

Although you can run the wizard and build your service profile without providing any custom information except for the name of your service and a file naming convention to be used for your service profile files, you can customize many other things to meet the needs of your service. For example, you can:

- Reconfigure user routing tables with your service profile in order to better manage your network traffic and security.
- Reconfigure user proxy settings to ensure that the user has appropriate access to internal and external resources while connected to your service.
- Merge previously created service profiles into the one you are building, in order to incorporate phone books and other features from those service profiles.
- Provide a customer-support phone number or other customer-support information in the Connection Manager logon dialog box.
- Provide a realm name (prefix or suffix) that is appended to the user name (to specify network routing and authentication information needed by your Internet service provider, without requiring your users to understand and incorporate the information themselves).
- Specify dial-up entries to be associated with phone numbers in the phone book you provide to your users.
- Support virtual private network (VPN) connections over the Internet.
- Incorporate custom actions that run at specific points during the connection process.
- Incorporate your own graphics in place of the default graphics provided in Connection Manager logon and phone book dialog boxes.
- Provide a phone book and phone-book update capabilities to your users.
- Incorporate your own custom icons in place of the default Connection Manager icons.
- Customize the menu associated with the notification area shortcut when your users are connected.
- Customize the default Help file provided with Connection Manager.
- Include Connection Manager 1.3 in your service profile.
- Incorporate an end-user license agreement (EULA) in your service profile that users must accept in order to install your service profile.
- Include additional support files in your service profile, such as user documentation files and custom programs and files needed to support custom actions that you have defined.

- Enhance security by enabling server callback to users.

You should consider each of these decisions for each service profile you create. Depending on the target audience and other factors, your decisions will vary for each service profile. Before you implement your decisions, you should also consider the effects of your implementation and any potential integration issues. For information on planning for integration, distribution, installation, and other implementation considerations, see Planning for effective implementation. This section provides the information you need to support effective and efficient planning and development efforts.

**Note**

- You must build profiles on a server operating system that is designed for the same processor set as the client computers on which users will install the profile. For example, if you want to build a profile for users running Windows XP Professional x64 Edition, you must build that profile on a server that is running an x64-based version of Windows Server 2003.

# Planning for effective implementation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Planning for effective implementation**
When you make decisions about customization, you should be aware of how your decisions affect Connection Manager implementation methods. When developing plans for a service profile, consider implementation impacts on:

- The number of service profiles to be developed.
- The distribution methods to be used.
- Streamlining installation with additional components.
- Integrating your Connection Manager service profile with an Internet Explorer installation package.
- The size of the service profile.
- Phone book support to be implemented.
- Maintenance and update requirements for the service profile, including all files included in the profile.
- The operating systems and processors of the client computers for which you want to create service profiles.

The following sections discuss how customizing your service profile can affect how it is implemented. For additional information on setting up multiple profiles and how each service profile is set up and maintained, see Setting up your service profiles.

**How many service profiles do you need?**
You can create additional service profiles to support specialized needs of specific groups or personnel. For example, if you support multiple geographic locations, you might want to create separate profiles for the specific locations, incorporating a unique local phone book in each. Or, you might want to create separate profiles for each operating system supported by your service.

If a user installs more than one service profile, each profile is installed in a separate folder. All profiles share the same copy of Connection Manager software.

To provide support for another language, you must run the Connection Manager Administration Kit (CMAK) wizard on a computer with an international version of a Microsoft operating system that uses the appropriate language.

**Note**

- You must build profiles on a server operating system that is designed for the same processor set as the client computers on which users will install the profile. For example, if you want to build a profile for users running Windows XP Professional x64 Edition, you must build that profile on a server that is running an x64-based version of Windows Server 2003.

**What distribution methods are appropriate?**
You can distribute your service profile by compact disc or downloadable file (over a private network or the Internet). You should consider the size of your customized profile, including all files that you add to it, when you determine which distribution method to use. Remember that download time can significantly affect users, especially those running modems at relatively slow speeds.

If you are using the Internet Explorer Administration Kit 5.5 (IEAK 5.5) to distribute Internet Explorer 5.5 to your users, you can simplify installation for them by including a Connection Manager profile in an Internet Explorer installation package. Files included in the Internet Explorer installation package should not be duplicated in the Connection Manager profile.

**What is the size of your service profile?**

It is important that the size of your service profile be compatible with your distribution method. Consider the features you want and how you plan to distribute the profile: by compact disc or download.

For example, if you distribute by download, consider how the download time affects users. In some cases, you might decide to use or offer users an alternate distribution method. The CMAK wizard does not support profiles that span multiple disks and does not prompt you if the profile does not fit on one disk.

A service profile that includes Connection Manager uses about 800 kilobytes (KB) of disk space. A profile without Connection Manager can use as little about 200 KB. The total size of your service profile depends on your customization options, such as the method you use to provide phone books, whether you include custom actions or other optional programs, and which graphics you incorporate.

**Note**

- If disk space allows, include Connection Manager in the service profile to ensure that your users always have the latest version.

**How can you streamline installation for your users?**
You can simplify installation and updates for your users by incorporating programs and files that can be automatically installed and configured as part of the Connection Manager installation package. You can tailor these features to the individual needs of specific user groups to control the size of the service profile that you distribute and to promote the effective use of your service. For example, if you support a corporate account with marketing and accounting departments, you might provide separate profiles for each department, so that you could provide the marketing department with a phone book covering the entire sales area, and you could provide the accounting department with a phone book containing only the numbers of the local access points.

**How can you integrate your service profile with an Internet Explorer installation package?**
Some of your planning decisions will depend on whether you are integrating Connection Manager and your custom service profile with an Internet Explorer installation package or other implementation package. You should determine your delivery method before creating a service profile, to determine any impacts of integration.

For example, if you decide to integrate your Connection Manager service profile with an installation package created with the Internet Explorer Administration Kit (IEAK), you might want to coordinate the graphics included in your profile with those you include in the installation package.

Also, if you decide to deliver your Connection Manager service profile with an Internet Explorer installation package, you must create the Connection Manager service profile first. Unlike the IEAK 5 wizard, which had a button to call CMAK directly, the IEAK 5.5 wizard has no direct link to CMAK.

After building your service profile, check the information in Phase Four: Preparing for Integration, Delivery, and Installation to determine additional customization that may be needed to integrate your service profile with other packages.

**What phone book support is required?**
You can provide a single phone number for user connection, or you can provide additional support for roaming access by providing a phone book of access numbers. Using Connection Point Services, you can provide phone book support with automatic updates, but you need to create the initial phone books and decide how the phone book support is to be implemented before running the CMAK wizard. For more information, see Connection Point Services and Connection Manager.

**What is required to maintain and use existing service profiles?**
You can incorporate many types of files in a service profile. You can edit or merge other profiles, include program files to support custom actions and monitored applications, and provide user documentation to customize Connection Manager appropriately for your users.

In order to maintain these service profiles so that you always use the appropriate version of an incorporated file, you should understand how the CMAK wizard incorporates and uses such files. For information about how files and folders for your profile are set up, see Setting up your service profiles.

When you edit a service profile that contains a merged service profile, the CMAK wizard attempts to use the latest version of the merged profile. If the CMAK wizard cannot find the merged profile in the appropriate \Program Files\CMAK\Profiles*ServiceProfileFileName* folder, it defaults to the current version of the merged profile that was originally stored with the profile being edited.

Plan your profiles, especially those with incorporated files, so that the information and elements are easily maintained and updated as needed.

# Creating profiles in multiple languages

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating profiles in multiple languages**
You can use language-specific versions of the Connection Manager Administration Kit (CMAK) wizard to create service profiles in different languages. If you create your profiles with the same wizard options in different languages, you can provide your users with the same connection experience independent of language. For example, you can allow your users who speak French and your users who speak Japanese to connect to your service or private network in the same way.

**Creating profiles for users of operating systems other than Windows XP or the Windows Server 2003 family**
You can purchase installation CDs for the Windows Server 2003 family in a variety of languages. However, each CD is specific to only one language, known here as the system language. To build a profile for users who are not running Windows XP or a member of the Windows Server 2003 family, you will need to purchase a separate CD for each language in which you intend to create a profile. For example, if you want to create a German service profile for users who are not running Windows XP or a member of the Windows Server 2003 family, you must purchase and install the German version of a Windows Server 2003 operating system.

The reason that you must purchase a separate CD is that profiles built with the Windows Server 2003 family require Connection Manager 1.3 to function. Users who are not running Windows XP or a member of the Windows Server 2003 family will not have Connection Manager 1.3, so you must include it when you build a profile for them. The version of Connection Manager 1.3 you include will appear in your system language, regardless of whether it matches the system language of your users. The only way to change your system language to match the system language of your users is to install a version of the operating system that is specific to the system language of your users. Even if you create a profile on a Multi-Language User Interface (MUI) version of the Windows Server 2003 family, Connection Manager still appears in the system language that is specific to that version.

**Creating profiles for users of Windows XP or the Windows Server 2003 family**
For users who are running Windows XP or a member of the Windows Server 2003 family, you do not need to include Connection Manager 1.3 when you create a profile. However, you must change your input language and your **Language for non-Unicode programs** settings so that they match the system language of your users. Your input language determines which characters you can type in the CMAK wizard and as you create phone books. The CMAK wizard itself and Phone Book Administrator will still appear in your system language. If your input language differs from your system language, a warning message appears when you start the CMAK wizard. The message should remind you that, if you include Connection Manager 1.3, it will appear on your users' computers in your system language, which might not match that of your users. If you do not plan to include Connection Manager 1.3, you can close the warning message and proceed with the wizard.

For more information about changing your input language, see Specify regional and language options and user's name during Setup and Regional and Language Options overview.

# Phase Two: Developing Custom Elements

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Phase two: Developing custom elements**

Depending on what you customize, you might need additional resources to prepare your elements. For example, if you want to include a phone book in your service profile, you must get copies of the phone book and region files. Or, if you want to include custom icons and bitmaps, you might need additional programs or graphics specialists to prepare them.

This section provides guidelines for the technical team members who are responsible for creating the graphics, information, programs, and other special elements to customize Connection Manager for your needs:

- Setting up your service profiles
- Specifying service and file names
- Providing a realm name
- Merging phone books and other features from existing service profiles
- Implementing VPN support
- Incorporating VPN entries
- Including a pre-shared key
- Providing phone book support
- Incorporating custom dial-up entries
- Including routing table updates
- Using automatic proxy configuration
- Incorporating custom actions
- Incorporating custom graphics
- Incorporating custom icons
- Customizing the notification area shortcut menu
- Providing custom Windows Help
- Providing support information in the logon dialog box
- Adding Connection Manager 1.3 to the service profile
- Incorporating a license agreement
- Including additional files
- Providing user documentation

- Advanced Customization

These guidelines can be reproduced and distributed to the individuals responsible for doing the design and development work.

# Setting up your service profiles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting up your service profiles**

Each time you run the Connection Manager Administration Kit (CMAK) wizard, you create a service profile. You can create as many profiles as needed to support each specific target audience. After creating an initial profile, you can use the CMAK wizard to edit it. You can save the edited profile under the same name to overwrite the existing profile, or you can specify a different service name and file name to save it to a separate profile (preserving the existing profile as it was before you started the edit).

**Notes**

- To create a service profile for another language, use the version of the operating system and the CMAK wizard that are appropriate for the language.
- When you edit a service profile created using a previous version of Connection Manager, the CMAK wizard automatically upgrades the profiles to Connection Manager 1.3. Any changes you have made manually to the .inf file (using advanced customization techniques) will not be retained in the upgraded file. However, the CMAK wizard creates a backup of the old .inf file before creating the updated file.
- If you change the file name, be sure to change the service name also. If a user installs two service profiles with the same service name but different file names, the service profiles do not work correctly.

Each service profile should be specific to a target audience. For example, you might set up separate profiles if:

- You want to make each service profile specific to a single operating system.
- You specify phone books to support each of your distinct geographic areas or corporate organizations.
- Different users require different connection methods (dial-up versus direct).
- You need to support virtual private network (VPN) connections only for specific users.
- The individual corporations or groups you support each want to use their own logos or other proprietary symbols or text.
- The help desk or other support is not the same for everyone and you want to provide specific information to each user group.
- You want to establish different administrative authorities for the groups you support.

**Note**

- To simplify administration of multiple service profiles, you can merge existing profiles into a parent service profile. See Merging phone books and other features from existing service profiles.

You must run the CMAK wizard again for each service profile you want to create, including each service name or file name you want to present to your users. For more information on service and file names, see Specifying service and file names.

It is easier to create additional service profiles if you edit an existing profile and then change the service name and file name.

When you create a service profile, the CMAK wizard copies all files that are incorporated in the profile into a \Program Files\CMAK\Profiles*ServiceProfileFileName* folder. When you edit existing profiles, the CMAK wizard always pulls the incorporated files from the ...*ServiceProfileFileName* folder. To make changes to the incorporated files, edit the incorporated file in the ...*ServiceProfileFileName* folder and then run the CMAK wizard again to update the service profile. Or, if you edit the file that is not in the ...*ServiceProfileFileName* folder, start the CMAK wizard, add the updated file (by browsing to find it), and then finish running the wizard.

**Note**

- Connection Manager supports user installation of multiple service profiles, running multiple instances of Connection Manager, and multiple user profiles for each service profile. If a user installs more than one service profile, each is installed in a separate folder. You can provide as many profiles to your users as necessary to support your service, but each must have a different service name and file name.

# Specifying service and file names

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Specifying service and file names**
You must specify a *service name* and a *file name* in the CMAK wizard to identify your service profile.

**Service name**
The service name identifies your service to the users. This name is limited to 35 characters. This name appears at several points when the user runs your service:

- In the title bar text for the logon dialog box for your service.
- In dialog boxes that appear during installation of Connection Manager and the service profile.
- As the desktop icon name for your service.
- On the program button on the taskbar that appears when the program is running.
- In the ToolTip that appears when the mouse points to the notification area shortcut, which is located at the far right of the taskbar.
- Within the service-profile files, for entries such as the default dial-up entry.
- In the **Network Connections** (Windows XP and the Windows Server 2003 family), **Network and Dial-up Connections** (Windows 2000), or **Dial-up Networking** (Windows 95, Windows 98, and Windows Millennium Edition) folder, as the name of the remote access connection.

This name is often a company or other business name. For example, the fictitious company Awesome Computers, which is used for many of the examples in this documentation, might specify "Awesome Computers" as the service name. Or, if Awesome Computers wanted to set up separate service profiles for each department, the service name for one of them might be "Awesome Computers - Marketing."

### Important

- Do not use any of the following characters in your service profile name: *** \ / : ? " < > | [ ] & ´ % ' `**

**File name**
The file name is the name given to the files created by the CMAK wizard when building the service profile. The file name can be up to 8 alphanumeric characters, with the following limitations:

- Do not use any of the following: **! , ; <space> * = \ / : ? ' " < > | . % + [ ] $ # & @ ( ) { } ´ ` ~**
- Do not use extended character sets in a file name. A file name created with extended character sets (such as those containing ü, é, and other extended characters) might not be properly installed.

### Notes

- Make sure that the service and file names are different from all other service and file names that you provide to your customers. If two service profiles on the same computer have the same service or file name, the associated connection icons do not work correctly.
- When editing an existing profile, if you do not want to write over the existing service profile, you must change the file name.

The file name is used for the following files created by the CMAK wizard, including:

- The folder containing the files needed to install Connection Manager and the service profile, located at \Program Files\CMAK\Profiles*ServiceProfileFileName*.
- The self-extracting executable (.exe) file.
- The .cms file, which contains the configuration data for Connection Manager features, such as the names of the phone book and connection methods.
- The .cmp file, which stores user-specified information, such as the name of the .cms file to be used.
- The .inf file, which is used for the setup and installation of Connection Manager on the user's computer.
- The .sed file, which specifies the contents of the .cab file and how to compress the files when the service profile is built.

The file name for the service profile is also used for the folder created on the user's computer when the .exe file is run.

For more information on what files are created by the CMAK wizard, see Using the CMAK wizard to build a service profile.

# Providing a realm name

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Providing a realm name**
Realm names are used for network routing and authentication. They provide the identification necessary to forward authentication requests to the server that holds the user's credentials. Realm information is only used for dial-up connections.

Using the CMAK wizard, you can specify a realm user-name prefix (such as **Awesome/**) or suffix (such as **@Awesome**) to be added to the user name that a user enters when connecting to your service. The realm name includes any separator characters, such as **@** or **/**. If you specify the realm, users do not have to provide it themselves because Connection Manager automatically places the realm name before or after the user's name so that the user does not have to understand network routing in order to log on.

If your service uses multiple networks or ISPs for access, you need to provide different realm information for each. In this case, create service profiles for each of the networks and then merge them together in a *top-level* profile.

**Notes**

- If the top-level profile contains realm information, it will take precedence over the information in the component profiles.
- For more information on merging profiles to incorporate multiple realms, see Merging phone books and other features from existing service profiles.

Internet Authentication Service (IAS) supports the use of realm names for remote authentication. You can use the realm name as authentication routing information for remote roaming users (users who travel and connect through different Internet access points). When the user connects through a network access server (NAS), the NAS sends the realm name, the user name, and the user password to the authentication server. For more information on IAS, see Internet Authentication Service.

# Merging phone books and other features from existing service profiles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Merging phone books and other features from existing service profiles**

If you have information in existing service profiles that you need in the service profile you are building, you can use the Connection Manager Administration Kit (CMAK) wizard to *merge* much of the information from existing profiles into the profile you are building. A profile that contains information from other service profiles is called the *top-level* profile. A service profile that has its information merged into another service profile is called a *component* profile.

**Why merge service profiles?**

Merging service profiles is especially useful for incorporating information from multiple phone books, including service types, Point of Presence (POP) names, and access numbers, and to consolidate different Internet access points that are covered by more than one of your phone books. By merging existing service profiles into the service profile you are building, you can make several dissimilar networks appear to be a single, cohesive service.

For example, you can merge service profiles from different geographical locations to create a worldwide profile. Or you can create profiles that have specific administration requirements and network configurations, including authentication and TCP/IP characteristics and, after they are created, you can merge them together within a top-level service profile. Merging service profiles is especially useful where multiple entities, whether corporations or Internet service providers (ISPs), share in providing a service. The following examples show how you can use merged service profiles to simplify network access through diverse access points:

- **Example 1: Creating a service profile to support access to the Internet from remote service areas.** If a local ISP contracts with a roaming consortium to provide dial-up services outside the ISP's primary service area, the local ISP could create a top-level service profile containing the local ISP's network information and merging the service profiles of the other members of the roaming consortium. Each component service profile could contain the individual phone-book and network attributes, including a unique realm name, of an individual ISP. Merging all of the component service profiles would support the need for users of the local ISP service to roam outside of the ISP's primary service area by enabling them to connect through the cooperating ISPs. All ISPs can maintain their own service profiles, simply redistributing profiles to other members of the consortium whenever they are updated. The consortium itself might also create a top-level service profile aggregating the services of all member ISPs.

- **Example 2: Implementing a corporate virtual private network (VPN).** Corporations using VPN connections for a session by establishing a tunnel through the Internet to the corporation often use ISP-provided dial-up access to support corporate access from remote locations. By merging service profiles, the corporation could combine its own phone book of internal dial-up numbers with those of remote ISPs contracted to provide access points for the remote corporate users, enabling VPN connections to be established even for dial-up connections through the public network access point of the ISP. The corporation and each ISP could maintain its own service profiles, but the corporation could merge all of the ISP service profiles into the corporate profile. The distribution of the top-level service profile by the corporation to all corporate users would support access from multiple locations. This access would appear to users as if it were made using the corporation's own access points.

**What information is merged**

The following table shows which features of a component service profile are merged into the top-level service profile and how the CMAK wizard incorporates the merged information. Only the items from the component service profile that are listed in the **Merged features** column are recognized and used by the top-level service profile.

| Merged features | Implementation notes |
|---|---|
| File name | Files contained in the component service profiles retain the names used by the component service profiles. |
| Merged profiles | You can merge only one level of service profiles. For example, if you merge service profile A, which contains component profiles B and C, these second-level component profiles (B and C) are ignored. |

| | |
|---|---|
| Realm name | If a realm name is specified in the top-level service profile, it will be used in all instances, and all realm names specified in the component service profiles are ignored. If no realm name is specified in the top-level service profile, the realm names specified in the component service profiles are used for connections that are made using entries from the component service profiles. |
| Dial-up entries | The script specified for each dial-up entry must have a unique name than all other scripts contained in the top-level service profile and any component profiles. |
| Phone books | If the same service types exist in more than one profile, the information is merged. If duplicate states (or provinces), or POPs exist among top-level and component service profiles, Connection Manager removes the duplicates when it runs the top-level service profile. Connection Manager treats two phone book entries as duplicates if they display the same information in the user interface (except that Connection Manager is not case sensitive). If two phone book entries appear as duplicates but have separate configuration data in the POP, Connection Manager still removes one of the phone book entries. |
| Download phone book | Each time the user establishes a connection, Connection Manager automatically checks for the phone books with each server that is running Phone Book Service (PBS). PBS checks the phone book version and, if necessary, downloads phone book updates to the user. Phone books specified in the top-level and component phone books are downloaded, as appropriate to the respective service profiles. |
| URL for downloads | The URLs specified in the top-level and component service profiles are used for downloads to phone books for the respective service profiles. |

The top-level service profile does not merge information related to the following features of the component profile. To affect these features, you must specify them in the top-level service profile:

- Service name
- Support information specified for the logon dialog box
- VPN support
- Custom actions
- Monitored applications
- Custom graphics for the logon dialog box and **Phone Book** dialog box
- Message to display next to the **More access numbers** box when alternate access numbers are available for the selected geographic location
- Custom icons
- Customization options for the notification area shortcut menu
- Custom Help files
- Option to include Connection Manager software in the service profile
- License agreement
- Additional files

**Note**

- To support VPN connections for component service profiles, in the **VPN Support** pane of the CMAK wizard, under **Establish a virtual private network (VPN) connection when the user dials a phone number from these phone books**, select the **Phone books from the merged profiles** check box.

**Where the files are located**
When you create a service profile, the CMAK wizard copies all files referenced in the service profile, including the component service-profile files, into the \Program Files\CMAK\Profiles*ServiceProfileFileName* folder for that service profile.

When you use the CMAK wizard to merge features, the top-level service profile includes references to the component (merged) service profiles. For example, for phone books in merged service profiles, the resulting service profile installs multiple files in the folder specified for the profile rather than combining the phone books into a single file. However, when users select a POP involving phone books merged from two other service profiles, the users see the information from all the phone books as a single phone book.

When you edit a top-level service profile, the CMAK wizard attempts to use the latest version of the component service profile. If the CMAK wizard cannot find the merged service profile in the \Program Files\CMAK\Profiles*MergedServiceProfileFileName* folder (for the top-level service profile), it uses the current version of the merged service profile that was originally stored with the service profile being edited.

**Special considerations for building merged profiles**
When building merged service profiles:

- If you merge a Connection Manager 1.0 service profile into a Connection Manager 1.3 service profile, the CMAK wizard automatically updates the merged information to Connection Manager 1.3. Any changes you have made manually to the .inf file (using advanced customization techniques) will not be retained in the upgraded file. However, the CMAK wizard creates a backup of the old .inf file before creating the updated file.

- You should provide separate service profiles for each network that has unique characteristics or requirements.

- You must ensure that all scripts specified for dial-up entries in the merged service profile are available when you build the top-level service profile.

# Implementing VPN support

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Implementing VPN support**

A virtual private network (VPN) connection provides remote access to private networks over the Internet (or other network). A VPN connection is established using a tunneling protocol to establish a tunnel through the Internet to the private network. To establish a VPN connection, users can connect directly to the private network through the tunnel by either dialing into a local Internet service provider (ISP) or by using a pre-existing connection to the Internet (direct connection).

This means that remote users can connect using worldwide Internet access points to access private resources as easily as local users. For corporations, it means that employees have remote access over the Internet to their corporate private networks, usually through a local phone number. By having users create VPN connections rather than dial-up connections, the company does not incur the considerable expenses associated with long distance telephone service without compromising security.

You can use the Connection Manager Administration Kit (CMAK) wizard to set up VPN connections, including:

- Make a direct connection to a private network.
- Tunnel to a private network over a public network, such as the Internet.
- Select a VPN server for the connection.

Using the CMAK wizard, you can set up support for VPN connections using Point-to-Point Tunneling Protocol (PPTP) or Layer Two Tunneling Protocol (L2TP). To use these VPN connections, you must have a remote access server on the private network configured to support the appropriate protocol.

**Important**

- A VPN connection requires the computer on which Connection Manager is run to be configured to use the same network protocols that the private network uses.
- VPN connections on computers running Windows Millennium Edition, Windows 98, or Windows 95 require that users have the latest **Dial-up Networking** software installed on their computers. Users can obtain the current **Dial-up Networking** software by downloading it as a Windows Update from the Microsoft Web site. You should document this requirement for your users. For more information on verifying and installing **Dial-up Networking** software, see Providing user documentation.

You can create a service profile with which users can establish direct VPN connections using a tunnel over pre-existing connections. For example, users who are already connected to the Internet through DSL or a cable modem can then connect to your private network using a VPN-only profile you created. To create a VPN-only profile:

1. Start the CMAK wizard.
2. On the **VPN Support** pane, select the **Phone book from this profile** check box, and specify a VPN server (by DNS name or IP address) or specify a VPN file (by typing the full path to the file).
3. Configure the VPN entry or entries with the correct security and addressing information for your network.
4. Do not specify a phone book file on the **Phone Book** pane, and clear the **Automatically download phone book updates** check box. You do not need to configure the default dial-up entry for the profile.
5. On the last pane of the wizard, select the **Advanced Customization** check box.
6. On the **Advanced Customization** pane, click the profile .cms file, click **[Connection Manager]**, and set the value of the **Dialup** key to zero.

7. Click **Apply**, and finish the wizard.

This process will create a VPN-only profile, without a **General** tab in the **Properties** dialog box for the profile. Users of your profile will not see any phone or dialing information.

Setting up a dial-up profile to support VPN connections might add an **Internet Logon** tab to the **Properties** dialog box. On this tab, users type the user name and password for the Internet service provider. In the logon dialog box, users type a private network user name, password, and logon domain.

To implement VPN connections in your service profiles, you must specify the address of at least one server to be used and how to handle authentication. As you run the CMAK wizard:

- You must have the VPN server address, specified either as a Domain Name System (DNS) name or as an IP address.
- If you do not want to let the server assign addresses for DNS and Windows Internet Name Service (WINS) servers, you can specify the addresses to be used.
- You must specify whether users enter the same user name and password for both logging on to the Internet using a dial-up connection and logging on to the private network server using a VPN connection. If you specify that the same credentials are to be used for both, the **Internet Logon** tab does not appear and the user only has to enter credentials once to connect.
- You must specify the VPN security settings to be used for connections made with this profile. By default, the security setting is selected to **Configure both basic and advanced settings**, which requires a configuration for profiles installed on Windows 95, Windows 98, Windows NT 4.0, and Windows Millinnium Edition, and a different configuration for profiles installed on Windows 2000, Windows XP, and the Windows Server 2003 family. Windows 2000, Windows XP, and Windows Server 2003 operating systems have more advanced security features and can support a higher level of security for your connection. You can choose to require the use of advanced security settings only, although this setting might prevent some clients on other operating systems from connecting with your profile. You can also choose to only use basic security settings that all operating systems that support Connection Manager can utilize. However, this means that all profiles will use the basic security settings, regardless of whether the operating system can support a higher level of security.

For more information on keys to be used with direct connections, see Advanced Customization.

**Enabling user choice of VPN server**

You can allow your users to choose from multiple VPN servers when they connect to your service. For example, a user could select a VPN server that is close to his or her location, or a user could choose a VPN server that has higher security settings. For service profiles that support this option, a **VPN** tab appears in the properties dialog box for the service profile. This tab contains a customized text message and a list of VPN servers.

To enable your users to choose a VPN server from a list when they connect to your service, you must create a VPN file before you start the CMAK wizard. A VPN file is a text file that you can create with any plain-text editor, such as Notepad. The table below identifies sections, keys, and values that compose a VPN file.

| **[Section] or key name** | **Value** |
|---|---|
| [Settings] | Section header for the keys that contain VPN settings. |
| Default | The friendly name of the default VPN server for this service profile. If you create this key but do not give it a value or if you do not create this key, the user must select a VPN server the first time the user connects with the service profile. |
| UpdateURL | The URL of the Web server that contains updates for this VPN file. If this key is added, a post-connect action is added automatically to the service profile. This post-connect action updates the VPN file. |
| Message | The text message that appears on the **VPN** tab in the properties dialog box for the service profile. This message cannot exceed 256 characters, and it must be a single paragraph. If this key is created but left blank, default text is used. |

| | |
|---|---|
| [VPN Servers] | Section header for the keys that identify VPN servers. |
| *FriendlyName* | The name of this key is the friendly name of one of the VPN servers available to your users. The value of this key is the DNS or IP address of the VPN server for which you named the key. If you want this VPN server to use a specific set of network and security settings, you must follow the DNS address with a comma and the name of a VPN entry that you will edit in the **VPN Entries** pane of the CMAK wizard. If you do not specify a VPN entry, the VPN server will use the settings for the default VPN entry. |

If the fictional company Awesome Computers wanted to provide its users with a choice of VPN servers, an administrator might create a VPN file similar to the example below.

```
[Settings]
default=Awesome Computers HQ
UpdateURL=http://awesomecomputers.microsoft.com/VPNfile.txt
Message=Please select a server from the following list. You might want to choose a
server closest to your location or to your data. Windows 98 users should choose Awesome
Computers Windows 98.

[VPN Servers]
Awesome Computers HQ=awesomecomputers.microsoft.com
Awesome Computers New York=ny.awesomecomputers.microsoft.com
Awesome Computers Spain=es.awesomecomputers.microsoft.com,Awesome International VPN
Settings
Awesome Computers Madagascar=ma.awesomecomputers.microsoft.com,Awesome International
VPN Settings
Awesome Computers Windows 98=awesomecomputers.microsoft.com,Awesome 98 VPN Settings
```

In the above example, the VPN servers Awesome Computers HQ and Awesome Computers New York use the settings specified in the default VPN entry. Awesome Computers Spain and Awesome Computers Madagascar will use the settings specified in the VPN entry named Awesome International VPN Settings. A VPN server has been created for clients running Windows 98, and it uses the settings specified in the VPN entry named Awesome 98 VPN Settings. Users will see the friendly names of the VPN servers you have defined.

Incorporating VPN entries
Advanced Customization

# Incorporating VPN entries

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Incorporating VPN entries**
You can configure connection and security settings for the VPN server or servers that support your service profile. If you customize these settings, you can better handle unique network authentication or routing requirements of particular service profiles.

Before you can configure a VPN entry to support a VPN server or servers, you must specify whether users of your service profile must use a particular server or they can choose between servers. You specify this in the **VPN Support** pane of the Connection Manager Administration Kit (CMAK) wizard. If you allow your users to choose between servers, each server you specify appears in a list on the **VPN** tab of the properties dialog box for the service profile. For more information, see Implementing VPN support.

You can specify the following settings for each VPN entry:

- Whether to enable file and printer sharing
- Whether to enable clients to log on to a network
- Whether to assign static or dynamic IP addresses for Domain Name System (DNS) and Windows Internet Name Service (WINS) servers
- Whether to make this connection the default gateway for the client
- What security settings to apply, based on the client operating system
    - What authentication methods to use
    - What encryption methods to use

You must edit each VPN entry to provide the network and security configuration necessary for a client to connect to any of your VPN servers that use that entry. For example, if you want to configure a profile to require smart cards, on the **VPN Entries** pane, click the VPN entry that you want to configure, click **Edit**, click the **Security** tab, click **Configure** for advanced security settings, click **Use Extensible Authentication Protocol (EAP)**, and then click **Smart Card or other certificate (encryption enabled)**.

All VPN servers use the default VPN entry unless you specify a different entry in the VPN file. If you do not edit the default VPN entry, it will use default settings provided by the CMAK wizard, which might not be appropriate for your network.

### Notes

- The VPN entry that you add or edit in **VPN Entries** must have exactly the same name as one you specified in the VPN file. If you add a VPN entry (by clicking **New**), you must add a matching entry manually to the VPN file to make the VPN server available to your users.
- On the **General** tab, the option **Disable file and printer sharing** affects only computers running Windows NT 4.0, Windows 2000, Windows XP, or a member of the Windows Server 2003 family.
- On the **General** tab, the option **Enable clients to log on to a network** affects only computers running Windows 95, Windows 98, or Windows Millennium Edition.

Remote Access Authentication Methods

# Including a pre-shared key

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Including a pre-shared key**
You can use a pre-shared key instead of a certificate for L2TP/IPSec authentication of your VPN clients that are running Windows XP or a member of the Windows Server 2003 family. Pre-shared keys do not require a public key infrastructure (PKI) for deployment, but they are a relatively weak authentication method. You can increase the security of your pre-shared key deployment by encrypting the pre-shared key with a personal identification number (PIN), which your users must enter before the profile will install.

**Advantages and disadvantages of pre-shared keys**
Using pre-shared key authentication does not require the infrastructure investment of a PKI. Pre-shared keys and certificates can be used on the same remote access server. If the pre-shared key on the remote access server is changed, no pre-shared key VPN clients will be able to access the server until the pre-shared key on the clients are changed by reissuing and reinstalling the service profile. Unlike certificates, the origin and history of a pre-shared key cannot be determined. Administrators who want a long-term, strong authentication method should consider using certificates.

**Considerations when creating pre-shared keys**
A pre-shared key is a string of text that is configured on both the remote access server and the client. A remote access server running a member of the Windows Server 2003 family can be configured with only a single pre-shared key. All L2TP/IPSec VPN clients that connect to the remote access server using a pre-shared key must use the same pre-shared key. The pre-shared key can be any non-null string of any combination of between 8 and 256 characters. If there is any deviation between the pre-shared key on the remote access server and the pre-shared key presented by the VPN client, client authentication will fail. For more information about routing and remote access on computers running any member of the Windows Server 2003 family, see Routing and Remote Access.

**Increasing the security of a pre-shared key by encrypting it with a PIN**
You can increase the security of the distribution of your pre-shared key profile by encrypting the pre-shared key with a PIN. By distributing the service profile and the PIN separately, you will reduce the chances that unauthorized users can install the profile and gain access to your network. A PIN must contain no fewer than 4 but no more than 15 characters. Be sure to distribute the PIN to your users in a secure manner. This PIN will be requested only when the user installs the profile.

**Configuring a service profile to use a pre-shared key**
To configure a service profile to use a pre-shared key:

1. On the **VPN Entries** pane, click the VPN entry that you want to configure to use a pre-shared key, and click **Edit**.
2. On the **Security** tab, under **Common security settings**, click **Configure**.
3. Under **VPN strategy**, click **Use L2TP/IPSec if available**, and select the **Use a pre-shared key when using L2TP/IPSec** check box. Finish configuring any other aspects of security that your profile requires, and click **OK**.
4. Edit each VPN entry that requires a pre-shared key, and click **Next**.
5. On the **Pre-shared Key** pane, type a pre-shared key.
6. Do one of the following:
   - Type a PIN to encrypt the pre-shared key.
   - Clear the **Encrypt the pre-shared key using a PIN** check box.
7. Click **Next**, and finish building the profile.

# Providing phone book support

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Providing phone book support**

Connection Point Services (CPS) provides support for creating, maintaining, and updating phone books. You can also create your own phone book (without CPS), but the complexity of the format and requirements makes this difficult if you have more than a single Point of Presence (POP). For more information, see Connection Point Services and Connection Manager.

**Specifying how the phone book is to be provided**

Using the Connection Manager Administration Kit (CMAK) wizard, you can either:

- Include a phone book in your service profile, without support for automatic upgrades. To do this, in the CMAK wizard:

  1. In the **Phone Book** pane, browse to the phone book (.pbk) file that you want to include in your service profile. Make sure that you have a region file with the same name located in the same folder as the .pbk file. For example, if your phone book file name is AwesomeE.pbk, the region file should be AwesomeE.pbr.

  2. Make sure that the **Automatically download phone book updates** check box is **not** selected.

- Include a phone book in your service profile, with support for automatic upgrades. To do this, in the CMAK wizard:

  1. In the **Phone Book** pane, browse to the phone book (.pbk) file that you want to include in your service profile. Make sure that you have a region file with the same name located in the same folder as the .pbk file. For example, if your phone book file name is AwesomeE.pbk, the region file should be AwesomeE.pbr. Make sure the **Automatically download phone book updates** check box is selected.

  2. In the **Phone Book Updates** pane, type the URL for the Phone Book Service (PBS) server from which upgrades are to be downloaded.

- Do not include a phone book in your service profile, but download the phone book (and upgrades) to your users later. To do this, in the CMAK wizard:

  1. In the **Phone Book** pane, select **Automatically download phone book updates**, but leave the **Phone book file** box blank.

  2. In the **Phone Book Updates** dialog box, type the name of the phone book (.pbk) file to be downloaded (but do not include the file name extension) and the URL for the PBS server from which it (and the upgrades) can be downloaded.

  If you use this method of providing the phone book, you will also be able to automatically download updates to your users, using the same phone book name and URL.

The phone book name that you provide must match the name of the phone book file created with CPS. This file name consists of a maximum of 8 alphanumeric characters and cannot include spaces or a file name extension. If you specify support for automatic updates, each time the user connects to your service, the PBS server automatically downloads any updates to the phone book.

**Using more access numbers**

Using Phone Book Administrator in CPS, you can set up phone books to list certain POPs under **Access numbers** and other POPs under **More access numbers**. If you want to separate phone numbers into two sets, you must configure the phone book for this purpose before you use it in a service profile. You can separate the numbers in different ways, such as by separating standard access numbers from 800 and 888 numbers or by separating no-surcharge access numbers from access numbers that incur a surcharge when a user uses one of them to connect. For more information, see Connection Point Services.

If your phone book specifies a second set of access numbers, those numbers appear in the **More access numbers** box in the **Phone Book** dialog box.

To customize information about these numbers:

- Provide a line of text to appear in the dialog box, next to the **More access numbers** box. This line of text should be no more than about 100 characters. (The maximum size varies based on line breaks and other formatting considerations.) This line of text appears only when alternate access numbers are available for the selected geographic area.

- Edit the definition Help for the list of alternate phone numbers. The default Help states that the user can be charged extra for using alternate phone numbers. If this is not true for your alternate phone numbers, edit these Help topics in the Cmtrb32.rtf file: IDH_PHONEBOOK_ACCESSNUMS and IDH_PHONEBOOK_MORE. For more information on customizing Help, see Providing custom Windows Help.

**Advanced customization for the phone book**
Through advanced customization, you can also:

- Control which service types (such as modem or ISDN) appear in the **Phone Book** dialog box.

- Change the message displayed during phone book updates (such as "Downloading new Awesome Computers backup company phone book.").

- Control the delay before downloading phone book updates.

For more information on advanced customization techniques, see Advanced Customization.

**Creating a single-POP phone book**
You can include a default phone book that contains a single phone number. This is useful if you want your customers to access your service through one POP. When you want to create a phone book for multiple POPs, you should use CPS.

To create a single-POP phone book, you must create both a phone book (.pbk) file and an region (.pbr) file. In the CMAK wizard, you specify only the name of the .pbk file, but the wizard requires that a .pbr file with the same name be located in the same folder as the .pbk file.

**Creating a .pbr file for a single-POP phone book**
The region file you create for your single-POP phone book must be in plain-text (.txt) and must have two lines:

- The first line contains a number specifying how many regions are in the region file.

- The second line contains the name of the state or province (or other geographical area). Do not use commas or semi-colons in this line. The file name (excluding the extension) cannot exceed eight characters.

For example, if the POP were located in Washington, the contents of the single-POP .pbr file would be:

```
1
Washington
```

**To create a .pbr file for a single-POP phone book**

1. Start a text editor such as Notepad.

2. Type a **1** and press **Enter**.

3. Type the name of the region and press **Enter**.

4. Save the file in plain-text (text-only) format, naming it in the following format:

   *PBname*.pbr

**Creating a .pbk file for a single-POP phone book**
The file you create for your single-POP phone book:

- Must be located in the same folder as the .pbr file. The file name (excluding the extension) cannot exceed eight characters and cannot contain spaces.

- Must be in plain-text (.txt), comma-delimited format, and must include fields in the following sequence and without any spaces (if necessary, please scroll this page to read all 11 fields):

  *Index,Country/dependencyID,RegionID,POPName,AreaCode,PhoneNumber,MinBaud,MaxBaud,Reserved,ServiceType,DUNEntry*

  For example, a single-POP phone book for our fictitious company, Awesome Computers, might have the following specification:

```
1,44,1,AwesomeE - Basecamp,999,555-0134,9600,56000,0,0,Awesome Dun
```

**Notes**

- The TAPI codes are updated as needed. The TAPI codes available to a user depends on the operating system they are running and which service updates have been installed. Ensure that the TAPI code you provide is correct for the level of operating system that your users are running.

- For more information about what to specify for each field, see Connection Point Services.

# Incorporating custom dial-up entries

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Incorporating custom dial-up entries**

The dial-up entries referenced in the **Dial-up Networking Entries** pane of the Connection Manager Administration Kit (CMAK) wizard correspond to dial-up entries specified in the Phone Book Administrator (PBA) of Connection Point Services. The CMAK wizard provides a method of customizing how users access specific Points of Presence (POPs). For more information, see Connection Point Services and Connection Manager.

Customizing the way in which specific entries are handled can provide more effective handling of unique network authentication or routing requirements for POPs in your phone book. For each entry, you can specify the Domain Name System (DNS) or Windows Internet Name Service (WINS) addresses to be used for POPs associated with that entry and, if desired, a script to be associated with it.

Before you run the CMAK wizard, you must decide which dial-up entries you want to customize, and the options to use for each.

For each dial-up entry, you must specify:

- The name of the entry. If you have already specified a phone book to use with this service profile, any dial-up entry names used by the POPs (as configured in PBA) will automatically appear in the **Dial-up networking entries** box on this pane. If you have not yet specified a dial-up entry to use with a POP but want to add an entry, you must type the entry name exactly as it will appear in the **Dial-Up Networking entry** box in PBA. If you want to set up a default for your service profile, the name must be specified as your *ServiceProfileServiceName* (conforming to the file naming rules for a service profile).

- Whether to let the server assign the addresses or to use specific DNS addresses, WINS addresses, or both. If you want to assign specific addresses, you can specify both primary and secondary DNS and WINS IP addresses.

- If your service requires it, a script (.scp) file can be associated with this entry.

- You must specify the security settings to be used for connections made with this profile. By default, the security setting is selected to **Configure both basic and advanced settings**, which requires a configuration for profiles installed on Windows 95, Windows 98, Windows NT 4.0, and Windows Millinnium Edition, and a different configuration for profiles installed on Windows 2000, Windows XP, and the Windows Server 2003 family. Windows 2000, Windows XP, and Windows Server 2003 operating systems have more advanced security features and can support a higher level of security for your connection. You can choose to require the use of advanced security settings only, although this setting might prevent some clients on other operating systems from connecting with your profile. You can also choose to only use basic security settings that all operating systems that support Connection Manager can utilize. However, this means that all profiles will use the basic security settings, regardless of whether the operating system can support a higher level of security.

For example, for Awesome Computers (the service name of our fictitious company):

- To set up custom properties for a specific entry, you could specify **Awesome Dun** in the **Dial-up networking entries** box in the CMAK wizard. In this case, all POPs that have **Awesome Dun** specified as the phone book entry would use the addresses, scripts, or both as specified in the CMAK wizard for the Awesome Dun entry.

- To set up default properties for all other POPs in the phone book of the Awesome Computers service profile (any without a specific entry), you could specify **Awesome1** in the **Dial-up networking entries** field. In this case, all phone book entries without explicit dial-up entries would use the addresses and scripts specified in the CMAK wizard for this default entry.

**To set up custom dial-up entries**

- Add phone book entries to the appropriate POPs:

1. Start **Phone Book Administrator** and click the phone book you want.

2. Add or edit a POP to include the dial-up entry on the **Settings** tab.

For more information, see Connection Point Services.

- Using the CMAK wizard, build a service profile and set up dial-up entries as follows:

  - If the entry you want to configure already exists, select it and click **Edit**.

  - If the entry does not exist, in the **Dial-up Networking Entries** pane, click **New**. In **New Dial-up Networking Entry**, type the same dial-up entry as the one you entered in the phone book file. If you want to assign specific DNS or WINS addresses or specify scripts for the entry, specify the appropriate information.

**Notes**

- Remember, the dial-up entry that you set up in your service profile must either exactly match the specific entries you set up in the phone book or, if defining the default, it must be the default service name.

- Under the **General** tab, the option "Disable file and printer sharing" only affects computers running Windows NT 4.0, Windows 2000, Windows XP, and members of the Windows Server 2003 family.

- Under the **General** tab, the option "Enable clients to log on to a network" only affects computers running Windows 95 and Windows 98, but it has security implications for networks that support Windows NT, Windows 2000, Windows XP, and the Windows Server 2003 family.

- For additional customization options for these dial-up entries, see Advanced Customization.

**Using phone-book Dial-up Networking Entries**

Connection Manager reads the entry specified in **Dial-up Networking Entries** associated with the phone number, and uses the custom properties (such as a DNS server and script) that you specified in the CMAK wizard for that entry to establish a connection.

If Connection Manager does not detect a specific dial-up entry for the phone number in the service profile, it then tries to find the default entry (the **Dial-up Networking** entry named *ServiceProfileFileName* in the .cms file).

# Including routing table updates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Including routing table updates**
You can alter client routing tables with your service profile in order to better manage your network traffic and security. You can include a routing table update file in the service profile, provide a URL to an update file hosted on a server, or both. You can choose to undo any routing changes you made when the connection ends.

**Advantages of including routing table update files**
Routing table update files are plain-text files that you can create and edit in any plain-text editor, such as Notepad. The files you create or edit modify the routes on client computers. You can manage significant network security requirements by including update files in your service profile. The benefits include the ability to:

- Control user access to a corporate intranet
- Route all users through the same remote access server
- Redirect Internet traffic for VPN connections without using a proxy server

**Distribution channels**
You can provide update files for use in a service profile in one of three ways:

- Include a file with the service profile package (static)
- Include a URL to a file with the service profile and host the file on a Web server (dynamic)
- Include a static file with the service profile and include a URL to an additional file

You can distribute an update file by including it with a service profile. When the user installs the profile, the file is installed in the same directory as the profile. You should consider two factors when designing a profile using this method of distribution. The routes in the file on the client computer are not secure, and you must create and distribute another profile if you want to update the file.

**Important**

- If the user has not logged on with administrative credentials for the client computer, routing table updates will not be applied. The user will still be able to connect using your service profile, but the routes on the client computer will not be updated.
- The user will not be able to connect if the client computer cannot find a routing table update file you included in a service profile.
- You should not change the value of the **Gateway_On_Remote** key when using routing table updates. By default, the dial-up entry and the VPN entry will have **Make this connection the default gateway** selected. You should leave this default in place, and remove any gateways by using the **REMOVE_GATEWAY** command in the routing table update file itself.

You can provide a URL to an update file hosted on a Web server. The file is downloaded every time the user completes the connection. The user cannot easily review any file you distribute in this way. You can also update that file at any time.

If you provide a URL to an update file hosted on a Web server, you must make two additional decisions. The first is whether to terminate the connection if the server is unreachable. The second is whether to delete the default gateway on the client computer.

You can provide an update file with the service profile and a URL to an additional update file. This approach allows more flexibility in your design. You can add or delete routes as necessary to the hosted file, but you cannot change the file included

with the service profile without recreating and redistributing the profile. You still need to decide whether to terminate the connection if the Web server is unreachable and whether to delete the default gateway on the client computer.

**Syntax of routing table update files**

Routing table update files are constructed as plain-text files. Each line in those files adds or deletes a route. The syntax of each line is as follows:

*Command Destination* **MASK** *Netmask Gateway* **METRIC** *Metric* **IF** *Interface*

Certain parameters can contain the value of **default**. In those cases, the appropriate information from the client computer is used. The table below provides more information on each parameter:

| Parameter | Description |
|---|---|
| *Command* | Commands are one of the following:<br><br>**ADD** adds a route.<br><br>**DELETE** deletes a route.<br><br>**REMOVE_GATEWAY** removes the default gateway. |
| *Destination* | Specifies the destination IP address on the target network. |
| **MASK** | Specifies that the next parameter is the netmask value. |
| *Gateway* | Specifies the gateway. Should contain the value of **default**. |
| **METRIC** | Specifies that the next parameter is the cost for the destination. Should contain the value of **default**. The METRIC parameter is optional, and its default value is 1. |
| **IF** | Specifies that the next parameter is the interface number. Should almost always contain the value of **default**. |

Therefore, if you want the connection to follow a different route, you could include a line in your update file similar to the following example:

**ADD** 192.168.123.231 **MASK** 255.255.255.0 default **METRIC** default **IF** default

To delete a route, you could include a line in your update file similar to the following example:

**DELETE** 192.168.123.232 **MASK** 255.255.255.0 default **METRIC** default **IF** default

**Important**

- If your update file includes a delete command for a non-existent route, the connection will fail.

To remove the default gateway, you can add the following line to the update file:

**REMOVE_GATEWAY**

Unlike adding or removing a route, no further syntax is required after the **REMOVE_GATEWAY** command.

**Routing table precedence**

During the connection process, update files are applied in a specific sequence. You should keep this sequence in mind when you design your profile.

1. All update files are retrieved.

2. If you provide an update file with the service profile (static file), routing information from that file is applied to the client computer first.

3. If you provide a URL to an update file, routing information from that file is applied to the client computer after the static file. The downloaded file is then immediately deleted.

4. If you included the **REMOVE_GATEWAY** command in either update file, this command is executed after all other routes

have been applied.

Because of this order of precedence, a dynamic file could add routes, replace routes specified in the static file included with the service profile, or both.

If you use the default interface value, the routing changes you specify are reversed when the user disconnects.

# Using automatic proxy configuration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using automatic proxy configuration**
Conflicting or improperly configured proxy settings on user computers can restrict user access to external sites while the user is connected to a corporate network. By reconfiguring user proxy settings, you can ensure that the user has appropriate access to internal and external resources.

**Requirements for proxy configuration**
In order for you to use this feature:

- Your users must have Internet Explorer 4.01, Internet Explorer 5.01, Internet Explorer 5.5, or Internet Explorer 6 installed on the computer.
- Your network must include a proxy server.

Internet Explorer 4.0 requires a slightly different approach than Internet Explorer 4.01, Internet Explorer 5.01, Internet Explorer 5.5, and Internet Explorer 6. With Internet Explorer 4.0, proxy settings apply to all connections on the computer. With Internet Explorer 4.01, Internet Explorer 5.01, Internet Explorer 5.5, and Internet Explorer 6, different settings can apply to different connections on the same computer. If any of your users run Internet Explorer 4.0, you should choose to restore the computer's previous proxy settings when the user disconnects.

**Note**

- You can choose to restore the previous proxy settings when users disconnect without adversely affecting users running later versions of Internet Explorer. Therefore, if you are building a profile for use with multiple versions of Internet Explorer, you should choose to restore the client settings.

**Syntax of proxy configuration files**
In order to use automatic proxy configuration in a service profile, you must create a plain text file that specifies the following values:

| Key | Value |
|---|---|
| [Automatic Proxy] | No value. Section header for automatic proxy settings. |
| [Manual Proxy] | No value. Section header for manual proxy settings. |
| AutoProxyEnable | 0 = Automatic proxy detection is disabled.1 = Automatic proxy detection is enabled.<br><br>Note: This feature is not supported for Internet Explorer 4.0 and earlier. |
| AutoConfigScriptEnable | 0 = Automatic proxy script will not be executed. 1 = Automatic proxy script will be executed. |
| AutoConfigScript | The URL that points to the automatic proxy script. |
| ProxyEnable | 0 = Manual proxy detection is disabled. 1 = Manual proxy detection is enabled. |
| ProxyServer | The name and the port of the proxy server. |
| ProxyOverride | The Domain Name System (DNS) addresses, separated by semi-colons, that should not be passed on to the proxy server. You can use the value <local> to bypass the proxy server for local addresses. If you include this value, it should be the final value in the string. |

The following is an example of a simple proxy text file for Awesome Computers, simpleproxy.txt:

```
[Automatic Proxy]
AutoProxyEnable=1
```

```
AutoConfigScriptEnable=1
AutoConfigScript=www.awesome.com/proxysettings.txt

[Manual Proxy]
ProxyEnable=0
```

You can configure far more complex proxy settings. In the following example, complexproxy.txt, automatic proxy detection is used where possible, and a manual proxy supports Internet Explorer 4.0 users, who cannot use automatic proxy detection. Different protocols use different proxy servers, and several addresses have been excluded from the proxy.

```
[Automatic Proxy]
AutoProxyEnable=1

[Manual Proxy]
ProxyEnable=1
ProxyServer=ftp=FTPProxyServer:2010;gopher=GopherProxyServer:1066;http=HTTPProxyServer:
42;https=SecureProxyServer:1984;socks=SocksProxyServer:5150
ProxyOverride=DNSaddress1;DNSaddress2;<local>
```

For more information about proxy settings in Internet Explorer, refer to the Internet Explorer Administration Kit.

For more information about Connection Manager keys and values, see Advanced Customization.

**Note**

- Users who select the **Log on using dial-up connection check box** gain access through an account designed for this method of logging on. The Log on to Windows account has only minimal permissions, and any customized settings for Connection Manager, including proxy configuration, are applied to the Log on to Windows account, rather than to the account of the user who logged on. For more information, see Incorporating Connection Manager with logon security.

# Incorporating custom actions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Incorporating custom actions**
You can enhance the connection experience for your users by providing additional programs that start seamlessly during the connection to your service. You can use the Connection Manager Administration Kit (CMAK) wizard to include custom actions in your service profiles to automatically start programs when users connect to your service. These custom actions can use programs that users have already installed, or you can include the programs with your service profile.

**What custom actions are supported and when do they run?**
Using the CMAK wizard, you can specify custom actions to run at nine points during the connection process. You can run:

- Pre-init actions
- Pre-connect actions
- Pre-dial actions (for dial-up connections only)
- Pre-tunnel actions (for virtual private network (VPN) connections only)
- Post-connect actions
- Monitored actions
- Disconnect actions
- On cancel actions
- On error actions

**Pre-init actions**
As soon as users start Connection Manager, it runs the pre-init actions you have specified in your service profile. These actions are run before the Connection Manager logon screen appears.

### Note

- Pre-init actions will run when the **Properties** dialog box is opened for the service profile.

**Pre-connect actions**
As soon as users click **Connect**, Connection Manager runs the pre-connect actions you have specified in your service profile. These are run before Connection Manager establishes a connection to your service. For actions that relate specifically to dialing, use pre-dial actions. For actions that relate specifically to tunneling, use pre-tunnel actions, not pre-dial actions.

You cannot set up a pre-connect action that requires an interaction with your service. If interaction is required for part of the action, split the action into a pre-connect action and either a pre-tunnel or post-connect action, depending on the interaction requirements.

For example, recording information to a local log at the start of the logon process can be a pre-connect action, but if you want the log to post to your service, you might set up a separate upload program to be run as a post-connect, or disconnect action.

**Pre-dial actions**
Connection Manager runs pre-dial actions after users click **Connect** but before the computer starts to dial the connection to your service. Pre-connect actions run before pre-dial actions.

For example, pre-dial actions might include a program to change the telephone number for the service profile, or they might include a program that affects how the profile dials the connection.

**Pre-tunnel actions (for VPN connections only)**
Connection Manager runs pre-tunnel actions after establishing a connection with the Internet server but before establishing a tunnel to the VPN server. This type of action is available only if you set up VPN in your service profile, and it will run only when users are using the VPN connection option.

For VPN connections, set up all custom actions that require interaction with an Internet server as pre-tunnel actions, because Connection Manager has limited access to an Internet server after a tunnel is established.

For example, this might be a program that verifies user credentials for accessing a corporate server behind a firewall or that checks the expiration dates of client certificates.

For direct VPN connections, Connection Manager runs both pre-connect and pre-tunnel actions before connecting.

**Post-connect actions**
Connection Manager runs post-connect actions after establishing a connection or, if using a VPN connection, after establishing the tunnel. Each post-connect action that you specify in the CMAK wizard runs every time the user connects to your service, whether the connection is a dial-up connection or a direct connection.

In the CMAK wizard **Custom Actions** pane, you might have the following built-in post-connect action:

- **Download phone-book updates**. If you set up the service profile to automatically download phone book updates, Connection Manager includes this post-connect action which sends a phone book request to the server running Phone Book Service (PBS). The server compares the client phone-book version with the most recent files available at the server and then downloads any available phone-book updates. The next time the user starts Connection Manager, the updated access numbers are available. You must provide the name of the phone book and the URL of the PBS server in order to set up this custom action. For more information on phone book updates, see Connection Point Services and Connection Manager.

**Note**

- If you have Connection Manager 1.0 service profiles that include connect actions, you should know that custom actions in Connection Manager 1.3 are the same as connect actions in Connection Manager 1.0. In fact, in Connection Manager 1.3, post-connect actions are specified in the [Connect Actions] section of the .cms file, as there is no section with the title of [Post-Connect actions]. This terminology has been maintained to support migration from the previous version.

**Monitored actions**
Connection Manager runs monitored actions after establishing a connection and, for a VPN connection, after establishing the tunnel. Each monitored action that you specify in the CMAK wizard runs every time the user connects to your service, whether the connection is a dial-up connection or a direct connection. Monitored actions cause the connection to end after specified programs have ended. For example, if you want to automatically run an e-mail program, and then automatically end the connection when the user quits the e-mail program, you must set up e-mail as a monitored action.

Monitored actions are similar to post-connect actions, except that:

- All monitored actions must be .exe files, because monitored actions are run asynchronously. A dynamic-link library (DLL) runs synchronously, so it cannot be run as a monitored action.

- Connection Manager automatically monitors the status of all monitored actions and starts the disconnect sequence when the last monitored action closes.

**Note**

- When the last monitored action closes, Connection Manager provides a prompt to allow the user to override the disconnect sequence. The user can click **Stay Online** to prevent disconnection, click **Disconnect Now** to disconnect immediately, or do nothing to let the connection close automatically after 30 seconds have elapsed.

As with post-connect actions, you must provide the appropriate information for each monitored action specified in the service profile, including the application to run, whether to include the application in the service profile, and any command-line parameters that you want to run with the application. Unlike post-connect actions, you do not specify a descriptive name for a monitored action.

**Important**

- Specify only applications that are complete program files. You can include only one file for each monitored action. If you specify an application that requires other files or is a *self-extracting* executable (.exe) file as a monitored action, these files might cause the program or connection to be interrupted. If a monitored action requires any files in addition to the executable file, you should specify them as Additional Files in the CMAK wizard. These files will be installed with the service profile but not run. For more information on how to include these support files in the service profile, see Including additional files.

You can specify a variety of applications as monitored actions. For example, you might want to include a commercially available e-mail application, a customized stock-ticker application, and an internal accounting application. The CMAK wizard can specify all three types of applications. You can also select whether the application for each monitored action is to be included in your service profile.

**Notes**

- If you have Connection Manager 1.0 service profiles that include connect actions, you should know that Monitored Actions in Connection Manager 1.3 are the same as Auto Applications in Connection Manager 1.0. In fact, in Connection Manager 1.3, you specify monitored actions in the [Auto-Applications] section of the .cms file, because there is no section with the title of [Monitored Applications] in that file. This terminology has been maintained to support migration from the previous version.

- If the application is one that users already have installed on their computers, do not include it in the service profile. Doing so will increase the size of your service profile and might cause problems on the users' computers.

- You should not specify Internet Explorer 4.0 or 4.01 as a monitored action if your users have installed an active desktop. Upgrading your users to the most recent version of Internet Explorer is advisable if you want to specify Internet Explorer as a monitored action.

**Disconnect actions**

Connection Manager runs disconnect actions immediately before disconnecting from your service. You can use a disconnect action for routine administration. For example, you might set up a custom action to collect status information from your service, such as total minutes online (if this information is tracked by your service). This information can then be displayed for the user.

**Important**

- Disconnect actions will run even if the disconnect was not initialized by Connection Manager. For example, if the user's connection is terminated by a disruption in telephone service, Connection Manager will attempt to run the disconnect actions specified in the service profile after the unexpected termination.

**On cancel actions**

As soon as users click **Cancel** during a connection attempt, Connection Manager runs the on cancel actions you have specified in the service profile. On cancel actions do not run if the user clicks the **Cancel** button to close the Connection Manager program. You might use on cancel actions to reverse any pre-init actions you specified in the service profile.

**On error actions**

Connection Manager runs on error actions whenever an error occurs during the connection. You might use on error actions to collect information about the error for later support.

**What types of programs can be used as custom actions?**

A custom action can be:

- A dynamic-link library (DLL)

- An executable file such as a .bat, .exe, or .cmd file

- A shell-executable file, such as a .txt or .doc file

**Including Dynamic Link Libraries (DLLs)**
Only DLLs run synchronously, meaning that Connection Manager starts the action and then waits for the function to return before continuing. The first argument, specified as the **Parameters** in the **Add/Edit Custom Actions**pane of the CMAK wizard, is the function name within the DLL to call. The syntax for each of these custom actions is:

```
HRESULT WINAPI function
    [IN] HWND hWndParent
    [IN] HINSTANCE hinstDll
    [IN] LPCSTR pszCommandLine
    [IN] DWORD dwReserved
```

Supported DLL parameters are:

| Parameter | Result |
|---|---|
| hWndParent | Handle to the Connection Manager logon dialog box or NULL; used as the parent window for any user interface displayed by the custom action. |
| hinstDll | Handle to the instance of this DLL. |
| pszCommandLine | String pointer to the command-line arguments. |
| dwReserved | Reserved for future use. |

DLLs often have a comment (entered in the description field of the CMAK wizard) that appears while it is being run. This comment has the form **Running Custom Action** *Description*. The Connection Manager window is frozen and does not accept input while this type of action runs.

Custom action DLLs require a return value. If the return value is less than 0, the DLL call failed (SUCCEEDED macro returns False). In the case of a failure, an error message (including the return value) is displayed in the form "**Custom Action** ***Description*** failed *return value*." If a pre-init, pre-dial, pre-connect, pre-tunnel, or post-connect DLL action fails, the connection attempt is ended.

The DLL is unloaded after the function call.

### Notes

- For .dll files that require extended times for the program to run, you should implement WM_PAINT messages in the .dll file to ensure that graphics are not disrupted by user actions.

- You must provide the exact name of exported functions when building custom action DLLs. If you are using a language that changes the exported name (such as C++), you can use a .def file to preserve the exported function names.

**Including executable files**
This type of custom action is run asynchronously, which means that Connection Manager starts the executable, including any command-line parameters, and continues without waiting for the process to exit. No comment appears in the Connection Manager status pane while these programs are run.

**Including shell-executable files**
These actions run asynchronously. Each shell-executable file needs to be opened by a particular program.

If this program is not included in Microsoft operating systems, you might need to include it with your service profile.

**How to specify a custom action**
In the CMAK wizard **Custom Actions** pane, click **New** to add a custom action or **Edit** to edit an existing custom action. A dialog box will appear, where you must provide the following information for each custom action:

- **Description:** Provide a short description of the program to run. If you do not provide a description, the CMAK wizard uses the program name (specified in the **Program to run**) as the description.

- **Program to run:** Specify the file name of the program or file, including the file extension (such as .dll, .exe, .bat, or .cmd).

- **Parameters:** Specify any command-line parameters that you want to run with the program. The following special command-line parameter macros are supported:

| Macro | Replaced with |
|---|---|
| %ServiceName% | The service name of the profile. |
| %UserPrefix% | The user-name prefix used for this connection. |
| %UserSuffix% | The user-name suffix used for this connection. |
| %UserName% | The user name, without any specified realm user-name prefix or suffix. |
| %Profile% | The location and file name of the active connection profile (.cmp) file. |
| %ServiceDir% | The path to the profile directory. |
| %Domain% | The domain for the connection. |
| %InetUserName% | The user name for the Internet connection. |
| %ConnectionType% | A value that identifies the connection type, 0, 1 or 2.<br>0 = dial-up<br>1 = direct<br>2 = double-dial (also known as VPN) |
| %DialRasPhoneBook% | The full path to the phone book file. |
| %TunnelRasPhoneBook% | The full path to the phone book file used for the VPN portion of this connection. |
| %DialRasEntry% | The service name or remote access entry name for the dial-up connection. |
| %TunnelRasEntry% | The service name or remote access entry name for the tunnel connection. |
| %AutoRedial% | A Boolean value that is 1 if this dial attempt is an automatic redial, or 0 if not an automatic redial. |
| %PopName% | The description for the phone number in the CM phone book. |
| %ErrorCode% | The Win32 error code. |
| %LastErrorSource% | The origin of the last error. |
| %CurrentFavorite% | The location settings selected in the **Use settings for** box. |
| %TunnelServerAddress% | The IP or DNS address of the VPN server, if any. |
| %ClientIPAddress% | The IP address of the computer on which the Connection Manager profile is installed. |
| %ServerIPAddress% | The IP address of the remote access server, if any. |
| %Interactive% | A Boolean value, used in a custom action to determine whether or not to display a user interface. You can incorporate this macro in a custom action to display an interactive user interface (such as an error message) only when Connection Manager is running in an interactive state, and to take other action (such as failing gracefully without an error message) when Connection Manager is running in a non-interactive state. This macro was designed to be used in conjunction with the **Program interacts with the user** check box. For example, if you deselect **Program interacts with the user**, you should add the **%interactive%** macro to the custom action parameters so that the custom action can behave according to the state in which Connection Manager is run. This might require modification to the custom action itself. |

When parameters are specified, Connection Manager reads the parameter string and passes it to the **pszCommandLine** parameter of the .dll or sends it as part of the command line to an executable (available through the Windows API **GetCommandLine**).

If the custom action is a DLL, then the first token of the parameter string is the function entry point to call. This token is removed from the parameters before the string is passed to the DLL (so the **pszCommandLine** string does not start with the .dll entry point name as the first parameter). When creating the DLL, ensure that the exported name of the DLL matches the name specified as the first parameter, as name decoration can result in different names. (For example, in C++, name decoration can cause the exported name to be different from the actual function name.)

If you use the macros shown in the previous table, Connection Manager replaces them with the actual run-time information for the parameter. For instance, if you wanted a custom action to collect information about which users are using which POPs, you might create a .dll (or other executable) for this purpose, and Connection Manager could pass it information such as user name (using the **%UserName%**macro), realm information (using the **%Prefix%** or **%Suffix%** macro), and POP name (using the **%PopName%** macro). To do this, in **Parameters**, type the following: **LogUserAndPopToServer %UserPrefix% %UserName% %UserSuffix% %PopName% http://logserver.awesome.microsoft.com %AutoRedial%**

Depending on the user connection method, the information passed to the DLL might be:

```
NULL jobrown @awesome.microsoft.com "Seattle 28,800"
http://logserver.awesome.microsoft.com 0
```

Connection Manager cannot denote a null pointer in a string, so it passes the string NULL (which it passes for all undefined parameters). Only use quotes when a parameter contains spaces, such as "Seattle 28,800". The number variables have to be parsed from the string. If you are using an executable other than a DLL, the function name (in the above example, **LogUserAndPopToServer**) is not required.

- **Action Type:** Specify the time at which the action is performed by selecting **Pre-init**, **Pre-connect**, **Pre-dial**, **Pre-tunnel**, **Post-connect**, **Monitored**, **Disconnect**, **On cancel**, or **On error**.

- **Run this custom action for:** Specify what kinds of connections for which this custom action should be run. You can choose to run this action for **All connections**, **All connections that involve dial-up**, **All connections that involve a tunnel**, **Connections that use only a tunnel**, or **Connections that use only dial-up**.

- **Include the custom action program with this service profile**. Select this check box to include the program with the service profile. If the program you want to run is not part of a standard Windows operating system or is not otherwise available to your users, you should include the program in your service profile. The custom action program is installed in the service profile folder.

- **Program interacts with the user**. This check box is selected by default. If this check box is selected, Connection Manager will not run the custom action if it is in a non-interactive state. If this check box is not selected, a program called by the custom action that interacts with the user will halt the connection process indefinitely, waiting for a response from the user. For more deterministic behavior, you can deselect this check box and use the *%interactive%* macro.

Specify only programs that are complete program files. You can include one program file per custom action. If any non-executable files are required to support a custom action, you should include them as additional files, not as custom actions. These additional files should be files that are installed with the service profile but do not have to be run. For more information on how to include these support files in the service profile, see Including additional files.

**Important**

- If a custom action runs when users log on to Windows, the custom action runs with system permissions. You should ensure that any custom actions that you enable do not pose unintended security risks.

**Notes**

- Custom actions are run in the order shown in the CMAK wizard.

- Not all system macros are supported on all Windows operating systems.

- By default, custom actions are not run when a profile is used to log on to Windows. For more information about whether to enable custom actions for use when logging on to Windows, see Incorporating Connection Manager with logon security.

- If you want settings not found in the Connection Manager macros, other settings can be accessed programmatically

through remote access Application Programming Interfaces (APIs), which are documented in the Microsoft Web site.

- Sample code for a custom action that dynamically updates the proxy server setting for direct Internet connection users based on their selection of a VPN server is available in the Remote Access Service sample section of the Microsoft Platform Software Development Kit. For more information, see the Microsoft Web site.

# Incorporating custom graphics

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Incorporating custom graphics**
You must specify in the CMAK wizard whether to use the Connection Manager default bitmaps or your own graphics. You can customize the user interface to include your company logo or another image that identifies your organization. You can replace the graphics in both the logon dialog box and the **Phone Book** dialog box. The replacement graphic must be a bitmap (.bmp) file.

**Logon graphic**
You can create a custom bitmap or use an existing bitmap to replace the default Connection Manager logon bitmap that appears at the top of the logon dialog box. The default bitmap is 330-by-140 pixels.

**Phone book graphic**
You can customize the bitmap in the **Phone Book** dialog box that users see when they select a phone number for dial-up connections. This bitmap appears on the left side of the **Phone Book** dialog box. The default bitmap is 114-by-309 pixels.

**Creating bitmaps**
You should consider the following when creating bitmaps for either of the two replaceable graphics:

- Each bitmap looks best if it has the same proportions as the default bitmap.

  Connection Manager automatically scales each bitmap to appear at the appropriate size, but the image may be distorted if the proportions are not correct.

- Connection Manager uses the same set of bitmaps, regardless of the display mode.

- You should use the Internet Explorer 256-color (halftone) palette when creating bitmaps.

Be sure to test each bitmap on all target operating systems and platforms.

You can also customize the three icons your users see. For more information, see Incorporating custom icons.

# Incorporating custom icons

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Incorporating custom icons**

You can provide custom icons for use with your service profile. You can provide one file that contains icons in multiple sizes or you can provide one file for each icon in each size. You use the CMAK wizard to specify the icons your users see.

- The large program icon is used as the desktop icon. It also appears in the ALT+TAB switch window, the Network Connections folder (Windows XP and the Windows Server 2003 family only), and in several other pop-up dialog boxes. This icon is 32 × 32 pixels.

- The small title-bar icon appears at the left edge of the title bar in the logon dialog box, in various pop-up dialog boxes and, when the program is running, on its program button on the taskbar. This icon is 16 × 16 pixels.

- After a connection is established, the small notification area shortcut appears in the notification area at the far right of the taskbar. This shortcut icon is 16 × 16 pixels.

Connection Manager contains default images for these three icons. If you prefer to use your own icons in place of the default icons, you can use an icon-editing program to create them. Consider creating icons that are similar to one another to unify the appearance of the service profile. To ensure that your icons appear correctly, consider creating icons that match the size and overall shape of the default icons.

A single icon file (.ico) can have multiple images, each with a different size, color depth, or both. If you create an icon that you want to use in place of all three default icons, you should build the icon to include both 16 × 16 pixel and 32 × 32 pixel icons in the same file. If you include an icon in only one size, the icon is scaled to fit the assigned area when it appears, but the image might be dithered or distorted. To specify a single custom icon to be used for all service-profile icons, you must specify the name of the custom .ico file in all three boxes in the **Icons** pane of the CMAK wizard. If a box is left blank, the appropriate default is used.

**Note**

- You can also customize the menu that appears when a user right-clicks the notification area shortcut. For more information on customizing this shortcut menu, see Customizing the notification area shortcut menu.

# Customizing the notification area shortcut menu

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Customizing the notification area shortcut menu**

The notification area shortcut appears in the notification area of the taskbar when the user is connected to your service. The notification area shortcut menu appears when a user right-clicks this notification area shortcut. This menu provides users with a shortcut to specific programs. On the Windows XP and Windows Server 2003 family platforms, the default commands on the menu are **Status**, **Disconnect**, and **Open Network Connections**. You can use the CMAK wizard to customize the shortcut menu by specifying which, if any, additional commands appear on the menu.

For each command that you want to add to the menu (other than the default commands), in the **Notification Area Shortcut Menu** pane, click **Add** and then specify:

- The name of the command as you want it to appear on the shortcut menu. If you do not specify a name for the command, the menu displays the file name and extension of the program to be run.
- The file name (including the extension) of the program that runs when the user selects the associated command from the menu.
- Any command-line parameters that you want to run with the program.
- Whether to include the program file in the service profile. If the program is not part of the standard operating systems of the target platforms or is otherwise not available on your users' computers, you can include it in the service profile. At installation, the service profile copies the program to the \Cm*ServiceProfileFileName* folder.

You can add keyboard access to a shortcut menu command by designating one of the letters in the command name as the access key. To specify an access key, type **&** immediately before the letter you want to use. For example, to add "Notepad" as a command name with the letter *N* specified as the access key, type **&Notepad**. When the user opens the shortcut menu, the access-key letter (*N*, in this example) is underlined in the command name (N**otepad**). The user would press **N** to carry out the **Notepad** command.

If you want to include the ampersand (**&**) character in the command name, type **&&**. For example, to use the command name **Update & Refresh**, type **Update && Refresh**. One ampersand appears in the shortcut menu, not as an access key. (**Update & Refresh**).

**Notes**

- You can control whether a notification area shortcut appears in the notification area of the taskbar by editing the **NoTrayIcon** key in the **[Connection Manager]** section of the .cms file.
- The default commands are not shown in the CMAK wizard in **Shortcut menu commands** or included in the service-profile files. They are part of the Connection Manager software and cannot be deleted.
- Only .exe files and other shell executables (such as URLs and other files with registered extensions) are supported as menu commands. DLLs are not supported.
- System macros are not supported for notification area shortcut commands.

For more information on using advanced customization techniques to edit the .cms file, see Advanced Customization.

# Providing custom Windows Help

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Providing custom Windows Help**

Using the CMAK wizard, you can customize the Connection Manager Help, which consists of definition Help and troubleshooting Help:

- Definition Help provides a brief description of each interface item. This type of Help topic appears in a small pop-up window. Users display topics by right-clicking an interface item and then clicking **What's This?** in the pop-up menu that appears. In all dialog boxes except the logon dialog box, users can also display definition Help by clicking the question-mark icon in the title bar and then clicking an interface item.

- Troubleshooting Help provides a structured approach to diagnosing and resolving many common connection problems. Users start the **Troubleshooting Help for Connection Manager** by clicking **Help** in the logon dialog box. The question-and-answer format guides users through the process of determining the most likely causes of the problem. The troubleshooter then provides possible solutions, based on the user's feedback.

Both the definition and troubleshooting Help files are compiled into a single .hlp file. This compiled file is incorporated into the service profile for distribution to users. The default Help is Cmmgr32.hlp. If you do not want to use the default Help, you can use the CMAK wizard to specify custom Help to replace the default in your service profile.

### Note

- There are two areas of Help information that you cannot customize in the definition Help. The first non-customizable Help is for the **Dialing Properties** dialog box, which users see when they click the **Dialing Rules** button on the **General** tab of the **Properties** dialog box. This dialog box, along with its associated Help, is a component of the Telephony Application Programming Interface (TAPI) and, although it is incorporated as a part of Connection Manager, it cannot be modified. The second area of non-customizable Help is for the **Advanced** tab. The contents of this tab is a component of the operating system, and, although it is incorporated as part of Connection Manager, it cannot be modified.

**How to customize the default Help files**

If you want to include custom Windows Help, you must prepare your files before you run the CMAK wizard. Your CMAK folder contains all the source files for the default Help. To create custom Help, you need to copy the default Help source files, including the project [.hpj] file, rename them, edit the renamed files, and recompile them. Putting them in a separate folder helps prevent the original files from being accidentally altered. Following is information for creating custom Help, including a description of all of the source files and the tools required to modify these source files. (A basic understanding of Windows Help systems and user-education concepts is assumed.)

### Notes

- Be careful when modifying the Help files. Troubleshooting any changes you make to these files may be difficult. Avoid changing Windows Help file footnotes. Do not change any of the topic IDs (the number sign [**#**] footnotes).

- When specifying your custom Help file in the CMAK wizard, browse to it. If you type the name, no validation is done on the file name (including the file extension).

- Be sure to test the Help files on all target platforms before delivering your service profile to your users. Test Help by starting Connection Manager and using both the definition Help and troubleshooting Help. Testing Help by opening the .hlp file outside of Connection Manager does not allow verification of functionality.

**Source files**

The following files are included with the Connection Manager Administration Kit. By copying and editing these source files, compiling your customized project (.hpj) file, and then specifying the name of your compiled custom Help file in the CMAK wizard, you can provide custom Help to your users.

- Cmmgr32.hlp (the default compiled Help file) is installed on your hard disk in the %windir%\system32 folder.
- The following online Help components are installed on your hard disk in the \Program Files\CMAK\Support\CMHelp folder.
    - Cmmgr32.hpj (the Help project file)
    - Cmctx32.rtf (the text document source for definition Help)
    - Cmtrb32.rtf (the text document source for troubleshooting Help)
    - Cmmgr32.h (the header file containing definition Help IDs)

**Note**

- Graphics (such as bullets) and the template file (What7.dot) are not included, so you should create these files as appropriate to the look you want to provide in your Help.

You must have all of these files if you want to customize and rebuild the online Help system. Suggestions for customizing entries in each file are discussed later in this section.

**Important**

- To customize the Help files for a service profile, copy the default Help files (except for the cmmgr32.hlp file), rename them, and then edit only the renamed files. Do not edit the original default files. When you rename the files, be sure to update the names referenced in the .hpj file, including the name of the .hlp file. If you customize Help but do not rename the .hlp file, the CMAK wizard could accidentally incorporate both the default and custom files when building the service profile.

**Note**

- In addition to Help files, you can provide custom readme and procedural documentation to your users. For more information on the additional documentation that you can customize for your users, see Providing user documentation.

**Required tools**

To customize Help files, you need both of the following:

- A word-processing program, such as Microsoft Word, that reads and writes .rtf files.
- A 32-bit Help compiler, such as Help Workshop version 4.01.

**Note**

- You can obtain the Help compiler (Hcw.exe) and associated files by downloading both the Microsoft Platform SDK build environment and the additional SDK components (tools) from the Microsoft SDKs at the Microsoft Developer Network (MSDN) on the Microsoft Web site. However, only limited documentation on how to create and edit Help is available in the SDK.

**What should be customized?**

The most commonly customized Help information is that contained in the .rtf files, including the text for both definition and troubleshooting Help.

**Customization suggestions for definition Help**

The text for definition Help is in the Cmctx32.rtf file. In the following list of customization suggestions, each topic is referred to by its topic ID (the **#** footnote).

| Help topic ID | Customization information |
|---|---|
| IDH_LOGON_SVCMSG | You can use this topic to provide definition Help for the support text in the logon dialog box. This topic is available to your users only if you specify support information when you run the CMAK wizard. The default text for this message is "No Help topic is associated with this item." You can modify this text to provide assistance for the support information specified for your users. For example, if you provide a phone number for customer support in the logon dialog box, you might want to provide a description of your customer support service in this topic. |
| IDH_PHONEBOOK_SERVICETYP | In the **Phone Book** dialog box, this topic provides Help for the **Service Type** list. You can customize this topic to reflect the service types that you support and provide a brief description of each. |
| IDH_PHONEBOOK_ACCESSNUMS and IDH_PHONEBOOK_MORE | In the **Phone Book** dialog box, these topics provide Help for the **Access Numbers** and **More Access Numbers** lists. You can edit the text to change it or add information about the available numbers, such as which numbers incur user fees and which do not. The default text specifies that additional charges are incurred for using these numbers. |
| IDH_PHONEBOOK_SVCMSG | In the **Phone Book** dialog box, this topic provides Help for the phone book customer service message area (next to the **More access numbers** box). This message appears only if alternate access numbers are available for the selected geographic area. You can use this topic to provide additional customer service information about the numbers that you make available in the **More access numbers** box. |

Throughout the Cmctx32.rtf file, you might want to convert the term "your service" to the name of your service. For example, IDH_LOGON_NAME contains: "The name you use to log on to your service." Changing "your service" to "Awesome Computers" (the name of the fictitious company used in this documentation) would change this information to: "The name you use to log on to Awesome Computers."

#### Customization suggestions for troubleshooting Help

Text for troubleshooting Help is in the Cmtrb32.rtf file. The following list of customization suggestions includes reference topics by title and by topic ID (the **#** footnote).

| Troubleshooter topic ID | Customization information |
|---|---|
| ICM_TRB (Logon troubleshooter) | This topic is the starting point for users to identify possible problems. If you have specific problems that you want to address, you can add your own paths to the troubleshooter, starting at this point or any other point. You can add topics to cover as many situations as you want. |
| ICM_TRB_CUSTSUP_NUMS (Contact customer support) | This topic provides users with customer support information. Add your specific customer support phone numbers, hours of operation, and any other useful information. Users display this topic from other topics that recommend contacting customer support. |
| ICM_TRB_GIVEUP and ICM_TRB_GIVEUP_PHONE (Next steps) | One of these two topics appears at the end of all troubleshooting paths. You can provide additional instructions for users who try all troubleshooting possibilities and still are not able to connect to your service. |

As with the definition Help, you might want to change the term "your service" to the name of your service, wherever it appears in this file.

#### Customizing and compiling the project file

If you customize the .rtf files, you must customize the project (.hpj) file (using Help Workshop 4.01 or another appropriate Help editor) to include the names of these custom .rtf files. You can also change other project information in the .hpj file. For example, if you do not want to use "Troubleshooting Help for Connection Manager" in the title bar of the Help screens, you can change the title in the .hpj file by changing "TITLE" under **[Options]** and "proc4" under **[Windows]**.

After you have finished editing the .hpj and .rtf files, you must compile the .hpj file to create the .hlp file. When you run the CMAK wizard to create your service profile, specify the name of your custom .hlp file in the wizard.

### Note

- The .h (mapping) file contains the topic IDs for the definition Help. Editing this file may prevent Connection Manager from displaying the appropriate definition Help.

# Providing support information in the logon dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Providing support information in the logon dialog box**

Using the CMAK wizard, you can specify a line of information to be displayed in the logon dialog box, directly above **Connection status**. This line of text can be a maximum of approximately 50 characters and usually gives users a number to call for support (for example, "Call 1-800-###-#### for customer service."). No default text exists for this option. If you do not specify a line of text, this area of the logon dialog box will be left blank.

It is a good idea to repeat this contact information in your readme files or other installation information in case a user is unable to display the logon dialog box.

If the contact information is dependent on the location from which the user is dialing, you may want to customize Help to list all customer support numbers (to support remote users roaming outside of their home service area). In the line of text in the logon dialog box, you can then include a reference to Help. (For example, "For customer support phone numbers, click Help.") If you do this, add a link to the initial Help screen that jumps to the topic ID containing your support numbers. For more information on customizing Help, see Providing custom Windows Help.

# Adding Connection Manager 1.3 to the service profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Adding Connection Manager 1.3 to the service profile**

Users must install Connection Manager 1.3 to run a Connection Manager 1.3 service profile. If your users do not already have it installed, you should include the software in your service profile. In the CMAK wizard, you can specify that this software be included in the service profile being built, so the software is installed when the user installs the service profile.

If you include Connection Manager 1.3 in the service profile and a user already has a previous version of Connection Manager installed, the software is automatically upgraded at installation. Connection Manager cannot be installed if the current or a newer version is already installed on the user's computer. For example, Connection Manager 1.3 is a component of the Windows XP operating system, so it does not get installed on computers running Windows XP. However, the service profile installs, even if the Connection Manager software included in the profile does not install.

### Notes

- You must include the Connection Manager 1.3 software for profiles intended for installation on computers running Windows 2000.

- Be sure to include the size of the Connection Manager software when calculating the size of your installation package. For more information on the size of the Connection Manager software, see Planning for effective implementation.

# Incorporating a license agreement

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Incorporating a license agreement**

Using the CMAK wizard, you can include your own license agreement with your service profile. This license agreement appears when the user clicks **OK** to begin the initial installation of your service profile. If the user accepts the license agreement, installation continues. If not, installation is cancelled.

Use a text-editor program such as Notepad to create your license agreement as a text (.txt) file. To avoid formatting problems, do not use hard returns (forced line breaks) at the end of lines. Line-wrapping for the license agreement is done automatically when the service profile is built.

# Including additional files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Including additional files**

Using the CMAK wizard, you can include additional files with your service profile to help your users implement your service. All files that are needed for your service that are not specified elsewhere in the CMAK wizard should be specified in the **Additional Files** pane. This section contains information on files that you might want to include as **Additional Files.**

**Custom action and monitored application files**

If you create a custom action, you include the program for the custom action by specifying it in the **Add/Edit Custom Actions** pane. However, you can specify only one program there for each custom action. You must specify any other files required to implement the custom action as **Additional Files**. The same is true for monitored applications. For more information on the files that should be included with custom actions and monitored applications, see Incorporating custom actions.

**User documentation files**

If you create user documentation for your service, you can include this information in your service profile by specifying the user documentation files as **Additional Files**.

**Other files**

If, after running the CMAK wizard, you do any advanced customization by editing any of the service-profile files, you may need to include additional files to support some of your advanced customization. You specify any files needed to implement advanced customization as **Additional Files**. For more information on this type of advanced customization, see Advanced Customization.

# Providing user documentation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Providing user documentation**

In addition to Providing custom Windows Help with your documentation, you can incorporate other types of user documentation in your service profile. You can also develop and incorporate your own user documentation. Start by reviewing the information provided:

- Sample procedures, included later in this topic:
    - "Setting up Connection Manager," including instructions for installing Point-to-Point Tunneling Protocol (PPTP) on Windows NT 4.0
    - "Establishing a connection"
    - "Removing Connection Manager"

To reduce your customer-support effort, make sure your setup and usage instructions clearly and completely guide users through both the setup of Connection Manager and connection to your service.

To include user documentation in your service profile, you can specify the files as additional files (in the **Additional Files** pane of the CMAK wizard). For more information, see Including additional files.

### Note

- Information included as additional documentation is not available to users until after the installation of your service profile. You may want to include some of the information (such as installation procedures) in a readme file to accompany your service profile, in a form that can be accessed by users before installation.

**User procedures**

You should provide user documentation to help your users install, run, and remove (if necessary) Connection Manager. You can customize the following procedures and put them in a readme file or other user documentation.

Throughout these user procedures, you should substitute the name of your service profile for each occurrence of *ServiceProfileFileName*, regardless of the context in which it is used. (The name you substitute should not be in italics.)

The following procedures contain glossary entries and links to a Web site. Depending on the format and support files you provide with your documentation, these may not work as implemented here. Change these as appropriate for your deliverables.

When you run the CMAK wizard to build the service profile, specify the file names of all user documentation that you want incorporated in the service profile (to be available after the service profile is installed) as additional files.

**Setting up Connection Manager**

Instruct your users to perform the following procedure for setting up Connection Manager.

**To set up Connection Manager**

1. Use the appropriate method to find the *ServiceProfileFileName* file:
    - If you received the program for your service on a floppy disk or compact disc:

    a. Insert it in the appropriate drive.

    b. Use Windows Explorer to find the file.

- If you downloaded Connection Manager from the Internet or a private network, browse to your download folder.

2. Double-click *ServiceProfileFileName*.exe.

3. After installation has finished, double-click the icon on your desktop to start the service. If prompted to install additional components, click **OK**.

**Verifying and installing the latest Dial-up Networking software for Windows 95**
If your service profile supports virtual private network (VPN) connections, your users who are running Windows 95 on their computers must have the latest version of **Dial-up Networking** installed on their computers. Provide the following instructions to your VPN users to ensure installation of the correct level:

**To verify and install Dial-up Networking software for Windows 95**

- If you are running Windows 95 on your computer, you must obtain and install the current **Dial-up Networking** software by downloading it as a Windows Update from the Microsoft Web site.

**Installing PPTP on Windows NT 4.0**
Users must manually install PPTP on computers running Windows NT 4.0. Provide the following instructions for users who need to install PPTP.

**To install PPTP on a computer running Windows NT 4.0**

1. Make sure your Windows NT 4.0 distribution disks are available during installation to provide access to system files. It is recommended that the latest Windows NT service pack be installed. Windows NT Service Pack 3 provides support for multiple modems or dial-up scripting. Windows NT Service Pack 4 provides additional support for virtual private network (VPN) connections. Users can obtain the current **Dial-up Networking** software by downloading it as a Windows Update from the Microsoft Web site.

2. Click **Start**, point to **Settings**, click **Control Panel**, and then double-click **Network**.

3. On the **Protocols** tab, click **Add**.

4. In **Network Protocol**, click **Point To Point Tunneling Protocol**, and click **OK**.

   If Setup needs to copy files, click **Continue** when prompted.

5. When prompted, click **OK** to set the number of virtual private networks to one (1).

6. In the **Remote Access Setup** dialog box, click **Add**, click **VPN1 - RASPPTM**, and then click **OK**.

7. Click **Configure**, and make sure the **Dial out only** check box is selected.

8. In the **Remote Access Setup** dialog box, click **Network**, make sure **TCP/IP** is selected, and then click **Continue**.

   You can now close the Network utility and restart your computer, and then reinstall any service packs required.

**Establishing a connection**
Have users follow these steps to connect to your service:

**To establish a connection on a computer running Windows XP or a member of the Windows Server 2003 family**

1. On the desktop, double-click the *ServiceProfileFileName* icon.

2. Type your *user name* and password.

   If you are using a VPN connection to connect to a private network, you might be prompted for a second user name and password. If so, type the user name and password that you use for the Internet service provider (ISP).

3. If you are using Connection Manager to connect for the first time, click **Properties**, click **Phone Book**, and then select a phone number from the list of access numbers. (Or you can type the phone number that you want to use to access the service.)

4. Click **OK** twice.

5. Click **Connect** to establish a connection.

   When you connect, the service might update your phone book if new or changed phone book information is available.

### Notes

- You can also start Connection Manager using the program icon in the **Network Connections** folder.

- Connection Manager supports user installation of multiple service profiles, running multiple instances of Connection Manager, and multiple user profiles for each service profile. If a user installs more than one service profile, each is installed in a separate folder. You can provide as many profiles to your users as necessary to support your service, but each must have a different service name and file name.

- For help with establishing a connection or with troubleshooting, use Help:

  - For troubleshooting Help, click **Help** in the Connection Manager logon dialog box.

  - For more information about an item in the dialog boxes, click the question mark [**?**] button in the title bar, and then click the item.

    Or right-click the item, and then click **What's This?**.

#### Removing your service

Have users follow these steps if they want to remove your service.

### Note

- This procedure removes only the service profile. The Connection Manager software remains on the user's computer, as users may require it for other profiles on the computer.

#### To remove your service

1. Right-click the desktop icon for your service.

2. Click **Delete**.

3. When prompted to continue with the deletion, click **OK**.

### Note

- Removing the software for your service does not remove the Connection Manager software required to run your service. You must remove the Connection Manager software separately.

# Advanced Customization

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Advanced customization**
The CMAK wizard supports most of the customization features that administrators need to build a custom Connection Manager service profile. However, you can customize additional features by editing the service profile files, thereby changing the manner in which Connection Manager handles certain functions.

This section covers:

- Uses for advanced customization
- Methods of editing service profile files
- Templates and service profile files
- Information files
- Tables of Key Names and Values

# Uses for advanced customization

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Uses for advanced customization**

By using advanced customization techniques, you can change the implementation of many Connection Manager functions. For example, you can:

- Create a custom button that appears on the Connection Manager user interface to start applications or run processes.
- Prepopulate user name, password, phone number, and dialing properties for use in your service profile.
- Show a particular set of phone numbers based on user selection of connection device.
- Remove the **General** tab from the **Properties** dialog boxes for VPN-only service profiles.
- Control whether the **Save password** check box appears on the Connection Manager user interface.
- Control whether the **Logon domain** field appears.
- Specify your multilink strategy.
- Specify logging behavior.
- Turn off balloon-tip help for Connection Manager.

**Note**

- Refer to Tables of Key Names and Values for complete lists of keys and values you can modify.

# Methods of editing service profile files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### Methods of editing service profile files

The CMAK wizard provides the ability to customize the most frequently used elements of a service profile. However, you might want to customize elements that you cannot configure in the wizard. By adding or editing keys and values to the individual files that make up a service profile, you can provide even higher levels of customization to meet the needs of the most advanced environments.

#### Service profile file types

Service profiles include files of the following types:

- **Service provider (.cms) files.** The .cms files specify the configuration of the phone book and most of the other functions of your service profiles. Most advanced customization for a service profile is done by editing the .cms file for a particular service profile.

- **Connection profile (.cmp) files.** The .cmp files contain information specified by the user. Because users can overwrite any changes you make to this file, any changes you make to this file will be available only the first time the service profile is used. Editing this file allows you to provide a first-time-only population of user information. For example, you can fill in the user name, the password, and the phone number fields for the first user to install and open your service profile.

- **Information (.inf) files.** The .inf files specify installation information for your service profiles. Although you can edit some setup and uninstall information in an .inf file, you should test the installation after you make any changes. You cannot edit information files from the **Advanced Customization** pane of the CMAK wizard. To edit .inf files, you must use a plain-text editor.

- **Connection profile (.sed) files.** The .sed files contain the instructions for building a self-extracting executable (.exe) file for your service profiles. You should never edit any .sed file.

**Important**

- You should not edit these files without a basic understanding of system configuration files. Troubleshooting changes to service-profile files is difficult, so you should be careful if you modify them. Read section and key descriptions carefully. It is advisable to make a backup of these files before you edit them.

#### Editing files

You can edit specific files used to build the service profile in one of two ways:

- Select the **Advanced customization** check box in the **Ready to Build the Service Profile** pane of the CMAK wizard. If you do this and then click Next, the **Advanced Customization** pane appears.

- Edit files after profile creation with any plain-text editor, such as Notepad.

You can use the **Advanced customization** pane to edit the .cms and .cmp files when you build a service profile. You can select or type in section names, keys, and values. You must click **Apply** after you specify each change. Some advantages of this method are that the changes you make are built directly into the service profile when you click **Next** and that you can make many changes quickly. However, if you mistype a section name or a key name and click **Apply**, you cannot edit or delete that section or key name directly. You can delete a key only by setting the value to blank, and you can delete a section only by setting one of the keys in it to blank.

**Important**

- If you set the value of a single key to blank in the **Advanced Customization** pane, you delete that key and all other keys in that section, as well as the section itself.

- Any user can modify the .cms and .cmp files of a service profile that is installed on a computer running Windows 98 or Windows Millennium Edition. Users who install profiles for individual use on computers that are running Windows Server 2003, Windows XP, or Windows 2000 can modify .cms and .cmp files of the profiles they install. Only members of the Administrators or System Operators groups can modify .cms and .cmp files of profiles installed for All Users on computers that are running Windows Server 2003, Windows XP, or Windows 2000. All members of the Administrators group on a local computer can modify the .cms and .cmp files of any service profile that is installed on that computer.

To customize a service profile after you have built it, you can edit any of the service profile files with any plain-text editor, such as Notepad. However, you must run the CMAK wizard again after editing the files in this way in order to incorporate your changes.

For more information, see Deciding what to customize, Uses for advanced customization, and ISP and Service Type keys.

# Templates and service profile files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Templates and service profile files**

You can edit service profile files to customize functions and features that are not controlled through the CMAK wizard. To do this advanced customization, you can edit two sets of service profile files:

- The template files that are used by the CMAK wizard to build all service profiles
- The files that are built when you run the CMAK wizard to create a specific service profile

Service profile files consist of the following file types:

- **Service provider (.cms) files.** The .cms files specify the configuration of the phone book and most of the other functions of your service profiles. Most advanced customization for a service profile is done by editing the .cms file for that service profile.
- **Connection profile (.cmp) files.** The .cmp files contain information specified by the user. Because users can overwrite this information, any changes you make to this file will be available only the first time the service profile is used. Editing this file allows you to provide a first-time-only population of user information. For example, you can fill in the user name, the password, and the phone number fields for the first user to install and open your service profile.
- **Information (.inf) files.** The .inf files specify the installation information for your service profiles. Although you can edit some setup and uninstall information in an .inf file, you should test the installation after you make the changes. Information files cannot be edited from the CMAK wizard **Advanced Customization** pane. To edit them, you must use a text editor.
- **Connection profile (.sed) files.** The .sed files contain the instructions for building a self-extracting executable (.exe) file for your service profiles. You should never edit any .sed file.

**Important**

- You should not edit these files without a basic understanding of system configuration files. Troubleshooting changes to service-profile files is difficult, so you should be careful if you modify them. Read section and key descriptions carefully. It is advisable to make a backup of these files before you edit them.
- Do not save template files in Unicode.

**Editing template files**

You can edit template files, specific service profile files, or both, depending on whether you want to apply your customization options to all service profiles or to a specific service profile only.

**Template files**

When you install CMAK, the following template files are installed in the \Program Files\CMAK\Support folder:

- Template.cms
- Template.cmp
- Template.inf
- Template.sed

These files contain the default settings that the CMAK wizard uses to build service profiles. If you want to incorporate the same custom functions in all service profiles that you build, edit the template files before building the service profiles. You must edit the template files with a plain-text editor, such as Notepad. You cannot edit template files with the CMAK wizard.

Generally, you should edit only the .cms template file.

**Note**

- Changes you make to the template files apply only to subsequent new service profiles you build using the CMAK wizard.

**Built files**

When you use the CMAK wizard to build a service profile, the wizard creates a self-extracting executable (.exe) file and several other files containing the settings that you specify. The service profile files are saved in the \Program Files\CMAK\Profiles*ServiceProfileFileName* folder. All service profile files have the name *ServiceProfileFileName*, which you specify in the CMAK wizard. In addition to the .exe file, the wizard creates the following files for each service profile:

- *ServiceProfileFileName*.cms
- *ServiceProfileFileName*.cmp
- *ServiceProfileFileName*.inf
- *ServiceProfileFileName*.sed

Changes to template files are reflected only in profiles built after you make the change. If you want profiles built before you make the change to match the template, you must update the profile. To incorporate template changes into a built file, you must run the CMAK wizard again.

For more information, see Deciding what to customize, Uses for advanced customization, and Finishing customization after running the CMAK wizard.

# Information files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Information files**
Only customize entries under the section headers in the information files as specified in this topic.

**Information (.inf) file entries**
By editing a profile's .inf file, you can specify commands and programs that run when the user installs or uninstalls your service profile. For example, you can specify:

- Setup programs that integrate any custom software that you include.
- Programs that automatically display a readme file.
- Configuration utilities or cleanup programs.

To add custom setup and uninstall programs to your service profile, you must first create the service profile by running the CMAK wizard and then you must specify any files needed as additional files. After you have built the service profile, specify the necessary commands or programs in the appropriate sections of the .inf file, and then run the CMAK wizard again to incorporate your changes.

The .inf file contains four section headers under which you can include commands and programs to be run at specific points. Use file names of eight characters or less. Do not use spaces in the file names.

| This .inf file section header | Contains commands or programs that run |
|---|---|
| RunPreSetupCommandsSection | Before Setup begins |
| RunPostSetupCommandsSection | After Setup finishes installing the service profile |
| RunPreUnInstCommandsSection | Before the uninstall program begins |
| RunPostUnInstCommandsSection | After the uninstall program runs |

Each entry beneath the header should include the name of the command or program to be run and any command line parameters. Each command specified in the .inf file is run only once during an installation or uninstallation process.

**Important**

- Incorrectly specified commands or programs in the .inf file can cause significant installation problems. Do not add entries to any of the sections in the .inf file except those previously specified. Thoroughly test all service profiles containing custom .inf entries for version, file, or other conflicts. Be sure that the file location is specified correctly.
- If you edit Connection Manager 1.0 service profiles in Connection Manager Administration Kit 1.3, the profile is upgraded to Connection Manager 1.3 and the new .inf file replaces the previous .inf file. After the upgrade, you must add your entries to the new .inf file if you want to continue using your custom setup and uninstall commands in the service profiles that you build.

For more information, see Phase Four: Preparing for Integration, Delivery, and Installation, Incorporating Connection Manager with logon security, and Finishing customization after running the CMAK wizard.

# Tables of Key Names and Values

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Tables of key names and values**

The tables in this section discuss the valid keys for each section of the .cms and .cmp files, the function and use of each key, and where each key can be set (in the CMAK wizard, the .cms file, or the .cmp file).

- ISP and Service Type keys
- Connection Manager keys
- Custom actions keys
- Networking keys
- Other sections, keys, and values

# ISP and Service Type keys

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ISP and Service Type keys**

You can change how Connection Manager defines ISPs and service types. To do this, you need to edit the service (.cms) file. The table in this topic covers the key names and values that are contained in the [ISP] and [Service Type] sections of the .cms file. This topic also describes the formats and conventions you should use in the .cms file.

**Formats and conventions**

Connection Manager creates service (.cms) files, which use the same format as Windows initialization (.ini) files and information (.inf) files. These files have several things in common:

- Each file is divided into sections, with specific entries, called keys, assigned to the sections. A section heading is enclosed within brackets (**[ ]**). For example, **[Strings]** is a section containing text strings for messages. The keys for a section are not enclosed within brackets.
- Each value specified for a numeric key must be an integer. Any non-integer value is truncated to an integer or ignored as invalid data. For example, 1.1 is truncated to 1 or ignored.
- The order in which sections appear is not important; a particular section can be placed anywhere in the file.
- Each comment in the file begins with a semicolon (**;**).

For more information on these formats and conventions, see the *Microsoft Platform Software Development Kit* (SDK) at the Microsoft Web site.

**Table of ISP and Service Type keys**

The following table shows the valid keys for the [ISP] and [Service Type] sections of the .cms file, the function and use of each key, and where you must set each key. You can set different keys in the Connection Manager Administration Kit (CMAK) wizard or the .cms file. If you change the .cms file with a text editor, rather than by using the **Advanced Customization** pane of the CMAK wizard, you must rebuild the profile afterward with the CMAK wizard.

### Notes

- In the following table, keys controlled by specific panes of the CMAK wizard are identified in the **Set in** column as **CMAK**. Although these keys appear in the .cms file, you should use the CMAK wizard to update these keys. If you change these keys by editing the .cms file, the CMAK wizard might overwrite them if you run it again on the same profile. Keys set in the **Advanced Customization** pane of the CMAK wizard are identified as .cms or .cmp, as appropriate.
- Specify file locations either with the full path or the relative path from the .cmp file directory, as appropriate to the key.

| [Section] or key | Definition and values | Set in |
|---|---|---|
| **[ISP]** | Connection types (such as modem or ISDN) that you want to list in the **Phone Book** dialog box and how you want phone numbers to appear for each connection type. The Mask and Match keys specify whether the number is listed under **Access numbers** or under **More access numbers**. Each Mask and Match key has a corresponding option in **Phone Book Administrator**. | CMAK<br>.cms |
| PBFile | Location of the phone book (.pbk) file used by the service profile. | CMAK |
| RegionFile | Location of the region (.pbr) file used by the service profile. | CMAK |
| PBURL | Uniform Resource Locator (URL) for the phone book update. | CMAK |
| Mask&*FilterName* | Mask value for *FilterName*. | .cms |

| | | |
|---|---|---|
| Match&*FilterName* | Match value for *FilterName*. | .cms |
| FilterA&*ServiceProfile* | List of filter names to be applied to the access numbers phone-book settings field, for example:<br><br>FilterA& = NosurchargeSignon<br><br>The selected phone numbers are listed in the Connection Manager **Phone Book** dialog box, in **Access numbers**.<br><br>Default = NosurchargeSignon | .cms |
| FilterB&*ServiceProfile* | List of filter names to be applied to the referenced phone book options field, for example:<br><br>FilterB& = SurchargeSignon<br><br>The selected phone numbers are listed in the Connection Manager **Phone Book** dialog box, in **More access numbers**.<br><br>Default = SurchargeSignon. | .cms |
| References | Service profiles merged through the CMAK wizard. Profile names are separated by commas, tabs, or spaces. Each name is used as a reference to that profile. | CMAK |
| CMSFile&*MergedProfile* | Location of a component service profile .cms file for a merged service profile. The format is CMSFile&*MergedProfile=Location*, where *MergedProfile* is the name of the top-level service profile and *Location* is the location of the .cms file for the component service profile, for example:<br><br>CMSFile&Awesome1 = Awesome1\AwesomeE.cms | CMAK |
| FilterA&*MergedProfile* | List of filter names to be applied to the component profile's phone book options field. The format is FilterA&*MergedProfile = FilterName*, where *MergedProfile* is the name of the merged service profile, as specified in the CMSFile*MergedProfile* key, and *FilterName* is the name of the filter to be applied, for example:<br><br>FilterA&AwesomeE = NoSurchargeSignon<br><br>The selected phone numbers are merged into the list in the Connection Manager **Phone Book** dialog box, in **Access numbers**. | CMAK |
| FilterB&*MergedProfile* | List of filter names to be applied to the component profile's phone book options field. The format is FilterB&*MergedProfile = FilterName*, where *MergedProfile* is the name of the merged service profile, as specified in the .cms file **References** key, and *FilterName* is the name of the filter to be applied, for example:<br><br>FilterB&AwesomeE = SurchargeSignon<br><br>The selected phone numbers are merged into the list in the Connection Manager **Phone Book** dialog box, in **More access numbers**. | CMAK |
| **[Service Types]** | Items that are listed in the **Phone Book** dialog box, under **Service type**. By default, this section contains two service types. At least two service types must be defined in order for phone numbers to appear in the Properties dialog box of the Connection Manager client. | CMAK<br><br>.cms |
| *ServiceType* | A service type as a filter name to be applied to the referenced phone book options field. The format of the entry is *ServiceType=FilterName*, where *ServiceType* is the name as it appears in the **Phone Book** dialog box, in the **Service type** list, and *FilterName* is the name of the filter to be associated with the entry, for example:<br><br>ISDN Multicast = MulticastISDN<br><br>A service type name should include no more than 25 characters. You can concatenate service type names by inserting a space between each name. At least two service types must be defined in order for phone numbers to appear in the Properties dialog box of the Connection Manager client. | .cms |

# Connection Manager keys

Updated: December 12, 2008

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connection Manager keys**
You can change how Connection Manager handles aspects of its own operation. To do this, you need to edit the service (.cms) file. The table in this topic covers the key names and values that relate to the operation of Connection Manager. It also describes the formats and conventions you should use in the .cms file.

**Formats and conventions**
Connection Manager creates service (.cms) files and connection profile (.cmp) files, which use the same format as Windows initialization (.ini) files and information (.inf) files. These files have several things in common:

- Each file is divided into sections, with specific entries, called keys, assigned to the sections. A section heading is enclosed within brackets (**[ ]**). For example, **[Strings]** is a section containing text strings for messages. The keys for a section are not enclosed within brackets.
- Each value specified for a numeric key must be an integer. Any noninteger value is truncated to an integer or ignored as invalid data. For example, 1.1 is truncated to 1 or ignored.
- The order in which sections appear is not important; a particular section can be placed anywhere in the file.
- Each comment in the file begins with a semicolon (**;**).

For more information on these formats and conventions, see the *Microsoft Platform Software Development Kit* (SDK) at the Microsoft Web site.

**Table of Connection Manager keys**
The following table shows the valid keys for the [Connection Manager] section of the .cms and .cmp files, the function and use of each key, and where each key can be set. You can set different keys in the Connection Manager Administration Kit (CMAK) wizard, the .cms file, or the .cmp file. If you change the .cms file with a text editor, rather than by using the **Advanced Customization** pane of the CMAK wizard, you must rebuild the profile afterward with the CMAK wizard.

### Notes

- In the following table, keys controlled by specific panes of the CMAK wizard are identified in the **Set in** column as **CMAK**. Although these keys appear in the .cms file, you should use the CMAK wizard to update these keys. If you change these keys by editing the .cms file, the CMAK wizard might overwrite them if you run it again on the same profile. Keys set in the Advanced Customization portion of the CMAK wizard are identified as .cms or .cmp, as appropriate.
- Any changes you make to the .cmp file will be available only the first time the service profile is used. Editing this file allows you to provide a first-time-only population of user information. For example, you can fill in the user name, the password and the phone number fields for the first user to install and open your service profile.
- Make sure that locations are specified either as the full path or in reference to the location of the .cmp file.

| [Section] or key | Description and values | Set in |
|---|---|---|
| **[Connection Manager]** | Miscellaneous service profile keys and values. | CMAK<br>.cms<br>.cmp |

| | | |
|---|---|---|
| Dialup | Whether dial-up connections are supported. If this key is set to 0, the **General** tab of the Properties dialog box will not be displayed in Connection Manager.<br><br>0 = No.<br><br>1 (default) = Yes. | .cms |
| Direct | Whether direct connections are supported.<br><br>0 = No.<br><br>1 (default) = Yes.<br><br>This key is valid only for virtual private network (VPN) service profiles. | .cms |
| ConnectionType | The connection method to be used.<br><br>0 (default) = Connect the VPN by using a dial-up connection.<br><br>1 = Connect the VPN by using a direct connection (for example, DSL).<br><br>The direct connection (for example, DSL) must already exist and cannot be set up by using CMAK. This key is valid only if both the **Dialup** key and the **Direct** key values are set to **1**. The user can change this option in the **Properties** dialog box, on the **General** tab. | .cmp |
| CMSFile | Name of the service profile file: (*Path**ServiceProfileFileName*.cms), as entered in **File name** on the **Service and File Names** pane. Do not use any of the following in this name: **! @ ^ & ( ) { } `´ ~ , ; <space> * = \ / : ? ' " < > \| . % + [ ] $ #**. Do not alter this value in the .cmp file. If a different name is required, use the CMAK wizard to edit the existing profile, specify new names for both the **Service name** and the **File name**, and then finish running the wizard. | CMAK |
| ServiceName | The primary identifier for the profile. This text appears in the Connection Manager logon dialog box as the service name and as the name of the connection.<br><br>Maximum = approximately 35 characters. Do not use any of the following in this name: *** \ / : ? " < > \| [ ]** | CMAK |
| ServiceMessage | Connection Manager logon dialog box service message, usually a customer-support number for the service.<br><br>Maximum = Approximately 50 characters. | CMAK |
| UserName | Name used to authenticate the user, for first-time use. | .cmp |
| InternetUserName | The user name provided for the dial-up portion of a double-dial VPN connection, for first-time use. | .cmp |
| UseSameUserName | Whether to use a separate user name and password when connecting to the Internet service provider (for a VPN connection).<br><br>0 (default) = Use the separate user name and password as specified by the user in the **Properties** dialog box, on the **Internet Logon** tab. Service profiles built to support VPN connections contain this additional tab.1 = Use the same user name and password when connecting to the Internet service provider as is specified in the Connection Manager logon dialog box for logging on to the private service. | CMAK |
| UseWinLogonCredentials | Whether or not to incorporate the user name, password, and domain specified when the user logged on most recently to Windows (Windows 2000, Windows XP, and members of the Windows Server 2003 family only).<br><br>0 = Do not use credentials.<br><br>1 (default) = Use credentials. | .cms |

| | | |
|---|---|---|
| GlobalCredentials | Windows XP and Windows Server 2003 family only. Whether to save the user name and password supplied for first-time use of the connection for all users of the connection.<br><br>0 (default) = Save the user name and password for a single user.<br><br>1 = Save the user name and password for all users of the connection. | .cmp |
| KeepDefaultCredentials | Whether to keep first-time credentials such as user name and password in the .cmp file of the profile, for persistent default display and usage for all first-time users of the profile. For single-user profiles, this information will only be displayed once.<br><br>0 (default) = Do not keep first-time credentials in the .cmp file.<br><br>1 = Keep first-time credentials in the .cmp file. | .cmp |
| UserNamePrefix | Prefix added to the user name. Enables access to a service that requires a realm name as a user name prefix. This key will not be used in a VPN connection. | CMAK |
| UserNameSuffix | Suffix appended to the user name. Enables access to a service that requires a realm name as a user name suffix. This key will not be used in a VPN connection. | CMAK |
| MaxUserName | Maximum length of the user name.<br><br>Default = 256 bytes. | .cms |
| UserNameOptional | Whether the user must type a user name in the Connection Manager logon and Internet logon dialog boxes.<br><br>0 (default) = User name required.<br><br>1 = User name not required. | .cms |
| HideUserName | Whether the **User name** box appears in the Connection Manager logon dialog box.<br><br>0 (default) = Display the box.<br><br>1 = Do not display the box.<br><br>If the box is hidden, the data is considered optional. | .cms |
| HideInternetUsername | Whether the **User name** box appears in the **Properties** dialog box, **Internet Logon** tab.<br><br>0 (default) = Display the box.<br><br>1 = Do not display the box.<br><br>If the box is hidden, the data is considered optional. If **HideInternetPassword** and **HideInternetUsername** are both 1, the **Internet Logon** tab is not displayed. | .cms |
| Password | The password that appears automatically the first time the profile is used. | .cmp |
| InternetPassword | The password provided for the dial-up portion of a double-dial VPN connection. The password appears automatically the first time the user tries to connect using a double-dial VPN connection. | .cmp |
| PasswordHandling | Method of handling the password during the logon process.<br><br>0 (default) = Normal (case sensitive).<br><br>1 = Lowercase password.<br><br>2 = Uppercase password. | .cms |

| | | |
|---|---|---|
| MaxPassword | Maximum length of the password that can be typed by the user.<br><br>Default = 127 bytes. | .cms |
| PasswordOptional | Whether the user must specify a password in the Connection Manager logon and Internet logon dialog boxes.<br><br>0 (default) = Password required.<br><br>1 = Password not required. | .cms |
| RememberPassword | Whether to have the **Save password** check box in the Connection Manager logon dialog box selected by default for a populated password. This key is ignored if the **Password** key is not set in the .cmp file.<br><br>0 (default) = The check box is not selected by default.<br><br>1 = The check box is selected by default, and the password is saved. | .cmp |
| RememberInternetPassword | Whether to have the **Save password** check box on the **Internet Logon** tab selected by default for a populated Internet password. This key is ignored if the **InternetPassword** key is not set in the .cmp file.<br><br>0 (default) = The check box is not selected by default.<br><br>1 = The check box is selected by default, and the password is saved. | .cmp |
| HideRememberInternetPassword | Whether to show the **Save Password** check box on the **Internet Logon** tab. If this key is not specified, the value of **HideRememberPassword** is used by default.<br><br>0 = Display check box.<br><br>1 = Do not display check box. | .cms |
| ResetPassword | Whether the **New** button appears in the Connection Manager logon dialog box to enable a user to change the password. You can use this button to set up a custom password option. Type the location (including the name) of the executable (.exe) program you use to support this process. You must provide an executable program for this option and include it as an additional file when you run the CMAK wizard. | .cms |
| HidePassword | Whether the **Password** box appears in the Connection Manager logon dialog box when using dial-up connections.<br><br>0 (default) = Display the box.<br><br>1 = Do not display the box.<br><br>If the box is hidden, the data is considered optional. | .cms |
| HideInternetPassword | Whether the **Password** box appears in the **Properties** dialog box, on the **Internet Logon** tab.<br><br>0 (default) = Display the box.<br><br>1 = Do not display the box.<br><br>If the box is hidden, the data is considered optional. If **HideInternetPassword** and **HideInternetUsername** are both 1, the **Internet Logon** tab is not displayed. | .cms |
| DomainOptional | Whether to require the user to enter a domain name when making a connection.<br><br>0 = Require a domain.<br><br>1 (default) = Do not require a domain. | .cms |

| | | |
|---|---|---|
| HideRememberPassword | Whether to display the **Save password** check box in the Connection Manager logon dialog box and on the **Internet Logon** tab.<br><br>0 (default) = Display the check box.<br><br>1 = Do not display the check box.<br><br>If **HideRememberPassword** is set to **1**, it overrides the **HideDialAutomatically** setting. | .cms |
| Domain | Logon domain name that appears automatically the first time the profile is used. | .cmp |
| MaxDomain | Maximum length of the domain name that can be typed by the user.<br><br>Default = 15 characters. | .cms |
| HideDomain | Whether the **Logon domain** box appears in the Connection Manager logon dialog box when using dial-up connections.<br><br>0 = Display the box.<br><br>1 = Do not display the box.<br><br>The default is 1. If the profile supports VPN connections, CMAK will set this value to 0 if you have not previously set a value. If the box is hidden, the data is considered optional. | .cms |
| DialAutomatically | Whether to have the **Connect automatically** check box in the Connection Manager logon dialog box selected by default and to connect automatically when the service profile is used for the first time.<br><br>0 (default) = Do not select the check box.<br><br>1 = Select the check box and connect automatically. | .cmp |
| DialAutoMessage | Text displayed when the **Dial Automatically** check box has been selected. | .cms |
| HideDialAutomatically | Whether the **Connect automatically** check box appears in the Connection Manager logon dialog box.<br><br>0 (default) = Display the check box.<br><br>1 = Do not display the check box.<br><br>If **HideRememberPassword** is set to **1**, that key value overrides the **HideDialAutomatically** setting. | .cms |
| Phone0 | Primary phone number populated for the user the first time the service profile is used, and used as the default phone number any time another phone number is not selected. | .cmp |
| Phone1 | Backup phone number populated for the user the first time the service profile is used. | .cmp |
| PhoneCanonical0 | The canonical format of the primary phone number the first time the service profile is used. | .cmp |
| PhoneCanonical1 | The canonical format of the backup phone number the first time the service profile is used. | .cmp |
| MaxPhoneNumber | Specifies a character limit for the phone number fields. The default for Windows 95, Windows 98, and Windows Millennium Edition is 36; the default for Windows NT 4.0, Windows 2000, Windows XP, and members of the Windows Server 2003 family is 80. | .cms |
| PhoneCountry0 | Telephony Application Programming Interface (TAPI) country/region code for the primary phone number set as default for the user the first time the service profile is used. | .cmp |

| | | |
|---|---|---|
| PhoneCountry1 | Telephony Application Programming Interface (TAPI) country/region code for the backup phone number set as default for the user the first time the service profile is used. | .cmp |
| UseDialingRules0 | Whether dialing rules are applied to the primary phone number the first time the service profile is used.<br><br>0 = Use the form of the number exactly as it appears in the phone book or as it is typed.<br><br>1 (default) = Apply dialing rules to the number when displaying and dialing. | .cmp |
| UseDialingRules1 | Whether dialing rules are applied to the backup number the first time the service profile is used.<br><br>0 = Use the form of the number exactly as it appears in the phone book or as it is typed.<br><br>1 (default) = Apply dialing rules to the number when displaying and dialing. | .cmp |
| NoDialingRules | Whether the user can use dialing rules on phone numbers selected from a phone book. Dialing rules check boxes are grayed out when this key value is set to 1.<br><br>0 (default) = Allow dialing rules.<br><br>1 = Do not allow dialing rules. | .cms |
| PhoneSource0 | Service profile for the primary phone number to be used the first time the user connects. | .cmp |
| PhoneSource1 | Service profile for the backup phone number to be used the first time the user connects. | .cmp |
| Description0 | Description of the primary phone number provided the first time the service profile is opened. Appears in the **Phone Book** dialog box as a Point of Presence (POP) name. | .cmp |
| Description1 | Description of the backup phone number provided the first time the service profile is opened. Appears in the **Phone Book** dialog box as a POP name. | .cmp |
| DUN0 | Dial-up entry used for the primary phone number the first time the service profile is opened. Value must exactly match the entry name specified in **Phone Book Administrator**. | .cmp |
| DUN1 | Dial-up entry used for the backup phone number the first time the service profile is opened. Value must exactly match the entry name specified in **Phone Book Administrator**. | .cmp |
| ServiceType0 | Default service type from the phone book for the primary phone number the first time that the service profile is opened. | .cmp |
| ServiceType1 | Default service type from the phone book for the backup phone number the first time that the service profile is opened. | .cmp |
| Region0 | Default state or province from the phone book for the primary phone number the first time that the service profile is opened. | .cmp |
| Region1 | Default state or province from the phone book for the backup phone number the first time that the service profile is opened. | .cmp |

| | | |
|---|---|---|
| Version | Version of the phone book. If you use Connection Point Services (CPS) to provide phone books, the CPS phone book server will use this value to determine how to handle phone book updates. If the version on the client is more than five versions out of date, the CPS phone book server downloads the complete phone book. Otherwise, the CPS phone book server downloads a delta file to the client. | .cms |
| DUN | Specifies the default network entry used when the **Dial-up Networking entry** field for a POP is blank.<br><br>Default = *ServiceProfileServiceName*. | .cms |
| RedialCount | Number of redials to attempt the first time the service profile is opened.<br><br>Default = 3. | .cmp |
| RedialDelay | Delay (in seconds) between dials. The delay is the elapsed time between the point of failure of the first call and the dialing of the first digit of the next phone number.<br><br>Default = 5 seconds. | .cms |
| IdleTimeout | Time (in minutes) that the connection must be idle before disconnecting the first time the service profile is used to connect.<br><br>Default = 10 minutes.<br><br>If set to 0, no time-out occurs. | .cmp |
| IdleThreshold | Maximum bytes per minute that can be received if an idle state is to be detected for the connection.<br><br>Default = 0.<br><br>This key is not available for use on Windows NT 4.0 systems. | .cms |
| AutoReconnect | Whether to automatically attempt to reconnect when a connection is terminated unexpectedly.<br><br>0 (default) = Do not automatically attempt to reconnect.<br><br>1 = Attempt to reconnect when the connection is terminated unexpectedly. | .cms |
| NoPromptReconnect | Whether the user is prompted for reconnection when the connection is inadvertently dropped.<br><br>0 (default) = Prompt the user.<br><br>1 = Do not prompt the user. | .cms |
| Icon | Location and name of the icon (.ico) file for the large program icon.<br><br>Default = The default value for this key is blank. When nothing is specified, the standard Connection Manager program icon is used. | CMAK |
| SmallIcon | Location and name of the icon (.ico) file for the small title-bar icon.<br><br>Default = The default value for this key is blank. When nothing is specified, the standard Connection Manager title-bar icon is used. | CMAK |
| TrayIcon | Location and name of the icon (.ico) file for the notification area shortcut.<br><br>Default = The default value for this key is blank. When nothing is specified, the Connection Manager notification area shortcut is used. | CMAK |

| | | |
|---|---|---|
| HideTrayIcon | Whether to display notification area shortcuts.<br><br>*NULL* = If **TrayIcon** is set, display the notification area shortcut specified. Otherwise, display the connection-status notification area shortcut ("blinking lights"). The *NULL* value is available for Windows 2000, Windows XP, and members of the Windows Server 2003 family only.<br><br>0 = If **TrayIcon** is set, display the notification area shortcut specified and the connection-status notification area shortcut ("blinking lights"). Otherwise, display the Connection Manager notification area shortcut and the connection-status notification area shortcut ("blinking lights").<br><br>1 = Do not display any notification area shortcuts.<br><br>If you choose not to display any notification area shortcuts, edit the Help file to remove references to it. | .cms |
| Logo | Location and name of the .bmp file displayed in the Connection Manager logon dialog box.<br><br>Default = The default value for this key is blank. When nothing is specified, the standard Connection Manager logon bitmap is used. | CMAK |
| PBLogo | Location and name of the .bmp file for the **Phone Book** dialog box.<br><br>Default = The default value for this key is blank. When nothing is specified, the standard Phone Book bitmap is used. | CMAK |
| PBMessage | Text in the **Phone Book** dialog box next to **More access numbers** when alternate access numbers are available for the selected geographic region.<br><br>Maximum = Approximately 100 characters. | CMAK |
| PBUpdateMessage | Text that appears in the dialog box during a phone book update.<br><br>Default = "Downloading new phone book." | .cms |
| DownloadDelay | Time (in seconds) to delay before downloading phone book updates. The delay time starts when the connection is established.<br><br>Default = 15 seconds.<br><br>This entry is valid only when, in the CMAK wizard, in the **Phone Book** dialog box, **Automatically download phone book updates** is selected. | .cms |
| HideDelay | Time (in seconds) to delay before displaying the **Phone Book Updates** dialog box (with progress indicators and message).<br><br>Default = Do not display the dialog box. | .cms |
| HelpFile | Location (including name) of the custom Help file.<br><br>Default Help file = The default value for this key is blank. When nothing is specified, the standard Help file for service profiles is used. | CMAK |
| Tunnel | Whether VPN connections are enabled for the phone numbers in the top-level phone book.<br><br>0 (default) = Not enabled.<br><br>1 = Enabled. | CMAK |
| TunnelDUN | Specifies the default networking entry used for VPN connections.<br><br>Default = *ServiceProfileServiceName* tunnel. | .cms |

| | | |
|---|---|---|
| TunnelFile | The relative path and file name to the VPN file. If you use macros in the relative path, make sure the macros are recognized on all operating systems to which you want to distribute the profile. | CMAK |
| TunnelAddress | IP address or domain name for the VPN server. | CMAK |
| TunnelReferences | Whether VPN connections are enabled for phone numbers taken from a component profile phone book in a top-level service profile.<br><br>0 (default) = Do not use a VPN connection when using any of these phone numbers.<br><br>1 = Use a VPN connection when using a phone number from a component profile. | CMAK |
| AnimatedLogo | Whether an animation is used instead of a static bitmap in the Connection Manager logon dialog box.<br><br>0 (default) = Do not use animated graphic.<br><br>1 = Use animated graphic.<br><br>The **[Animated Logo]** section specifies the location of the animation (.spl or .swf) file. This function is provided for compatibility with Connection Manager 1.0, which supports Macromedia Flash animation files. | CMAK<br><br>.cms |
| CheckOSComponents | Whether Connection Manager checks the operating system components.<br><br>0 (default) = Check the operating system components only when an error occurs.<br><br>1 = Always check the operating system components on service profile initialization. | .cms |
| DoNotCheckBindings | Whether to include the TCP/IP bindings when checking operating system components.<br><br>0 (default) = Include the TCP/IP bindings in the TCP/IP check and bind all that are not bound.<br><br>1 = Do not include the TCP/IP bindings when checking operating system components.<br><br>TCP/IP services that sit between the TCP/IP protocol and the dial-up adapter are protected from checking only if this option is set to 1 in all installed service profiles. This option does not prevent bindings from being checked by other service profiles or programs. | .cms |
| IsdnDialMode | Whether Connection Manager binds two channels on the same ISDN device.<br><br>0 (default) = Do not bind (use single channel only).<br><br>1 = Always bind the two channels (connect both channels automatically). If a dual channel connection cannot be made, the connection attempt will fail. This entry is valid only for Windows NT 4.0, Windows 2000, Windows Millennium Edition, Windows XP, and members of the Windows Server 2003 family.<br><br>2 = Attempt to bind the two channels (connect with both channels). If the two channels cannot be bonded, use single channel. This entry is valid only for Windows 2000, Windows XP, and members of the Windows Server 2003 family. | .cms |

| | | |
|---|---|---|
| EnableICF | Windows XP and Windows Server 2003 family only. Whether to turn on Internet Connection Firewall (ICF) or Windows Firewall for this connection with default settings.<br><br>0 = Do not adjust ICF or Windows Firewall settings. Default for the original releases of the Windows XP and Windows Server 2003 operating systems.<br><br>1 = Enable ICF or Windows Firewall for the connection with default settings. Default for Windows XP with Service Pack 2 and for Windows Server 2003 with Service Pack 1.<br><br>Note: Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition. | .cms |
| DisableICS | Windows XP and Windows Server 2003 family only. Whether to suppress the user's ability to share the connection with Internet Connection Sharing (ICS).<br><br>0 (default) = Do not suppress ICS settings.<br><br>1 = Disable ICS settings for this connection.<br><br>Note: Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems. | .cms |
| HideAdvancedTab | Windows XP and Windows Server 2003 family only. Whether to suppress the display of the Advanced tab in the Connection Manager user interface for this connection.<br><br>0 (default) = Do not suppress display of the Advanced tab.<br><br>1 = Suppress display of the Advanced tab. | .cms |
| CustomButtonText | Text displayed on a custom button on the main connect screen. This feature is not supported when logging on to Windows. | .cms |
| CustomButtonToolTip | Text displayed on a tooltip for a custom button on the main connect screen. This feature is not supported when logging on to Windows. | .cms |
| MonitorCallingProgram | When Connection Manager is called programmatically, whether to handle Connection Manager as a monitored custom action when the calling process terminates.<br><br>0 = Do not monitor.<br><br>1 (default) = Monitor. | .cms |
| EnableLogging | Whether a log file is created for the connection the first time the service profile is opened. The log file is named *ServiceProfileServiceName*.log for an all user profile, and *ServiceProfileServiceName* (Single User).log for a single user profile.<br><br>0 = Do not create a log file.<br><br>1 (default) = Create a log file. | .cmp |
| HideBalloonTips | Whether to suppress display of balloon-tip help for this connection.<br><br>0 (default) = Do not suppress balloon-tip help.<br><br>1 = Suppress balloon-tip help. | .cms |
| InternetConnection | Windows XP and Windows Server 2003 family only. Whether to inform the operating system that this connection is a connection to the Internet.<br><br>0 (default) = Do not inform the operating system that this connection connects to the Internet for the purposes of automatically connecting when no connection is present.<br><br>1 = Allow the system to register this connection as a connection to the Internet. | .cms |

# Custom actions keys

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Custom actions keys**

You can change how Connection Manager handles custom actions. To do this, you need to edit the service (.cms) file. The table in this topic covers the key names and values that pertain to the custom actions sections of the .cms file. This topic also describes the formats and conventions you should use in the .cms file.

**Formats and conventions**

Connection Manager creates service (.cms) files, which use the same format as Windows initialization (.ini) files and information (.inf) files. These files have several things in common:

- Each file is divided into sections, with specific entries, called keys, assigned to the sections. A section heading is enclosed within brackets (**[ ]**). For example, **[Strings]** is a section containing text strings for messages. The keys for a section are not enclosed within brackets.
- Each value specified for a numeric key must be an integer. Any noninteger value is truncated to an integer or ignored as invalid data. For example, 1.1 is truncated to 1 or ignored.
- The order in which sections appear is not important; a particular section can be placed anywhere in the file.
- Each comment in the file begins with a semicolon (**;**).

For more information on these formats and conventions, see the *Microsoft Platform Software Development Kit* (SDK) at the Microsoft Web site.

**Table of custom actions keys**

The following table shows the valid keys for custom actions in the .cms file, the function and use of each key, and where each key can be set. You can set different keys in the Connection Manager Administration Kit (CMAK) wizard or in the .cms file. If you change the .cms file with a text editor, rather than by using the **Advanced Customization** pane of the CMAK wizard, you must rebuild the profile afterward with the CMAK wizard.

### Notes

- In the following table, keys controlled by specific panes of the CMAK wizard are identified in the **Set in** column as **CMAK**. Although these keys appear in the .cms file, you should use the CMAK wizard to update these keys. If you change these keys by editing the .cms file, the CMAK wizard might overwrite them if you run it again on the same profile. Keys set in the **Advanced Customization** pane of the CMAK wizard are identified as .cms or .cmp, as appropriate.
- Make sure that locations are specified either as the full path or in reference to the location of the .cmp file.

| [Section] or key name | Value | Set in |
|---|---|---|
| **[Pre-Init Actions]** | Pre-init actions that run as soon as the profile is accessed. This section uses the following keys: **#**, **#&Flags**, and **#&Description**. | CMAK .cms |
| **[Pre-Connect Actions]** | Pre-connect actions that run before a connection is established. This section uses the following keys: **#**, **#&Flags**, and **#&Description**. | CMAK .cms |
| **[Pre-Dial Actions]** | Pre-dial actions that run immediately before dialing. This section uses the following keys: **#**, **#&Flags**, and **#&Description**. | CMAK .cms |

| | | |
|---|---|---|
| **[Pre-Tunnel Actions]** | Pre-tunnel actions that run after a connection is established but before a VPN connection is established. This section uses the following keys: **#**, **#&Flags**, and **#&Description**. | CMAK .cms |
| **[Connect Actions]** | Post-connect actions that run after a connection is established and, if using a VPN connection, after the tunnel is established. This section uses the following keys: **#**, **#&Flags**, and **#&Description**. | CMAK .cms |
| **[Disconnect Actions]** | Disconnect actions that run immediately before disconnecting. If a connection is prematurely dropped, these actions are run immediately after the disconnect. This section uses the following keys: **#**, **#&Flags**, and **#&Description**. | CMAK .cms |
| **[On-Cancel Actions]** | On cancel actions that run when the user cancels a session after the connection attempt has been started (any time that the user clicks **Connect** and then clicks **Cancel**). This section uses the following keys: **#**, **#&Flags**, and **#&Description**. | CMAK .cms |
| **[On-Error Actions]** | On error actions that run when an error occurs. This section uses the following keys: **#**, **#&Flags**, and **#&Description**. | CMAK .cms |
| **[Auto Applications]** | Monitored actions that run during a connection. Monitored actions are similar to custom actions, but they cause the disconnect sequence to start as soon as the last monitored application closes. This section uses the following keys: **#**, **#&Flags**, and **#&Description**. Unlike other custom actions, monitored actions do not support DLLs. | CMAK .cms |
| # | A single custom action. The format of the value is # = *Program*, where # is an ID number from 0 to *n* and *Program* is the complete name of the program, including the extension and the path to the program. Programs start in sequence: 0 first, 1 next, and so on. Environmental variables, such as **%UserName%** and **%ErrorCode%**, are set in Connection Manager and can be used as parameters for custom action programs. | CMAK |
| #&Flags | Whether a custom action runs when a specific type of connection is established. The format of the value is #&Flags = *n*, where # is the ID number of a defined custom action and *n* is a value indicating how dial-up and direct connections for that custom action are handled:<br>• If *n* = 0 (default), all connections trigger this custom action. (The default key does not appear in the .cms file.)<br>• If *n* = 1, all direct tunnel connections trigger this custom action.<br>• If *n* = 2 , all connections that involve dialing (direct or double) trigger this custom action.<br>• If *n* = 4, only connections that use direct dial-up trigger this custom action.<br>• If *n* = 8, only connections that involve a tunnel trigger this custom action. | CMAK |
| #&Description | A short description of a custom action. The format of the value is #&Description = *text*, where # is the number of a defined custom action and *text* is the descriptive information for that custom action. This option can provide useful information when a synchronous custom action does not run properly.<br>Default = the name of the custom action program. | CMAK |

# Networking keys

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Networking keys**
You can change how Connection Manager handles networking. To do this, you need to edit the service (.cms) file. The table in this topic covers the key names and values that pertain to the networking sections of the .cms file. This topic also describes the formats and conventions you should use in the .cms file.

**Formats and conventions**
Connection Manager creates service (.cms) files, which use the same format as Windows initialization (.ini) files and information (.inf) files. These files have several things in common:

- Each file is divided into sections, with specific entries, called keys, assigned to the sections. A section heading is enclosed within brackets (**[ ]**). For example, **[Strings]** is a section containing text strings for messages. The keys for a section are not enclosed within brackets.

- Each value specified for a numeric key must be an integer. Any noninteger value is truncated to an integer or ignored as invalid data. For example, 1.1 is truncated to 1 or ignored.

- The order in which sections appear is not important; a particular section can be placed anywhere in the file.

- Each comment in the file begins with a semicolon (**;**).

For more information on these formats and conventions, see the *Microsoft Platform Software Development Kit* (SDK) at the Microsoft Web site.

**Table of networking keys**
The following table shows the valid keys for networking in the .cms file, the function and use of each key, and where each key can be set. You can set different keys in the Connection Manager Administration Kit (CMAK) wizard or the .cms file. If you change the .cms file with a text editor, rather than by using the **Advanced Customization** pane of the CMAK wizard, you must rebuild the profile afterward with the CMAK wizard.

### Notes

- In the following table, keys controlled by specific panes of the CMAK wizard are identified in the **Set in** column as **CMAK**. Although these keys appear in the .cms file, you should use the CMAK wizard to update these keys. If you change these keys by editing the .cms file, the CMAK wizard might overwrite them if you run it again on the same profile. Keys set in the **Advanced Customization** pane of the CMAK wizard are identified as .cms or .cmp, as appropriate.

- Make sure that locations are specified either as the full path or in reference to the location of the .cmp file.

| [Section] or key | Value | Set in |
|---|---|---|
| **[Server& *TunnelDUN* ]** | Configuration to be used for all VPN connections. In this section title, ***TunnelDUN*** is the value of the **TunnelDUN** key in the **[Connection Manager]** section, for example, **[Server&Awesome1 Tunnel]**. This section uses the same format as the **[Server&*EntryName*]** section, including all keys valid under that section. | CMAK<br><br>.cms |
| **[Server& *EntryName* ]** | Configuration where *EntryName* is the name of the dial-up entry, for example, **[Server&Awesome1]**. | CMAK |

| | | |
|---|---|---|
| SecureLocalFiles | For Windows NT, Windows 2000, Windows XP, and the Windows Server 2003 family only. Whether to share local files and allow printer sharing. If the value of the key is set to 1, it will disable NetBT on Windows 2000, Windows XP, and the Windows Server 2003 family. This key value will be ignored on Windows XP and the Windows Server 2003 family if a value is assigned to the SecureClientForMSNet key, the SecureFileAndPrint key, or both.<br><br>0 (default) = Share local files.<br><br>1 = Do not share local files. | CMAK |
| SecureClientForMSNet | For Windows XP and Windows Server 2003 family only. Whether to allow the use of NetBT. If this key is set, the value of the SecureLocalFiles key will be ignored on Windows XP and the Windows Server 2003 family.<br><br>0 (default) = Allow the use of NetBT.<br><br>1 = Do not allow the use of NetBT. | .cms |
| SecureFileAndPrint | For Windows XP and Windows Server 2003 family only. Whether to enable file and print sharing. If this key is set, the value of the SecureLocalFiles key will be ignored on Windows XP and the Windows Server 2003 family.<br><br>0 (default) = Enable.<br><br>1 = Disable. Files and print resources will not be shared. | .cms |
| DataEncrypt | Whether to force data encryption. On Windows 2000, Windows XP, and Windows Server 2003 family, if the EncryptionType key is set, the value of the DataEncrypt key is ignored.<br><br>0 (default for dial-up entries) = Do not encrypt data.<br><br>1 (default for VPN entries) = Encrypt data. | CMAK |
| EncryptionType | Which encryption level is to be used.<br><br>0 = None.<br><br>1 (default for VPN) = Require.<br><br>3 (default for dial-up) = Optional.<br><br>Valid only for Windows 2000, Windows XP, and the Windows Server 2003 family. | CMAK |
| DontNegotiateMultilink | For Windows XP and Windows Server 2003 family only. Whether to allow multilinking.<br><br>0 (default) = Allow multilink.<br><br>1 = Do not allow multilink. | .cms |
| DontUseRasCredentials | For Windows XP and Windows Server 2003 family only. Whether to cache the user's credentials in **Stored User Names and Passwords** for use when accessing resources after logging onto the network.<br><br>0 (default) = Cache and use credentials.<br><br>1 = Do not cache and use credentials. | .cms |
| NetworkLogon | Whether to log on to the network.<br><br>0 = Do not log on. This is the default for dial-up connections.<br><br>1 = Log on. This is the default for VPN connections. | CMAK |
| SW_Compress | Whether to negotiate PPP software compression of data.<br><br>0 = Do not negotiate.<br><br>1 (default) = Negotiate. | .cms |

| | | |
|---|---|---|
| Disable_LCP | Whether to enable Link Control Protocol (LCP) extensions.<br><br>0 (default) = Enable.<br><br>1 = Disable. | .cms |
| PW_Encrypt | Whether to encrypt a password when authenticating.<br><br>0 (default) = Do not encrypt.<br><br>1 = Encrypt. | CMAK |
| PW_EncryptMS | Whether to require MS-CHAP version 1 for this connection.<br><br>0 = Do not require MS-CHAP v1.<br><br>1 = Require MS-CHAP v1. | CMAK |
| Negotiate_TCP/IP | Whether to negotiate TCP/IP.<br><br>0 = Do not negotiate.<br><br>1 (default) = Negotiate. | .cms |
| Negotiate_IPX | Whether to negotiate the IPX protocol.<br><br>0 (default) = Do not negotiate.<br><br>1 = Negotiate.<br><br>The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family. | .cms |
| Negotiate_NetBEUI | Whether to negotiate the NetBIOS extended user interface (NetBEUI) protocol.<br><br>0 (default) = Do not negotiate.<br><br>1 = Negotiate | .cms |
| Require_PAP | Whether Password Authentication Protocol (PAP) is allowed.<br><br>0 (default) = Not allowed.<br><br>1 = Allowed.<br><br>Valid only for Windows 2000, Windows XP, and the Windows Server 2003 family. | CMAK |
| Require_SPAP | Whether SPAP is allowed.<br><br>0 (default) = Not allowed.<br><br>1 = Allowed.<br><br>Valid only for Windows 2000, Windows XP, and the Windows Server 2003 family. | CMAK |
| Require_EAP | Whether Extensible Authentication Protocol (EAP) is allowed. Valid only for Windows 2000, Windows XP, and the Windows Server 2003 family.<br><br>0 (default) = Not allowed.<br><br>1 = allowed. | CMAK |
| Require_CHAP | Whether Challenge Handshake Authentication Protocol (CHAP) is allowed.<br><br>0 = Not allowed.<br><br>1 (default) = Allowed.<br><br>Valid only for Windows 2000, Windows XP, and the Windows Server 2003 family. | CMAK |

| | | |
|---|---|---|
| Require_MSCHAP | Whether MSCHAP is allowed.<br><br>0 = Not allowed.<br><br>1 (default) = Allowed.<br><br>Valid only for Windows 2000, Windows XP, and the Windows Server 2003 family. | CMAK |
| Require_MSCHAP2 | Whether MSCHAP2 is allowed.<br><br>0 = Not allowed.<br><br>1 (default) = Allowed.<br><br>Valid only for Windows 2000, Windows XP, and the Windows Server 2003 family. | CMAK |
| Require_W95MSCHAP | Whether W95MSCHAP is allowed. If the value for this key is set to 1, the value for **Require_MS-CHAP** must also be set to 1.<br><br>0 (default) = Not allowed.<br><br>1 = Allowed.<br><br>Valid only for Windows 2000, Windows XP, and the Windows Server 2003 family. | .cms |
| Custom_Security | Applies specific security settings on computers that are running Windows 2000, Windows XP, or a member of the Windows Server 2003 family.<br><br>0 = Use standard configuration.<br><br>1 (default) = Use custom configuration.<br><br>Valid only for Windows 2000, Windows XP, and the Windows Server 2003 family. | CMAK |
| CustomAuthKey | The ID of the Extensible Authentication Protocol (EAP) to be used with this connection. The format is CustAuthKey=*ID*, where *ID* is the Internet Assigned Numbers Authority (IANA) ID for the EAP. If no ID is specified, no attempt will be made to read the CustomAuthData value.<br><br>Valid only for Windows 2000, Windows XP, and the Windows Server 2003 family. | CMAK |
| CustomAuthData# | The configuration data for the EAP. The format is CustomAuthData#=*EAPConfigurationData*, where # is the number of the specific line of data, for example:<br><br>CustomAuthData0=1AFGKLMOFGH23K<br><br>Each line can contain a maximum of 128 characters. If the ID has more than 128 characters, it must be specified as multiple lines, incrementing the # for each line of data. For example:<br><br>CustomAutData0=*First128Characters*<br><br>CustomAuthData1=*Next128Characters*<br><br>CustomAuthData2=*FinalCharacters*<br><br>Valid only for Windows 2000, Windows XP, and the Windows Server 2003 family. | CMAK |
| EnforceCustomSecurity | Whether to enforce the user to select a phone book entry that includes support for advanced security settings.<br><br>0 (default) = Do not enforce phone book entry selection (Windows 95, Windows 98, Windows NT 4.0, and Windows Millennium Edition only).<br><br>1 = Enforce selection of phone book entries that support advanced security settings. | CMAK |

| | | |
|---|---|---|
| DisableNbtOverIP | Whether to disable the NetBT routing protocol for this connection.<br><br>0 (default) = Do not disable NetBT.<br><br>1 = Leave NetBT enabled. | .cms |
| **[TCP/IP& *TunnelDUN* ]** | TCP/IP configuration to be used for all VPN connections. In this section title, ***TunnelDUN*** is the value of the **TunnelDUN** key in the **[Connection Manager]** section, for example, **[TCP/IP&Awesome1 Tunnel]**. This section uses the same format as the **[TCP/IP&*EntryName*]** section, including all keys valid under that section. This section is created by the CMAK wizard, but the keys can be edited in the .cms file. | CMAK<br><br>.cms |
| **[TCP/IP& *EntryName* ]** | Configuration where *EntryName* is the name of the dial-up entry, for example: **[TCP/IP&Awesome1]** | CMAK<br><br>.cms |
| Specify_IP_Address | Whether to specify a static IP address.<br><br>0 (default) = Do not specify.<br><br>1 = Specify. | .cms |
| IP_Address | Static IP addresses. | .cms |
| Specify_Server_Address | Whether to specify static DNS or Windows Internet Name Service (WINS) addresses.<br><br>0 (default) = Do not specify.<br><br>1 = Specify. | CMAK |
| DNS_Address | DNS address. | CMAK |
| DNS_Alt_Address | Alternate DNS address. | CMAK |
| WINS_Address | WINS address. | CMAK |
| WINS_Alt_Address | Alternate WINS address. | CMAK |
| IP_Header_Compress | Whether to enable IP header compression.<br><br>0 = Not enabled.<br><br>1 (default) = Enabled. | CMAK |
| Gateway_On_Remote | Whether to use the default gateway on the remote private network.<br><br>0 = Do not use.<br><br>1 (default) = Use. | CMAK |
| DNSSuffix | DNS suffix to use for the connection. Valid only for Windows XP and Windows Server 2003 family. | .cms |
| TcpWindowSize | For Windows 2000, Windows XP, and the Windows Server 2003 family only. Sets the size (expressed in bytes) of the window offered by the connection. Number of bytes of information to send before expecting a return packet. Minimum value is 4,096; maximum value is 65,500. If this key is not set, the default window size for the operating system and the connection type will be used. | .cms |
| **[Networking& *TunnelDUN* ]** | The single configuration to be used for all VPN connections. In this section title, ***TunnelDUN*** is the value of the **TunnelDUN** key in the **[Connection Manager]** section, for example, **[Networking&Awesome1 Tunnel]**. | CMAK |

| | | |
|---|---|---|
| VpnStrategy | Which tunneling protocol to use when establishing a VPN connection.<br><br>1 = Use PPTP only.<br><br>2 = Try PPTP first.<br><br>3 = Use L2TP only.<br><br>4 = Try L2TP first.<br><br>Valid only for Windows 2000, Windows XP, and the Windows Server 2003 family. | CMAK |
| UsePreSharedKey | Windows 2000, Windows XP, and the Windows Server 2003 family only. Whether to use a pre-shared key for L2TP/IPSec authentication.<br><br>0 (default) = Do not use a pre-shared key.<br><br>1 = Use a pre-shared key. | CMAK |
| VPNEntry | Specifies to CMAK whether the entry is a VPN entry and not a dial-up entry.<br><br>0 = Dial-up entry.<br><br>1 = VPN entry. | CMAK |
| **[Scripting&** *EntryName* **]** | Location (path and file name) of the script (.scp) file, where *EntryName* is the name of the dial-up entry, for example: **[Scripting&Awesome1]**). | CMAK |
| Name | Location (including path and file name) of the script (.scp) file for the dial-up entry. | CMAK |
| UseTerminalWindow | For Windows 2000, Windows XP, and the Windows Server 2003 family only. Whether to use a terminal window when connecting to a service.<br><br>0 (default) = Do not use a terminal window.<br><br>1 = Use a terminal window. | .cms |

# Other sections, keys, and values

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Other sections, keys, and values**
This topic covers sections, keys, and values that might appear in service (.cms) files, particularly those created with older versions of the Connection Manager Administration Kit (CMAK) wizard.

**Formats and conventions**
Connection Manager creates service (.cms) files, which use the same format as Windows initialization (.ini) files and information (.inf) files. These files have several things in common:

- Each file is divided into sections, with specific entries, called keys, assigned to the sections. A section heading is enclosed within brackets (**[ ]**). For example, **[Strings]** is a section containing text strings for messages. The keys for a section are not enclosed within brackets.
- Each value specified for a numeric key must be an integer. Any noninteger value is truncated to an integer or ignored as invalid data. For example, 1.1 is truncated to 1 or ignored.
- The order in which sections appear is not important; a particular section can be placed anywhere in the file.
- Each comment in the file begins with a semicolon (**;**).

For more information on these formats and conventions, see the *Microsoft Platform Software Development Kit* (SDK) at the Microsoft Web site.

**Table of other sections, keys, and values**
The following table shows valid sections, keys, and values in the .cms file, the function and use of each key, and where each key can be set. You can set different keys in the CMAK wizard or the .cms file. If you change the .cms file with a text editor, rather than by using the **Advanced Customization** pane of the CMAK wizard, you must rebuild the profile afterward with the CMAK wizard.

### Notes

- In the following table, keys controlled by specific panes of the CMAK wizard are identified in the **Set in** column as **CMAK**. Although these keys appear in the .cms file, you should use the CMAK wizard to update these keys. If you change these keys by editing the .cms file, the CMAK wizard might overwrite them if you run it again on the same profile. Keys set in the **Advanced Customization** pane of the CMAK wizard are identified as .cms or .cmp, as appropriate.
- Make sure that locations are specified either as the full path or in reference to the location of the .cmp file.

| [Section] or key | Value | Set in |
|---|---|---|
| **[Logging]** | Section header for logging keys. | .cms |
| FileDirectory | Location of the log file. If the value is blank, the log file is created in the temp folder. | .cms |
| MaxFileSize | The maximum file size (in kilobytes) before the log is cleared. The file size is checked at initialization to prevent data loss during a connection. The default is 100. | .cms |
| **[Menu Options]** | Shortcut menu that appears when a user right-clicks the notification area shortcut for your service. | CMAK<br>.cms |

| | | |
|---|---|---|
| *MenuItemName* | Command to be run from the shortcut menu. Shortcut menu commands use the format *MenuItemName* = *Program*, where *MenuItemName* is the descriptive name that appears on the shortcut menu and *Program* is the name of the executable file (.exe or other shell executable), including any parameters required for the program. For example, if you wanted to add Notepad to the menu with the command name "Editor," the line would be **Editor = Notepad.exe**.<br><br>Default commands = **Status** and **Disconnect**.<br><br>These programs are available in a shortcut menu that appears when a user right-clicks the notification area shortcut. Applications are listed in the menu in the same sequence as they are listed in the .cms file. | CMAK |
| **[Animated Logo]** | Animation for the Connection Manager logon dialog box.<br><br>The **[Animated Logo]** section specifies the location of the animation (.spl or .swf) file. This function is provided for compatibility with Connection Manager 1.0, which supports Macromedia Flash animation files.<br><br>**AnimatedLogo** in the **[Connection Manager]** section determines whether an animation is used. | .cms |
| Movie | Location of the animation file displayed in place of the static bitmap in the logon dialog box. Settings in the **[Animated Actions]** section control how the animation plays based on the connection state. | .cms |
| *Parameter* | Other animation parameters passed from software used to create the animation, such as Quality = 3. | .cms |
| **[Animated Actions]** | When to play segments of the animation. | CMAK<br><br>.cms |
| Initial | Starting frame number; plays when Connection Manager starts. | .cms |
| Dialing0 | Starting frame number; plays while the primary phone number is dialed. | .cms |
| Pausing | Starting frame number; plays during pauses between dials. | .cms |
| Dialing1 | Starting frame number; plays while the backup phone number is dialed. | .cms |
| Authenticating | Starting frame number; plays during user authentication. | .cms |
| Tunneling | Starting frame number; plays while establishing a VPN connection. | .cms |
| Connected | Starting frame number; plays when a connection is established. | .cms |
| Error | Starting frame number; plays at any connection error. | .cms |
| **[CustomButton Actions]** | Controls what programs start when the custom button is clicked. The format of the value is # = *Program*, where # is an ID number from 0 to *n* and *Program* is the complete name of the program, including the extension and the path to the program. Programs start in sequence: 0 first, 1 next, and so on. Custom button programs cannot be DLL files. | CMAK<br><br>.cms |
| **[Profile Format]** | Service profile version. | CMAK<br><br>.cms<br><br>.cmp |
| Version | Format version of the profile or service file. | .cms<br><br>.cmp |

# Phase Three: Running the CMAK Wizard and Creating a Service Profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Phase three: Running the CMAK wizard and creating a service profile**
Using the Connection Manager Administration Kit (CMAK) wizard, you can quickly and easily build the required service profiles to configure Connection Manager.

All custom elements must be ready before you run the CMAK wizard to build a service profile. Get organized before you start the wizard, and ensure that you have everything you need, including all external files required to implement the custom elements.

This section covers information that you need to know to run the CMAK wizard and create a service profile:

- Preparing to run the CMAK wizard
- Using the CMAK wizard to build a service profile
- Finishing customization after running the CMAK wizard

# Preparing to run the CMAK wizard

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Preparing to run the CMAK wizard**
You run the Connection Manager Administration Kit (CMAK) wizard to create a service profile. As you step through the wizard, you are prompted to select customizable options and type the location of customized elements that you have prepared. Before you can run the wizard, you must set it up on your computer and ensure that all custom elements are available. To help prepare for creating a service profile, you can complete the planning worksheet that is available in the Microsoft Windows Server 2003 *Resource Kit*. For more information about Connection Manager, see "Deploying Remote Access Clients Using Connection Manager" at the Microsoft Windows Resource Kits Web site.

**Setting up the CMAK wizard**
No set up of the CMAK wizard is required once it is installed, but before running the CMAK wizard, make sure that you have read the information in the readme file (CMAKRead.htm) to ensure that you understand any restrictions on how to use the CMAK wizard to set up your service profile. For more information, see The Connection Manager Administration Kit Wizard.

**Editing the templates**
Before you use the CMAK wizard to build a service profile, locate the advanced customization information provided by the network administrator or other technical lead. Advanced customization of the templates must be done before you run the wizard. For more information on editing the template files, see Advanced Customization.

**Setting up a folder for custom elements**
All custom elements prepared by you and other members of your team must be accessible as you run the CMAK wizard. Create a folder in which to place all custom files to be incorporated into the service profile. Using a single location for custom elements makes it easier to build profiles when you run the CMAK wizard. You might want to set up a folder at a network location so your team can share a common location to save and access files as they develop the custom elements.

**Creating multiple customized versions**
To build multiple service profiles, you should create a separate worksheet for each profile to be built. To simplify building a service profile similar to one you already have, you can duplicate the existing service profile and edit it as appropriate.

**To build a new service profile from an existing profile**

1. In the **Service Profile Selection** pane, click **Existing profile**, and then select the appropriate existing profile from the drop-down list.

2. In the **Service and File Names** pane, specify a new service name and file name for the new profile.

3. Proceed through the wizard, changing any specific options as appropriate, to build the new service profile.

### Important

- The existing service profile is not affected, as long as you specify a different service name and file name for the service profile you are building. If you do not specify a new file name, the CMAK wizard will prompt you that you want to overwrite the existing service profile. If you specify a new file name but do not specify a new service name, users who have the existing service profile installed and then install the new service profile will experience problems in connecting using the service profile.

**Updating and editing existing service profiles**
When you create a service profile, the CMAK wizard copies all incorporated files into the CMAK folder for that service profile (Program Files\CMAK\Profiles*ServiceProfileFileName*). When you edit an existing profile, the wizard always pulls the incorporated files from this CMAK folder. To make changes to the incorporated files, you can either edit the incorporated file in this CMAK folder and then run the wizard again to update the service profile, or you can start the wizard, delete the referenced files, add the updated file by browsing to it, and then finish running the wizard.

### Notes

- When you edit an existing service profile created with a previous version of the Connection Manager Administration Kit,

the CMAK wizard automatically updates the profile. Any changes you have made manually to the .inf file (using advanced customization techniques) will not be retained in the upgraded file. However, the CMAK wizard creates a backup of the old .inf file before creating the updated file.

- When you use the CMAK wizard to edit a top-level service profile, the wizard attempts to use the latest version of the merged service profile. If the CMAK wizard cannot find the merged service profile in the \Program Files\CMAK\Profiles*ServiceProfileFileName* folder, it defaults to the current version of the merged service profile, originally stored with the service profile that you are editing.

# Using the CMAK wizard to build a service profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using the CMAK wizard to build a service profile**
You create a service profile in three overall steps:

1. Start the Connection Manager Administration Kit (CMAK) wizard.
2. Run the CMAK wizard and enter all the necessary information.
3. Let the CMAK wizard build your customized service profile.

**Starting the CMAK wizard**
Do not start the CMAK wizard until you have collected all the information you need and have prepared all the custom bitmaps, Help files, and other items, as described in earlier sections.

**To start the CMAK wizard**

- To start the CMAK Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Connection Manager Administration Kit**.

**Running the CMAK wizard**
Other sections in this documentation provide details on how to build a service profile, describing them in the order in which panes appear when you run the CMAK wizard. To help prepare for creating a service profile, you can complete the planning worksheet that is available in the Microsoft Windows Server 2003 *Resource Kit*. For more information about Connection Manager, see "Deploying Remote Access Clients Using Connection Manager" at the Microsoft Windows Resource Kits Web site. If you completed the planning worksheet, based on the options you select in the wizard, some panes might be skipped. These should correspond to nonselected items on the worksheet.

When specifying the file location of any custom element (such as the phone book, bitmaps, icons, and so on), type the complete path or browse to find the appropriate file.

After you enter information and select options on each pane, click **Next** to advance to the next pane. If you want to change information that you entered in previous panes, you can click **Back** as many times as necessary to find the settings you want to change. Make your changes, and then click **Next** to continue moving forward through the CMAK wizard.

If at any time you want more information about the information to be included in a particular pane of the CMAK wizard, click **Help** in the pane to open a topic that contains Help specific to the content of that pane.

**Finishing the CMAK wizard and building a service profile**
When you finish entering information and are ready for the CMAK wizard to build a service profile, click **Next**. After the CMAK wizard builds the service profile, a dialog box appears, indicating the folder and file name that were used to save the service profile.

### Caution

- After you click **Next** in **Ready to Build the Service Profile**, the **Back** button will be grayed out. To change the profile, you will have to run the CMAK wizard again.
- To perform advanced customization using the CMAK wizard, you must select the **Advanced Customization** check box before clicking **Next**. For more information, see Advanced Customization.

### Note

- After you finish, you can continue with manual advanced customization, including editing the .cms files and other service-profile files. For more information, see Advanced Customization. Be sure to rerun the CMAK wizard after completing advanced customization.

# Finishing customization after running the CMAK wizard

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Finishing customization after running the CMAK wizard**

You can make most advanced customization changes within the **Advanced Customization** pane in the CMAK wizard. After you use the CMAK wizard to build a service profile, you can make further advanced customization changes to the service profile files by editing them with any plain-text editor, such as Notepad. You must run the CMAK wizard again after making these changes.

### Note

- The changes made to the .cms file for a service profile are specific to that service profile. To make a change that you want applied to all future service profiles, edit the template file. For more information on editing template files, see Templates and service profile files.

**To edit a .cms file for the service profile**

1. Locate the *ServiceProfileFileName*.cms file in the \Program Files\CMAK\Profiles*ServiceProfileFileName* folder and make backup copies of the file.

2. Use a text editor such as Notepad to edit the file. Be sure to save your changes before you close the file.

3. Restart the CMAK wizard, and then click **Next** to proceed to the **Service Profile Selection** pane.

4. Click **Existing profile** and then select the name of the service profile being edited.

5. Proceed through all other panes without making any changes, and then click **Finish** to rebuild your service profile. During the rebuilding process, the advanced customization that you did in the .cms file is applied to the service profile.

**To edit other files for the service profile**

Most advanced customization is done in the .cms file, but you can also edit the .inf and .cmp files. For more information, see Advanced Customization.

### Important

- If you do edit the .inf file, be extremely cautious.

If the service profile specifies it, edit these other files using the same procedures as specified above for the .cms files. These files are located in the same folder as the .cms file. To save time, edit all required files before rerunning the CMAK wizard to incorporate the changes.

# Phase Four: Preparing for Integration, Delivery, and Installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Phase four: Preparing for integration, delivery, and installation**
Connection Manager and your service profile can be delivered and installed on its own or integrated with another installation package, such as Internet Explorer. How you package and deliver your customized version will affect the way it is provided to your users. This section covers those options and considerations:

- Including Connection Manager in custom applications
- Incorporating Connection Manager with logon security
- Signing your code

# Including Connection Manager in custom applications

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Including Connection Manager in custom applications**
You can include Connection Manager and a service profile with your own custom installation package. The Connection Manager installation program, cmstp.exe, has several parameters that control how a service profile package is installed. You can also call Connection Manager programmatically from within a custom application.

### Note

- If you use the Internet Explorer Administration Kit (IEAK) to integrate a Connection Manager service profile with an Internet Explorer installation package, the Internet Explorer Customization wizard incorporates the command-line parameters needed to integrate the two installation programs.

**Delivering a custom installation package**
Using command-line parameters, you can integrate Connection Manager in an installation package and deliver it to users in a variety of ways. For example, you might want to:

- Distribute and install the Connection Manager service profile over a corporate network using Microsoft Systems Management Server (SMS) to automatically handle the process without user intervention.
- Integrate the Connection Manager service profile with another product's installation package and install them both in a single process.
- Post the Connection Manager service profile to a Web site to enable users to access and install the service profile in a standard way (specifying certain installation options for the user).

You can set up these distribution and installation options programmatically only after you have used the Connection Manager Administration Kit (CMAK) wizard to build your service profile.

**Syntax**
The command-line syntax for cmstp.exe follows one of two formats. One is for use with a service profile self-extracting executable (.exe) file, and the other is for use with a service profile information (.inf) file.

If you are building a custom installation or uninstallation package with the service profile executable file, you will want to use the following syntax:

*ServiceProfileFileName* **.exe** [**/q:a**] **/c:"cmstp.exe***ServiceProfileFileName***.inf** [*Parameters*]**"**

If you are building a custom installation or uninstallation package without the service profile executable file, you must use the following format in your custom package, and you must know the full path to the .inf file:

**cmstp.exe** [*Parameters*] **"***[drive][full path]ServiceProfileFileName***.inf"**

### Notes

- *ServiceProfileFileName* is the file name of the service profile you build with the CMAK wizard.
- The optional parameter, **/q:a**, prevents the profile from opening automatically after it has been installed. The verification message that the installation has succeeded will still appear.
- The command, **/c:"cmstp.exe**, tells the extraction program to override the installation defaults.
- Do not use brackets [] when specifying the full path to the .inf file.
- *Parameters* are the command-line parameters supported by the cmstp.exe installer.

- You can copy your service profile executable (.exe) file during installation and store it in a known directory. This action helps ensure that you will be able to refer to the file in the future.

**Parameters**

The following parameters are supported for installation:

- **/ni** - Do not create a desktop icon (valid only on Windows 95, Windows 98, Windows NT 4.0, and Windows Millennium Edition). On these platforms, the desktop icon is the only method provided by Connection Manager to enable users to open or delete a profile. If you use this parameter, you must provide your users with a different way to open or delete the service profile.

- **/ns** - Do not create a desktop shortcut to the connection in the **Network and Dial-up Connections** folder (Windows 2000 only) or the **Network Connections** folder (Windows XP and the Windows Server 2003 family only). Unless the silent install parameter is also specified, this only overrides the default user preference, so the user will still see the check box in the user interface. The first time a user installs a profile, the default is not to have a desktop shortcut. The user's preference is stored in the registry and is used for each subsequent installation.

- **/s** - Install silently. This option allows automatic installation of the service profile without requiring user action to complete the installation. The profile will not automatically start after it is installed.

- **/sd** - Set the installed profile as the default connection for Internet Explorer.

- **/su** - Install for a single user (valid only on Windows 2000, Windows XP, and the Windows Server 2003 family). If this parameter is used, the user does not have the option to install the software for use by all users.

- **/au** - Specifies that the service profile should be installed for all users. This parameter is only valid for computers running a member of the Windows Server 2003 family, Windows 2000, or Windows XP.

The parameters supported for uninstalling are as follows:

- **/u** - Uninstall the service profile. The only other parameter that can be used with this parameter is the **/s** parameter.

**Important**

- Any user can modify the .cms and .cmp file of a service profile that is installed on a computer running Windows 98 or Windows Millennium Edition. Users who install profiles for individual use on computers that are running Windows Server 2003, Windows XP, or Windows 2000 can modify .cms and .cmp files of the profiles they install. Only members of the Administrators or System Operators groups can modify .cms and .cmp files of profiles installed for All Users on computers that are running Windows Server 2003, Windows XP, or Windows 2000. Any member of the Administrators group on a local computer can modify the .cms and .cmp files of any service profile that is installed on that computer.

**Notes**

- To display Help for the command-line installation parameters, type **cmstp.exe /?**.

- To find the full path to the service profile information (.inf) file, you can use information extracted from registry keys, as shown in the examples below.

If you do not specify parameters for the cmstp.exe file, the following defaults are used:

- On a computer running Windows 95, Windows 98, Windows NT 4.0, or Windows Millennium Edition, a desktop icon is created, the profile is installed for all users, and the profile automatically starts after it is installed.

- On a computer running Windows 2000, the profile is installed for use by all users. If the Connection Manager software is included in the profile, that software is also installed.

- On a computer running Windows XP or a member of the Windows Server 2003 family, the profile is installed for use by all users, but Connection Manager is not installed.

- If a user is not logged on as an Administrator on a computer running Windows 2000, Windows XP, or a member of the Windows Server 2003 family, the software is installed for use by a single user.

#### Integrating the Connection Manager software within a custom application

You can start Connection Manager from within a custom application. A Connection Manager service profile presents a customized connection experience for your users. By integrating Connection Manager with a custom application, you can ensure that all your users connect in exactly the same way.

If you are writing an application for computers running Windows 2000, Windows XP, or a member of the Windows Server 2003 family and you want to open the Connection Manager logon screen, you can use the **RasDialDlg** function. If you want to open the **Properties** dialog box (for instance, if you want the users to select a phone number before dialing), you can use the **RasEntryDlg** function. For more information about these functions and how to use them, search for these function names on the Microsoft Web site or consult the Microsoft Platform Software Development Kit.

The **RasDialDlg** and **RasEntryDlg** functions are not supported for Windows 95, Windows 98, or Windows Millennium Edition. Although these functions are supported on Windows NT 4.0, using them in conjunction with a Connection Manager service profile is not supported. If you are writing an application for computers running one of these operating systems, you can instead use a function such as **ShellExecute** or **CreateProcess** to start cmmgr32.exe. To open the Connection Manager logon screen, use cmmgr32.exe, followed by the full path to the .cmp file of the service profile you want to open. For example, to open the Awesome Computers service profile on a computer running Windows 98, use:

**cmmgr32.exe "c:\Windows\All Users\Application Data\Microsoft\Network\Connections\Cm\Awesome1.cmp"**

If you want to open the **Properties** dialog box, use **cmmgr32.exe** followed by **/settings** followed by the full path to the .cmp file. For example, to open the **Properties** dialog box for the Awesome Computers service profile on a computer running Windows 98, use:

**cmmgr32.exe /settings "c:\Windows\All Users\Application Data\Microsoft\Network\Connections\Cm\Awesome1.cmp"**

### Notes

- Cmmgr32 runs as an asynchronous action. No response is returned to your program unless you add a custom action to the service profile to provide one. You can also wait for cmmgr32 to finish.

- If the path to the service profile includes spaces, use double quotes (") around the path.

#### Examples

The following examples describe a possible installation and a possible uninstallation for the Awesome Computers service profile.

#### Installation example for Awesome Computers

Awesome Computers wants to build a custom installation package and include a service profile, Awesome1.exe, in the package. The company wants a silent install. The company does not want to create a desktop icon or a desktop shortcut to the profile. The company would like the Awesome1 service profile to become the default connection for Internet Explorer.

In its custom installation package, Awesome Computers includes this command:

**Awesome1.exe /q:a c:"cmstp.exe Awesome1.inf /s /ni /ns /sd"**

#### Uninstallation example for Awesome Computers

Awesome Computers wants to build a custom uninstallation package. The company does not know whether its users still have the Awesome1.exe file on their computers, so the company must get the .cmp path from the registry and extrapolate the .inf path from that information. The company wants a silent uninstall.

1. The custom uninstallation application queries one of two registry keys.

   All users profile:

   **HKLM\Software\Microsoft\Connection Manager\Mappings**

Single user profile:

**HKCU\Software\Microsoft\Connection Manager\Mappings**

The call provides a name value of **Awesome Computers** (the full service profile name) and returns a data value of the full path to the Awesome1.cmp file.

2. The custom uninstall application changes the Awesome1.cmp path into the Awesome1.inf path by replacing Awesome1.cmp with Awesome1\Awesome1.inf. For example, a .cmp path of C:\Documents and Settings\All Users\Application Data\Microsoft\Network\Connections\Cm\Awesome1.cmp must be converted to C:\Documents and Settings\All Users\Application Data\Microsoft\Network\Connections\Cm\Awesome\Awesome1.inf.

3. The custom uninstallation application includes this command:

   **cmstp.exe /u /s "c:\Documents and Settings\All Users\Application Data\Microsoft\Network\Connections\Cm\Awesome\Awesome1.inf"**

### Notes

- The credentials of the user installing or uninstalling the package will affect how cmstp.exe operates. If the user does not have administrative credentials, he or she will not be able to install or uninstall a profile for all users. The profile will be installed for his or her own use.

- If you use the following key, the initial portion of the data value might contain a system macro.
  **HKCU\Software\Microsoft\Connection Manager\Mappings**

For more information, see Verifying customization and Troubleshooting process.

# Incorporating Connection Manager with logon security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Incorporating Connection Manager with logon security**
On computers running Windows 2000, Windows XP, or a member of the Windows Server 2003 family, a user can choose to log on to Windows using a Connection Manager profile.

**Logging on using a Connection Manager profile**
A user can log on using a dial-up connection (including a Connection Manager connection) only if the computer is a member of a domain. If the computer is not a member of a domain, the **Log on using dial-up connection** check box does not appear.

In the **Log On to Windows** dialog box, the user can select the **Log on using dial-up connection** check box. After clicking **OK**, the user is prompted to choose a network connection.

After the user chooses a connection, the Connection Manager logon screen appears. Connection Manager starts the connection process when the user clicks **Connect**.

**Administrative issues when using Connection Manager profiles to log on**
If you intend to build and distribute a service profile that will be regularly used to log on, you might want to consider the following:

- By default, Connection Manager uses the credentials the user types at the Windows logon screen. If you want Connection Manager to ignore those credentials, add the key **UseWinLogonCredentials=0** to the **[Connection Manager]** section of the .cms file for your service profile.

- Users who select the **Log on using dial-up connection** check box gain access to Windows through an account designed for this method of logging on. Any customized settings for Connection Manager are applied to the Log on to Windows account, rather than to the account of the user who logged on. The user can customize the Log on to Windows account in the same ways as any other account (for example, save settings for phone numbers). However, permissions granted to specific users, such as access to Help, are not granted to users logging on to Windows, even after the connection completes.

For security reasons, the following functionality is not available when a user logs on to Windows using a dial-up connection:

- If the .cms file for the profile contains the **ResetPassword** key, any value for that key is ignored.

- Custom buttons do not appear or function.

- The **View Log** button is disabled.

- The **Advanced** tab does not appear in the properties dialog box for the service profile.

- Keys in the .cmp file that provide user credentials for first-time use (such as **UserName**) are not available. Internet connection credential keys such as **InternetUserName** are available.

- Macromedia animation does not display. If you are building a profile that uses Macromedia animation, you should include a default bitmap to display in this circumstance.

- Custom actions do not run unless those actions have been enabled by editing the registry. Even after custom actions have been enabled, the custom action will not automatically work with registered shell extensions. You must indicate the program to use with the file, as well as the path to the file.

- Connection Manager Help (including context-sensitive help) is disabled during the connection process.

- If a system component is missing when the user attempts to log on using a dial-up connection, the connection attempt fails. The user will not be able to install the system component until he or she logs on.

**Enabling custom actions that run when a user logs on by using a dial-up connection**

For a custom action to run during the logon process, you must enable that action by specifying a value for the following registry key:

**HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Connection Manager** *ProfileName* **\WinLogon Actions**

The format for the value of the registry key is:

| Field | Description |
|---|---|
| Name | The name of the executable file that will run. |
| Type | REG_DWORD |
| Data | A value indicating the location of the executable. |

Supported values for the Data field are:

| Value | Location of executable |
|---|---|
| 0x00000000(0) | *%windir%*\system32 |
| 0x00000001(1) | Profile directory |

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

The following example enables automatic phone book downloads at connection time. If you set the value of:

**HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Connection Manager** *Profile Name* **\WinLogon Actions**

as:

**cmdl32.exe REG_DWORD 0x00000000(0)**

then you must also include:

**[Xnstall.AddReg.AllUsers] "HKLM", "%AppAct%\%ServiceName%\WinLogon Actions","cmdl32.exe",0x00010001,0**

in the .inf file of the profile.

**Important**

- Modifying .inf files can cause significant installation problems. Thoroughly test all service profiles containing custom .inf entries for version, file, or other conflicts. Be sure that the file location is specified correctly.

- If a custom action runs when users log on to Windows, the custom action runs with system permissions. You should ensure that any custom actions that you enable do not pose unintended security risks.

- Any user can modify the .cms and .cmp files of a service profile that is installed on a computer running Windows 98 or Windows Millennium Edition. Users who install profiles for individual use on computers that are running Windows Server 2003, Windows XP, or Windows 2000 can modify .cms and .cmp files of the profiles they install. Only members of the Administrators or System Operators groups can modify .cms and .cmp files of profiles installed for All Users on computers that are running Windows Server 2003, Windows XP, or Windows 2000. All members of the Administrators group on a local computer can modify the .cms and .cmp files of any service profile that is installed on that computer.

# Signing your code

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Signing your code**

After you have completed all customization, it is recommended that you sign your code before distributing it. Signing your code with a digital signature assures your users that the programs are from a known source and have not been altered.

You should digitally sign your customized service profile and any custom programs to ensure that users do not receive warnings when they install Connection Manager. Users may be prevented from installing ActiveX controls and other packages that are not signed.

Further information on code signing can be found in the Internet Explorer Administration Kit (IEAK). If you include a Connection Manager service profile in an Internet Explorer installation package created using Internet Explorer Connection wizard in the IEAK and you specify the digital signature option in the wizard, the digital signature support provided for the installation package will include the Connection Manager service profile.

For information on code signing, go to the Microsoft Developer Network (MSDN) on the Microsoft Web site, click **Search** on the MSDN screen, and type **digital signature** or **code signing** as search words for a Boolean search on the entire Microsoft site.

# Phase Five: Testing Your Deliverables

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Phase five: Testing your deliverables**
Before you distribute the service profile that you created with the CMAK wizard, you must test it. This section describes how to install and test service profiles. It also describes things you should consider if you want to provide users with your own installation program to install service profiles.

This section covers:

- Test process
- Verifying customization

# Test process

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Test process**

Test your service profiles to ensure that all planned functionality is implemented and working as planned.

Install and use each of your service profiles on each target operating system. If you distribute the service profile on disk and by e-mail, test each method. If you are providing multiple language versions, test each one on the operating system with the appropriate national language.

**Note**

- If you have users with previous versions of your service profile, test Connection Manager on computers on which your previous service profiles are installed, as well as on computers that have not had previous versions installed.

Following are basic testing steps:

For each service profile and scenario, use Connection Manager to do all of the following:

**To test your service profile**

1. Install the service profile, as described in a readme or other documentation that you provide to the user.
2. Provide the required user data (user name, user password, and so on) needed to connect.
3. Select a Point of Presence (POP) from the phone book and establish a connection.
4. View network resources while connected to your service (check connection while viewing URL).
5. Disconnect from your service.
6. Uninstall the service profile.

**Test criteria**

As you install and use Connection Manager, ensure that each service profile has the appearance, features, functionality, and usability that you want:

- Do the screens contain the appropriate titles, text, and graphics, and does each screen appear completely and correctly?
- Are all of the required programs included in the service profile? If not, are all required programs available on all target operating systems?
- Do all menu items for the notification area shortcut function appropriately?
- Do you have appropriate Help topics, including troubleshooting Help, for all functions and features? Do these Help files match the service profile? If you customized any Help topics, do they appear as expected?
- Is everything formatted and spelled correctly, including the license agreement, the screen text, the text in the Connection Manager dialog box, and other user information?
- Is all the information needed to install and use Connection Manager and the service profile available when and where it is needed?
- If you provided custom dial-up entries (especially scripts), do they work as intended?

- If you support such connections, can you establish both direct and VPN connections?
- If you included any pre-connect, pre-tunnel, post-connect, pre-dial, on-error, on-cancel, or disconnect custom actions or monitored applications, do they work as expected?
- If you edited your .cms and other service-profile files, do your custom entries perform as expected?
- If you use code signing, does it display the authentication notice as expected?
- Can you connect using POPs in the phone book for each of the service types you support?
- If you use a firewall, are the firewall proxy settings correct?
- Do the components of Connection Point Services provide the required functionality, as described in the Connection Point Services documentation?

**Note**

- You must build profiles on a server operating system that is designed for the same processor set as the client computers on which users will install the profile. For example, if you want to build a profile for users running Windows XP Professional x64 Edition, you must build that profile on a server that is running an x64-based version of Windows Server 2003.

# Verifying customization

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Verifying customization**
There are several instances in which customization requirements are very stringent. This section repeats the information that is most commonly overlooked.

**Verify that the service name and file name are valid**
If you are updating an existing service profile, the service and file names should be identical to the previous ones. If you are creating a new profile (from scratch or by editing an existing service profile and renaming it), make sure that the service name and file name are not identical to any other service profiles that you provide to your customers. If you do not specify a file name that is different from the one users already have installed on their computers, the original service profile will be overwritten. If you specify a new file name but do not specify a new service name, users who have the existing service profile installed and then install the new service profile with the different service name will experience problems in connecting. The problems can include not being able to connect using either or both service profiles.

If you need to make changes to an existing profile, use the Connection Manager Administration Kit (CMAK) wizard to edit the profile instead of creating a new file with the same name.

**Verify that the dial-up entry is correct in CMAK and the phone book**
The phone book dial-up entry that you set up in the phone book must exactly match the entry you set up in your service profile. Use a text editor such as Notepad to open the Phone Book Administrator file and verify that the entries you specified in the phone book (at the end of each line) match the entries you set up in the CMAK wizard in **Dial-up Networking Entry**.

**Verify that all required protocols are specified correctly**
Verify that the required network protocols, including TCP/IP, IPX, and NetBEUI (as appropriate), are specified in the **[Server&*EntryName*]** section of the .cms file for the specified dial-up entry. The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

**Verify that proxy settings are set as required to support successful connection to your service**
If your service requires special proxy settings, verify that any required custom actions have been designed and implemented to adjust the settings on the user's computer as required.

**Verify that resident programs on users' computers can be opened**
If your custom actions or other custom settings depend on the program being available on your users' computers (that is, you are not providing it in your service profile), verify that the program is in the default path and available to Connection Manager. Not all programs that appear on the **Start** menu are necessarily set up to use the default path. Connection Manager may not be able to find the installed program if it is not in the default path.

**Verify that your service-profile updates are complete**
When you edit a service profile created using a previous version of Connection Manager, the CMAK wizard automatically upgrades the profiles to Connection Manager 1.3. Any changes you have made manually to the .inf file (using advanced customization techniques) will not be retained in the upgraded file. However, the CMAK wizard creates a backup copy of the old .inf file before creating the updated file.

**Verify that your time-outs are not preventing access to your domain**
For VPN connections, users sometimes get a message that the domain controller couldn't be found, even though the routing information is correct. In this case, setting the LanaTimeout entry in the .cms file may correct the problem. This increases the time (in seconds) to wait before attempting to connect to a VPN server. Increase this value if the connection consistently fails to find a domain controller.

# Phase Six: Supporting Your Customers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Phase six: Supporting your customers**

Effective customer support depends on your ability to resolve customer questions, problems and needs quickly and effectively. This section contains information intended to help you and your users address the more common situations:

- Troubleshooting process
- Frequently Asked Questions

# Troubleshooting process

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting process**

The first level of troubleshooting is provided in the Help files that are included with your service profile. This troubleshooting Help information makes it possible for many problems to be resolved directly for the user. Each problem that cannot be resolved leads to a Help topic that instructs the user to call customer support. You should customize this Help topic with a phone number for your customer support group, additional information specific to your service, and other information that may help your users.

To resolve problems most effectively:

1. Make sure that all system requirements have been met.

2. Make sure that the right access numbers are used and that they are entered appropriately. Verify that the users understand that dialing rules are applied only to numbers selected from a phone book. If a number is typed or edited by the user, the user must then type all dialing information, including information such as long-distance and external access numbers. If the user chooses to use dialing rules, the user must configure those dialing rules appropriately for the location.

3. Make sure that users know how to access the Connection Manager troubleshooter Help, and verify the path that they have taken through the troubleshooter Help.

4. Check the appropriate readme files (including CMAKRead.htm) to determine if the problem is a known issue.

5. Look for common mistakes. Make sure that:

    - The modem is on.

    - The appropriate version of Connection Manager is installed. To determine this, instruct your users to check the About tab of the **Properties** dialog box (Windows NT 4.0, Windows 95, Windows 98, and Windows Millennium Edition only) or the log file.

    - The latest version of the appropriate connection software is installed.

    - The latest service pack is installed.

    - The Internet Explorer proxy settings are correct.

    - All required network protocols are installed and configured correctly on the user's computer. (If the user can get to the network but cannot reach any services, a protocol on the user's computer may be misconfigured.)

    - If your service profile supports VPN connections, Point-to-Point Tunneling Protocol (PPTP) is installed and configured correctly and completely. (This is usually a problem only on Windows NT 4.0, where Connection Manager does not automatically install PPTP.)

    - The dial-up entry used is appropriate for the user’s operating system.

    - If a user has installed remote access or PPTP on a computer running Windows NT 4.0, the user reinstalled any service pack previously installed on their computer.

    - If a user is using Internet Connection Sharing, Internet Connection Firewall, or Windows Firewall, the connection is shared correctly, and the firewall is not blocking the connection. For more information, see Connecting to the Internet in a home or small office network, Internet Connection Firewall, and Help: Windows Firewall.

**Notes**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

6. Users have received all workarounds and solutions, as appropriate. For information on networking problems, including those involving remote access, search the Microsoft Developer Network (MSDN) on the Microsoft Web site.

7. Ask users to generate and send a log file for the connection. The log file contains valuable troubleshooting information. Logging is typically enabled by default. Users can enable or disable logging after the profile is installed.

   - If logging was enabled, instruct the user to send the log file. Make sure that the user did not turn off logging. Depending on the size of the log file, decide whether you want the user to clear the log file and try the connection again before sending the log file. To direct the user to the log file, instruct the user to click **Properties** on the Connection Manager logon screen. Instruct the user to click the **Options** tab and then to click the **View Log** button. After the user has opened the log file, instruct the user to save the file and send it to you.
   - If logging was not enabled, instruct the user to turn on logging, try the connection, and then send the log file. To enable logging, instruct the user to click **Properties** on the Connection Manager logon screen. Instruct the user to click the **Options** tab and to select the **Enable Logging** check box.
   - If the user is attempting to log on to Windows using a Connection Manager profile, the **View Log** button will be unavailable. To find the log file, instruct the user to log on to the computer without using a Connection Manager profile. After the user has logged on, instruct the user to click **Start**, point to **Search**, and click **For Files or Folders**. After the **Search Results** dialog box appears, instruct the user to click **Search Options**, select the **Advanced Options** check box and to select the **Search system folders** check box. Instruct the user to search for the log file by typing in the first three letters of the service profile name, followed by an asterisk (*) and the log file extension (.log). For example, if the service profile is named **Awesome**, the user should search for **Awe*.log**. The file is stored in %windir%\temp by default.

**Note**

- On computers running Windows NT 4.0, Windows 2000, Windows XP, or a member of the Windows Server 2003 family, the log file will be in Unicode format. To view the log file on an operating system other than these, open the log file with a Unicode text viewer, such as Microsoft Word.

For more information about Connection Manager, see "Connection Manager" at the Microsoft Windows Resource Kits Web site.

# Frequently Asked Questions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Frequently Asked Questions**
The following are some of the most frequently asked questions regarding Connection Manager and the Connection Manager Administration Kit (CMAK). These questions are based on actual calls to Microsoft product support services and might save you time and effort.

Unexpected profile actions

- My users can connect to the server when using the service profile, but authentication fails.
- My VPN service profile takes too long to connect.
- The connection failed to complete after the user was authenticated.
- My ISDN users connect at 64 kilobits per second.
- My merged service profile does not work the way I expect.
- The Connection Manager interface appears unexpectedly.
- Nothing happens when my Windows 2000 users double-click the connection icon in the Network and Dial-up Connections folder.
- My service profile does not work properly when users log on to Windows with it.

Profile administration

- The phone book for the service profile is not being updated.
- I cannot populate a previously installed service profile with user credentials and phone numbers.
- I want to dynamically change the VPN address for a service profile.

Profile creation and development

- I do not understand the difference between networking settings and dial-up entry names.
- I want to create a profile in which some numbers dial directly to my corporate network and other numbers connect through a virtual private network (VPN) tunnel.
- I want to create a VPN-only profile.
- I want to provide user credentials and phone numbers for my service profile for first-time users.
- I want to create Connection Manager profiles in more than one language.

**Unexpected profile actions**
**My users can connect to the server when using the service profile, but authentication fails.**
**Cause:** The server running Routing and Remote Access cannot connect to the authentication server.

**Solution:** Verify connectivity between the server running Routing and Remote Access and the authentication server.

**Cause:** The authentication server has been improperly specified or configured for dial-up access.

**Solution:** Verify that the authentication server specified in the service profile is correct. Check the user account and make sure that dial-up access has been enabled. Look up any Group Policy rules that might restrict access by time or date.

**Cause:** Settings for one or more dial-up entries have been improperly specified.

**Solution:** Check the security settings for each dial-up entry, including component service profiles. The simplest way to do this is to run the CMAK wizard and choose to edit the service profile. When you reach **Dial-up Networking Entries**, click each entry, and choose **Edit**. On the **Security** tab, make sure that all of the security settings are properly specified. One common error is to select **Use advanced security settings** for a service profile issued to users using Windows 98.

**Solution:** Make sure that the phone book files (.pbk) have the correct settings for each dial-up entry. For each phone book you include in the service profile, open the .pbk file, and check the **Dial-up Networking entry** field, which is the eleventh field, in each POP. Make sure that this field is specified appropriately for each POP in each phone book.

**See also:** Advanced Customization; Add, edit, or delete POPs by command line

**Cause:** Prefix and suffix information might have been specified differently in one or more of the component profiles merged into the issued service profile.

**Solution:** Check the **UserNamePrefix** and **UserNameSuffix** keys in every .cms file in the service profile. A value for this key specified in the component profile will override the top-level service profile settings.

**See also:** Merging phone books and other features from existing service profiles; Providing a realm name; Advanced Customization

**My VPN service profile takes too long to connect.**
**Cause:** Certificates are invalid or missing.

**Solution:** Delays in excess of one minute often indicate a failure in the L2TP/IPSec protocol negotiation. Make sure all service profile users have the newest certificates installed on their computers.

**See also:** Certificate Services

**Cause:** A round robin server solution is causing delays in authentication.

**Solution:** If you are using a round robin server solution for L2TP/IPSec VPN servers, a failure to authenticate on one or more servers can result in variable delays. Depending on the profile settings, Connection Manager might redial each VPN server multiple times. Make sure that each VPN server is configured to accept the profile and that each server is responding.

**See also:** Configuring round robin

**The connection failed to complete after the user was authenticated.**
**Cause:** The service profile contains improper post-connect actions.

**Solution:** Check the **[Connect Actions]** section in the service profile's .cms files for proper behavior on target platforms.

**See also:** Incorporating custom actions

**Cause:** The routing table update file is attempting to delete a route that does not exist.

**Solution:** Check the routing table update file for outdated or inaccurate route changes.

**See also:** Including routing table updates

**My ISDN users connect at 64 kilobits per second.**
**Cause:** The **ISDNDialMode** key value is not set to bind dual channels.

**Solution:** Use advanced customization techniques to change the value of the **ISDNDialMode** key to the appropriate value and reissue the profile.

**See also:** Advanced Customization; Connection Manager keys

**My merged service profile does not work the way I expect.**
**Cause:** The settings in component service profiles conflict.

**Solution:** Check phone book filtering. Your region settings might not be the same in all phone book region (.pbr) files. If you

are using custom service types in any or all phone books, you need to apply these to each .cms file.

**Solution:** Check the realm name information in each .cms file included in the merged service profile. Any realm information in a component profile will be overridden by realm information specified in the .cms file of the top-level profile. You should leave the realm name field in the top-level service profile blank if you need to merge profiles with different realm information.

**Solution:** Check the tunnel addressing information. Tunnel addressing information specified for the top-level service profile is used for all phone books merged into it.

**Solution:** Check the settings for the **DUN** and **TUNNELDUN** keys in all the .cms files included in the merged service profile. The default dial-up settings originate in the .cms file associated with the user-selected phone book, while VPN settings originate from the top-level .cms file.

**See also:** Advanced Customization; Providing a realm name; Implementing VPN support; Merging phone books and other features from existing service profiles

**The Connection Manager interface appears unexpectedly.**
**Cause:** Internet Explorer is improperly configured for your service.

**Solution:** Assist your users in changing their Internet Explorer options. In Internet Explorer, click the **Tools** menu. Click **Internet Options**, click the **Connections** tab, and choose the appropriate dial-up option. The default option is to always dial the default connection. However, your profile might work best if a connection is never dialed or if a connection is dialed only when an Internet-based program is started and a network connection is not present.

**Cause:** Custom actions requiring Internet access continue to run after the connection has been terminated.

**Solution:** Test the service profile to make sure that all custom actions terminate properly. If necessary, reissue the service profile after you add a disconnect action that ensures that programs terminate properly.

**See also:** Incorporating custom actions

**Nothing happens when my Windows 2000 users double-click the connection icon in the Network and Dial-up Connections folder.**
**Cause:** The installation of the Connection Manager 1.3 software did not complete correctly. Mismatched Connection Manager software binaries are causing the connection software to fail.

**Solution:** Instruct the user to uninstall the Connection Manager 1.3 software and then to reinstall the profile. To uninstall Connection Manager 1.3, click **Start**, point to **Settings**, click **Control Panel**, double-click **Add or Remove Programs**, click **Microsoft Connection Manager 1.3**, and click **Remove**. This process restores the Windows 2000 Connection Manager binaries on the user's computer. The user should then reinstall the Connection Manager service profile that included the Connection Manager 1.3 software.

**See also:** Troubleshooting process; Adding Connection Manager 1.3 to the service profile

**My service profile does not work properly when users log on to Windows with it.**
**Cause:** Custom actions have not been enabled to run when users log on to Windows with your service profile.

**Solution:** Check whether you need to change user registry settings in order to run custom actions when users log on to Windows with your profile. Consider issuing a profile without custom actions for use in logging on to Windows.

**See also:** Incorporating Connection Manager with logon security

**Cause:** Connection Manager treats "Log on using dial-up connection" as a separate user with limited permissions. Settings applied to "Log on using dial-up connection," such as proxy configuration, are not applied to individual user accounts after logging on.

**Solution:** Consider advising your users to log on to their local computers before using a Connection Manager profile to log on to your domain.

**See also:** Incorporating Connection Manager with logon security

**Profile administration**
**The phone book for the service profile is not being updated.**
**Cause:** Improperly set Internet proxy settings is preventing phone book downloads.

**Solution:** Check the proxy settings for the service profile. If you are using automatic proxy configuration in your service profile, check those settings and the proxy server.

**See also:** Common problems and their solutions; Using automatic proxy configuration

**Cause:** One or more Phone Book Service (PBS) servers is out of service.

**Solution:** Check the log files on your PBS servers for error messages.

**See also:** Phone Book Service error messages

**Cause:** A URL in the service profile points to a server that cannot be found.

**Solution:** Check the URLs specified in the service profile. You can do this by editing the profile in the CMAK wizard or by checking the settings directly in the **[ISP]** section of the .cms file. If the profile in question was created by merging other service profiles, check the URLs in all the .cms files used by the profile.

**See also:** Advanced Customization; Providing phone book support; Merging phone books and other features from existing service profiles

**I cannot populate a previously installed service profile with user credentials and phone numbers.**
**Cause:** Updated profiles cannot overwrite user settings.

**Solution:** Populate the credentials in the .cmp file of the service profile when you create it. Run the CMAK wizard again. Issue the new service profile to your users. Include a custom uninstallation and reinstallation package or instructions on how to uninstall the old service profile and install the new version.

**I want to dynamically change the VPN address for a service profile.**
**Solution:** Write a custom pre-tunnel action that adjusts the VPN address in the .cms file as needed. This feature might not be available in future releases. Consider the security implications of dynamically changing a VPN address before you implement this solution.

**See also:** Incorporating custom actions

**Profile creation and development**
**I do not understand the difference between networking settings and dial-up entry names.**
**Solution:** Dial-up entry names identify combinations of networking settings. You can specify different networking settings for each dial-up entry. You usually name dial-up entries on the **Settings** tab of the **Add POP** pane of Phone Book Administrator. Those names appear in the **Dial-up Networking Entries** pane of the CMAK wizard. Connection Manager uses a dial-up entry to determine which combination of networking settings are required for a service profile.

**See also:** Incorporating custom dial-up entries

**I want to create a profile in which some numbers dial directly to my corporate network and other numbers connect through a virtual private network (VPN) tunnel.**
**Solution:** Create two phone books, one for a direct dial connection and the other for a VPN tunnel to your network. Create a profile with your direct dial phone book. Create a top-level profile that merges the direct dial profile and incorporates the VPN phone book. On the **VPN Support** pane, select the **Phone book from this profile** check box.

**See also:** Merging phone books and other features from existing service profiles; Implementing VPN support

**I want to create a VPN-only profile.**
**Solution:** To create a VPN-only profile, start the CMAK wizard. Select the **Phone book from this profile** check box on the **VPN Support** pane, and specify a VPN server or a VPN file. Configure the VPN entry or entries with the correct security and addressing information for your network. Do not specify a phone book file on the **Phone Book** pane, and clear the **Automatically download phone book updates**check box. You do not need to configure the default dial-up entry for the profile. On the last pane of the wizard, select the **Advanced Customization** check box. On the **Advanced Customization** pane, click the profile .cms file, click the **[Connection Manager]** section, and set the value of the **Dialup** key to zero. Click **Apply**, and finish the wizard. This will create a VPN-only profile, without a **General** tab in the **Properties** dialog box for the profile. Users of your profile will not see any phone or dialing information.

**See also:** Implementing VPN support; Incorporating VPN entries

**I want to provide user credentials and phone numbers for my service profile for first-time users.**
**Solution:** Use advanced customization techniques to assign values to the keys for which you want to provide first-time use data, such as **Username**. These keys must be assigned in the .cmp file, and they will only be available the first time the profile is used. For passwords, you must edit three keys: **PCS**, **RememberPassword**, and **Password**. The **PCS** key should always be set to 0; the values of the other keys will vary according to your profile needs. If you want this password to be available to all users who connect from the same computer, you must edit an additional key, **KeepDefaultCredentials**. If this key is not set to the appropriate value, only the person who installs this profile will have access to the credentials you provide for first-time use. Consider the security implications of providing a password for the first user who installs and uses the profile.

**See also:** Advanced Customization

**I want to create Connection Manager profiles in more than one language.**
**Solution:** You can use the Multi-User Language Interface (MUI) with the CMAK wizard to build a Connection Manager profile in a language other than the one installed with your operating system. You can include the Connection Manager software with that profile, but Connection Manager will appear in the language installed with your operating system, not in the MUI language. You can choose not to include the Connection Manager software with the profile, but your users might not have access to all the current features of Connection Manager.

To include a version of Connection Manager in the same language as the profile, you must build the profile using the CMAK wizard on an operating system that was installed with the appropriate language. The CMAK wizard comes with Windows Server 2003 operating systems. You can also install the CMAK wizard on Windows XP Professional with the Windows Server 2003 Administration Tools Pack.

**See also:** Creating profiles in multiple languages

# Connection Point Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connection Point Services**
Connection Point Services (CPS) works in conjunction with Connection Manager to automate the process of updating your users' computers with new Points of Presence (POP). CPS consists of Phone Book Service (a utility for distributing your phone books) and Phone Book Administrator (a tool to create and maintain your phone book files). For complete information about Connection Manager, see Connection Manager Administration Kit.

- Before installing, configuring, or administering CPS, see Connection Point Services Checklists.
- For helpful tips, see Connection Point Services Best Practices.
- For help with specific tasks, see Connection Point Services How To....
- For general information, see Connection Point Services Concepts.
- For problem-solving strategies and error messages, see Connection Point Services Troubleshooting.

# Connection Point Services Checklists

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklists**

- Checklist: Installing Connection Point Services
- Checklist: Configuring Connection Point Services
- Checklist: Administering phone books with Phone Book Administrator
- Checklist: Administering phone books by command line

# Checklist: Installing Connection Point Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Installing Connection Point Services**

While installing a Windows Server 2003 family operating system, you might have chosen to add Connection Manager components, which include Connection Point Services (CPS). If you did not install CPS at that time, you can install it now.

| Step | Reference |
| --- | --- |
| Connection Point Services (CPS): what it is and how it works. | Understanding Connection Point Services |
| Important information to prepare you for installing CPS. | Install Connection Point Services |
| Install CPS | Install and Configure Connection Point Services |

# Checklist: Configuring Connection Point Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Configuring Connection Point Services**

When you configure Connection Point Services (CPS), you provide security by setting permissions for directory access.

| Step | Reference |
|---|---|
| Connection Point Services (CPS): what it is and how it works. | Understanding Connection Point Services |
| Set up an account with administrative credentials on your Phone Book Service (PBS) host. | Manage Users; Active Directory |
| Add a user account on your PBS server for posting phone books, and make that account a member of the Guests group. Disable this user account from logging on locally and from logging on through Terminal Services. | Set permissions early; Create a local user account; Add a member to a local group; Deny log on locally; Deny log on through Terminal Services |
| Configure the FTP service for specific users for use when posting phone book data. | Set up FTP accounts for known users |
| Set permissions for the PBS folder (Windows NTFS file system only). | Set permissions for the Phone Book Service folder (NTFS only) |
| Set Write permissions for FTP. | Set the Write permission for the FTP virtual directory |

# Checklist: Administering phone books with Phone Book Administrator

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Administering phone books with Phone Book Administrator**

Connection Point Services (CPS) provides two ways to administer phone books: by using the Phone Book Administrator (PBA) interface and by using the command line. This checklist can help guide you through administration with Phone Book Administrator. You are advised to create and publish your first phone book using the PBA interface, even if you plan to use the command line for your usual publishing procedures.

| Step | Reference |
|---|---|
| Connection Point Services (CPS): what it is and how it works. | Understanding Connection Point Services |
| Create a phone book. | Add and configure a new phone book |
| To add, edit, delete, or import regions. | Add, edit, or delete a region<br><br>Import a region list |
| Add POPs to your phone book. | Add or edit a POP |
| Publish the phone book. | Publish a phone book |

# Checklist: Administering phone books by command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Administering phone books by command line**

Connection Point Services (CPS) provides two ways to administer phone books: by using the Phone Book Administrator (PBA) interface and by using the command line. This checklist can help guide you through administration by command line. However, you are advised to create and publish your first phone book by using the PBA interface, even if you plan to use the command line for your usual publishing procedures.

| Step | Reference |

| Connection Point Services (CPS): what it is and how it works | Understanding Connection Point Services |
| Create a phone book and then set or edit the phone book options. | Create and Manage Phone Books by Command Line |
| Import a region file | Add, edit, or delete regions by command line<br><br>Import a region list by command line |
| Import a POP file | Add, edit, or delete POPs by command line<br><br>Import an existing POP list by command line |
| Publish the phone book | Publish a phone book by command line |

# Connection Point Services Best Practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

The following list provides recommended practices for configuring and administering Connection Point Services.

- Specify POP settings (sometimes called *service types*) so users can search for the POPs that suit their needs and filter out the ones they do not want. For more information, see Make the most of POP settings.
- Set up permissions before attempting to publish phone books to Phone Book Service (PBS). For more information, see Set permissions early.
- Secure the Phone Book Administrator (PBA) and PBS folders to avoid synchronization problems and to prevent unauthorized personnel from posting to the host server. For more information, see Safeguard your files.
- Back up phone book databases and other important files to preserve POP and region information. For more information, see Back up your data.

# Make the most of POP settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Make the most of POP settings**

POP settings (sometimes called *service types*) provide you with the ability to specify the way users are presented with POP choices. For example, you can set some POPs to appear only when a user is dialing with a modem. Users can then use the differences between POP connections to search for the POPs that suit their needs and filter out the ones they do not want. The more you can differentiate between POPs, the less a user will need to search.

The following table shows available POP settings and what they do. The first column lists options for each POP setting, with default options in bold type. You can set these options when you add or edit POPs, whether you are using the Phone Book Administrator (PBA) graphical interface or command-line interface.

| POP setting | Action determined for the POP |
|---|---|
| **Sign on** | Users can connect to the POP to sign on to your service. |
| Sign up | Users can connect to the POP to sign up for your service. |
| **Modem** | Users can connect to the POP by modem. |
| **ISDN** | Users can connect to the POP using an ISDN connection device. |
| Custom 1 | The POP is assigned a custom service setting. You can specify custom service settings in the Connection Manager service profile. |
| **Multicast** | The POP supports IP multicast protocols. |
| Surcharge | The access number for the POP appears in the **More access numbers** box in the Connection Manager **Phone Book** dialog box. You can charge your users an additional fee when they use this POP. |
| Custom 2 | The POP is assigned a custom service setting. You can specify custom service settings in the Connection Manager service profile. |

# Set permissions early

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set permissions early**

Before you can publish phone books to a Phone Book Service (PBS) server, you must create a specific user account that has the necessary permissions to post your phone books. The NTFS file system should be running on the server host.

Failure to set permissions is likely to prevent you from posting phone books to the server.

- **Set up a user account on your PBS server for posting phone books.** Set permissions for the user account so that users have the minimum necessary permissions to post to your server. This user account should be a local user account on the PBS server, not on a domain, even if the PBS server is a member of a domain. For additional security, you should make this account a member of the Guests group, and you should disable this user account from logging on locally and from logging on through Terminal Services. To post phone books, the user account must have a password, and the password cannot be null. The user account must also have Write permission to the PBSData folder in the FTP virtual directory. For more information, see Create a local user account, Set the Write permission for the FTP virtual directory, Add a member to a local group, Deny log on locally, and Deny log on through Terminal Services.

- **Configure FTP service for specific users when posting phone book data**. When you install PBS, FTP is also installed with anonymous FTP access disabled. Because passwords for FTP sessions are sent as plaintext, you should not use the user account that you use for posting phone book data for any other purpose. Do not activate this account until you are ready to post data, and disable this account as soon as you finish posting data. For more information, see Set up FTP accounts for known users and Disable or activate a local user account.

- **Set permissions for the Phone Book Service folder** (optional but recommended; NTFS file system only). For added security, you should change access to the Phone Book Service folder from all authenticated users to specific user accounts or groups. For more information, see Set permissions for the Phone Book Service folder (NTFS only) and Security information for Connection Point Services.

- **Set the Write permission for the PBSData folder in the FTP virtual directory.** Before you can post, you must set this permission on the FTP virtual root. For enhanced security, set this permission only when you are about to post to the server, and then clear it immediately after posting. For more information, see Set the Write permission for the FTP virtual directory.

# Safeguard your files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Safeguard your files**
To avoid phone book synchronization problems and to prevent unauthorized personnel from changing files and posting to the host server, you should secure the Phone Book Administrator (PBA) and Phone Book Service (PBS) folders.

**Avoid synchronization and version problems during remote administration**
For each phone book server, you must have only one PBA folder, which must reside on your primary PBA computer. One administration tool can post multiple phone books, each to a different server, but each phone book should be administered with only one PBA computer.

You can administer phone books from the primary PBA computer or from a remote computer. A remote computer could be a portable computer or other computer that you plan to use when you cannot administer from your primary PBA computer. For example, you might be traveling and need to administer from a laptop computer, or you may want to administer from one of several workstations located in your office. You can install PBA on any remote computer, but after installing PBA you must delete the PBA folder from the remote computer to avoid synchronization and version problems.

Deleting only the PBA folder prevents an accidental start of PBA from the remote computer, but it leaves the necessary system files intact.

For more information on administering from a remote computer, see Administer from a remote computer or Administer from a remote computer by command line.

**Limit access to the PBS and PBA directories**
Connection Point Services setup configures the PBS folder with default permissions. For added security, you should limit access to the PBS folder to specific users.

If you want only certain people to post phone books to the server, make sure that the primary PBA computer is secure by protecting the PBA folder.

For more information on securing your PBS and PBA directories, see Set Permissions.

**Important**

- If your primary PBA computer is used by several people, users who do not have access to the PBA folder still have a link to Phone Book Administrator on the **Start** menu. If these users click that link, a message box gives them a choice between deleting the link, fixing it, or canceling out of the message box. They must click **Cancel**. Do not allow them to delete or fix it. Deleting this link could delete it for everyone.

# Back up your data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Back up your data**

The process of backing up and restoring data can vary greatly, depending on your network configuration. Backing up and restoring is critical to preserving POP and region information. Backing up the database and .cab files on the server is not as critical as backing up the phone book databases and other important files located on the primary computer where Phone Book Administrator (PBA) resides. Be sure to back up the following three important data files:

- PBServer.mdb
- *phone_book*.mdb
- PBAdmin.ini

# Connection Point Services How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install and Configure Connection Point Services
- Monitor the Activity of Connection Point Services
- Administer Phone Books with Phone Book Administrator
- Administer Phone Books by Command Line
- Stop Phone Book Service
- Remove Connection Point Services

# Install and Configure Connection Point Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Install and configure Connection Point Services**

- Install Phone Book Service on a server
- Install Phone Book Administrator
- Test for production readiness
- Set Permissions

# Install Phone Book Service on a server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install Phone Book Service on a server**

1. Open the Windows Components wizard.
2. In **Components**, click **Management and Monitoring Tools** (but do not select or clear the check box), and then click **Details**.
3. In **Subcomponents of Management and Monitoring Tools**, select the **Connection Point Services** check box.
4. Click **OK**, and then click **Next**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open the Windows Components Wizard, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.
- Certain Windows components require configuration before they can be used. If you installed one or more of these components but did not configure them, when you click **Add/Remove Windows Components**, a list of components that need to be configured is displayed. To start the Windows Components Wizard, click **Components**.
- If you are installing your server for the first time, skip step 1 of the installation procedure.
- The FTP service must reside on your server. If you do not want FTP to run while PBA is not in use, stop the service through the Internet Service Manager and then enable it when you are ready to post your phone book. Do not uninstall FTP, because doing so will automatically uninstall PBS.
- During installation, you will be advised that PBS requires Internet Server Application Programming Interface (ISAPI), part of Internet Information Services (IIS). If you do not choose to enable IIS, PBS will not function properly. You will have to enable PBS at a later time by using the IIS Security Wizard.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install Phone Book Administrator

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install Phone Book Administrator**

1. Insert your Windows Server 2003 family CD into your CD-ROM drive.
2. Click **Perform additional tasks**.
3. Click **Browse this CD**.
4. Browse to SUPPORT\PBA.
5. Double-click **PBAInst.exe**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- You can install Phone Book Administrator (PBA) from VALUEADD\MSFT\MGMT\PBA on the product CD for the Windows XP Professional operating system or the original release of a Windows Server 2003 operating system.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Test for production readiness

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To test for production readiness**

1. Create a test phone book, add one or more POPs, and then publish the phone book.

2. On the Phone Book Service (PBS) host, browse to \Program Files\Phone Book Service\Data and verify the presence of a new data folder named for the phone book and containing a .cab file.

3. Using the Connection Manager Administration Kit, create a service profile that is set to download this phone book from the correct PBS host. Do not include the phone book files when you create this profile.

4. Install the new service profile on your test client computer.

5. Edit the Connection Manager service provider (.cms) file to prevent automatic deletion of the .tmp file created during a phone book download:

   a. Using Notepad on the test client computer, open the .cms file.

   b. Edit the key 0=cmdl32.exe %profile% located in the [Connect Actions] section by typing **/no_delete**. After editing, the section should appear as follows:

   ```
   [Connect Actions]
   0=cmdl32.exe %profile% /no_delete
   ```

   c. Save the edited .cms file, and use the profile to connect Connection Manager to Connection Point Services.

   d. Once a connection is established and information is downloaded, disconnect from the server.

6. Using Notepad on the client computer, open the .tmp file and verify that PBS is working properly. The name of the .tmp file varies, but it is located in the same directory as the .cmp file of the service profile. The directory will likely contain more than one .tmp file. The .tmp file created by a successful phone book download should contain control characters and file names such as *[phone_book]*.pbk. If PBS is not working properly, all the .tmp files will contain error messages.

7. Open Connection Manager and verify whether the phone book appears when you click **Phone Book**.

**Notes**

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

- Do not open your .tmp file before disconnecting from the server. Doing so could prevent a proper phone book update.

- You can simulate a client request by typing the following in the browser **Address** box on the test client computer and then pressing ENTER:

  **http://localhost/pbserver/pbserver.dll?osarch=0&ostype=0&osver=1&cmver=1&lcid=1033&pbver=0&pb=***[phone_book_name]*

  For example, if the phone book name is Awesome, you would type:

  **http://localhost/pbserver/pbserver.dll?**

**osarch=0&ostype=0&osver=1&cmver=1&lcid=1033&pbver=0&pb=Awesome**

If you want to see Phone Book Service error messages while you simulate client requests, you must turn off the display of friendly HTTP error messages in Internet Explorer. On the **Tools** menu, click **Internet Options**, and click the **Advanced** tab. Clear the **Show friendly HTTP error messages** check box.

- If your .tmp file does not contain a phone book, the following list might help you identify areas for further investigation.
    - An empty .tmp file indicates that the phone book request did not generate a response from the PBS host.
    - An error number of 5*xx* typically indicates that PBS is not installed or is not running.
    - An error number of 4*xx* typically indicates that you requested a phone book that did not exist in the PBS database.
    - An error number of 204 indicates that the client phone book version number is high enough that you do not need a phone book update.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set Permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set permissions**

- Set permissions for the Phone Book Service folder (NTFS only)
- Set up FTP accounts for known users
- Secure your Phone Book Administrator folder (NTFS only)
- Set the Write permission for the FTP virtual directory

# Set permissions for the Phone Book Service folder (NTFS only)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set permissions for the Phone Book Service folder (NTFS only)**

1. Open Windows Explorer.
2. Double-click the Program Files folder, right-click the Phone Book Service folder, and then click **Properties**.
3. At the bottom of the **Security** tab, click **Advanced**. Clear the **Allow inheritable permissions from the parent to propagate to this object and all child objects.** check box.
4. In the **Security** dialog box, click **Remove**.
5. Click **Add**, type the name of the user or group to which you are granting posting permissions, and then click **OK**.
6. In the **Permissions** list, select the appropriate check boxes.
7. Click **OK** for the server to register the changes.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- Before anyone attempts to post to the server, verify that you have set the Write permission for the FTP virtual directory.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Set the Write permission for the FTP virtual directory

How the components work together

# Set up FTP accounts for known users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set up FTP accounts for known users**

1. Open Internet Information Services (IIS) Manager.
2. In the console tree, double-click the server name, double-click **FTP Sites**, and then click **Default FTP Site**.
3. On the **Action** menu, click **Properties**.
4. On the **Security Accounts** tab, make sure that the **Allow Anonymous Connections** check box is cleared. If the check box is selected, clear it.
5. If a warning appears indicating that unencrypted passwords can be transmitted over the network, click **Yes** to close the warning.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Internet Services Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Services Manager**.
- Do not allow Write permissions to the PBSData folder until you are ready post data, and remove the Write permission as soon as you finish posting data. For more information, see Related Topics.
- You should create a user account that is used solely for posting phone books. This user account should be a local user account on the PBS server, not on a domain, and it should be a member of the Guests group. Do not activate this account until you are ready to post data, and disable this account as soon as you finish posting data. You should also disable this user account from logging on locally and from logging on through Terminal Services. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Secure your Phone Book Administrator folder (NTFS only)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To secure your Phone Book Administrator folder (NTFS only)**

1. Open Windows Explorer.
2. Double-click the Program Files folder, right-click the PBA folder, and then click **Properties**.
3. At the bottom of the **Security** tab, click **Advanced**. Clear the **Inherit from parent the permission entries that apply to child objects** check box.
4. In the **Security** dialog box, click **Remove**.
5. Click **Add**, type the name of the user or group to which you are granting posting permissions, and then click **OK**.
6. In the **Permissions** list, select the appropriate check boxes, and then click **OK** for the server to register the changes.

### Important

- If your primary PBA computer is used by several people, users who do not have access to the PBA folder still have a link to Phone Book Administrator on the **Start** menu. If these users click that link, a message box gives them a choice between deleting the link, fixing it, or canceling out of the message box. They must click **Cancel**. Do not allow them to delete or fix it. Deleting this link could delete it for everyone.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- Before anyone attempts to post to the server, verify that you have set the Write permission for the FTP virtual directory. For information about the Write permission, see Related Topics.
- You must have an account on the server to which you are posting.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set the Write permission for the FTP virtual directory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the Write permission for the FTP virtual directory**

1. Click **Start**, point to **Administrative Tools**, and then click **Internet Information Services (IIS)**.
2. In the console tree, double-click the server name.
3. Double-click **FTP Sites**, double-click **Default FTP Site**, and then click **PBSData**.
4. On the **Action** menu, click **Properties**.
5. On the **Virtual Directory** tab, select the **Write** check box, and then click **OK** for the server to register the changes.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- For enhanced security, set the Write permission only when you are about to post to the server, and then clear it immediately after posting.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Monitor the Activity of Connection Point Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitor the activity of Connection Point Services**

- Monitor the activity of Phone Book Service
- Monitor Phone Book Activity

# Monitor the activity of Phone Book Service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To monitor the activity of Phone Book Service**

1. Open Performance.
2. In the console tree, click System Monitor.
3. In the details pane, right-click the empty graph, and then click **Add Counters**.
4. Click **Select counters from computer** and enter a computer name.
5. In **Performance object**, click **PBServer Monitor**.
6. Do one of the following:
   - To select all counters, click **All counters**, and then click **Add**.
   - To select specific counters, click **Select counters from list**, click the counter you want to use, and then click **Add**.

     Repeat this step for each counter you want to add.
7. Click **Close**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- PBServer Monitor counters are not available unless PBS has been started. PBS starts automatically when a client computer requests a phone book. To simulate a client request, type the following in the **Address** box of your browser, and then press ENTER:

  `http://localhost/pbserver/pbserver.dll?osarch=0&ostype=0&osver=1&cmver=1&lcid=1033&pbver=0&pb=`*[phone_book_name]*

  For example, if the phone book name is Awesome, you would type:

  `http://localhost/pbserver/pbserver.dll?osarch=0&ostype=0&osver=1&cmver=1&lcid=1033&pbver=0&pb=Awesome`

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

- View the history of a phone book

# View phone book files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view phone book files**

1. Open Phone Book Administrator.
2. In **Phone books**, click the phone book.
3. On the **Tools** menu, click **View Phone Book Files**.
4. In **File**, click the phone book you want to view.

## Notes

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- To open Phone Book Administrator, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Phone Book Administrator**.
- A phone book file contains a list of all of the available (in-service) POPs that will be downloaded to your users when you publish the phone book. If you have previously published the phone book, this list also contains new updates for POPs that you've previously published. POP fields appear in the same order as you would create them in the command-line interface.
- You should inspect your phone book files before posting them:
    - After you create new POPs.
    - After you edit existing POPs.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Administer Phone Books with Phone Book Administrator

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administer phone books with Phone Book Administrator**

- Administer from a remote computer
- Create and Manage Phone Books
- Create and Manage Regions
- Create and Manage POPs

# Administer from a remote computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To administer from a remote computer**

1. Install Phone Book Administrator (PBA) on your remote computer.
2. Delete *only* the PBA *folder* from the remote computer where you just installed PBA.
3. Establish a network connection with your primary PBA computer.
4. Establish a network connection with your primary Phone Book Service (PBS) computer.
5. On your remote computer, map a network drive to the PBA directory on your primary PBA computer.
6. Start PBA on your primary PBA computer from your remote computer.
7. Administer phone books as if you were at your primary PBA computer.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- The default location of the PBA folder is [*drive*:]\Program Files\PBA.
- A remote computer could be a portable computer or other computer that you plan to use when you cannot administer from your primary PBA computer. For example, you might be traveling and unable to administer from the primary PBA computer in your office.
- Deleting the PBA folder from the remote computer prevents an accidental start of PBA from the remote computer (which can result in data files being out of sync), but it leaves the necessary system files intact.
- For each server, you must have only one PBA folder (the one on your primary PBA computer). One administration tool can post multiple phone books, each to a different server, but each phone book should be administered with only one PBA computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create and Manage Phone Books

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Create and manage phone books**

- Add and configure a new phone book
- Edit phone book options
- Copy a phone book
- Delete a phone book
- Print a phone book
- Publish a phone book

# Add and configure a new phone book

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add and configure a new phone book**

1. Open Phone Book Administrator.

2. On the **File** menu, click **New Phone Book**.

3. In **New phone book name**, type the phone book name, and then click **OK**.

   A phone book name must contain no more than eight characters, cannot consist of all digits, and must not contain a space or any symbols, including but not limited to: **! , ; * = / \ : ? ' " < > | . & % {} [] @ ( ) ´ ` ~**

   If you are creating a customized phone book for use with a Connection Manager profile, the phone book name must match the one you typed in the **Phone Book Updates** pane in the Connection Manager Administration Kit Wizard.

4. In **Phone books**, click the new phone book.

5. On the **Tools** menu, click **Options**.

6. In the **Options** dialog box, type the server name or address, user name, and password used to post phone books to the Phone Book Service (PBS) server.

   Do not use spaces in these entries.

**Notes**

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

- To open Phone Book Administrator, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Phone Book Administrator**.

- The account used for posting the phone book must have a password. The password cannot be null or contain spaces.

- You can change options for this phone book at any time by repeating steps 5 and 6.

- When you publish the phone book, the user name and password will be used to send it using FTP to the server specified in the **Options** dialog box.

- For better security, do not provide a user name and password in the **Options** dialog box until you are ready to post a phone book. After you have posted a phone book, clear the user name and password entries before you close Phone Book Administrator (PBA).

- Phone Book Administrator is available only in English, French, German, Japanese, and Spanish. However, you can create a phone book in another language by running PBA on an operating system optimized for that language.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Copy a phone book

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To copy a phone book**

1. Open Phone Book Administrator.
2. In **Phone books**, click the phone book to be copied.
3. On the **File** menu, click **Copy Phone Book**.
4. In **New phone book name**, type a new name for the copy.

   A phone book name must contain no more than eight characters, cannot consist of all digits, and must not contain a space or any of the following symbols: **! , ; * = / \ : ? ' " < > | . & % {} [] @ ( ) ´ ` ~**

   If you are creating a customized phone book for use with a Connection Manager profile, the phone book name must match the one you typed in the **Phone Book Updates** pane in the Connection Manager Administration Kit Wizard.

   If you intend to administer a phone book from the command line, the path to the phone book should not contain any spaces.

## Notes

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- To open Phone Book Administrator, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Phone Book Administrator**.
- You cannot copy a phone book to a pre-existing phone book name.
- You can change options for this phone book at any time by clicking the phone book in **Phone books** and then, on the **Tools** menu, clicking **Options**.
- All phone book data in the original phone book file is maintained in the copy except for the version number and the history. The default release directory is changed to the new name and the version number is reset to 1.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a phone book

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a phone book**

1. Open Phone Book Administrator.
2. In the **Phone books** list, click the phone book to be deleted.
3. On the **File** menu, click **Delete Phone Book**.

   A dialog box appears asking whether you want to delete the phone book.
4. Click **Yes**.

## Notes

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- To open Phone Book Administrator, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Phone Book Administrator**.
- Deleting a phone book removes the indexed references. However, released .cab files remain on the Phone Book Administrator (PBA) and Phone Book Service (PBS) file systems. If you want to remove the .cab files, you must manually delete the phone book directory and all its contents. You should delete the directory and files from the PBS server any time you delete a phone book.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Print a phone book

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To print a phone book**

1. Open Phone Book Administrator.
2. In **Phone books**, click the phone book that you want to print.
3. In **Filter by**, click a filter name.

   If you want to print all of the POPs in the phone book, click **All POPs**, and then go on to step 5.
4. In **Containing**, type the attribute, such as a numerical area code, that must be shared by all POPs on the list you want to print.
5. Click **Apply**.
6. On the **File** menu, click **Print POP List**.

## Notes

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- To open Phone Book Administrator, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Phone Book Administrator**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Publish a phone book

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To publish a phone book**

1. Open Phone Book Administrator.
2. In **Phone books**, click the phone book.
3. If you have not yet specified a server address for this phone book, on the **Tools** menu, click **Options**, and then type a server address, user name, and password for your Phone Book Service (PBS) host.
4. On the **Tools** menu, click **Publish Phone Book**.
5. In **Release directory**, browse to the directory in which you want to keep your files.
6. Click **Create**, and then click **Post**.

## Notes

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- To open Phone Book Administrator, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Phone Book Administrator**.
- Before attempting to post, make sure that you have set the Write permission for the Phone Book Service (PBS) FTP virtual directory. If the Write permission is not set, the phone book will not post.
- If you specify a release directory on a remote computer, you may have to reset the directory every time you publish a phone book.
- Every time you propagate a phone book by posting, it increments the version number of the phone book. If you post to multiple servers, the version numbers will be inaccurate. To propagate a phone book to multiple servers, you can use the replication capability of the Windows Server 2003 family.
- You cannot create or post a phone book if no changes have been made to that phone book.
- Phone Book Administrator is available only in English, French, German, Japanese, and Spanish. However, you can create a phone book in another language by running PBA on an operating system optimized for that language.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create and Manage Regions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Create and manage regions**

- Import a region list
- Add, edit, or delete a region

# Import a region list

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To import a region list**

1. Open Phone Book Administrator.
2. In **Phone books**, click the phone book.
3. On the **Tools** menu, click **Regions Editor**.
4. In the **Regions Editor** dialog box, click **Import**.
5. Browse to the region file, and then click **Open**.

## Notes

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- To open Phone Book Administrator, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Phone Book Administrator**.
- Duplicate regions will be ignored.
- The Regions Editor is not case-sensitive.
- The Regions Editor does not accept more than 30 characters for a region name.
- A region name must not contain a double quotation mark (") or a comma (,).
- To import correctly into Phone Book Administrator (PBA), a region file must be in .pbr format. A number on the first line corresponds with the number of regions the file contains. For example:

```
3
Alaska
Arizona
California
```

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add, edit, or delete a region

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add, edit, or delete a region**

1. Open Phone Book Administrator.
2. On the **Tools** menu, click **Regions Editor**.
3. In the **Regions Editor** dialog box, do one of the following, and then click **OK**:
   - To add a region, click **Add**, and then type a region name of no more than 30 characters.

     A region name must not contain a double quotation mark (") or a comma (,).
   - To edit a region, click the region, click **Edit**, and then type the change.
   - To delete a region, click the region, and then click **Delete**.

## Notes

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- To open Phone Book Administrator, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Phone Book Administrator**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create and Manage POPs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Create and manage POPs**

- Add or edit a POP
- Delete a POP
- Assign a region to a POP
- Find POPs
- Print a POP list

# Add or edit a POP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add or edit a POP**

1. Open Phone Book Administrator.
2. In **Phone books**, click the phone book.
3. Do one of the following:
   - To add a POP, on the **Edit** menu, click **Add POP**.
   - To edit a POP, click a POP entry in the **POP Name** list, and then on the **Edit** menu, click **Edit POP**.
4. On the **Access Information** tab, enter or edit the information.
   - For countries or dependencies without area codes, type a space in **Area code**.
   - **In Service** status includes the POP in future updates of the phone book file, and **Not In Service** status excludes them.
5. On the **Settings** tab, do the following (optional):
   - In **POP settings**, select the options that apply to this POP. Entries in **bold text** are automatically preselected.

| **Select** | **If** |
|---|---|
| **Sign on** | Subscribers must sign on each time they dial in. |
| Sign up | The POP allows people to sign up with your service. |
| Surcharge | You can charge subscribers a surcharge for this POP. |
| **Modem** | Subscribers can dial in using a modem. |
| **ISDN** | Subscribers can dial in using an ISDN line. |
| **Multicast** | The POP supports IP multicast. |
| Custom 1 and Custom 2 | Your service has assigned a value to these service settings in the Connection Manager file. |

   - In **Dial-Up Networking entry**, type a name that matches the name in the **Dial-up Networking Entries** pane in the Connection Manager Administration Kit Wizard.
   - In **Analog speed**, enter the minimum and maximum rate supported.
6. On the **Comments** tab, type any comments (for administrative reference only).
7. Click **Save**.

**Notes**

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- To open Phone Book Administrator, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Phone Book Administrator**.
- The country.txt file included in the PBA directory will help you determine the required country or dependency code.
- When you set the surcharge key, Connection Manager treats the POP as an alternate access number. For more information, see Related Topics.
- Sign up is not a default option in Connection Manager. You need to specify it, just as you do in Custom 1 and Custom 2.
- Do not clear the **Sign on** check box. This option must remain selected so that Connection Manager can display the access number.
- Although Phone Book Administrator is only available in English, French, German, Japanese, and Spanish, and the country/dependency list is only available in English, country/dependency names chosen from the English list appear in the same language as the Connection Manager profile. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign a region to a POP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign a region to a POP**

1. Open Phone Book Administrator.
2. In **Phone books**, click a phone book.

   If you have not already added the region that you want to assign to this POP, add it to the phone book now.

   a. On the **Tools** menu, click **Regions Editor**.

   b. In the **Regions Editor** dialog box, click **Add**, and then type a region name of not more than 30 characters.

      A region name must not contain a double quotation mark (") or a comma (,).
3. In the **POP Name** list, click a POP.
4. On the **Edit** menu, click **Edit POP**.
5. In **Region**, click a region, and then click **OK**.

## Notes

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- To open Phone Book Administrator, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Phone Book Administrator**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Find POPs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To find POPs**

1. Open Phone Book Administrator.
2. In **Phone books**, click a phone book.
3. To find POPs by access number, area code, country/dependency, name, region, or status, click an option in **Filter by**.
4. In **Containing**, type a whole or partial word or number.
5. Click **Apply**.

   POPs that match your filter criteria appear in the list of POPs.

## Notes

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- To open Phone Book Administrator, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Phone Book Administrator**.
- You can sort your POP list by POP name, area code, access number, country/dependency, region, or status by clicking column titles.
- To turn filtering off and find all POPs in the phone book, in **Filter by**, click **All POPs**, and then click **Apply**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Administer Phone Books by Command Line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administer phone books by command line**

- Administer from a remote computer by command line
- Create and Manage Phone Books by Command Line
- Create and Manage Regions by Command Line
- Create and Manage POPs by Command Line

# Administer from a remote computer by command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To administer from a remote computer by command line**

1. Install Phone Book Administrator (PBA) on your remote computer.
2. Delete *only* the PBA *directory* from the remote computer where you just installed PBA.
3. Establish a network connection with your primary PBA computer.
4. Establish a network connection with your primary Phone Book Service (PBS) computer.
5. On your remote computer, map a network drive to the PBA directory on your primary PBA computer.
6. Change your directory on the remote computer to the mapped network drive.
7. Administer phone books as if you were at your primary PBA computer.

### Important

- If you intend to administer PBA from the command line, do not use spaces in the path to pbadmin.exe or in the path to the phone book files.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- The default location of the PBA directory is [*drive*:]\Program Files\PBA.
- A remote computer could be a portable or other computer that you plan to use when you cannot administer from your primary PBA computer. For example, you might be traveling and be unable to administer from the PBA computer in your office.
- Deleting the PBA directory prevents an accidental start of PBA from the remote computer, but it leaves the necessary system files intact.
- You must administer each phone book using only one installation of PBA. Administering the same phone book using multiple installations of PBA causes version conflicts that will prevent your users from obtaining the most recent version of the phone book.
- You can publish multiple phone books to the same phone book server, even if you administer each phone book with a different installation of PBA.
- You must not publish the same phone book to more than one phone book server. Publishing the same phone book to more than one phone book server causes version conflicts that will prevent your users from obtaining the most recent version of the phone book. However, you can replicate the phone book to multiple servers from the server to which you published the phone book. You can use the Distributed File System (DFS) console to automate replication, or you can replicate the phone book yourself by copying the folder to the other servers. For more information about DFS, see Distributed File System in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create and Manage Phone Books by Command Line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Create and manage phone books by command line**

- Add a new phone book by command line
- Set or edit phone book options by command line
- Publish a phone book by command line

# Add a new phone book by command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a new phone book by command line**

1. Open Command prompt.

2. At the command prompt, type the following:

   **cd \Program Files\PBA**

3. At the command prompt, type the following, using the appropriate file name for the new phone book:

   **Pbadmin.exe /N***[phone_book_name]*

   A phone book name must contain no more than eight characters, cannot consist of all digits, and must not contain a space or any of the following symbols: **! , ; * = / \ : ? ' " < > | . & % {} [] @ ( ) ´ ` ~**

   For example, if you want to create a phone book with the name of Awesome, you type:

   **Pbadmin.exe /N Awesome**

   Command-line parameters are case-sensitive.

4. Press ENTER to add your new phone book to the database.

### Important

- If you intend to administer PBA from the command line, do not use spaces in the path to pbadmin.exe or in the path to the phone book files.

### Notes

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

- To open the command prompt window, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- If you are creating a customized phone book for use with a Connection Manager profile, the phone book name must match the one you typed in the **Phone Book** pane in the Connection Manager Administration Kit Wizard.

- For more information about the **pbadmin** command, type **pbadmin /?** at the command prompt, or see **pbadmin** in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set or edit phone book options by command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set or edit phone book options by command line**

1. Open Command prompt.

2. At the command prompt, type the following:

   **cd \Program Files\PBA**

3. At the command prompt, type the following, using the appropriate phone book file name, and then a server name or address, user name, and password to set or edit those options for the phone book:

   **Pbadmin.exe /O***[phone_book_name][server_name][user_name][password]*

   For example, if you want to set options for a phone book with the name of Awesome, using a server name of Rainier, a user name of jobrown, and a password of Tr6f23nN, you type:

   **Pbadmin.exe /O Awesome Rainier jobrown Tr6f23nN**

   Command-line parameters are case-sensitive.

4. Press ENTER.

### Important

- If you intend to administer PBA from the command line, do not use spaces in the path to pbadmin.exe or in the path to the phone book files.

### Notes

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

- To open the command prompt window, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- For more information about the **pbadmin** command, type **pbadmin /?** at the command prompt, or see **pbadmin** in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Publish a phone book by command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To publish a phone book by command line**

1. Open Command prompt.
2. At the command prompt, type the following:

   **cd \Program Files\PBA**

3. At the command prompt, type the following:

   **Pbadmin.exe /B** *[phone_book_name]*

   Command-line parameters are case-sensitive.

4. Press ENTER.

### Important

- If you intend to administer PBA from the command line, do not use spaces in the path to pbadmin.exe or in the path to the phone book files.

### Notes

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- To open the command prompt window, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- Before you post, make sure that:
  - The host server is running.
  - You are connected to the network.
  - You have FTP, File, and Write permissions to post to the host server.
  - The account used for posting the phone book has a password. The password cannot be null.
  - You have set the host server name, user name, and password in the command line (by using the /O parameter) or in the PBA graphical interface. For more information on how to set a host server name, a user name, and a password, see Related Topics.
- For more information about the **pbadmin** command, type **pbadmin /?** at the command prompt, or see **pbadmin** in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create and Manage Regions by Command Line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Create and manage regions by command line**

- Add, edit, or delete regions by command line
- Import a region list by command line

# Add, edit, or delete regions by command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add, edit, or delete regions by command line**

1. Do one of the following:

    - If no region input file exists, create one by using a plain-text editor such as Notepad.
    - Export data from your existing database into a plain-text input file. Make sure that the data is formatted according to the steps in this procedure.

2. Open the plain-text input file, and do one of the following:

    - To add a region, on a new line, type the following:

A unique ID number for the region you are adding.

A comma delimiter.

A new region name of no more than 30 characters and with no double quotation marks (") or commas (,).

For example, with an ID number of 13 and a region name of Alaska, you type:

**13,Alaska**

- To edit a region, on a new line, type the following:

The ID number of the region.

A comma delimiter.

A new region name of no more than 30 characters and with no double quotation marks (") or commas (,).

For example, for an ID number of 12, and a new name of California, you type:

**12,California**

- To delete a region, on a new line, type the following:

The ID number of the record to be deleted, followed by a comma.

Leave the name field blank.

For example, if the ID number of the field were 12, you type:

**12,**

1. Press ENTER.

2. Repeat steps 2 and 3 for each region you want to add, edit, or delete, and then save the file with a .txt extension.

3. Import the region file from the command line.

**Important**

- If you intend to administer PBA from the command line, do not use spaces in the path to pbadmin.exe or in the path to the phone book files.

### Notes

- Do not leave blank lines in the file.
- POPs and regions must be in separate files.
- A command line region record consists of two fields: an ID number (integer) and a region name, delimited by a comma. The ID number must be unique. When it matches the ID number of an existing region, it overwrites that region.
- Phone book files saved in formats other than plain text (for example, Microsoft Word, WordPad, or Rich-Text Format) do not work properly.
- Before you can import phone book or region files into a particular phone book, the phone book name must be registered in the Phone Book Administrator (PBA) phone books list. If the phone book name does not appear in that list, you must use PBA to create the phone book.
- Command-line region files do not match the region-file format imported or generated by the PBA user interface.
- For a list of U.S. states that you can copy, see Related Topics.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Import a region list by command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To import a region list by command line**

1. Open Command prompt.
2. At the command prompt, type the following:

   **cd \Program Files\PBA**

3. At the command prompt, type the following, using the appropriate paths and file names:

   **Pbadmin.exe /I***[phone_book_name]***/R***[region_file_path]******[region_file_name]*

   Command-line parameters are case-sensitive.

4. Press ENTER.

### Important

- If you intend to administer PBA from the command line, do not use spaces in the path to pbadmin.exe or in the path to the phone book files.

### Notes

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- To open the command prompt window, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- For more information about the **pbadmin** command, type **pbadmin /?** at the command prompt, or see **pbadmin** in Related Topics.
- Before you can import phone book or region files into a particular phone book, the phone book name must be registered in the Phone Book Administrator (PBA) phone books list. If the phone book name does not appear in that list, you must use PBA to create the phone book.
- Phone book files saved in formats other than plain text (for example, Microsoft Word, WordPad, or Rich-Text Format) do not work properly.
- Command-line region files do not match the region-file format imported or generated by the PBA user interface.
- POPs and regions must be in separate files.
- If you have not yet posted your phone book, you can import up to 32,000 POPs. If, however, you have already posted, the limit is 6,000 POPs (combined adds, edits, and deletes) for each subsequent post.
- If you are importing POP files and region files by using separate commands, and if your POPs require region information, import your region file first.
- Phone Book Administrator should not be open while you are importing files.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create and Manage POPs by Command Line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Create and manage POPs by command line**

- Add, edit, or delete POPs by command line
- Import an existing POP list by command line

# Add, edit, or delete POPs by command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add, edit, or delete POPs by command line**

1. Do one of the following:

   - If no POP input file exists, create one by using a plain-text editor such as Notepad.
   - Export data from your existing database into a plain-text input file. Make sure that the data is formatted according to the steps in this procedure.

2. Open the plain-text input file and do one of the following:

   - To add or edit a POP: On a new line and using the following syntax for each POP you want to add or edit, type the data for each field in the order given. Follow each data item except the last with a comma and a space. These items are described in the following table.

     *[POP index]*, *[Country/dependency ID]*, *[Region ID]*, *[POP name]*, *[Area code]*, *[Access number]*, *[Minimum baud]*, *[Maximum baud]*, *[Reserved flag]*, *[Service flag]*, *[Dial-up entry]*

     For example:

     1, 1, 0, Redmond, 425, 555-0134, 9600, 56000, 0, 120, ISP

| Field | Description | Data type | Characters allowed | Limit |
|---|---|---|---|---|
| POP index | Numerical POP identifier | Integer | All numbers | 32,000 rows |
| Country/dependency ID | TAPI code | Integer | All numbers | No limit |
| Region ID | Numerical region identifier | Integer | All numbers (A zero (0) identifies all regions.) | No limit |
| POP name | Name given to the POP (maximum of 30 characters) | Text | All except comma (,) and double quotation mark (") | 30 characters |
| Area code | Area code for the access number | Text | All numbers, hyphen (-), space ( ) | 10 characters |
| Access number | Phone number that subscribers can dial to reach your service | Text | All numbers, number sign (#), asterisk (*), hyphen (-), space ( ) | 35 characters |
| Minimum baud | Minimum baud rate of the POP | Integer | Typical modem speeds | No limit |
| Maximum baud | Maximum baud rate of the POP | Integer | Typical modem speeds | No limit |
| Reserved flag | Unassigned flag that must always be set to zero (0) | Integer | Zero (0) | No limit |

| | | | | |
|---|---|---|---|---|
| Service flag | Decimal value representing a combination of POP settings | Integer | See Related Topics | No limit |
| Dial-up entry | Name of the entry created in the **Dial-up Networking Entries** pane in the Connection Manager Administration Kit, used in the Connection Manager profile (.cms file) | Text | All except comma (,), ampersand (&), percent (%), apostrophe ('), acute (´), agave (`), and double quotation mark (") | 50 characters |

- To delete a POP:On a new line, first type the index number of the POP you want to delete. In each of the next nine fields, type a zero, followed by a comma. Leave the 11th field blank.

  In the following example, the POP index number is 12:

  12,0,0,0,0,0,0,0,0,0,

3. Press ENTER.

4. Repeat steps 2 and 3 for each POP you want to add, edit, or delete, and then save the file with a .txt extension.

5. Import the file.

**Important**

- If you intend to administer PBA from the command line, do not use spaces in the path to pbadmin.exe or in the path to the phone book files.

**Notes**

- POPs and regions must be in separate files.

- The ID number must be unique. If it matches the ID number of an existing POP, it overwrites that POP.

- Phone book files saved in formats other than plain text (for example, Microsoft Word, WordPad, or Rich-Text Format) do not work properly.

- Before you can import phone book files into a particular phone book, the phone book name must be registered in the **Phone books** list in Phone Book Administrator (PBA). If the phone book name does not appear in that list, you must create the phone book.

- If you are importing POP files and region files by using separate commands, and if your POPs require region information, import your region file first.

- The country.txt file included in the PBA directory will help you determine the required country or dependency code you will need for your POP files.

- Phone Book Administrator (PBA) is available only in English, French, German, Japanese, and Spanish. However, you can create a phone book in another language by running PBA on an operating system optimized for that language.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Import an existing POP list by command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To import an existing POP list by command line**

1. Open Command prompt.
2. At the command prompt, type the following:

   **cd \Program Files\PBA**

3. At the command prompt, type the following, using the appropriate paths and file names:

   **Pbadmin.exe /l***[phone_book_name]***/P***[POP_file_path]******[POP_file_name]

   Command-line parameters are case-sensitive.

4. Press ENTER.

### Important

- If you intend to administer PBA from the command line, do not use spaces in the path to pbadmin.exe or in the path to the phone book files.

### Notes

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- To open the command prompt window, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- For more information about the **pbadmin** command, type **pbadmin /?** at the command prompt, or see **pbadmin** in Related Topics.
- Before you can import phone book or region files into a particular phone book, the phone book name must be registered in the Phone Book Administrator (PBA) phone books list. If the phone book name does not appear in that list, you must use PBA to create the phone book.
- Phone book files saved in formats other than plain text (for example, Microsoft Word, WordPad, or Rich-Text Format) do not work properly.
- Command-line region files do not match the region-file format imported or generated by the PBA user interface.
- POPs and regions must be in separate files.
- If you have already posted, your import file must contain no more than 6,000 POPs (combined adds, edits, and deletes) for each subsequent post.
- If you are importing POP files and region files by using separate commands, and if your POPs require region information, import your region file first.
- Phone Book Administrator should not be open while you are importing files.

# Stop Phone Book Service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To stop Phone Book Service

1. Click **Start**, point to **Administrative Tools**, and then click **Internet Information Services (IIS)**.
2. Double-click the name of your server.
3. If Phone Book Service is running in its own process, double-click the default Web site for your server. Right-click **PBServer**, and click **Properties**.
4. If Phone Book Service is not running in its own process, right-click the default Web site for your server, and click **Properties**. Click the **Home Directory** tab.
5. In the **Application Settings** area, click **Unload**, and click **OK**.

### Caution

- If you unload applications from the **Home Directory** tab of **Default Web Site Properties**, you will unload all Web applications for the default Web server that are not running in their own processes. You might need to restart some or all of your Web applications manually.

### Note

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove Connection Point Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remove Connection Point Services**

- Change directory access (NTFS partitions only)
- Remove Phone Book Service from a server
- Remove Phone Book Administrator
- Delete phone book data

# Change directory access (NTFS partitions only)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change directory access (NTFS partitions only)**

1. Open Windows Explorer.
2. Do one of the following:
   - If you are changing access for Phone Book Service, browse to the Program Files folder, right-click the Phone Book Service folder, and then click **Properties**.
   - If you are changing access for Phone Book Administrator, browse to the Program Files folder, right-click the PBA folder, and then click **Properties**.
3. On the **Security** tab, in **Name**, click the group to which you belong.
4. In **Permissions**, select the **Full Control** check box under **Allow**, and then click **OK** to register the changes.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove Phone Book Service from a server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove Phone Book Service from a server**

1. Open the Windows Components wizard.
2. In **Components**, click **Management and Monitoring Tools** (but do not select or clear its check box), and then click **Details**.
3. In **Subcomponents of Management and Monitoring Tools**, clear the **Connection Point Services** check box.
4. Click **OK**, and then click **Next**.

### Important

- If you have not already installed Internet Information Services (IIS), IIS components will be installed when you install Connection Point Services components. If you remove Connection Point Services components from your server, you do not automatically remove IIS components. You must use the Windows Components Wizard to remove IIS components. For more information, see the Microsoft Web site.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open the Windows Components Wizard, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.
- Certain Windows components require configuration before they can be used. If you installed one or more of these components but did not configure them, when you click **Add/Remove Windows Components**, a list of components that need to be configured is displayed. To start the Windows Components Wizard, click **Components**.
- When you remove Phone Book Service (PBS), not all data files are removed. You must delete those files manually.
- Before deleting data, you may first need to change security settings in order to obtain access.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove Phone Book Administrator

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove Phone Book Administrator**

1. Open Add or Remove Programs.
2. Select **Phone Book Administrator**.
3. Click **Change/Remove**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Add or Remove programs, click **Start**, click **Control Panel**, and then double-click **Add or Remove programs**.
- When you remove Phone Book Administrator (PBA), not all data files are removed. These include phone book databases and .pbk, .pbr, and .cab files, both on the PBA computer and on the computer running Phone Book Service. You must delete those files manually.
- Before deleting data, you may first need to change security settings in order to obtain access.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Connection Point Services overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connection Point Services overview**

Connection Point Services (CPS) is a component that provides Internet service providers (ISPs) and corporations with the ability to automatically update phone book files residing on the client computers of employees or Internet users. These phone book files work with Connection Manager (CM), configurable connection software that also resides on client computers. For complete information about Connection Manager, see the Connection Manager Administration Kit.

As a CPS administrator, you can:

- Make it easy for your new users to get online by providing updated access numbers.
- Create and manage phone book databases containing customized information about local access numbers that provide connectivity to points of presence (POPs) in a wide area network.
- Automatically download new access numbers to your users when POPs change.
- Host multiple phone books on a single server.

CPS consists of two major components, Phone Book Administrator (PBA) and Phone Book Service (PBS). For more information about PBA and PBS, see Major components and their roles.

PBS must run on your server, but administrators often use PBA on workstations. PBS is a component in Management and Monitoring Tools on your Microsoft® Windows Server 2003 family CD. PBA is available from the Valueadd directory on your product CD for Microsoft Windows XP Professional or the original release of Windows Server 2003. You can also install PBA from the Support folder on your product CD for Windows Server 2003 with Service Pack 1.

# Major components and their roles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Major components and their roles**
Connection Point Services (CPS) consists of two major components: Phone Book Service (PBS) and Phone Book Administrator (PBA).

**Phone Book Service**
Phone Book Service (PBS) is an Internet Information Services (IIS) extension. When users query your phone book server, PBS automatically compares their phone book versions with the most recent files in your database and then downloads the appropriate updates to the Connection Manager profiles residing on their computers.

To run PBS, your server must be using IIS running both File Transfer Protocol (FTP) and the World Wide Web (WWW) services. The FTP service accepts updated phone book information posted from Phone Book Administrator (PBA), and the WWW service handles Connection Manager queries. For more information about PBS and security, see Security information for Connection Point Services.

**Phone Book Administrator (PBA)**
PBA enables you to do the following:

- Create and edit up to one hundred unique phone books. Each phone book is a collection of POPs, each one represented by a local access number for a specific region within a country or dependency.
- Choose service types (connection settings, such as ISDN access or multicast connection) for each POP. Service types, also called *POP settings*, help users to easily find POPs that suit their needs.
- Add and delete new regions and POPs.
- Associate POPs with network configurations defined in Connection Manager.
- Publish new phone book information to PBS.
- Using the command-line interface, import phone book information from other applications for distribution to end users.

Before publishing, or *posting*, to the server, PBA uses a utility to compress the phone book files, increasing the speed at which you can download the new information to your users.

**Connection Manager**
Connection Manager is not an actual component of CPS; it is a companion software package that you must have in order to use CPS.

Connection Manager is a client dialer and connection software tool that you can customize by using the Connection Manager Administration Kit (CMAK), which is a wizard that you run to build a customized service profile (a set of files that you distribute to your users so they can easily install and run your custom version of Connection Manager). Connection Manager supports a variety of features:

- Branding: You can customize the graphics, icons, logon messages, and Help.
- Custom actions: You can customize functionality, including your own programs to enhance the connection experience for your users.
- Simplified distribution: You can create a self-installing executable file that can be distributed on compact disc or downloaded by your users.
- Custom phone books: Using the CMAK wizard, you can specify the phone books to be provided to your users. Using PBS, you can provide automatic phone book updates when your users log on. And to simplify maintenance, you can combine existing phone books by merging existing service profiles.

**Notes**

- PBA and PBS need a TCP/IP connection in order to post phone book information through FTP.

- FTP service must reside on your server. If you do not want FTP to run while PBA is not in use, stop the service through the Internet Services Manager and then enable it when you are ready to post. Do not uninstall FTP, because doing so will automatically uninstall PBS.

- You can use the current version of PBS with earlier versions of PBA.

# How the components work together

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How the components work together**

When you provide Phone Book Administrator (PBA) with new phone book information, PBA posts the updates to the Phone Book Service (PBS). The next time a user connects to your network using a Connection Manager profile, Connection Manager queries PBS for updated phone book information. PBS compares the phone book name and version sent from Connection Manager with the updated phone book files and then downloads any new phone book information to the client computer.

PBA relies on the FTP service to post the phone book files to PBS. PBS relies on the WWW service, provided through Internet Information Services (IIS), to receive phone book queries from Connection Manager and download the appropriate updates.

PBA and PBS need a TCP/IP connection in order to transfer phone book information through FTP.

The following diagram and accompanying table illustrate the publishing process.

| Step 1: Establish database | Step 2: Post to server | Step 3: Update client computer |
|---|---|---|
| You can use PBA to create new phone book files. Or, if you already have a database in another application, you can import that data file using the PBA command-line interface. | Imported files or data you entered using PBA are stored in the phone book database. When you publish phone books, PBA publishes changes to PBS through FTP. | Using Connection Manager, clients query the phone book server. If the versions of their phone books are outdated, PBS automatically sends the appropriate update. |

**Notes**

- You can use the current version of PBS with earlier versions of PBA.
- You must administer each phone book using only one installation of PBA. Administering the same phone book using multiple installations of PBA causes version conflicts that will prevent your users from obtaining the most recent version of the phone book.
- You can publish multiple phone books to the same server running a member of the Windows Server 2003 family, even if you administer each phone book with a different installation of PBA.
- You must not publish the same phone book to more than one phone book server. Publishing the same phone book to more than one phone book server causes version conflicts that will prevent your users from obtaining the most recent version of the phone book. However, you can replicate the phone book to multiple servers from the server to which you published the phone book. You can use the Distributed File System (DFS) console to automate replication, or you can replicate the phone book yourself by copying the folder to the other servers. For more information about DFS, see Distributed File System (DFS).
- The FTP service must reside on your server. If you do not want FTP to run while PBA is not in use, stop the service through the Internet Services Manager and then enable it when you are ready to post. Do not uninstall FTP, because doing so will automatically uninstall PBS.

# Security information for Connection Point Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security information for Connection Point Services**
Before you deploy Connection Point Services (CPS), you should recognize and plan for its specific security requirements. CPS comprises Phone Book Administrator (PBA) and Phone Book Service (PBS). Each component has its own implications, and there are additional security considerations for the interaction between the two programs.

To deploy CPS securely, you must also consider the general security of all of your servers, including your PBS server. For more information about server security, see Security.

When you plan your CPS deployment, you should consider the following:

- **Using PBA or PBS**. A user must be a member of either the Power Users or the Administrators group in order to use PBA or to start or stop PBS. A user must be a member of the Administrators group to install PBA or PBS. You should limit the membership of the Power Users and Administrators groups to the minimum number of users required to administer the server.

- **Managing the File Transfer Protocol (FTP) service**. PBA requires FTP to publish and update phone books to the PBS server. The PBS server requires FTP to receive phone books. To increase security, you might want to:

    - Start the FTP service on the computer running PBA immediately before you publish or update a phone book, and stop the service immediately after you finish. Make sure that no processes are using the FTP service before you stop it. For more information about how to start and stop services such as FTP, see Start, stop, pause, resume, or restart a service.

    - Do not enable anonymous access for FTP on your PBS server. Anonymous access is disabled by default when you install PBS, even if it was previously enabled. You should not install PBS on a server that allows anonymous FTP access. You can also check a log file to see who has posted files to that server. For more information, see Set up FTP accounts for known users.

    - Restrict the account that you create on the PBS server for posting phone book data to minimal permissions, and use that account only for posting phone book data. The user posting phone book data to the PBS server must have a user account on that server, the account must have a password, and Write permission to the PBSData virtual directory must be enabled. This user account should be a local user account on the PBS server, not on a domain, even if the PBS server is a member of a domain. For additional security, you should make this user account a member of the Guests group, and you should disable this user account from logging on locally and from logging on through Terminal Services. For more information, see Add a member to a local group, Deny log on locally, and Deny log on through Terminal Services.

    - FTP automatically sends passwords in plaintext. Do not activate the user account that you created for posting phone book data until you are ready to post data, and disable this account as soon as you finish posting data. Consider changing the password for this user account often, possibly after each posting. If one or more PBS servers are directly connected to the Internet without a firewall, you should consider alternatives to using FTP across the Internet. For example, you can host a PBS server inside your network and use file replication over a virtual private network (VPN) connection to update the PBS servers on the Internet. For more information, see Administer phone books and Disable or activate a local user account.

- **Protecting phone book files**. Phone book files are plain text files that any user can edit with any plain text editor, such as Notepad. Users do not need to be members of the Power Users or the Administrators group to read, change, or delete these files. To minimize the possibility that users might change these files, you might want to:

    - Limit access to the directories that contain phone book files so that only specific users or user groups can change or delete those files. For example, you can change the permissions on the PBA directories to allow only users with administrative credentials to access those directories. By default, any member of the Power Users or the Administrators groups can access the PBS and PBA directories. For more information on securing your PBS and

PBA directories, see Set Permissions.

- If you are issuing a phone book as part of a Connection Manager profile, encourage your users to install the profile for their individual use only (Windows 2000, Windows XP, and the Windows Server 2003 family only). If a user installs a profile for all users, any user can modify or delete phone book information. For more information, see Security information for the Connection Manager Administration Kit.

- **Securing Internet Information Services (IIS)**. PBS requires IIS to function. You should take steps to secure your PBS server, including but not limited to running the IIS Security Wizard. For more information, see Installing IIS.

# Example system configurations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Example system configurations**
Connection Point Services (CPS) lends itself to various configurations, according to your needs. A few examples follow.

**Dedicated single server**
**Example uses**:

- Testing
- Small company
- Small Internet service provider

You can maintain both Phone Book Service (PBS) and Phone Book Administrator (PBA) on a single computer running an operating system in the Windows Server 2003 family.

Even though PBA posts to the same server on which it resides, you must use the same procedures for setting permissions and posting phone books as you would with any other configuration.

**Dedicated Phone Book Service server with a Phone Book Administrator client**
**Example uses**:

- Medium to large corporations
- When ownership and responsibilities for phone book administration and server maintenance are split between groups

In this configuration, PBS and PBA are installed on separate computers. PBA could be installed on a server or on a workstation running Windows XP Professional. The following illustration shows this configuration.

**Dedicated Phone Book Service server with remote administration of Phone Book Administrator client**
**Example use**: When the primary computer running Phone Book Administrator is not physically accessible to the administrator, you can use this dual-mode system.

You can configure PBA to run on a primary (dedicated) computer and on a remote workstation at the same time.

The following illustration shows this configuration.

All data files reside on the primary computer, never on the remote workstation. The remote workstation accesses the data files on the primary computer.

**Multiple servers with firewall**
**Example uses**:

- Highly secured environment
- Very large Internet service providers

- Phone book replication among multiple Internet service providers

You can install PBA on a primary computer and on multiple remote workstations. PBS is installed on a staging server and on multiple host servers residing in a less secure environment outside a firewall. The following illustration shows this configuration.

The remote workstations access phone book data on the primary PBA computer. Phone book updates are posted to the staging server. Using a content replication method, phone book updates are then copied from the staging server through the firewall to the host servers.

# Using Connection Point Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Connection Point Services**

- Determine how many servers you need
- Install Connection Point Services
- Administer phone books
- Use your existing database with Phone Book Administrator
- Example Implementations
- Monitor Activity

# Determine how many servers you need

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Determine how many servers you need**

Every time a user logs on, the Phone Book Service (PBS) server is "hit" with an HTTP query, initiating the phone-book update process. Along with hardware throughput and update (.cab) file size, the number of hits and the processor speed are important factors in determining how many servers you may need.

The following table details how many hits the listed processors are capable of handling on a dedicated server with 128 megabytes (MB) of RAM.

| Processor | Hits/sec | Hits/hour | Hits/day |
|---|---|---|---|
| Pentium III 600 MHz | 275 | 990,000 | 23,760,000 |
| Pentium III 500 MHz (dual processors) | 250 | 900,000 | 21,600,000 |
| Celeron 400 MHz | 125 | 450,000 | 10,800,000 |
| Pentium II 300 MHz | 125 | 450,000 | 10,800,000 |

To get an accurate data pool to determine if an additional server is needed, take an average of the number of logons your network receives during peak hours for a week.

**Notes**

- The maximum number of hits per second depends on the size of the update (.cab) file. Larger update files can slow performance by as much as 25 percent. The numbers in the table assume small update files of about 5 kilobytes (KB).
- Your server performance might increase if you run PBS in the Internet Information Services (IIS) process.

# Install Connection Point Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Install Connection Point Services**

Before you install Connection Point Services (CPS), you must prepare for the installation:

- Determine and verify the computer names and IP addresses of all the computers on which you will be installing CPS. You might want to have a dedicated server so phone book requests do not interfere with the response time of your other services.
- Be aware that the Phone Book Service (PBS) server will be using Internet Information Services (IIS) to run the FTP and WWW services. This is necessary for PBS to receive posts from Phone Book Administrator (PBA) and to download updated files to client computers. For more information about PBS and security, see Security information for Connection Point Services.
- If you have multiple servers running PBS, consider how you want to replicate data. You can use PBA to publish a phone book to only one server. You will need to replicate the phone book data to the other servers.
- Document all of your processes, as well as the choices and tradeoffs that you made. This information will be valuable for troubleshooting your system and for future reference.

For information on CPS installation and configuration, see Install and Configure Connection Point Services.

After installing Connection Point Services, you must set directory access permissions and test your installation.

To test the installation, create a test phone book and post it to the server. However, to fully test server functionality, you must connect to the server with Connection Manager, using a service profile built by the Connection Manager Administration Kit wizard.

The FTP service already resides on your server. If you do not want FTP to run while PBA is not in use, stop the service and then enable it when you are ready to post.

**Important**

- Do not uninstall FTP, because doing so will automatically uninstall PBS.
- You must administer each phone book using only one installation of PBA. Administering the same phone book using multiple installations of PBA causes version conflicts that will prevent your users from obtaining the most recent version of the phone book.
- You can publish multiple phone books to the same phone book server, even if you administer each phone book with a different installation of PBA.
- You must not publish the same phone book to more than one phone book server. Publishing the same phone book to more than one phone book server causes version conflicts that will prevent your users from obtaining the most recent version of the phone book. However, you can replicate the phone book to multiple servers from the server to which you published the phone book. You can use the Distributed File System (DFS) console to automate replication, or you can replicate the phone book yourself by copying the folder to the other servers. For more information about DFS, see Distributed File System (DFS).

# Administer phone books

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administer phone books**
Connection Point Services (CPS) provides two ways to administer phone books: by using the Phone Book Administrator (PBA) interface and by using the command line. You are advised to create and publish your first phone book by using the PBA interface, even if you plan to use the command line for your usual publishing procedures.

**Phone books**
Establishing a new phone book is as easy as giving it a name and configuring it with a server name or address, user name, and password. Because Connection Manager (CM) must be configured to query the Phone Book Service database for phone books, the phone book names you choose must match the ones in the service profile created by the Connection Manager Administration Kit (CMAK) wizard. If your Connection Manager profile will use multiple phone books, name them intuitively, according to their use.

For a comprehensive understanding of how CPS works with Connection Manager, run the CMAK wizard and explore CM concepts.

Make sure that you plan a method for maintaining phone books. Ask yourself:

- Who will be entering data?
- If you will be using the command line for administration, who will create and maintain data files? Will you be exporting data from an existing database or typing new files by hand?
- Do you want to use the same phone book for all locales, or should you translate and maintain multiple language versions: one for each country or dependency? Phone Book Administrator is available only in English, French, German, Japanese, and Spanish. However, you can create a phone book in another language by running PBA on an operating system optimized for that language.

After you create a phone book, you must add POPs, and you can create regions. You can update either of these as often as necessary.

For information on how to create a phone book, see Add and configure a new phone book or Add a new phone book by command line.

**Regions**
To reduce the number of POPs that Connection Manager displays at any one time, you may want to designate areas within a country or dependency as regions. Such a filtered list makes the task of choosing the closest POP easier for your users.

For information on how to add regions, see Add, edit, or delete a region or Add, edit, or delete regions by command line.

**Points of Presence (POPs)**
The primary purpose of adding and editing POPs is to make updated access information available to your users.

POP information specifies how Connection Manager establishes a connection and how access numbers are displayed to users. For example, when you select the **Surcharge** POP setting, Connection Manager displays the POP in the **More access numbers** box instead of the **Access numbers** box. This feature can be used to differentiate automatically between remote-access numbers for corporate private networks and secure connections.

In preparing to create a POP, ask yourself the following questions:

- In what country or dependency does the POP exist? The list of countries and dependencies provided by CPS associates the Telephony Applications Program Interface (TAPI) country/dependency code with the POP. Although Phone Book Administrator is only available in English, French, German, Japanese, and Spanish, and the country/dependency list only appears in English, country/dependency names chosen from the English list appear in the same language as the Connection Manager profile.
- Does your POP belong to a region?

- What name will you give the POP?
- What is the area code for the access number?
- What is the access number?
- What POP settings will you need? For information about POP settings, see Service types (POP settings).
- What special dial-up settings will you need? Connection Manager and CPS must use the same dial-up entry name.
- What is the minimum baud for the POP?
- What is the maximum baud for the POP?
- What is the POP status: In Service or Not In Service? (When you publish to Phone Book Server, only in-service POPs are used to create or update the phone book files).

For information on how to create POPs, see Add or edit a POP or Add, edit, or delete POPs by command line.

**Publishing**

Before attempting to publish a phone book, make sure that you have set the Write permission for the FTP virtual directory on the computer running Phone Book Service. If the Write permission is not set, the phone book will not post.

You can publish multiple phone books to a server. However, every time you publish a phone book, CPS increments the version number of the phone book. If you publish the same phone book to multiple servers, the version numbers will be inaccurate. To publish a phone book to multiple servers, you can use file replication.

For information on how to publish a phone book, see Publish a phone book or Publish a phone book by command line.

# Use your existing database with Phone Book Administrator

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use your existing database with Phone Book Administrator**

If you already maintain your phone book data in other databases, you can import both entire files and incremental updates to your phone books by using the command line interface to Phone Book Administrator (PBA).

You can write a query that exports the changes from your database into two text files: one for regions and one for POPs. Once you have these files, you can use the command-line interface to import changes.

You should keep a record in your database of the last time that you created import files for PBA. You can use this time stamp to create just the change (delta) files to be imported into PBA.

For information on creating new POP and region files, and exporting data, see Add, edit, or delete POPs by command line and Add, edit, or delete regions by command line.

**Notes**

- POPs and regions must be in separate files.
- Command-line region files do not match the region-file format imported or generated by the PBA user interface.
- You might want to create and publish your first phone book with the user interface to ensure that all authentication and configuration issues are worked out.
- If you have not yet posted your phone book, you can import up to 32,000 POPs. If, however, you have already posted, the limit is 6,000 POPs (combined adds, edits, and deletes) for each subsequent post.

# Example Implementations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Example implementations**

- ISP model
- Corporation model

# ISP model

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ISP model**

The following hypothetical situation illustrates how Connection Point Services (CPS) can support an expanding Internet service provider (ISP).

Awesome Computers, an ISP, is growing rapidly and must accommodate increasing numbers of subscribers. Many of the subscribers access Awesome Computers locally, but the ISP also has corporate customers whose employees want increased access capabilities while traveling. At the same time, Awesome Computers wants to replace its expensive, 800-number access charges with a remote-access solution that costs less.

To accommodate its growing business needs, the company plans to expand its existing remote access infrastructure and also offer a "Business Class" set of higher-quality Points of Presence (POPs) for demanding corporate customers. Awesome Computers joins an alliance of ISPs in order to provide coverage outside its service area.

Because many of the new subscribers are inexperienced computer users, Awesome Computers realizes that increasing the number of regional access numbers and providing remote POPs will generate a higher volume of calls to technical support. Faced with an immediate need to automate the process of updating subscribers with access numbers, the company decides to use CPS.

Awesome Computers installed Phone Book Service (PBS) and Phone Book Administrator (PBA) on a computer running an operating system in the Windows Server 2003 family. Personnel authorized by Awesome Computers use the administration tool to create a phone book that contains all of the trunk-line and connect information that the ISP offers for Internet access. When access numbers change, the personnel can quickly make the changes and publish them.

Publishing creates the updated phone book files and copies them to PBS. Awesome Computers keeps all the phone books for each corporate customer on the server running PBS. In addition, Awesome Computers has chosen to deploy a number of PBS servers within the infrastructure, thereby ensuring accessibility for users who connect to the Internet from various geographical regions.

With the file replication capability of the Windows Server 2003 family, the phone book can easily be automatically distributed from a master PBS server to a number of subordinate PBS servers.

Awesome Computers uses the Connection Manager Administration Kit wizard to create a customized Connection Manager profile that includes the company logo and tailored online Help. Awesome Computers then packages the profile and Connection Manager for distribution on compact disc or the World Wide Web.

After Connection Manager and the service profile have been installed on individual computers, CPS automatically downloads the most current list of local access phone numbers every time the subscriber connects to Awesome Computers.

# Corporation model

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Corporation model**

The following hypothetical situation illustrates how Connection Point Services (CPS) can help a corporation offer a cost-effective means of telecommuting.

Lucerne Publishing is a multinational company that spends a significant amount of money on maintaining toll-free numbers and long-distance dial-up fees so its employees can telecommute. The toll-free numbers are used by home-office employees who live outside the calling area and by employees on business trips. Home-office employees living inside the calling area use a local access number.

The company administrators decide to use CPS. They realize that by merging access numbers in their existing phone book with the access numbers of a large ISP they can save money on long distance charges while maintaining a high level of security.

Employees making phone calls from within the calling area of Lucerne Publishing connect to the company remote-access server. Employees residing or traveling outside the calling area of the corporation are able to call local ISP phone numbers, thereby connecting to the ISP remote-access server and avoiding long distance charges previously incurred by the maintenance of the toll-free numbers.

Lucerne Publishing uses the Connection Manager Administration Kit and Connection Manager to automatically differentiate between its local access numbers and the Points of Presence (POPs) provided by the ISP outside the local calling area. As a result, the difference between local access to the corporate private network and the extended remote access over the Internet using a secure connection is transparent to their employees. Connection Manager connects to the corporate private network when an employee uses a local access number and establishes a secure connection to the corporate private network when an employee uses an ISP phone number.

Lucerne Publishing and the ISP each maintain Phone Book Service (PBS) servers for their respective phone books. Each PBS server automatically downloads the most current list of local access phone numbers every time the employee connects to Lucerne Publishing.

# Monitor Activity

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitor activity**

- Phone Book Service activity
- Phone book history

# Phone Book Service activity

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Phone Book Service activity**

Counters in System Monitor produce statistical information on the processor, memory, cache, network, and other object types.

The following table lists PBServer Monitor counters. (Delta files contain only the current, incremental phone book updates, not the entire phone book file.)

| Name | Description |
|---|---|
| Delta Upgrade Hits | The total number of delta phone book files (incremental phone book changes only) that have been successfully downloaded. |
| Delta Upgrade Hits/Sec | The number of delta phone book files that are successfully downloaded per second. |
| Error Hits | The total number of requests that could not be satisfied by PBS. |
| Error Hits/Sec | The number of requests per second that could not be satisfied by PBS. |
| Full Upgrade Hits | The total number of full phone book files that have been successfully downloaded. |
| Full Upgrade Hits/Sec | The number of full phone book files that are successfully downloaded per second. |
| No Upgrade Hits | The total number of requests for phone book files that did not require an update to the phone book file on the client computer. |
| No Upgrade Hits/Sec | The number of requests for phone book files per second that do not require an update to the phone book file on the client computer. |
| Total Hits | The total number of requests for phone book files. |
| Total Hits/Sec | The number of requests per second for phone book files. |

**Notes**

- For information on how to monitor phone book activity, see Monitor the activity of Phone Book Service

- PBServer Monitor counters are not available unless PBS has been started. PBS starts automatically when a client computer requests a phone book. To simulate a client request, you can type:

  **http://localhost/pbserver/pbserver.dll?osarch=0&ostype=0&osver=1&cmver=1&lcid=1033&pbver=0&pb=***[phone_book_name]*

  in the **Address** box of your browser, and then press ENTER. For example, if the phone book name is Awesome, you would type:

  **http://localhost/pbserver/pbserver.dll?osarch=0&ostype=0&osver=1&cmver=1&lcid=1033&pbver=0&pb=Awesome**

# Phone book history

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Phone book history**

Phone Book Administrator (PBA) maintains a log for each phone book that records its activity, including creating, deleting, or editing a POP, as well as posting the phone book to the server. If you move a phone book log file off the system or change its name, PBA creates a new file the next time activity occurs for that phone book.

Because these log files can become large enough over time to take up valuable hard disk space and to inhibit searching for useful information, you should save and archive them periodically.

For information on monitoring phone book history, see View the history of a phone book.

# Connection Point Services Resources

Updated: January 21, 2005

**Resources**

- Important phone book files
- Example region files containing U.S. states
- Service types (POP settings)
- Example phone book history

# Important phone book files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Important phone book files**

Connection Point Services (CPS) needs services, software, and data files to update the database, post the database and data files to the server, query the server database, and download the appropriate file to Connection Manager.

Phone Book Administrator (PBA) creates the database and files for the server and then transfers the data using the File Transfer Protocol (FTP). Phone Book Service (PBS) compares phone book versions based on the query variables sent by Connection Manager and responds with the appropriate compressed phone book (.cab) file.

Phone book data elements are described in the following table.

| Element | Description |
|---|---|
| Cabinet (.cab) files | Compressed data files that contain phone book information for Connection Manager. There are two types of .cab files, Full.cab and Delta.cab files. |
| Phone book (.pbk) files | Text files that contain lists of POP information. Phone book files are compressed before they are transferred to the server. |
| Region (.pbr) file | Text file that helps categorize POPs. A POP can reference one of many geographical regions listed in the Region file. |
| Version (.ver) file | Text file that keeps track of the latest phone-book release. |
| PBServer.mdb | A database that contains updated query tables for your phone books. PBA transfers the database to the server as Newpb.mdb every time a phone book is published. |
| *Phone_book*.mdb | A database that contains POP information. |

# Example region files containing U.S. states

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Example region files containing U.S. states**

The format you use for the list of U.S. states depends on whether you are using Phone Book Administrator or the command line. You will need to use .pbr format (the first list) for Phone Book Administrator. If you are importing by command line, use the second list.

The following list shows the names of all fifty U.S. states, plus the District of Columbia, in .pbr format:

```
51
Alabama
Alaska
Arizona
Arkansas
California
Colorado
Connecticut
Delaware
District of Columbia
Florida
Georgia
Hawaii
Idaho
Illinois
Indiana
Iowa
Kansas
Kentucky

# Service types (POP settings)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service types (POP settings)**

Connection Point Services (CPS) uses a combination of eight service *types* (sometimes called POP settings) to determine how a connection is established.

Service types enable your users to filter for POPs specific to their needs.

Each service type has two possible options with values of 0 (zero) or 1 (one), and you convert these eight values into a decimal number to use in the **Service Flag** field of the POP file you plan to import.

If one of the flags for a POP is not set in the **Service Types** section of the .cms file in the Connection Manager profile, then even if you set the flag for this POP in Phone Book Administrator (PBA), a user may not be able to filter for the POP in **Access numbers** in the Connection Manager interface. For example, service types Custom 1 and Custom 2 are advanced and require manual editing of the Connection Manager service profile.

For each service type, the bitflag table (later in this topic) contains four fields. The first field is the bit number representing each option of any given service type. The second field contains integers representing the availability of each of the service type options. The third and fourth fields contain text that describes the service type option.

Options shown in bold are the default values for POPs in Connection Manager.

Immediately after the following table is an example of its use.

**Bitflag table for service types**

| Bit number | Option values | Option descriptions | Notes |
|---|---|---|---|
| 0 | **0**<br>1 | **Sign on**<br>Not Sign on | Users can connect to the POP to sign on to your service. If you set this option to 1, you must also set the same option to 1 in Connection Manager. |
| 1 | **0**<br>1 | **Not Sign up**<br>Sign up | Users can connect to the POP to sign up for your service. If you set this option to 1, you must also set the same option to 1 in Connection Manager. |
| 2 | **0**<br>1 | **Modem**<br>Not Modem | Users can connect to the POP by modem. |
| 3 | **0**<br>1 | **ISDN**<br>Not ISDN | Users can connect to the POP using an ISDN connection device. |
| 4 | **0**<br>1 | Not Custom 1<br>Custom 1 | The POP is assigned a custom service setting. You can specify custom service settings in the Connection Manager service profile. |
| 5 | **0**<br>1 | **Multicast**<br>Not Multicast | The POP supports IP multicast protocols. |
| 6 | **0**<br>1 | **Not Surcharge**<br>Surcharge | The access number for the POP appears in the **More access numbers** box in the Connection Manager **Phone Book** dialog box. You can charge your users an additional fee when they use this POP. |

| | | | |
|---|---|---|---|
| 7 | **0**<br><br>1 | Not Custom 2<br><br>Custom 2 | The POP is assigned a custom service setting. You can specify custom service settings in the Connection Manager service profile. |

To determine the correct decimal value to use for the **Service Flag** field in your command-line import file, create an eight-bit binary number where each bit has the value given in the table. Then, convert this binary number into a decimal number.

**Example**

The following list begins with the service type with the least mathematical significance. If you created a POP with these service types, the binary value would be 01111000, which converts to 120 in decimal notation:

Sign on (0)

Not Sign up (0)

Modem (0)

Not ISDN (1)

Custom 1 (1)

Not Multicast (1)

Surcharge (1)

Not Custom 2 (0)

A POP using this decimal number (shown in *italics*) as its service flag might look like this:

1, 1, 0, Redmond, 425, 555-0135, 9600, 56000, 0, *120*, ISP

# Example phone book history

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Example phone book history**

The example later in this topic shows the POP activity of one phone book. Each change is on a new line that begins with a date, and fields are separated by commas. Each line shows the following:

- Date and time of the change
- Action taken (for example, POP Add or POP Edit)
- Key field (POP name)
- Eleven fields representing the POP data:
    1. POP index
    2. Country/dependency
    3. Region identifier
    4. POP name
    5. Area code
    6. Access number
    7. Minimum baud rate
    8. Maximum baud rate
    9. Reserved flag
    10. Service flag
    11. Dial-up entry
- POP status (in or out of service)
- Date of change (repeated)
- Two reserved fields

The following example shows phone book history as it appears in the phone-book history text file. Note that the five field names in the first line of the text file (Date, Action, and so on) do not list every data field.

```
Date, Action, Key Field, Record ( ; delimited )

1/27/01 3:40:35 PM, POP Add, Albany, 3;1;0;Albany;912;555-0100;0;56000;0;48;ISP;1;1/27/01;;0

1/27/01 3:40:38 PM, POP Edit, Albuquerque, 5;1;0;Albuquerque;505;555-0121;0;56000;0;48;;1;1/27/01;;0

1/27/01 10:07:18 AM, POP Delete, Portland, 305;1;0;Portland;1;1;0;0;0;48;;1;1/27/01;;0
```

The following table supplies field names and their corresponding POP data for all of the fields in the first data line of the

example.

| Name of field | Data |
|---|---|
| Date and time | 1/27/01 3:40:35 PM |
| Action | POP Add |
| Key field | Albany |
| POP index | 3 |
| Country/dependency | 1 |
| Region ID | 0 |
| POP name | Albany |
| Area code | 912 |
| Access number | 555-0100 |
| Minimum baud rate | 0 |
| Maximum baud rate | 56000 |
| Reserved flag | 0 |
| Service flag | 48 |
| Dial-up entry | ISP |
| POP status | 1 |
| Date of change | 1/27/01 |
| Reserved | |
| Reserved | 0 |

**Notes**

- Phone book history files can also contain information on region and publishing activities.
- The dial-up entry name corresponds exactly with the dial-up entry created in the **Dial-up Networking Entries** pane in the Connection Manager Administration Kit Wizard.

# Connection Point Services Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**

- Phone Book Service error messages
- Phone Book Administrator command-line error messages
- Common problems and their solutions

# Phone Book Service error messages

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Phone Book Service error messages**

The following table describes Phone Book Service (PBS) events and the actions you can take to correct errors.

| MessageID | Type | Message | Action to perform |
|---|---|---|---|
| 30002 | Error | Unable to get query parameters | No action is required. If the problem persists, restart IIS Admin Service. |
| 30003 | Error | Error in sending HTML header | Make sure that IIS is running properly. If the problem persists, restart IIS Admin Service. |
| 30004 | Error | Error in sending HTML content | Make sure that IIS is running properly. If the problem persists, restart IIS Admin Service. |
| 30005 | Error | Cannot open file | Make sure the file exists and the file permissions are set properly. |
| 30010 | Error | Internal Error | Free up the memory currently in use by closing any nonessential applications. You might also want to increase the physical or virtual memory of your system. Also, make sure that IIS is running properly. |
| 30015 | Error | Failure when waiting for child thread to terminate | Restart IIS Admin service. |

# Phone Book Administrator command-line error messages

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Phone Book Administrator command-line error messages**

The following table describes Phone Book Administrator error messages that you may encounter while importing files by command line and the actions you can take to correct errors. After you correct the problem, remember to re-import your files.

| Message | Action to perform |
|---|---|
| Error during file creation | Make sure that you have set the appropriate file permissions for the PBA and release directories. See Secure your Phone Book Administrator folder (NTFS only). |
| Invalid path for input file | Make sure you have typed the full path. |
| Problem while reading import file | Make sure the file is in plain text format. |
| Phone book passed as a command-line parameter does not exist | Make sure you have typed the correct phone book name as it appears in the Phone Book Administrator interface. |
| Error during command line processing | See Import.log in the application directory for details. |
| Wrong number of fields | Make sure that all of your POPs have 11 fields and all regions have two fields. |
| Length of input field exceeds allowed value | Edit the input field. For field restrictions, see Add, edit, or delete POPs by command line. |
| Numeric input field contains non-numeric characters | Replace with numeric characters. |
| Incomplete configuration data for publishing | Set the options for this phone book. See Set or edit phone book options by command line. |
| Duplicate region name found | Delete duplicate region name from the input file. |
| Region specified for phone book import does not exist | Add or import the missing region. See Add, edit, or delete regions by command line or Import a region list by command line. |
| Country or dependency specified for phone book import does not exist | Specify the correct TAPI code for country or dependency as defined in the phone book. You can find the default list in the Country.txt file. |
| Total length of the Area Code and Access Number fields exceeds allowed value | Edit area code and access number to contain a total of no more than 36 characters. |
| Wrong or missing command line option | At the command prompt, type **pbadmin /?** for a list of valid command-line parameters. |

# Common problems and their solutions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Common problems and their solutions**
What problem are you having?

- I need more help using Phone Book Administrator.
- I am unable to post to Phone Book Service (PBS).
- I am unable to import a phone book file or region file from the command line.
- No POPs appear in Connection Manager.
- When a client computer sent a query to Phone Book Service, the phone book did not download.
- Phone Book Administrator will not display particular characters.
- The application log available through Event Viewer does not contain messages about phone book activity.

**I need more help using Phone Book Administrator.**
**Solution:** In the **Phone Book Administrator** dialog box, open the **Help** menu, click **What's This?**, and then click the component you do not understand. A message will be displayed with information about the component. In other dialog boxes, click **?** and then click the component you do not understand.

**I am unable to post to Phone Book Service (PBS).**
**Possible solutions:**

Make sure that:

- The server is turned on.
- You are connected to the network.
- The PBS server has FTP installed and running.
- FTP is not set to **Allow only anonymous connections**.
- Write permission is turned on for the FTP virtual directory.
- The server name or address, user name, and password are typed correctly in the **Options** dialog box. Null passwords and passwords that contain spaces are not supported.
- You have logged on with an account that has permission to write to the hard drive on the server. These include FTP service, share, and file permissions (NTFS only).
- You have connectivity to the PBS host. Try PING and TRACERT to verify that the TCP/IP connection is correctly configured.
- The proxy settings in Internet Explorer are set correctly. The proxy might have changed, or someone might have reset it.
- Firewall issues are not interfering.

**See also:** Set permissions early; Set the Write permission for the FTP virtual directory; Set up FTP accounts for known users

**I am unable to import a phone book file or region file from the command line.**
**Possible solutions:**

Make sure that:

- You have the appropriate permissions to alter the phone book database.
- You typed the full path to the phone book file or region file. The file path cannot contain spaces.
- Your file is in plain-text format.
- You typed the correct phone book name as it appears in the Phone Book Administrator interface.
- All of the POPs have 11 fields. All regions have two fields.
- You did not exceed the limit for any of the input fields.
- None of the numeric input fields contain nonnumeric characters.
- The country, region, or dependency that you specified exists in the phone book.
- You used the correct import command. At the command prompt, type **pbadmin /?** for a list of valid command-line parameters.
- You used the correct import format for your region file. Command-line region files do not match the region-file format imported or generated by the Phone Book Administrator user interface.
- You did not try to import more than 6,000 POPs. If you have not yet posted your phone book, you can import up to 32,000 POPs. If, however, you have already posted, the limit is 6,000 POPs (combined adds, edits, and deletes) for each subsequent post.

**See also:** Set permissions early; Use your existing database with Phone Book Administrator; Import a region list by command line; Phone Book Administrator command-line error messages

**No POPs appear in Connection Manager.**
**Possible solutions:**

Make sure that:

- The profile created with the Connection Manager Administration Kit wizard is set up correctly to use your phone books.
- No files are missing. If they are, use your backup copies to restore them.
- The name of the phone book in Phone Book Administrator matches the name typed in when the profile was built using the Connection Manager Administration Kit wizard.
- You did not exceed the limit for any of the input fields. (For a table that describes limits, see Add, edit, or delete POPs by command line.)
- None of the numeric input fields contain nonnumeric characters.
- You specified the correct country or dependency for the POP.
- You and your users have the appropriate version of Internet Explorer installed. Phone book downloads require that Internet Explorer 5.01, Internet Explorer 5.5, or Internet Explorer 6 be installed on the computer. Internet Explorer does not have to be set as the default browser.

**See also:** Back up your data; Use your existing database with Phone Book Administrator

**When a client computer sent a query to Phone Book Service, the phone book did not download.**
**Possible solutions:**

Make sure that:

- The server is turned on.
- The client computer is connected to the network.
- The name of the phone book in Phone Book Administrator (PBA) matches the name in Connection Manager.
- The user gave the phone book enough time to download.
- WWW is currently running on the server. Even though WWW is installed, it may not be running.
- The proxy settings in the client computer are set correctly.
- The current network configuration still passes your previous tests for production readiness.
- The security attribute is set properly on the phone book update files. It should not be set to **Read Only**.
- Firewall issues are not interfering with phone book downloads.
- Your users have the appropriate version of Internet Explorer installed. Phone book downloads require that Internet Explorer 5.01, Internet Explorer 5.5, or Internet Explorer 6 be installed on the computer. Internet Explorer does not have to be set as the default browser.
- Anonymous access is enabled for the Phone Book Service virtual root directory. Connection Manager requests phone books through the anonymous account.
- You have looked at the application log in Event Viewer on the PBS host server for error messages. If Event Viewer messages have been enabled for PBS and the phone book file is missing, you will see error 30005: "Cannot open file."
- The phone book file is present on the host server, and that the host server is accessible. The phone book file might be missing from the host server, or access to the host server might be denied.
- The phone book is posted to the phone book server. A profile might have been configured to ask for a phone book, but the administrator might not have posted that phone book to the server.
- The phone book has been posted to the production environment. The phone book might have been posted to a staging server but not replicated to the production environment. Try editing a POP in the phone book and then posting the file again. (You can edit the POP to repeat the existing data.) When you edit a POP, PBA changes the version number of the phone book. PBA does not post to the host server unless the phone book version number changes.

If your Connection Manager profile uses Connection Manager 1.3, have the user enable logging and check the Connection Manager log file for more information about the problem.

**See also:** Set permissions early; Phone Book Service error messages; Test for production readiness; Connection Manager Administration Kit

**Phone Book Administrator will not display particular characters.**
**Cause:** Phone Book Administrator does not support Unicode.

**Solution:** Set **Language for non-Unicode programs** to match the language that you want to display:

1. Open Regional and Language Options. To open Regional and Language Options, click **Start**, click **Control Panel**, and then double-click **Regional and Language Options**.
2. Click the **Advanced** tab. In the **Language for non-Unicode programs** section, click the appropriate language version.

3. Click **Apply**.

   This may cause your system to restart.

**The application log available through Event Viewer does not contain messages about phone book activity.**
**Cause:** PBS cannot, by default, write to the application log.

**Solution:** On computers that are running a Windows Server 2003 family operating system, applications that are members of Guests cannot, by default, write to the application log. You can change this behavior, but you should first consider whether the security implications of doing so outweigh the benefits. To change this behavior, you can set the following registry key to a value of zero:

**HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\EventLog\Application\RestrictGuestAccess**

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

# Virtual Private Networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Virtual private networks**
The Microsoft® Windows Server 2003 Routing and Remote Access service provides virtual private network (VPN) services for remote access and router-to-router VPN connections by using either Point-to-Point Tunneling Protocol (PPTP) or Layer Two Tunneling Protocol (L2TP) with Internet Protocol security (IPSec).

- Before installing a VPN server, see VPN Checklists.
- To find features that have been moved in the Windows Server 2003 family, see New ways to do VPN tasks.
- For tips about using VPNs, see VPN best practices.
- For general background information, see VPN Concepts.
- For problem-solving instructions, see VPN Troubleshooting.

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# VPN Checklists

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklists**

This section covers:

- Checklist: Installing and configuring a VPN server
- Checklist: Installing and configuring a PPTP server
- Checklist: Installing and configuring an L2TP server

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# Checklist: Installing and configuring a VPN server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Installing and configuring a VPN server**

| Step | Reference |
|---|---|
| Review key concepts. | Virtual Private Networks Overview |
| Install the hardware. | Manufacturer's documentation |
| Verify the compatibility of all hardware to be installed in the computer running a Windows Server 2003 operating system. | The Compatible Hardware and Software section at Support resources |
| Verify that the hardware is successfully installed. | Device Manager |
| Install the Routing and Remote Access service, and configure the server using the Routing and Remote Access Server Setup Wizard. | Enable the Routing and Remote Access service |
| Configure dial-in properties and remote access policies for dial-in permission, authentication, and encryption settings. | Introduction to remote access policies |
| Configure packet filters on your firewall. | VPN servers and firewall configuration |
| (Optional) Configure the virtual private network (VPN) server as a RADIUS client. | Use RADIUS authentication |

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# Checklist: Installing and configuring a PPTP server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Installing and configuring a PPTP server**

| Step | Reference |
|---|---|
| Review key concepts. | Virtual Private Networks Overview |
| Install the hardware. | Manufacturer's documentation |
| Verify the compatibility of all hardware to be installed in the computer running a Windows Server 2003 operating system. | The Compatible Hardware and Software section at Support resources |
| Verify that the hardware is successfully installed. | Device Manager |
| Install the Routing and Remote Access service, and configure the server using the Routing and Remote Access Server Setup Wizard. | Enable the Routing and Remote Access service |
| Configure packet filters on your firewall. | VPN servers and firewall configuration |
| Configure dial-in properties and remote access policies for dial-in permission, authentication, and encryption settings. | Introduction to remote access policies |

**Notes**

- Point-to-Point Tunneling Protocol (PPTP) is automatically installed.
- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# Checklist: Installing and configuring an L2TP server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Installing and configuring an L2TP server**

| Step | Reference |
|---|---|
| Review key concepts. | Virtual Private Networks Overview |
| Install the hardware. | Manufacturer's documentation |
| Verify the compatibility of all hardware to be installed in the computer running a Windows Server 2003 operating system. | The Compatible Hardware and Software section at Support resources |
| Verify that the hardware is successfully installed. | Device Manager |
| Install the Routing and Remote Access service, and configure the server using the Routing and Remote Access Server Setup Wizard. | Enable the Routing and Remote Access service |
| Configure packet filters on your firewall. | VPN servers and firewall configuration |
| Install computer certificates on the Layer Two Tunneling Protocol (L2TP) server computer and L2TP client computers. | Computer certificates for L2TP/IPSec VPN connections;Network access authentication and certificates |
| Configure dial-in properties and remote access policies for dial-in permission, authentication, and encryption settings. | Introduction to remote access policies |

**Notes**

- L2TP is automatically installed.
- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# New ways to do VPN tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

The following table lists common tasks for configuring virtual private networks (VPNs). The user interface for performing these tasks is different in this version of Windows from the way it was in Windows NT 4.0 or Windows NT 4.0 with the Routing and Remote Access Service (RRAS).

**Notes**

- There are no significant user interface differences between Windows 2000, Windows XP, and the Windows Server 2003 family for this component.
- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

Please choose your upgrade path:

- Windows NT 4.0 to a product in the Windows Server 2003 family
- Windows NT 4.0 with RRAS to a product in the Windows Server 2003 family

**Windows NT 4.0 to a product in the Windows Server 2003 family**

| If you want to | In Windows NT 4.0 use | In this version of Windows |
|---|---|---|
| Install the Point-to-Point Tunneling Protocol (PPTP) | **Protocols** tab of **Network** in Control Panel | PPTP is automatically installed. |
| Set the maximum number of PPTP connections | **Protocols** tab of **Network** in Control Panel | Use Properties of **Ports** in Routing and Remote Access. |
| Set PPTP packet filtering | The **Advanced IP Addressing** dialog box from the properties of the TCP/IP protocol (**Protocols** tab of **Network** in Control Panel) | PPTP packet filtering is set by default when you run the Routing and Remote Access Setup Wizard or set manually when you use Properties of the IP interface in **General** under **IP Routing** in Routing and Remote Access. |

**Windows NT 4.0 with RRAS to a product in the Windows Server 2003 family**

| If you want to | Windows NT 4.0 with RRAS use | In this version of Windows |
|---|---|---|
| Install the Point-to-Point Tunneling Protocol (PPTP) | **Protocols** tab of **Network** in Control Panel | PPTP is automatically installed. |
| Set the maximum number of PPTP connections | **Protocols** tab of **Network** in Control Panel | Use Properties of **Ports** in Routing and Remote Access. |

| | | |
|---|---|---|
| Set PPTP packet filtering | Properties of the IP interface in **Summary** under **IP Routing** in Routing and RAS Admin | PPTP packet filtering is set by default when you run the Routing and Remote Access Setup Wizard or set manually when you use Properties of IP interface in **General** under **IP Routing** in Routing and Remote Access. |

# VPN best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **Use the virtual private network (VPN) server to allocate IP address leases to remote access clients.**

  If your VPN server handles more than 20 concurrent remote access connections, then use the VPN server to allocate IP address leases to remote access clients. When you create the IP address pool on the VPN server, be certain not to allocate addresses already in use by DHCP servers on your network.

  If you did not install a DHCP server, and you have a single subnet with computers configured with static IP addresses, configure the VPN server with an IP address pool that is a subset of addresses for the subnet to which the VPN server is attached. For more information, see Create a static IP address pool.

- **Use strong authentication.**

  - Use strong passwords that are more than 8 characters long and that contain a mixture of uppercase and lowercase letters, numbers, and permitted punctuation. Do not use passwords based on names or words. Strong passwords are more resistant to a dictionary attack, where an unauthorized user attempts to determine a password by sending a series of commonly used names and words.

  - Although EAP-TLS works with registry-based user certificates, it is highly recommended that you use only EAP-TLS with smart cards for remote access VPN connections. Because smart cards are distributed to trusted users and require a personal identification number (PIN), they are more secure than registry-based user certificates.

  - If you are using password-based user authentication, then use MS-CHAP version 2. You can obtain the latest MS-CHAP updates for VPN clients running Windows NT 4.0, Windows 95, or Windows 98 from Microsoft. For more information, see MS-CHAP version 2.

- **Use strong encryption.**

  Use the strongest level of encryption that your situation allows. The levels of encryption that are available when configuring the profile properties of a remote access policy are: Basic, Strong, and Strongest. For more information, see Configure encryption and Elements of a remote access policy.

# VPN Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**
This section provides general background information about the virtual private network (VPN) services included with the Windows Server 2003 family:

- Virtual Private Networks Overview
- Understanding Virtual Private Networks
- Deploying Virtual Private Networks
- VPN Resources

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# Virtual Private Networks Overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Virtual private networks overview**
This section covers:

- Security issues for VPN
- Introduction to virtual private networks
- New features for virtual private networks
- VPN Connections
- Types of Virtual Private Networks

# Security issues for VPN

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security information for VPN**

It is important to follow best practices for security when using VPN servers on your network. For more information, see Best practices for security.

If your VPN servers are configured as Remote Authentication Dial-In User Service (RADIUS) clients, see Security information for IAS.

The following are known security issues for VPN connections:

- **Many authentication methods are too weak to provide adequate security for most organizations.**

  Many organizations use authentication methods that expose their network to a variety of security attacks. The most secure method of authentication is Extensible Authentication Protocol-Transport Level Security (EAP-TLS) when used in conjunction with smart cards. However, EAP-TLS and smart cards require a public key infrastructure (PKI), which can be complicated to deploy.

**Recommendations:**

- When you use password-based authentication, enforce strong password policies on your network to make dictionary attacks more difficult. For more information, see Strong passwords.

- Make sure that Password Authentication Protocol (PAP), Shiva Password Authentication Protocol (SPAP), and Challenge Handshake Authentication Protocol (CHAP) are disabled. PAP, SPAP, and CHAP are disabled by default on the profile of a remote access policy.

- Disable Microsoft Challenge Handshake Authentication Protocol (MS-CHAP). MS-CHAP is enabled by default on the profile of a remote access policy. Before you disable MS-CHAP, ensure that all of the clients of your access server are capable of using MS-CHAP version 2 (MS-CHAP v2). If your server is not running Microsoft® Windows Server 2003 , you will need the latest service packs and dial-up networking updates in order to support MS-CHAP v2.

- If you do not disable MS-CHAP, disable LAN Manager authentication for MS-CHAP. LAN Manager authentication for MS-CHAP is enabled by default on clients running earlier versions of Windows.

- To disable LAN Manager authentication, set the registry value **Allow LM Authentication** to **0** at the following registry key:

  **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RemoteAccess\Policy**

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**Note**

- You can change an entry in the registry using Registry Editor. For more information, see Registry Editor and Change a value.

- Make sure that MS-CHAP v2 is enabled. MS-CHAP v2 is enabled by default on the profile of a remote access policy.

- For wireless clients running Windows XP, enable Protected Extensible Authentication Protocol (PEAP) with Extensible Authentication Protocol (EAP)-MS-CHAP v2. PEAP with EAP-MS-CHAP v2 provides mutual authentication: the IAS server is authenticated with a certificate, while user authentication is accomplished with password-based credentials. For more information, see New features for IAS. For an example of a remote access policy that uses PEAP, see Wireless access with secure password authentication.

- Enable EAP-TLS. EAP-TLS is disabled by default on the profile of a remote access policy. When you use the EAP-TLS authentication protocol, you must install a computer certificate on the IAS server. For client and user authentication, you can install a certificate on the client computer, or you can use smart cards. Before you deploy certificates, you must design the certificate with the correct requirements. For more information, see Network access authentication and certificates and Computer certificates for certificate-based authentication.

- **Remote access account lockout can deny network access to authorized users.**

  When remote access account lockout is enabled, if a malicious user attempts a dictionary attack with the logon name of an authorized user, both the malicious user and the authorized user are locked out of the account until the account lockout threshold is reached.

**Recommendations:**

- Be cautious when defining account lockout policy. For more information, see Password Best practices.

- When the lockout count for a user account is reset to 0, due to either a successful authentication or an automatic reset, the registry subkey for the user account is deleted. To manually unlock a user account (before the account lockout threshold is automatically reset), delete the following registry subkey that corresponds to the account name of the user:

  **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\AccountLockout***DomainName:UserName*

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**Notes**

- You can change an entry in the registry using Registry Editor. For more information, see Registry Editor and Change a value.

- Remote access account lockout is not related to the **Account locked out** setting on the **Account** tab on the properties of a user account.

  Remote access account lockout does not distinguish between malicious users who attempt to access your intranet and authentic users who attempt remote access but have forgotten their current passwords. Users who have forgotten their current password typically try the passwords that they remember and, depending on the number of attempts and the MaxDenials setting, might be locked out of their accounts.

- **The default domain functional level setting (Windows 2000 mixed) can create security holes.**

  You should use only servers that are running Windows 2000 or Windows Server 2003 , if possible. Using servers running Routing and Remote Access in conjunction with servers that are running Windows NT® 4.0 and either Remote Access Service (RAS) or Routing and Remote Access Service (RRAS) decreases your network security. For more information, see Domain and forest functionality and Member server in a domain.

**Additional recommendations:**

- **Allow the VPN server or a DHCP server to assign IP address leases to VPN clients.**

  Do not allow VPN clients to specify their own IP address. The method by which the VPN server assigns addresses to remote access clients (either using addresses that the VPN server obtains from a DHCP server or using addresses from a specified range of addresses that you configure) is set when you run the Routing and Remote Access Server Setup Wizard. For more information, see L2TP-based remote access VPN deployment and DHCP.

- **Always use Layer Two Tunneling Protocol/Internet Protocol security (L2TP/IPSec) connections for the strongest encryption.**

  Use smart cards for the most secure authentication and certificates when smart cards are not practical.

- **Use certificates for Internet Key Exchange (IKE) negotiations.**

  Do not use preshared keys, as they are susceptible to dictionary attacks.

# Introduction to virtual private networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Virtual private networks**

A virtual private network (VPN) is the extension of a private network that encompasses links across shared or public networks like the Internet. With a VPN, you can send data between two computers across a shared or public network in a manner that emulates a point-to-point private link. Virtual private networking is the act of creating and configuring a virtual private network.

To emulate a point-to-point link, data is encapsulated, or wrapped, with a header that provides routing information, which allows the data to traverse the shared or public network to reach its endpoint. To emulate a private link, the data is encrypted for confidentiality. Packets that are intercepted on the shared or public network are indecipherable without the encryption keys. The link in which the private data is encapsulated and encrypted is a virtual private network (VPN) connection.

The following illustration shows the logical equivalent of a VPN connection.

Users working at home or on the road can use VPN connections to establish a remote access connection to an organization server by using the infrastructure provided by a public network such as the Internet. From the user's perspective, the VPN is a point-to-point connection between the computer (the VPN client) and an organization server (the VPN server). The exact infrastructure of the shared or public network is irrelevant because it appears logically as if the data is sent over a dedicated private link.

Organizations can also use VPN connections to establish routed connections with geographically separate offices or with other organizations over a public network such as the Internet while maintaining secure communications. A routed VPN connection across the Internet logically operates as a dedicated WAN link.

With both remote access and routed connections, an organization can use VPN connections to trade long-distance dial-up or leased lines for local dial-up or leased lines to an Internet service provider (ISP).

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. For more information about feature availability on Windows Server 2003, Web Edition, see Overview of Windows Server 2003, Web Edition. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

There are two types of Point-to-Point Protocol (PPP)-based VPN technology in the Microsoft Windows 2003 family:

1. Point-to-Point Tunneling Protocol (PPTP)

   PPTP uses user-level PPP authentication methods and Microsoft Point-to-Point Encryption (MPPE) for data encryption.

2. Layer Two Tunneling Protocol (L2TP) with Internet Protocol security (IPSec)

   L2TP uses user-level PPP authentication methods and computer-level certificates with IPSec for data encryption, or IPsec in tunnel mode, in which IPsec itself provides encapsulation (for IP traffic only).

For more information on the types of VPN connections, see VPN Connections. For information on how to design and deploy VPN connections, see Deploying Virtual Private Networks.

# New features for virtual private networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New features for virtual private networks**

The Microsoft® Windows® Server 2003 family provides the following new features for virtual private networks (VPNs):

- Network address translation (NAT) transparency

  VPN servers running Windows Server 2003 support Layer Two Tunneling Protocol over Internet Protocol security (L2TP/IPSec) traffic that originates from VPN clients behind NATs. For this feature to function properly, the client computer must support the following IPSec Protocol Working Group Internet drafts:

  - Negotiation of NAT-Traversal in the IKE (draft-ietf-ipsec-nat-t-ike-02.txt).
  - UDP Encapsulation of IPsec Packets (draft-ietf-ipsec-udp-encaps-02.txt).

**Important**

- An IPSec NAT-T deployment for Windows that includes VPN servers that are located behind network address translators is not recommended. When a server is behind a network address translator, and the server uses IPSec NAT-T, unintended behavior might occur because of the way network address translators translate network traffic.

- VPN deployment with Network Load Balancing

  VPN servers running Windows Server 2003 support VPN deployment in conjunction with Network Load Balancing to create high-availability VPN solutions. Support is included for Point-to-Point Tunneling Protocol (PPTP) and L2TP/IPSec VPN solutions with Network Load Balancing.

- NetBIOS over TCP/IP (NetBT) name resolution proxy

  When a remote access VPN client connects to a VPN server, it relies on DNS or WINS servers on the target network for name resolution.

  DNS and WINS servers are common in organizations that use DNS for host name resolution or WINS for NetBIOS name resolution. However, in a small office or home office environment, these servers might not be present. In this case, the names of the computers to which communications are attempted need to be resolved by another means for successful communication to occur.

  NetBIOS names can be resolved, without the use of a WINS or DNS server, by a VPN server running Windows Server 2003 because Windows Server 2003 operating systems include the NetBT proxy. With NetBT proxy, connected VPN clients and the nodes on network segments to which the VPN server is attached can resolve each other's NetBIOS names, as follows:

  1. When a VPN client needs to resolve a name to an IP address without a configured DNS or WINS server, it sends a NetBIOS Name Query packet to the VPN server. When a node on a network segment that is attached to the VPN server needs to resolve a name to an IP address without a configured DNS or WINS server, it sends a NetBIOS Name Query packet as a broadcast on the network segment.

  2. The VPN server receives the NetBIOS Name Query packet, checks its local cache of resolved NetBIOS names and, if the name is not found, forwards the NetBIOS Name Query as a NetBIOS broadcast on all attached interfaces, except the logical interface that is connected to all VPN clients.

  3. The node that has registered the NetBIOS name sends a positive NetBIOS Name Query Response to the VPN

server.

4. The VPN server receives the positive NetBIOS Name Query Response and then forwards it on the interface from which the NetBIOS Name Query packet originated to the sending node.

The result is that network nodes on network segments that are attached to the VPN server (and all connected VPN clients) can automatically resolve each other's names without a DNS or WINS server.

- Preshared key configuration for L2TP connections

  The Windows Server 2003 family supports both computer certificates and a preshared key as authentication methods to establish an IPSec security association for L2TP connections. A preshared key is a string of text that is configured on both the VPN client and VPN server. Preshared key is a relatively weak authentication method, therefore it is recommended that you use preshared key authentication only while your public key infrastructure (PKI) is being deployed to obtain computer certificates or when a preshared key is required by VPN clients. You can enable the use of a preshared key for L2TP connections and specify the preshared key from the **Security** tab on the properties of a server running Routing and Remote Access. For more information, see View properties of the remote access server.

  Preshared key authentication is also supported by remote access VPN clients running Windows XP. You can enable preshared key authentication and configure a preshared key from **IPSec settings** on the **Security** tab on the properties of a VPN connection in Network Connections. For more information, see Configure a pre-shared key on a remote access client.

  Preshared key authentication is also supported for site-to-site VPN connections between computers running a Windows Server 2003 operating system. You can enable preshared key authentication and configure a preshared key for demand-dial interfaces from **IPSec settings** on the **Security** tab on the properties of a demand-dial interface in Routing and Remote Access. For more information, see Configure a pre-shared key for a demand-dial routing interface and Configure a pre-shared key on a remote access server.

The following features for virtual private networks were new in Windows 2000:

- L2TP

  In addition to PPTP, the the Windows Server 2003 family includes the industry standard L2TP, which is used in conjunction with IPSec to create secure virtual private network connections. The use of L2TP and IPSec is referred to as L2TP/IPSec.

- Remote access policies

  Remote access policies are a set of conditions and connection settings that allow network administrators more flexibility in setting remote access permissions and connection restraints. With remote access policies, you can force the use of strong authentication and encryption for VPN users and use a different set of authentication and encryption constraints for dial-up users.

  For more information, see Remote Access Policies.

- MS-CHAP version 2

  Microsoft Challenge Handshake Authentication Protocol (MS-CHAP) version 2 significantly strengthens the security for the passing of security credentials and the generation of encryption keys during the negotiation of a remote access connection. MS-CHAP version 2 was specifically designed for authenticating VPN connections.

  For more information, see MS-CHAP version 2.

- Extensible Authentication Protocol

  Extensible Authentication Protocol (EAP) allows new authentication methods to be used, a feature that is especially

important for the deployment of security based on smart cards. EAP is an architecture that allows other authentication modules to plug into PPP in Windows 2000, Windows XP, and products in the Windows Server 2003 family. Both EAP-MD5 CHAP and EAP-TLS (used for smart card and certificate-based authentication) are supported. You can configure your VPN server to handle authentication, or the VPN server can be configured to forward authentication requests to RADIUS servers.

For more information, see EAP and Internet Authentication Service.

- Remote access account lockout

  Remote access account lockout is a security feature that denies access after a configured number of failed authentication attempts. Remote access account lockout is designed to help prevent dictionary attacks. A dictionary attack occurs when an unauthorized user attempts to log on by using a known user name and a list of common words as the password. Remote access account lockout is disabled by default.

  For more information, see Remote access account lockout.

# VPN Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**VPN connections**
Creating a VPN connection is very similar to establishing a point-to-point connection by using dial-up connections and demand-dial routing. There are two types of VPN connections:

- Remote access VPN connection
- Router-to-router VPN connection

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# Remote access VPN connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote access VPN connection**
A remote access client (a single user computer) makes a remote access VPN connection that connects to a private network. The VPN server provides access to the entire network to which the VPN server is attached. The packets sent from the remote client across the VPN connection originate at the remote access client computer.

The remote access client (the VPN client) authenticates itself to the remote access server (the VPN server) and, for mutual authentication, the server authenticates itself to the client.

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

Computers running Microsoft Windows 95, Windows 98, Windows NT® 4.0, Windows 2000, Windows Millennium Edition, Windows XP, or a Windows Server 2003 operating system can create remote access VPN connections to a VPN server running Windows Server 2003. VPN clients may also be any non-Microsoft Point-to-Point Tunneling Protocol (PPTP) client or Layer Two Tunneling Protocol (L2TP) client with Internet Protocol security (IPSec).

For more information on PPTP and L2TP, see Understanding VPN Tunneling Protocols. For more information on deploying remote access VPN connections, see Deploying VPNs for Remote Access. For an example implementation of a remote access VPN connection, see Virtual Private Network Implementation Examples.

# Router-to-router VPN connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Router-to-router VPN connection**

A router makes a router-to-router VPN connection that connects two portions of a private network. The VPN server provides a routed connection to the network to which the VPN server is attached. On a router-to-router VPN connection, the packets sent from either router across the VPN connection typically do not originate at the routers.

The calling router (the VPN client) authenticates itself to the answering router (the VPN server) and, for mutual authentication, the answering router authenticates itself to the calling router.

Computers running Microsoft® Windows NT® 4.0 with the Routing and Remote Access Service (RRAS), Windows® 2000 Server, or a Windows 200 Server or a Windows Server 2003 operating system can create router-to-router VPN connections. VPN clients may also be any non-Microsoft Point-to-Point Tunneling Protocol (PPTP)-capable router or Layer Two Tunneling Protocol (L2TP)-capable router with Internet Protocol security (IPSec).

For more information on PPTP and L2TP, see Understanding VPN Tunneling Protocols. For more information on deploying router-to-router VPN connections, see Deploying Router-to-Router VPNs. For an example implementation of router-to-router VPN connections, see Virtual Private Network Implementation Examples. For information about creating router-to-router connections by using IPSec Encapsulating Security Payload (ESP) tunnel mode, see Tunnel mode.

# Types of Virtual Private Networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Types of virtual private networks**

You can use VPN connections whenever you need a secure point-to-point connection to connect users or networks. Typical VPN connections are either Internet-based or intranet-based. This section covers:

- Internet-based VPNs
- Intranet-based VPNs

# Internet-based VPNs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet-based VPNs**
By using an Internet-based VPN connection, you can avoid long-distance and 1-800 telephone charges while taking advantage of the global availability of the Internet.

**Remote access over the Internet**
Rather than making a long distance or 1-800 call to a corporate or outsourced network access server (NAS), a remote access client can call a local ISP. By using the established physical connection to the local ISP, the remote access client initiates a VPN connection across the Internet to the organization's VPN server. Once the VPN connection is created, the remote access client can access the resources of the private intranet.

The following illustration shows remote access over the Internet.

For more information on deploying remote access VPN connections across the Internet, see Deploying VPNs for Remote Access. For an example implementation of a remote access VPN connection across the Internet, see Virtual Private Network Implementation Examples.

**Connecting networks over the Internet**
When networks are connected over the Internet, a router forwards packets to another router across a VPN connection. This is known as a router-to-router VPN connection. To the routers, the VPN operates as a data-link layer link.

The following illustration shows connecting networks over the Internet.

**Using dedicated WAN links**
Rather than using an expensive long-distance dedicated WAN link between branch offices, the branch office routers are connected to the Internet by using local dedicated WAN links to a local ISP. A router-to-router VPN connection is then initiated by either router across the Internet. Once connected, routers can forward directed or routing protocol traffic to each other by using the VPN connection.

**Using dial-up WAN links**
Rather than making a long distance or 1-800 call to a corporate or outsourced NAS, a branch office router can call a local ISP. By using the established connection to the local ISP, a router-to-router VPN connection is initiated by the branch office router to the corporate office router across the Internet. The corporate office router acts as a VPN server and must be connected to a local ISP by using a dedicated WAN link.

It is possible to have both the corporate office and the branch office connected to the Internet by using a dial-up WAN link. However, this is only feasible if the ISP supports demand-dialing routing to customers--the ISP calls the customer router when an IP datagram is to be delivered to the customer. Demand-dial routing to customers is not widely supported by ISPs.

For more information on deploying router-to-router VPN connections across the Internet, see Deploying Router-to-Router VPNs. For an example implementation of router-to-router VPN connections across the Internet, see Virtual Private Network Implementation Examples.

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# Intranet-based VPNs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Intranet-based VPNs**
The intranet-based VPN connection takes advantage of IP connectivity on an organization intranet.

**Remote access over an intranet**
On some organization intranets, the data of a department, such as a human resources department, is so sensitive that the department's network is physically disconnected from the rest of the organization's intranet. While this protects the department's data, it creates information accessibility problems for those users who are not physically connected to the separate network.

With a VPN connection, the department's network is physically connected to the organization intranet but separated by a VPN server. The VPN server does not provide a direct routed connection between the organization intranet and the department's network. Users on the organization intranet with the appropriate user rights can establish a remote access VPN connection with the VPN server and access the protected resources of the sensitive department's network. Additionally, all communication across the VPN connection is encrypted for data confidentiality. For those users who do not have the user rights to establish a VPN connection, the department's network is hidden from view.

The following illustration shows remote access over an intranet.

For more information on deploying remote access VPN connections across an intranet, see Deploying VPNs for Remote Access.

**Connecting networks over an intranet**
You can also connect two networks over an intranet by using a router-to-router VPN connection. Organizations with departments in separate locations, whose data is highly sensitive, may use a router-to-router VPN connection to communicate with each other.

For example, the finance department might need to communicate with the human resources department to exchange payroll information. The finance department and the human resources department are connected to the common intranet with computers that can act as VPN routers. Once the VPN connection is established, users on computers on either network can exchange sensitive data across the corporate intranet.

The following illustration shows connecting networks over an intranet.

For more information on deploying router-to-router VPN connections across an intranet, see Deploying Router-to-Router VPNs.

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# Understanding Virtual Private Networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding virtual private networks**
This section covers:

- Components of virtual private networks
- Properties of VPN connections
- A dial-up router-to-router VPN connection
- VPN servers and firewall configuration
- VPN servers and Microsoft ISA Server
- Network access authentication and certificates
- VPN Tunneling Protocols
- VPN Security

# Components of virtual private networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Components of virtual private networks**

A VPN connection includes the following components:

- VPN server

  A computer that accepts VPN connections from VPN clients.

- VPN client

  A computer that initiates a VPN connection to a VPN server. A VPN client can be an individual computer or a router.

- Tunnel

  The portion of the connection in which your data is encapsulated.

- VPN connection

  The portion of the connection in which your data is encrypted. For typical secure VPN connections, the data is encrypted and encapsulated along the same portion of the connection.

  **Note**

  - It is possible to create a tunnel and send the data through the tunnel without encryption. This is not a VPN connection because the private data is sent across a shared or public network in an unencrypted and easily readable form.

- Tunneling protocols

  Protocols that are used to manage tunnels and encapsulate private data. Data that is tunneled must also be encrypted to be a VPN connection. The Windows Server 2003 family includes the PPTP and L2TP tunneling protocols. For more information, see Point-to-Point Tunneling Protocol and Layer Two Tunneling Protocol.

- Tunneled data

  Data that is usually sent across a private point-to-point link.

- Transit internetwork

  The shared or public network crossed by the encapsulated data. For the Windows Server 2003 family, the transit internetwork is always an IP internetwork. The transit internetwork can be the Internet or a private IP-based intranet.

The following illustration shows the components of a virtual private network.

**Notes**

- Typically, the tunnel and the VPN connection are along the same portion of the connection. However, in a compulsory

tunneling configuration, the tunnel (the encapsulation) and the VPN connection (the encryption) are not defined along the same portion of the connection.

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# Properties of VPN connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Properties of VPN connections**
VPN connections that use PPTP and L2TP/IPSec have the following properties:

- Encapsulation
- Authentication
- Data encryption

**Encapsulation**
With VPN technology, private data is encapsulated with a header that provides routing information, which allows the data to traverse the transit internetwork. For examples of encapsulation, see Understanding VPN Tunneling Protocols.

**Authentication**
Authentication for VPN connections takes three different forms:

1. User-level authentication by using PPP authentication

   To establish the VPN connection, the VPN server authenticates the VPN client that is attempting the connection by using a Point-to-Point Protocol (PPP) user-level authentication method and verifies that the VPN client has the appropriate authorization. If mutual authentication is used, the VPN client also authenticates the VPN server, which provides protection against computers that are masquerading as VPN servers.

2. Computer-level authentication by using IKE

   To establish an IPSec security association, the VPN client and the VPN server use the Internet Key Exchange (IKE) protocol to exchange either computer certificates or a preshared key. In either case, the VPN client and server authenticate each other at the computer level. Computer certificate authentication is highly recommended as it is a much stronger authentication method. For more information, see Internet Key Exchange. Computer-level authentication is only done for L2TP/IPSec connections.

3. Data origin authentication and data integrity

   To verify that the data sent on the VPN connection originated at the other end of the connection and was not modified in transit, the data contains a cryptographic checksum based on an encryption key known only to the sender and the receiver. Data origin authentication and data integrity are only available for L2TP/IPSec connections.

**Data encryption**
To ensure confidentiality of the data as it traverses the shared or public transit internetwork, the data is encrypted by the sender and decrypted by the receiver. The encryption and decryption processes depend on both the sender and the receiver using a common encryption key.

Intercepted packets sent along the VPN connection in the transit internetwork are unintelligible to anyone who does not have the common encryption key. The length of the encryption key is an important security parameter. You can use computational techniques to determine the encryption key. However, such techniques require more computing power and computational time as the encryption keys get larger. Therefore, it is important to use the largest possible key size to ensure data confidentiality.

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time.

Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# A dial-up router-to-router VPN connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**A dial-up router-to-router VPN connection**

A router-to-router VPN connection is typically used to connect remote offices together when both routers are connected to the Internet through permanent WAN links, such as T1 or Frame Relay. In this configuration, the VPN connection is always available. However, when a permanent WAN link is not possible or practical, you can configure a dial-up router-to-router VPN connection.

The following illustration shows a dial-up router-to-router VPN connection.

A dial-up router-to-router VPN connection consists of two demand-dial interfaces and two static routes that are configured on the VPN client (the calling router):

1. A demand-dial interface to dial in to a local Internet service provider (ISP).
2. A demand-dial interface for the router-to-router VPN connection.
3. A static host route to dynamically connect to the Internet.
4. A static route to reach the locations of the corporate office.

A dial-up router-to-router VPN connection is automatically established when you route traffic to a specific location. For example, in a branch office configuration, when a packet is received to be routed to the corporate office, the branch office router uses a dial-up link to connect to a local Internet service provider (ISP) and then creates a router-to-router VPN connection with the corporate office router located on the Internet.

**Note**

- This discussion assumes that the corporate office router (the answering router) is connected to the Internet by using a permanent WAN link. It is possible to have both routers connected to the Internet by using a dial-up WAN link. However, this is only feasible if the ISP supports demand-dialing routing to customers; the ISP calls the customer router when an IP datagram is to be delivered to the customer. Demand-dial routing to customers is not widely supported by ISPs.

To configure a dial-up router-to-router VPN connection at the branch office router, do the following:

1. Create a demand-dial interface for the Internet connection that is configured for the appropriate equipment (a modem or ISDN device), the phone number of the local ISP, and the user name and password to gain Internet access.
2. Create a demand-dial interface for the VPN connection with the corporate office router that is configured for a VPN port (a PPTP or L2TP port), the IP address of the interface on the Internet for the corporate office router, and a user name and password that can be verified by the VPN server. The user name must match the name of a demand-dial interface on the corporate office router.
3. Create a static host route to the corporate office router that uses the ISP demand-dial interface.
4. Create a static route (or routes) for the IP network IDs of the corporate intranet that uses the VPN demand-dial interface.

To configure the corporate office router, do the following:

1. Create a demand-dial interface for the VPN connection with the branch office that is configured for a VPN device (a PPTP or L2TP port). The demand-dial interface must have the same name as the user name in the authentication credential that is used by the branch office router to create the VPN connection.

2. Create a static route (or routes) for the IP network IDs of the branch office that uses the VPN demand-dial interface.

The router-to-router VPN connection is automatically initiated by the branch office router through the following process:

1. Packets sent to a corporate hub network location from a computer in the branch office are forwarded to the branch office router.

2. The branch office router checks its routing table and finds a route to the corporate intranet network ID, which uses the VPN demand-dial interface.

3. The branch office router checks the state of the VPN demand-dial interface and finds it is in a disconnected state.

4. The branch office router retrieves the configuration of the VPN demand-dial interface.

5. Based on the VPN demand-dial interface configuration, the branch office router attempts to initialize a router-to-router VPN connection at the IP address of the corporate office router on the Internet.

6. To establish a VPN, either a TCP (by using PPTP) or UDP (by using L2TP/IPSec) packet must be sent to corporate office router that acts as the VPN server. The VPN establishment packet is created.

7. To forward the VPN establishment packet to the corporate office router, the branch office router checks its routing table and finds the host route that is using the ISP demand-dial interface.

8. The branch office router checks the state of the ISP demand-dial interface and finds it is in a disconnected state.

9. The branch office router retrieves the configuration of the ISP demand-dial interface.

10. Based on the ISP demand-dial interface configuration, the branch office router uses its modem to dial and establish a connection with its local ISP.

11. Once the ISP connection is made, the VPN establishment packet is sent to the corporate office router.

12. A router-to-router VPN connection is negotiated between the branch office router and the corporate office router. As part of the negotiation, the branch office router sends authentication credentials that are verified by the corporate office router.

13. The corporate office router checks its demand-dial interfaces and finds one that matches the user name sent during authentication and changes the interface to a connected state.

14. The branch office router forwards the routed packet across the VPN and the corporate office router forwards the packet to the appropriate intranet location.

15. When the intranet location responds to the packet sent to it by the user in the branch office, the packet is forwarded to the corporate office router.

16. The corporate office router checks its routing table and finds a route to the branch office network that uses the VPN demand-dial interface.

17. The corporate office router checks the state of the VPN demand-dial interface and finds it is in a connected state.

18. The response packet is forwarded across the Internet by using the VPN connection.

19. The response packet is received by the branch office router and is forwarded to the original user.

# VPN servers and firewall configuration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

There are two approaches to using a firewall with a VPN server:

- **VPN server in front of the firewall**. The VPN server is attached to the Internet, and the firewall is between the VPN server and the intranet.

- **VPN server behind the firewall**. The firewall is attached to the Internet, and the VPN server is between the firewall and the intranet.

**VPN server in front of the firewall**

When the VPN server is in front of the firewall and attached to the Internet, you need to add packet filters to the Internet interface that allow only VPN traffic to and from the IP address of the VPN server's Internet interface.

For inbound traffic, when the tunneled data is decrypted by the VPN server, it is forwarded to the firewall. Through the use of its filters, the firewall allows the traffic to be forwarded to intranet resources. Because the only traffic that crosses the VPN server is generated by authenticated VPN clients, in this scenario, firewall filtering can be used to prevent VPN users from accessing specific intranet resources. Because the only Internet traffic allowed on the intranet must pass through the VPN server, this approach also prevents the sharing of File Transfer Protocol (FTP) or Web intranet resources with non-VPN Internet users.

The following illustration shows the VPN server in front of the firewall.

For the Internet interface on the VPN server, configure the following input and output filters using Routing and Remote Access:

**Packet filters for Point-to-Point Tunneling Protocol (PPTP)**

Configure the following input filters with the filter action set to **Drop all packets except those that meet the criteria below**:

- Destination IP address of the VPN server's Internet interface, subnet mask of 255.255.255.255, and TCP destination port of 1723.

  This filter allows PPTP tunnel maintenance traffic from the PPTP client to the PPTP server.

- Destination IP address of the VPN server's Internet interface, subnet mask of 255.255.255.255, and IP Protocol ID of 47.

  This filter allows PPTP tunneled data from the PPTP client to the PPTP server.

- Destination IP address of the VPN server's Internet interface, subnet mask of 255.255.255.255, and TCP [established] source port of 1723.

  This filter is required only when the VPN server is acting as a VPN client (a calling router) in a router-to-router VPN connection. TCP [established] traffic is accepted only when the VPN server initiated the TCP connection.

Configure the following output filters with the filter action set to **Drop all packets except those that meet the criteria below**:

- Source IP address of the VPN server's Internet interface, subnet mask of 255.255.255.255, and TCP source port of 1723.

  This filter allows PPTP tunnel maintenance traffic from the VPN server to the VPN client.

- Source IP address of the VPN server's Internet interface, subnet mask of 255.255.255.255, and IP Protocol ID of 47.

  This filter allows PPTP tunneled data from the VPN server to the VPN client.

- Source IP address of the VPN server's Internet interface, subnet mask of 255.255.255.255, and TCP destination port of 1723.

  This filter is required only when the VPN server is acting as a VPN client (a calling router) in a router-to-router VPN connection. TCP [established] traffic is sent only when the VPN server initiated the TCP connection.

For more information, see Add PPTP Filters.

**Packet filters for Layer Two Tunneling Protocol over Internet Protocol security (L2TP/IPSec)**
Configure the following input filters with the filter action set to **Drop all packets except those that meet the criteria below**:

- Destination IP address of the VPN server's Internet interface, subnet mask of 255.255.255.255, and UDP destination port of 500.

  This filter allows Internet Key Exchange (IKE) traffic to the VPN server.

- Destination IP address of the VPN server's Internet interface, subnet mask of 255.255.255.255, and UDP destination port of 1701.

  This filter allows L2TP traffic from the VPN client to the VPN server.

- Destination IP address of the VPN server's Internet interface, subnet mask of 255.255.255.255, and UDP destination port of 4500.

  This filter allows IPSec network address translator traversal (NAT-T) traffic.

Configure the following output filters with the filter action set to **Drop all packets except those that meet the criteria below**:

- Source IP address of the VPN server's Internet interface, subnet mask of 255.255.255.255, and UDP source port of 500.

  This filter allows IKE traffic from the VPN server.

- Source IP address of the VPN server's Internet interface, subnet mask of 255.255.255.255, and UDP source port of 1701.

  This filter allows L2TP traffic from the VPN server to the VPN client.

- Source IP address of the VPN server's Internet interface, subnet mask of 255.255.255.255, and UDP source port of 4500.

  This filter allows IPSec NAT-T traffic.

For more information, see Add Add L2TP over IPSec Filters.

There are no filters required for Encapsulating Security Payload (ESP) traffic at the IP protocol of 50. The ESP header is removed by the IPSec components before the L2TP packet is passed to Routing and Remote Access.

**Important**

- An IPSec NAT-T deployment for Windows that includes VPN servers that are located behind network address translators is not recommended. When a server is behind a network address translator, and the server uses IPSec NAT-T, unintended behavior might occur because of the way network address translators translate network traffic.

**VPN server behind the firewall**
In a more common configuration, the firewall is attached to the Internet, and the VPN server is an intranet resource that is attached to the Perimeter Network. The VPN server has an interface on both the perimeter network and the intranet. In this scenario, the firewall must be configured with input and output filters on its Internet interface that allow tunnel maintenance traffic and tunneled data to pass to the VPN server. Additional filters can allow traffic to pass to Web, FTP, and other types of servers on the perimeter network. For an additional layer of security, the VPN server can also be configured with PPTP or L2TP/IPSec packet filters on its perimeter network interface.

Because the firewall does not have the encryption keys for each VPN connection, it can filter only on the plaintext headers of the tunneled data. In other words, all tunneled data passes through the firewall. This is not a security concern, however, because the VPN connection requires an authentication process that prevents unauthorized access beyond the VPN server.

The following illustration shows the VPN server behind the firewall on the perimeter network.

For both the Internet and perimeter network interfaces on the firewall, configure the following input and output filters using the firewall's configuration software:

**Packet filters for PPTP**
Separate input and output packet filters can be configured on the Internet interface and the perimeter network interface.

**Filters on the Internet interface**
Configure the following input packet filters on the Internet interface of the firewall to allow the following types of traffic:

- Destination IP address of the VPN server's perimeter network interface and TCP destination port of 1723 (0x6BB).

  This filter allows PPTP tunnel maintenance traffic from the PPTP client to the PPTP server.

- Destination IP address of the VPN server's perimeter network interface and IP Protocol ID of 47 (0x2F).

  This filter allows PPTP tunneled data from the PPTP client to the PPTP server.

- Destination IP address of the VPN server's perimeter network interface and TCP source port of 1723 (0x6BB).

  This filter is required only when the VPN server is acting as a VPN client (a calling router) in a router-to-router VPN connection. This filter should be used only in conjunction with the PPTP packet filters described in VPN server in front of the firewall and configured on the VPN server's perimeter network interface. By allowing all traffic to the VPN server from TCP port 1723, there exists the possibility of network attacks from sources on the Internet that use this port.

Configure the following output filters on the Internet interface of the firewall to allow the following types of traffic:

- Source IP address of the VPN server's perimeter network interface and TCP source port of 1723 (0x6BB).

  This filter allows PPTP tunnel maintenance traffic from the VPN server to the VPN client.

- Source IP address of the VPN server's perimeter network interface and IP Protocol ID of 47 (0x2F).

  This filter allows PPTP tunneled data from the VPN server to the VPN client.

- Source IP address of the VPN server's perimeter network interface and TCP destination port of 1723 (0x6BB).

  This filter is required only when the VPN server is acting as a VPN client (a calling router) in a router-to-router VPN connection. This filter should be used only in conjunction with the PPTP packet filters described in VPN server in front of the firewall and configured on the VPN server's perimeter network interface. By allowing all traffic from the VPN server

to TCP port 1723, there exists the possibility of network attacks from sources on the Internet using this port.

**Filters on the perimeter network interface**

Configure the following input filters on the perimeter network interface of the firewall to allow the following types of traffic:

- Source IP address of the VPN server's perimeter network interface and TCP source port of 1723 (0x6BB).

  This filter allows PPTP tunnel maintenance traffic from the VPN server to the VPN client.

- Source IP address of the VPN server's perimeter network interface and IP Protocol ID of 47 (0x2F).

  This filter allows PPTP tunneled data from the VPN server to the VPN client.

- Source IP address of the VPN server's perimeter network interface and TCP destination port of 1723 (0x6BB).

  This filter is required only when the VPN server is acting as a VPN client (a calling router) in a router-to-router VPN connection. This filter should be used only in conjunction with the PPTP packet filters described in VPN server in front of the firewall and configured on the VPN server's perimeter network interface. By allowing all traffic from the VPN server to TCP port 1723, there exists the possibility of network attacks from sources on the Internet using this port.

Configure the following output packet filters on the perimeter network interface of the firewall to allow the following types of traffic:

- Destination IP address of the VPN server's perimeter network interface and TCP destination port of 1723 (0x6BB).

  This filter allows PPTP tunnel maintenance traffic from the PPTP client to the PPTP server.

- Destination IP address of the VPN server's perimeter network interface and IP Protocol ID of 47 (0x2F).

  This filter allows PPTP tunneled data from the PPTP client to the PPTP server.

- Destination IP address of the VPN server's perimeter network interface and TCP source port of 1723 (0x6BB).

  This filter is required only when the VPN server is acting as a VPN client (a calling router) in a router-to-router VPN connection. This filter should be used only in conjunction with the PPTP packet filters described in VPN server in front of the firewall and configured on the VPN server's perimeter network interface. By allowing all traffic to the VPN server from TCP port 1723, there exists the possibility of network attacks from sources on the Internet using this port.

**Packet filters for L2TP/IPSec**

Separate input and output packet filters can be configured on the Internet interface and the perimeter network interface.

**Filters on the Internet interface**

Configure the following input packet filters on the Internet interface of the firewall to allow the following types of traffic:

- Destination IP address of the VPN server's perimeter network interface and UDP destination port of 500 (0x1F4).

  This filter allows IKE traffic to the VPN server.

- Destination IP address of the VPN server's perimeter network interface and UDP destination port of 4500 (0x1194).

  This filter allows IPSec NAT-T traffic to the VPN server.

- Destination IP address of the VPN server's perimeter network interface and IP Protocol ID of 50 (0x32).

  This filter allows IPSec ESP traffic from the VPN client to the VPN server.

Configure the following output packet filters on the Internet interface of the firewall to allow the following types of traffic:

- Source IP address of the VPN server's perimeter network interface and UDP source port of 500 (0x1F4).

  This filter allows IKE traffic from the VPN server.

- Source IP address of the VPN server's perimeter network interface and UDP source port of 4500.

  This filter allows IPSec NAT-T traffic from the VPN server.

- Source IP address of the VPN server's perimeter network interface and IP Protocol ID of 50 (0x32).

  This filter allows IPSec ESP traffic from the VPN server to the VPN client.

There are no filters required for L2TP traffic at the UDP port of 1701. All L2TP traffic at the firewall, including tunnel maintenance and tunneled data, is encrypted as an IPSec ESP payload.

**Important**

- An IPSec NAT-T deployment for Windows that includes VPN servers that are located behind network address translators is not recommended. When a server is behind a network address translator, and the server uses IPSec NAT-T, unintended behavior might occur because of the way network address translators translate network traffic.

**Filters on the perimeter network interface**

Configure the following input packet filters on the perimeter network interface of the firewall to allow the following types of traffic:

- Source IP address of the VPN server's perimeter network interface and UDP source port of 500 (0x1F4).

  This filter allows IKE traffic from the VPN server.

- Source IP address of the VPN server's perimeter network interface and UDP source port of 4500.

  This filter allows IPSec NAT-T traffic from the VPN server.

- Source IP address of the VPN server's perimeter network interface and IP Protocol ID of 50 (0x32).

  This filter allows IPSec ESP traffic from the VPN server to the VPN client.

Configure the following output packet filters on the perimeter network interface of the firewall to allow the following types of traffic:

- Destination IP address of the VPN server's perimeter network interface and UDP destination port of 500 (0x1F4).

  This filter allows IKE traffic to the VPN server.

- Destination IP address of the VPN server's perimeter network interface and UDP destination port of 4500 (0x1194).

  This filter allows IPSec NAT-T traffic to the VPN server.

- Destination IP address of the VPN server's perimeter network interface and IP Protocol ID of 50 (0x32).

  This filter allows IPSec ESP traffic from the VPN client to the VPN server.

There are no filters required for L2TP traffic at the UDP port of 1701. All L2TP traffic at the firewall, including tunnel maintenance and tunneled data, is encrypted as an IPSec ESP payload.

**Important**

- An IPSec NAT-T deployment for Windows that includes VPN servers that are located behind network address translators

is not recommended. When a server is behind a network address translator, and the server uses IPSec NAT-T, unintended behavior might occur because of the way network address translators translate network traffic.

# VPN servers and Microsoft ISA Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**VPN servers and Microsoft ISA Server**
Microsoft Internet Security and Acceleration (ISA) Server can be installed on a virtual private network (VPN) server running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition, and provides the capabilities of both the Windows Server 2003 Routing and Remote Access service and the ISA Server.

When ISA Server is installed, all of the packet filters that are configured on the VPN server are ignored by ISA. ISA creates its own packet filters when it is configured to allow VPN connections. After ISA is installed, use ISA Administrator, instead of Routing and Remote Access, to configure additional filters.

ISA Server includes two wizards that you can use to connect two ISA server computers with a router-to-router VPN connection:

- Local ISA VPN Wizard

  This wizard is used to create a .vpc (VPN configuration) file.

- Remote ISA VPN Wizard

  This wizard is used to read the .vpc file. After the servers have been configured, both ISA servers can initiate and accept VPN connections.

For more information about ISA Server packet filtering capabilities and support for VPNs, see Microsoft Internet Security and Acceleration (ISA) Server online Help.

# Network access authentication and certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network access authentication and certificates**
This topic contains the following sections:

- Overview
- Certificate requirements for EAP
- Computer authentication by IPSec
- Certificate-based authentication and wireless clients
- Certificate enrollment methods and domain membership
- Choosing a certificate enrollment method
- CA Web enrollment services

**Overview**
Certificates are used for network access authentication because they provide strong security for authenticating users and computers and eliminate the need for less secure password-based authentication methods. This topic describes how Internet Authentication Service (IAS) and virtual private network (VPN) servers use Extensible Authentication protocol-Transport Level Security (EAP-TLS), protected Extensible Authentication protocol (PEAP), or Internet protocol security (IPSec) to perform certificate-based authentication for many types of network access, including VPN and wireless connections. Additionally, this topic describes certificate enrollment methods to help you determine the best certificate enrollment method for your use.

When discussing authentication, a server is defined as a VPN or IAS server that is a TLS end point. You can configure VPN servers to perform network access authentication without IAS, or you can use IAS for authentication when you have multiple Remote Access Dial-In User Service (RADIUS) clients (such as VPN servers and wireless access points) on your network.

Two authentication methods use certificates: Extensible Authentication protocol-Transport Level Security (EAP-TLS) and protected Extensible Authentication protocol (PEAP). Both methods always use certificates for server authentication. Depending on the authentication type configured with the authentication method, certificates might be used for user authentication and client authentication. For more information, see EAP and PEAP.

The use of certificates for authentication of VPN connections is the strongest form of authentication available with the Windows Server 2003 family. You must use certificate-based authentication for VPN connections based on Layer Two Tunneling protocol over Internet protocol security (L2TP/IPSec). Point-To-Point Tunneling protocol (PPTP) connections do not require certificates, although you can configure PPTP connections to use certificates for computer authentication when you use EAP-TLS as the authentication method. For wireless clients (computing devices with wireless network adapters, such as your portable computer or personal digital assistant), PEAP with EAP-TLS and smart cards or certificates is the recommended authentication method. For more information, see Layer Two Tunneling Protocol, Point-to-Point Tunneling Protocol, and Wireless Networking.

**Notes**

- During authentication attempts for PPTP connections, computer authentication does not occur. When EAP-TLS is used as the authentication method with PPTP connections, user authentication is performed with a certificate from the certificate store on the local computer or from a smart card.

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

In order to deploy certificates to users and computers, you must first do the following:

- Design a public key infrastructure (PKI).
- Deploy a certification authority (CA) using Certificate Services.
- Design and publish one or more certificates using Certificate Templates, which is installed with Certificate Services.
- Select one or more distribution methods (also known as certificate enrollment methods) to install the certificates on computers and distribute them to users.

### Notes

- This topic assumes that you have designed and deployed a PKI according to the guidelines provided in Certificate Services Best practices. For more information, see Public Key Infrastructure.
- PEAP is not supported for VPN or dial-up connections.

#### Example certificate deployments

- Remote access VPN connections

  L2TP/IPSec or PPTP connections between VPN server and VPN client with EAP-TLS used as the authentication method. IPSec uses computer certificates between the client and the server for authentication, and EAP-TLS uses a certificate (from a smart card or the user's local certificate store) for user authentication. The IAS or VPN server certificate must contain the server Authentication purpose, and the client computer or user certificate must contain the Client Authentication purpose in the Enhanced Key Usage (EKU) extensions of the certificate.

  For more information, see L2TP-based remote access VPN deployment and PPTP-based remote access VPN deployment.

- Router-to-router VPN connections

  L2TP/IPSec connections for dedicated or dial-on-demand connections between servers with EAP-TLS as the authentication method. Both servers must have certificates that contain the server Authentication and Client Authentication purposes in EKU extensions.

  For more information, see Deploying Router-to-Router VPNs.

- IEEE 802.1X wireless or switch clients

  PEAP-EAP-MS-CHAPv2 is configured as the authentication method, and the **Validate server certificate** option is enabled on the client computers. The IAS server certificate EKU extensions contain the server Authentication purpose, and the certificate is used to identify the server to the client. User authentication is accomplished with user name and password.

  For more information, see Enable smart card or other certificate authentication and Configuring wireless network settings on client computers.

- IEEE 802.1X wireless or switch clients

  L2TP/IPSec is used, and EAP-TLS with certificates is configured as the authentication method. The IAS server certificate contains the server Authentication purpose in EKU extensions to identify itself to the client, and the client uses a certificate (from a smart card or the user's local certificate store) to identify itself to the IAS server. (The wireless access points are configured as RADIUS clients on the IAS server, which is the EAP authenticator.)

**Note**

- User authentication and network access authorization are performed by either the VPN server or a RADIUS server, such as Internet Authentication Service (IAS), as configured on the VPN gateway. For more information, see Use RADIUS authentication.

**Certificate requirements for EAP**

When you use EAP with a strong EAP type (such as TLS with smart cards or certificates), both the client and the server use certificates to verify their identities to each other. Certificates must meet specific requirements in order to allow the server and the client to use them for successful authentication.

One such requirement is that the certificate is configured with one or more purposes in EKU extensions that correlate to the certificate use. For example, a certificate used for the authentication of a client to a server must be configured with the Client Authentication purpose. Similarly, a certificate used for the authentication of a server must be configured with the server Authentication purpose. When certificates are used for authentication, the authenticator examines the client certificate, seeking the correct purpose object identifier in EKU extensions. For example, the object identifier for the Client Authentication purpose is 1.3.6.1.5.5.7.3.2.

Certificate Templates allow customization of the certificates issued by Certificate Services, including both how certificates are issued and what they contain, including their purposes. In Certificate Templates, you can use a default template, such as the Computer template, to define the template that the CA uses to assign certificates to computers. You can also create a certificate template and assign purposes in EKU extensions to the certificate. By default, the Computer template includes the Client Authentication purpose and the server Authentication purpose in EKU extensions.

The certificate template that you create can include any purpose for which the certificate will be used. For example, if you use smart cards for authentication, you can include the Smart Card Logon purpose in addition to the Client Authentication purpose.

When using IAS, you can configure IAS to check certificate purposes before granting network authorization. IAS can check additional EKUs and Issuance Policy purposes (also known as Certificate Policies).

Some non-Microsoft CA software might contain a purpose named All, which represents all possible purposes. This is indicated by a blank (or null) EKU extension. Although All means all possible purposes, the All purpose cannot be substituted for the Client Authentication purpose, the server authentication purpose, or any other purpose related to network access authentication.

For more information, see Certificate Templates and Manage Certificate Templates for an Enterprise Certification Authority.

You can view certificates and their purposes by using the Certificates console to open the certificate store. Certificate stores can be viewed in Logical Store mode or in Purpose mode. For information about how to view certificate purposes, see Display certificate stores in Purpose mode.

**Minimum certificate requirements**

All certificates that are used for network access authentication must meet the requirements for X.509 certificates and work for connections that use Secure Sockets Layer-Transport Level Security (SSL/TLS). After this minimum requirement is met, both client and server certificates have additional requirements.

**Client certificate requirements**

With EAP-TLS or PEAP-EAP-TLS, the server accepts the client authentication attempt when the certificate meets the following requirements:

- The client certificate is issued by an enterprise CA or mapped to a user or computer account in Active Directory.

- The user or computer certificate on the client chains to a trusted root CA, includes the Client Authentication purpose in EKU extensions (the object identifier for Client Authentication is 1.3.6.1.5.5.7.3.2), and fails neither the checks that are performed by CryptoAPI and specified in the remote access policy nor the Certificate object identifier checks that are

specified in IAS remote access policy.

- The 802.1X client does not use registry-based certificates that are either smart card-logon or password-protected certificates.

- For user certificates, the Subject Alternative Name (SubjectAltName) extension in the certificate contains the user principal name (UPN). To configure the UPN name in a certificate template:

1. Open Certificate Templates.

2. In the details pane, right-click the certificate template that you want to change, and then click **properties**.

3. Click the **Subject Name** tab, and then click **Build from this Active Directory information**.

4. In **Include this information in alternate subject name**, select **User principal name (UPN)**.

- For computer certificates, the Subject Alternative Name (SubjectAltName) extension in the certificate must contain the client's fully qualified domain name (FQDN), which is also called the DNS name. To configure this name in the certificate template:

1. Open Certificate Templates.

2. In the details pane, right-click the certificate template that you want to change, and then click **properties**.

3. Click the **Subject Name** tab, and then click **Build from this Active Directory information**.

4. In **Include this information in alternate subject name**, select **DNS name**.

With PEAP-EAP-TLS and EAP-TLS, clients display a list of all installed certificates in the Certificates snap-in, with the following exceptions:

- Wireless clients do not display registry-based and smart card-logon certificates.

- Wireless clients and VPN clients do not display password-protected certificates.

- Certificates that do not contain the Client Authentication purpose in EKU extensions are not displayed.

**Server certificate requirements**

Clients can be configured to validate server certificates by using the **Validate server certificate** option. With PEAP-EAP-MS-CHAPv2, PEAP-EAP-TLS, or EAP-TLS as the authentication method, the client accepts the server's authentication attempt when the certificate meets the following requirements:

- The Subject name contains a value. If you issue a certificate to your IAS server that has a blank Subject, the certificate is not available to authenticate your IAS server. To configure the certificate template with a Subject name:

1. Open Certificate Templates.

2. In the details pane, right-click the certificate template that you want to change, and then click **properties**.

3. Click the **Subject Name** tab, and then click **Build from this Active Directory information**.

4. In **Subject name format**, select a value other than **None**.

- The computer certificate on the server chains to a trusted root CA and does not fail any of the checks that are performed by CryptoAPI and specified in the remote access policy.

- The IAS or VPN server computer certificate is configured with the server Authentication purpose in EKU extensions (the object identifier for server Authentication is 1.3.6.1.5.5.7.3.1).

- The server certificate is configured with a required cryptographic service provider (CSP) value of **Microsoft RSA SChannel Cryptographic provider**. To configure the required CSP:

1. Open Certificate Templates.

2. In the details pane, right-click the certificate template that you want to change, and then click **properties**.

3. Click the **Request Handling** tab, and then click **CSPs**.

4. In **CSP Selection**, select **Requests must use one of the following CSPs**.

5. In **CSPs**, select the **Microsoft RSA SChannel Cryptographic provider** checkbox. Clear all other checkboxes in **CSPs**.

- The Subject Alternative Name (SubjectAltName) extension, if used, must contain the DNS name of the server. To configure the certificate template with the DNS name of the enrolling server:

1. Open Certificate Templates.

2. In the details pane, right-click the certificate template that you want to change, and then click **properties**.

3. Click the **Subject Name** tab, and then click **Build from this Active Directory information**.

4. In **Include this information in alternate subject name**, select **DNS name**.

With PEAP and EAP-TLS, servers display a list of all installed certificates in the computer's certificate store, with the following exceptions:

- Certificates that do not contain the server Authentication purpose in EKU extensions are not displayed.

- Certificates that do not contain a Subject name are not displayed.

- Servers do not display registry-based and smart card-logon certificates.

**Note**

- You can designate which certificate is used by the IAS or VPN server in the remote access policy profile. When you configure EAP and PEAP authentication methods that require a certificate for server authentication and you do not select a specific certificate in the **Smart Card or other Certificate properties** dialog box, the IAS or VPN server automatically selects a certificate from the computer certificate store. If the server obtains a newer certificate, it uses the new certificate. This might cause the IAS or VPN server to use a certificate that is not correctly configured for authentication, causing authentication to fail as the result. To prevent this, always select a server certificate when configuring PEAP and EAP authentication methods that require one. For more information, see Configure PEAP and EAP methods.

**Computer authentication by IPSec**

Computer authentication is first performed during L2TP/IPSec connection attempts between remote access client and server. When a secure channel is established between the client and the server, the user authentication and authorization attempt proceeds.

Computer authentication by IPSec is performed using preshared keys or computer certificates. The recommended method of authentication is the use of a PKI and certificates. If certificates are used, a computer certificate is required to establish IPSec trust during the Internet Key Exchange (IKE) negotiation in L2TP/IPSec-based VPN connections.

In order for a VPN server running Windows Server 2003 and a VPN client running Windows 2000 or Windows XP to establish trust for an L2TP/IPSec VPN connection, both computers must have a computer certificate that was issued by the same trusted enterprise root CA. When both computers have and exchange certificates that were issued by the trusted root CA during IPSec negotiation, they extend trust to each other, and the security association is made.

**How VPN servers use certificates**

When an L2TP/IPSec VPN connection is attempted between VPN client and server, computer authentication fails if the VPN client certificate (from a smart card or the certificate store on the local computer) is not configured with the Client Authentication purpose in EKU extensions, and the VPN server certificate is not configured with the server Authentication purpose in EKU extensions. IPSec checks the EKU extensions for the client certificate to determine whether the Client Authentication purpose object identifier is present. When the EKU extension includes the Client Authentication purpose object identifier, IPSec can use the certificate for authentication. Similarly, the client checks the VPN server certificate for the server Authentication purpose object identifier in EKU extensions.

Although VPN servers that end connections for remote users need a certificate configured with the server Authentication purpose in EKU extensions only, a VPN servers that is used as an end point for a VPN connection with another VPN server originates (as a client) and ends (as a server) VPN connections. For this reason, the certificate on these servers must contain both the server Authentication purpose and the Client Authentication purpose in EKU extensions. In addition, due to the way in which automatic certificate selection functions, both purposes (server Authentication and Client Authentication) must be contained in the same certificate.

Automatic certificate selection can provide IPSec with any certificate in the certificate store that chains to the trusted enterprise root CA, regardless of the purposes contained in the certificate. If two certificates are installed on the server--one that contains the Client Authentication purpose and one that contains the server Authentication purpose--it is possible that automatic certificate selection could use the wrong certificate for authentication. For example, the certificate with the Client Authentication purpose might be required, but the certificate provided through automatic certificate selection contains the server Authentication purpose. In this and similar instances, computer authentication fails.

**Certificate-based authentication and wireless clients**

IEEE 802.1X authentication provides authenticated access to 802.11 wireless networks and to wired Ethernet networks. 802.1X provides support for secure EAP types, such as TLS with smart cards or certificates. You can configure 802.1X with EAP-TLS in a variety of ways. If the **Validate server certificate** option is configured on the Windows XP Professional client, the client authenticates the server by using its certificate. Client computer and user authentication can be accomplished using certificates from the client certificate store or a smart card, providing mutual authentication.

With wireless clients, PEAP-EAP-MS-CHAPv2 can be used as the authentication method. PEAP-EAP-MS-CHAPv2 is a password-based user authentication method that uses TLS with server certificates. During PEAP-EAP-MS-CHAPv2 authentication, the IAS or RADIUS server supplies a certificate to validate its identity to the client (if the **Validate server certificate** option is configured on the Windows XP Professional client). Client computer and user authentication is accomplished with passwords, which eliminates some of the difficulty of deploying certificates to wireless client computers.

802.1X wireless and switch clients can also use PEAP-EAP-TLS, which provides strong security. PEAP-EAP-TLS uses a public key infrastructure (PKI) with certificates used for server authentication and either smart cards or certificates for client computer and user authentication. For more information, see PEAP.

For more information about 802.1X authentication, see Understanding 802.1X authentication for wireless networks.

**Certificate enrollment methods and domain membership**

The domain membership of computers for which you want to enroll certificates affects the certificate enrollment method that you can choose. Certificates for domain member computers can be enrolled automatically (also known as auto-enrollment), while an administrator must enroll certificates for non-domain member computers using the Web or a floppy disk. The certificate enrollment method for non-domain member computers is known as a trust bootstrap process, through which certificates are created and then manually requested or distributed securely by administrators, to build common trust.

**Domain member certificate enrollment**

If your VPN server, IAS server, or client running Windows 2000 or Windows XP is a member of a domain running Windows Server 2003 and Active Directory, you can configure the auto-enrollment of computer and user certificates. After auto-enrollment is configured and enabled, all domain member computers receive computer certificates when Group Policy is refreshed next, whether the refresh is triggered manually with the **gpupdate** command, or by logging on to the domain.

If your computer is a member of a domain where Active Directory is not installed, you can install computer certificates

manually by requesting them through Certificates.

For more information, see Computer certificates for L2TP/IPSec VPN connections.

**Note**

- Computers running Windows 2000 can auto-enroll computer certificates only.

**Non-domain member certificate enrollment**

Certificate enrollment for computers that are not domain members cannot be done with auto-enrollment. When a computer is joined to a domain, a trust is established that allows auto-enrollment to occur without administrator intervention. When a computer is not joined to a domain, trust is not established and a certificate is not issued. Trust must be established using one of the following methods:

- An administrator (who is, by definition, trusted) must request a computer or user certificate using the CA Web enrollment tool.

- An administrator must save a computer or user certificate to a floppy disk and install it on the non-domain member computer. Or, when the computer is not accessible to the administrator (for example, a home computer connecting to an organization network with an L2TP/IPSec VPN connection), a domain user whom the administrator trusts can install the certificate.

- An administrator can distribute a user certificate on a smart card (computer certificates are not distributed on smart cards).

Many network infrastructures contain VPN and IAS servers that are not domain members. For example, a VPN server in a perimeter network might not be a domain member for security purposes. In this case, a computer certificate with the server Authentication purpose contained in the EKU extensions must be installed on the non-domain member VPN server before it can successfully negotiate L2TP/IPSec-based VPN connections with clients. Note that if the non-domain member VPN server is used as an end point for a VPN connection with another VPN server, EKU extensions must contain both the server Authentication and Client Authentication purposes.

**Choosing a certificate enrollment method**

If you are running an enterprise certification authority (CA) on a computer running Windows Server 2003, Standard Edition, you can use the following table to determine the best certificate enrollment method for your requirements:

| Object and domain membership | Certificate template | Certificate purposes | Preferred certificate enrollment method | Alternate certificate enrollment method |
|---|---|---|---|---|
| VPN or IAS server, domain member | Computer | Server Authentication | Auto-enrollment | Request a certificate with the Certificates snap-in |
| VPN server with site-to-site connection, domain member | Computer | Server Authentication and Client Authentication | Auto-enrollment | Request a certificate with the Certificates snap-in |
| Windows XP client, domain member | Computer | Client Authentication | Auto-enrollment | Request a certificate with the Certificates snap-in |
| VPN or IAS server, non-domain member | Computer | Server Authentication | CA Web enrollment tool | Install from a floppy disk |
| VPN server with site-to-site connection, non-domain member | Computer | Server Authentication and Client Authentication | CA Web enrollment tool | Install from a floppy disk |
| Windows XP client, non-domain member | Computer | Client Authentication | CA Web enrollment tool | Install from a floppy disk |
| User, domain user | User | Client Authentication | Auto-enrollment | Use a smart card or the CA Web enrollment tool |

If your certification authority is on a computer running one of the following operating systems, the RAS and IAS servers and Workstation Authentication templates are available for use:

- Windows Server 2003, Enterprise Edition
- Windows Server 2003, Datacenter Edition
- Windows Server 2003, Enterprise Edition for Itanium-based Systems
- Windows Server 2003, Datacenter Edition for Itanium-based Systems
- Windows Server 2003, Enterprise x64 Edition
- Windows Server 2003, Datacenter x64 Edition

Use the following table to determine when to use these templates.

| Object and domain membership | Certificate template | Certificate purpose | Preferred certificate enrollment method | Alternate certificate enrollment method |
|---|---|---|---|---|
| VPN or IAS server, domain member | RAS and IAS server | Server Authentication | Auto-enrollment | Request a certificate with the Certificates snap-in |
| Windows XP client, domain member | Workstation Authentication | Client Authentication | Auto-enrollment | Request a certificate with the Certificates snap-in |
| VPN or IAS server, non-domain member | RAS and IAS server | Server Authentication | CA Web enrollment tool | Install from a floppy disk |
| Windows XP client, non-domain member | Workstation Authentication | Client Authentication | CA Web enrollment tool | Install from a floppy disk |

**Important**

If your server running IAS is not a domain controller but is a member of a domain with a Windows 2000 mixed functional level, you must add the server to the access control list (ACL) of the **RAS and IAS server** certificate template. You must also configure the correct permissions for autoenrollment. There are different procedures for adding single servers and groups of servers to the ACL.

To add an individual server to the ACL for the **RAS and IAS server** certificate template:

In Certificate Templates, select the template **RAS and IAS server**, and then add the IAS server to the template **Security** properties. For more information, see Allow subjects to request a certificate that is based on the template. After you have added your IAS server to the ACL, grant **Read**, **Enroll**, and **Autoenroll** permissions.

To manage a group of servers, add the servers to a new global or universal group, and then add the group to the ACL of the certificate template:

1. In Active Directory Users and Computers, create a new global or universal group for IAS servers. For more information, see Create a new group. Next, add to the group all computers that are IAS servers, are not domain controllers, and are members of a domain with a Windows 2000 mixed functional level. For more information, see Add a member to a group.

2. In Certificate Templates, select the **RAS and IAS server** template, and then add the group you created to the template **Security** properties by completing the steps in Allow subjects to request a certificate that is based on the template. After you have added your new group, grant **Read**, **Enroll**, and **Autoenroll** permissions.

For more information, see Domain and forest functionality.

**CA Web enrollment services**

A set of CA Web pages is provided with Certificate Services in the Windows Server 2003 family. These Web enrollment pages allow you to connect to the CA through a Web browser and perform common tasks, such as requesting certificates from a CA.

For more information, see Certification authority Web enrollment services and Set up certification authority Web enrollment support.

After your PKI has been designed and deployed and you are assigned the required permissions on the certificate templates, you can request certificates for computers by using the CA Web enrollment pages. You can request a certificate for a non-domain member computer using the CA Web enrollment tool by completing the following steps. You must be an administrator on the local computer to complete these steps.

**Install a computer certificate on the local computer**

1. Use your Web browser to log onto the Web enrollment tool at **http://***serverName***/certsrv**, where *serverName* is the name of the server hosting the CA, the CA Web pages, or both. Click **Request a certificate**.

2. In **Request a certificate**, click **Advanced Certificate Request**.

3. In **Advanced Certificate Request**, click **Create and submit a request to this CA**. A Web form that contains the sections **Certificate Template**, **Key Options**, and **Additional Options** becomes available. Select the following:

   - **Certificate template:** Administrator
   - **Key options:** Create new key set
   - **CSP:** Microsoft Enhanced Cryptographic provider v1.0
   - **Key usage:** Exchange
   - **Key size:** 1024
   - **Automatic key container name:** Selected
   - **Mark keys as exportable:** Selected
   - **Use local machine store:** Selected
   - **Request format:** PKCS 10
   - **Hash:** SHA-1
   - **Friendly name:** VPN server name

4. Click **Submit**.

5. Click **Install this certificate**

   The certificate you requested is installed on your local computer.

**Save a computer certificate to floppy disk**

1. Use your Web browser to log onto the Web enrollment tool at **http://***serverName***/certsrv**, where *serverName* is the name of the server hosting the CA, the CA Web pages, or both. Click **Request a certificate**.

2. In **Request a certificate**, click **Advanced Certificate Request**.

3. In **Advanced Certificate Request**, click **Create and submit a request to this CA**. A Web form that contains the sections **Certificate Template**, **Key Options**, and **Additional Options** becomes available. Select the following:

   - **Certificate template:** Administrator

- **Key options:** Create new key set
- **CSP:** Microsoft Enhanced Cryptographic provider v1.0
- **Key usage:** Exchange
- **Key size:** 1024
- **Automatic key container name:** Selected
- **Mark keys as exportable:** Selected
- **Export keys to file:** Selected
- **Full path name:** The path location where you want to save the file and the file name (for example, *\\serverName\ShareName\FileName.pvk*.).
- **Request format:** PKCS 10
- **Hash:** SHA-1
- **Friendly name:** VPN server name

4. Click **Submit**.
5. Create and confirm your private key password.
6. In **Certificate Issued**, select **DER encoded** and **Download certificate chain**.
7. Insert a floppy disk in your disk drive.
8. When prompted by your browser, select **Save this file to disk**, and then click **OK**.
9. Browse to your floppy drive, and then click **OK**.

   The certificate you requested is downloaded and saved to floppy disk.

For more information, see Submit an advanced certificate request via the Web.

For information about installing a certificate from floppy to the certificate store of a local computer, see Import a certificate.

**Note**

- If you have issued a certificate to your IAS server that has a blank Subject, the certificate is not available to authenticate your IAS server. To change this, you can use Certificate Templates to create a new certificate for enrollment on your IAS server. In the certificate properties, on the **Subject Name** tab, in **Subject name format**, select a value other than **None**.

# Understanding VPN Tunneling Protocols

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**VPN tunneling protocols**
This section covers:

- Point-to-Point Tunneling Protocol
- Layer Two Tunneling Protocol

# Point-to-Point Tunneling Protocol

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Point-to-Point Tunneling Protocol**
Point-to-Point Tunneling Protocol (PPTP) is a tunneling protocol first supported in Windows NT 4.0 and Windows 98. PPTP is an extension of Point-to-Point Protocol (PPP) and leverages the authentication, compression, and encryption mechanisms of PPP. Client support for PPTP is built-in to the Windows XP remote access client.

VPN server support for PPTP is built in to members of the Windows Server 2003 family. PPTP is installed with the TCP/IP protocol. Depending on your choices when running the Routing and Remote Access Server Setup Wizard, PPTP is configured for five or 128 PPTP ports. For more information, see Checklist: Installing and configuring a PPTP server.

PPTP and Microsoft Point-to-Point Encryption (MPPE) provide the primary VPN services of encapsulation and encryption of private data.

**Encapsulation**
A PPP frame (an IP, IPX, or Appletalk datagram) is wrapped with a Generic Routing Encapsulation (GRE) header and an IP header. In the IP header is the source and destination IP address that correspond to the VPN client and VPN server.

The following illustration shows PPTP encapsulation for a PPP frame.

**Encryption**
The PPP frame is encrypted with Microsoft Point-to-Point Encryption (MPPE) by using encryption keys generated from the MS-CHAP, MS-CHAP v2, or EAP-TLS authentication process. Virtual private networking clients must use the MS-CHAP, MS-CHAP v2, or EAP-TLS authentication protocol in order for the payloads of PPP frames to be encrypted. PPTP is taking advantage of the underlying PPP encryption and encapsulating a previously encrypted PPP frame.

For more information on deploying PPTP-based VPN connections, see Deploying Virtual Private Networks. For a PPTP-based VPN server checklist, see Checklist: Installing and configuring a PPTP server. For an example implementation of PPTP-based VPN connections, see Virtual Private Network Implementation Examples. For information on configuring PPTP-based VPN connections in a test lab, see Virtual Private Network Test Lab.

## Notes

- It is possible to have a nonencrypted PPTP connection where the PPP frame is sent in plaintext. However, a nonencrypted PPTP connection is not recommended for VPN connections over the Internet because communications of this type are not secure.

- The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# Layer Two Tunneling Protocol

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Layer Two Tunneling Protocol**
Layer Two Tunneling Protocol (L2TP) is an RFC-based tunneling protocol that is an industry standard and was first supported in the Windows 2000 client and server operating systems. Unlike PPTP, L2TP in servers running Windows Server 2003 does not utilize Microsoft Point-to-Point Encryption (MPPE) to encrypt Point-to-Point Protocol (PPP) datagrams. L2TP relies on Internet Protocol security (IPSec) for encryption services. The combination of L2TP and IPSec is known as L2TP/IPSec. L2TP/IPSec provides the primary virtual private network (VPN) services of encapsulation and encryption of private data.

Both L2TP and IPSec must be supported by both the VPN client and the VPN server. Client support for L2TP is built-in to the Windows XP remote access client, and VPN server support for L2TP is built in to members of the Windows Server 2003 family.

L2TP is installed with the TCP/IP protocol. Depending on your choices when running the Routing and Remote Access Server Setup Wizard, L2TP is configured for five or 128 L2TP ports. For more information, see Checklist: Installing and configuring an L2TP server.

For more information about IPSec, see Internet Protocol Security Overview.

**Encapsulation**
Encapsulation for L2TP/IPSec packets consists of two layers:

1. L2TP encapsulation

   A PPP frame (an IP datagram or an IPX datagram) is wrapped with an L2TP header and a UDP header.

2. IPSec encapsulation

   The resulting L2TP message is then wrapped with an IPSec Encapsulating Security Payload (ESP) header and trailer, an IPSec Authentication trailer that provides message integrity and authentication, and a final IP header. In the IP header is the source and destination IP address that corresponds to the VPN client and VPN server.

The following illustration shows L2TP and IPSec encapsulation for a PPP datagram.

**Encryption**
The L2TP message is encrypted with either Data Encryption Standard (DES) or Triple DES (3DES) by using encryption keys generated from the Internet Key Exchange (IKE) negotiation process.

For more information on deploying L2TP/IPSec VPN connections, see Deploying Virtual Private Networks. For configuration checklists, see VPN Checklists. For an example implementation of L2TP/IPSec VPN connections, see Virtual Private Network Implementation Examples. For information on configuring L2TP/IPSec VPN connections in a test lab, see Virtual Private Network Test Lab.

### Notes

- It is possible to have a nonencrypted L2TP connection where the PPP frame is sent in plaintext. However, a nonencrypted L2TP connection is not recommended for virtual private network connections over the Internet because communications of this type do not provide data confidentiality.

- The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# VPN Security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**VPN security**
This section covers:

- Authorization
- Authentication of VPN clients
- Data encryption between VPN server and client
- Using packet filtering

# Authorization

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authorization**
Virtual private network (VPN) connections are only accepted for those users and routers that have been authorized. In the Windows Server 2003 family, authorization of VPN connections is determined by the dial-in properties on the user account and remote access policies. For more information, see Remote Access Policies.

You do not need to create additional user accounts just for VPN connections. VPN servers use the user accounts specified in the available user accounts databases according to security in Windows Server 2003 operating systems.

**How security works at connection**
The following steps describe what happens during a connection attempt from a Point-to-Point Tunneling Protocol (PPTP)-based VPN client to a PPTP-based VPN server running Windows Server 2003:

1. The VPN client creates a PPTP tunnel with the VPN server.
2. The server sends a challenge to the client.
3. The client sends an encrypted response to the server.
4. The server checks the response against the user accounts database.
5. If the account is valid, and the connection is authorized, the server accepts the connection subject to the remote access policies and user account properties for the VPN client.

**Note**

- Steps 2 through 4 assume that the VPN client and the VPN server use the MS-CHAP or CHAP authentication protocols. The sending of client credentials may vary for other authentication protocols.

The following steps describe what happens during a connection attempt from a Layer Two Tunneling Protocol over Internet Protocol security (L2TP/IPSec)-based VPN client to an L2TP/IPSec-based VPN server running Windows Server 2003:

1. The IPSec security association is created by using computer certificates and the Internet Key Exchange (IKE) negotiation process.
2. The VPN client creates an L2TP tunnel with the VPN server.
3. The server sends a challenge to the client.
4. The client sends an encrypted response to the server.
5. The server checks the response against the user accounts database.
6. If the account is valid, and the connection is authorized, the server accepts the connection subject to the remote access policies and user account properties for the VPN client.

**Note**

- Steps 3 through 5 assume that the VPN client and the VPN server use the MS-CHAP v1 or CHAP authentication protocols. The sending of client credentials may vary for other authentication protocols.

**Security after the connection is made**

After passing authorization and authentication and connecting to the LAN, VPN clients for remote access VPN connections can only access network resources for which they have permission. Remote access VPN clients are subject to security in Windows Server 2003 operating systems--just as they are at the office. In other words, remote access VPN clients cannot do anything for which they lack sufficient rights, nor can they access resources for which they do not have permission.

The VPN server must authenticate the remote access VPN clients before they can access or generate traffic on the network. This authentication is a separate step from logging on to a Windows Server 2003 domain.

You use packet filters based on a remote access policy profile to restrict access for remote access VPN connections for IP traffic. With profile packet filters, you can configure the IP traffic that is allowed out of the connection (output filters) or into the connection (input filters) on an exception basis: either all remote access traffic except traffic specified by the filters or no traffic except traffic specified by the filters. Remote access policy profile filtering applies to all remote access connections that match the remote access policy.

For more information, see Elements of a remote access policy.

**Credential caching**

When remote access servers are configured to accept a user's domain credentials (user name and password) as the means for authenticating access requests, the credentials used for remote access are the same as those needed for access to network resources (such as file servers, application servers, and e-mail servers). Each time the remote access client tries to access a server on the network, the server challenges the client for its credentials to ensure that only authorized users can utilize server resources.

If the client computer is a member of the server's domain, then the client responds automatically with the user's logon credentials and gains access to resources for which the user has security permissions. If the client computer is not a member of the server's domain (for example, when the client is a non-domain member home computer), then the client does not have the appropriate logon credentials to meet the server's challenge; for each network resource the user attempts to access, the user is either prompted to enter credentials or is denied access.

When the client is running Windows XP or a Windows Server 2003 operating system, the credentials that are used for authentication to the remote access server are cached, or saved, by the client. If the non-domain member client attempts to access a domain server for which it has not previously established its credentials, the client responds to the server's challenge with the cached remote access credentials and gains access to resources for which the user has security permissions. Because the credentials are cached and sent automatically upon server challenge, users on non-domain member computers are not prompted for credentials every time they attempt to access network resources.

# Authentication of VPN clients

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authentication**

The authentication of virtual private network (VPN) clients by the VPN server is a vital security concern. Authentication takes place at two levels:

1. Computer-level authentication

   When Internet Protocol security (IPSec) is used for a Layer Two Tunneling Protocol (L2TP) over IPSec (L2TP/IPSec) VPN connection, computer-level authentication is performed through the exchange of computer certificates or a preshared key during the establishment of the IPSec security association. For more information, see Internet Key Exchange.

2. User-level authentication

   Before data can be sent over the Point-to-Point Tunneling Protocol (PPTP) or L2TP tunnel, the remote access client or demand-dial router that requests the VPN connection must be authenticated. User-level authentication occurs through the use of a Point-to-Point Protocol (PPP) authentication method. For more information, see Remote Access Authentication Methods.

For more information, see Network access authentication and certificates.

# Data encryption between VPN server and client

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Data encryption**

You must use data encryption to provide data confidentiality for the data that is sent between the VPN client and the VPN server across a shared or public network, where there is always a risk of unauthorized interception. You can configure the VPN server to force encrypted communications. Users who connect to that server must encrypt their data or a connection is not allowed. For VPN connections, the Windows Server 2003 family uses Microsoft Point-to-Point Encryption (MPPE) with the Point-to-Point Tunneling Protocol (PPTP) and Internet Protocol security (IPSec) encryption with the Layer Two Tunneling Protocol (L2TP).

Because data encryption is performed between the VPN client and VPN server, data encryption is not necessary on the communication link between a dial-up client and its Internet service provider (ISP). For example, a mobile user uses a dial-up connection to dial in to a local ISP. Once the Internet connection is made, the user creates a VPN connection with the corporate VPN server. If the VPN connection is encrypted, encryption is not needed on the dial-up connection between the user and the ISP.

### Notes

- Data encryption for Point-to-Point Protocol (PPP) or PPTP connections is available only if you use MS-CHAP, MS-CHAP v2, or EAP-TLS as the user-level authentication method. Data encryption for L2TP connections relies on IPSec computer-level authentication, which does not require any specific user-level authentication method.

- VPN data encryption does not provide end-to-end data encryption. End-to-end encryption is data encryption between the client application and the server hosting the resource or service that is accessed by the client application. To get end-to-end data encryption, you can use IPSec to create a secure connection *after* the VPN connection is made.

# Using packet filtering

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Packet filtering**

To secure the VPN server from sending or receiving any traffic on its Internet interface except VPN traffic, you need to use PPTP or L2TP/IPSec input and output filters on the interface that corresponds to the connection to the Internet. For router-to-router VPN connections, you must also configure the calling router (the VPN client) with PPTP or L2TP/IPSec packet filters, a step that is done automatically when you configure your remote access server using the Routing and Remote Access Setup Wizard.

Because, by default, IP routing is enabled on intranet interfaces and the interface that corresponds to the connection to the Internet, the computer running a Windows Server 2003 operating system forwards IP packets between the Internet and your intranet. This provides a direct, routed connection between your intranet and possible attackers on the Internet. To protect your intranet so that the only traffic that is forwarded to the intranet is the traffic that is sent and received over secure VPN connections, you must use PPTP or L2TP/IPSec filters on the Internet interface.

If you have a firewall, you must configure packet filters on the firewall to allow traffic between the VPN router and the routers on the Internet. For more information, see VPN servers and firewall configuration.

For more information about PPTP filters, see Add PPTP Filters. For more information about L2TP/IPSec filters, see Add L2TP over IPSec Filters.

# Deploying Virtual Private Networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying virtual private networks**

This section covers:

- Deploying VPNs for Remote Access
- Deploying Router-to-Router VPNs
- Deploying Certificate-based Authentication for VPN Connections

# Remote access VPN design considerations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote access VPN design considerations**

To prevent problems, you should consider the following design issues before you implement remote access VPN connections:

- Choosing between PPTP-based connections or L2TP/IPSec connections
- Installing certificates
- Configuring firewall packet filters
- Creating a remote access policy for remote access VPN connections
- Using an IAS server
- Using Connection Manager

For more information, see Remote access VPN connection.

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

**Choosing between PPTP-based connections or L2TP/IPSec connections**

A VPN server running Windows Server 2003 provides support for both Point-to-Point Tunneling Protocol (PPTP) and Layer Two Tunneling Protocol (L2TP). When choosing between PPTP-based and L2TP/IPSec remote access VPN solutions, consider the following:

- PPTP can be used with a variety of Microsoft clients including Windows 95 (with the Dial-up Networking Upgrade 1.3 and later), Windows 98, Windows Millennium Edition, Windows NT 4.0, Windows 2000, and Windows XP. PPTP does not require a public key infrastructure (PKI) to issue computer certificates. By using encryption, PPTP-based VPN connections provide data confidentiality (captured packets cannot be interpreted without the encryption key). PPTP-based VPN connections, however, do not provide data integrity (proof that the data was not modified in transit) or data origin authentication (proof that the data was sent by the authorized user).
- L2TP can only be used with client computers running Windows 2000 or Windows XP. L2TP supports either computer certificates or a preshared key as the authentication method for Internet Protocol security (IPSec). Computer certificate authentication, the recommended authentication method, requires a PKI to issue computer certificates to the VPN server computer and all VPN client computers. By using IPSec, L2TP/IPSec VPN connections provide data confidentiality, data integrity, and data authentication.

**Installing certificates**

In order to create L2TP/IPSec remote access VPN connections using computer certificate authentication for IPSec, you must install computer certificates, also known as machine certificates, on the VPN client and the VPN server. For more information, see Network access authentication and certificates and Computer certificates for L2TP/IPSec VPN connections.

**Configuring firewall packet filters**

If you have a firewall, you must configure packet filters on the firewall to allow traffic between VPN clients on the Internet and the VPN server. For more information, see VPN servers and firewall configuration.

**Creating a remote access policy for remote access VPN connections**
By using remote access policies, you can create a policy that requires remote access VPN connections to use a specific authentication method and encryption strength.

For example, you can create an Active Directory group called VPN Users whose members are the user accounts of the users creating remote access VPN connections across the Internet. Then, you create a policy with two conditions on the policy: **NAS-Port-Type** is set to **Virtual (VPN)** and **Windows-Group** is set to **VPN Users**. Finally, you configure the profile for the policy to select a specific authentication method and encryption strength.

For more information, see Introduction to remote access policies.

**Using an IAS server**
If you have multiple VPN servers running Windows Server 2003 , you need to configure remote access policies and logging for each VPN server. If you want to take advantage of centralized remote access policies and logging, you can configure the VPN servers as Remote Authentication Dial-In User Service (RADIUS) clients to a single computer (a RADIUS server) running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition; and Internet Authentication Service (IAS).

You should also use an IAS server if you have VPN servers running Windows NT 4.0 with the Routing and Remote Access Service (RRAS), and you want to take advantage of remote access policies available in products in the Windows Server 2003 family. You cannot configure VPN servers running Windows NT 4.0 as RADIUS clients. You must upgrade a VPN server running Windows NT 4.0 to a VPN server running Windows NT 4.0 and RRAS.

For more information, see Using RADIUS for multiple remote access servers.

**Using Connection Manager**
For a large remote access VPN deployment, you can use Connection Manager and the Connection Manager Administration Kit to provide a custom dialer with preconfigured VPN connections to all remote access clients across your organization.

For more information about Connection Manager, see Connection Manager Administration Kit. For information about implementing VPN support with the Connection Manager Administration Kit, see Implementing VPN support.

# Remote access VPN security considerations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote access VPN security considerations**
You can enhance remote access VPN security through:

- L2TP connections
- Strong authentication
- Data encryption
- PPTP or L2TP/IPSec packet filtering
- Firewall packet filtering
- Multi-use VPN servers
- Preventing traffic routed from remote access clients
- Remote access policy profile packet filtering

For more information, see Remote access VPN connection.

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

**L2TP connections**
A VPN server running Windows Server 2003 provides support for both Point-to-Point Tunneling Protocol (PPTP) and Layer Two Tunneling Protocol (L2TP). By using encryption, PPTP-based VPN connections provide data confidentiality (captured packets cannot be interpreted without the encryption key). PPTP-based VPN connections, however, do not provide data integrity (proof that the data was not modified in transit) or data origin authentication (proof that the data was sent by the authorized user). By using Internet Protocol Security (IPSec), L2TP/IPSec VPN connections provide data confidentiality, data integrity, and data origin authentication. However, L2TP can only be used with Windows 2000 and Windows XP clients.

L2TP/IPSec connections can use the following methods to authenticate the IPSec security association:

- A computer certificate

  Computer certificates are the recommended method of authentication as they provide strong authentication and are very difficult to impersonate or compromise. Computer certificate authentication requires a public key infrastructure (PKI) to issue computer certificates to the VPN server computer and all VPN client computers.

- A preshared key

  A preshared key is a string of text that is configured on both the VPN client and VPN server. Preshared key is a relatively weak authentication method, therefore it is only recommended that you use preshared key authentication while your PKI is being deployed or when preshared key is required by the VPN server to which your VPN clients are connecting.

**Strong user authentication**
For user authentication, use the strongest authentication scheme that is possible for your remote access VPN configuration. The strongest authentication scheme is the use of EAP-TLS with certificates. For more information, see Deploying Certificate-based Authentication for VPN Connections and Network access authentication and certificates.

Otherwise, use MS-CHAP version 2 authentication and enforce the use of strong passwords on your network. For more information, see MS-CHAP version 2.

**Data encryption**
For encryption, you can use either link encryption or end-to-end encryption with link encryption:

- Link encryption encrypts the data only on the link between the VPN client and the VPN server. For PPTP connections, you must use Microsoft Point-to-Point Encryption (MPPE) in conjunction with either MS-CHAP, MS-CHAP v2, or EAP-TLS authentication. For L2TP/IPSec connections, IPSec provides encryption on the link between the VPN client and the VPN server.

- End-to-end encryption encrypts the data between the source host and its final destination. You can use IPSec *after* the VPN connection is made to encrypt data from the source host to the destination host.

To require encryption, select the appropriate encryption strengths on the **Encryption** tab of the remote access policy profile that is used by your remote access VPN clients. For more information, see Configure encryption.

Encryption on client computers is configured in the properties of the network connection.

**PPTP or L2TP/IPSec filtering**
To secure the VPN server from sending or receiving any traffic on its Internet interface except VPN traffic, you need to ensure that PPTP or L2TP/IPSec input and output filters are configured on the interface that corresponds to the connection to the Internet. For more information about PPTP filters, see Add PPTP Filters. For more information about L2TP/IPSec filters, see Add L2TP over IPSec Filters.

Because IP routing is enabled on the Internet interface, if PPTP or L2TP/IPSec filters are not configured on the Internet interface, then any traffic received on the Internet interface is routed, which may forward unwanted Internet traffic to your intranet.

**Firewall packet filtering**
It is a common practice to provide protection to intranet hosts, such as a VPN server, from Internet hosts using a firewall. If you have a firewall, you must configure packet filters on the firewall to allow traffic to and from VPN clients on the Internet and the VPN server. For more information, see VPN servers and firewall configuration.

**Multi-use VPN servers**
Due to the way in which routes are created on VPN remote access clients, it is possible for the VPN client to send some unencrypted traffic to the VPN server rather than through the encrypted tunnel of the VPN connection. For example, the VPN client might connect to other services running on the VPN server without routing traffic across the VPN connection. Only traffic that is destined to the public IP address of the VPN server is sent in the clear. If traffic from the client uses the internal or private interface IP address of the VPN server, however, it will be encrypted.

When a remote access VPN client creates a VPN connection with a VPN server, it creates a series of routes in the IP routing table on the VPN client:

- Default route that uses the VPN connection

  The new default route for the VPN connection effectively replaces the existing default route for the duration of the connection. After the connection is made, all traffic that does not match an address on the directly connected network or the address of the VPN server is sent in an encrypted form over the VPN connection.

- Host route to the VPN server that uses the local network connection

  The host route for the address of the VPN server is created so that the VPN server is reachable using the locally attached network. If the host route is not present, VPN traffic to the VPN server cannot be sent.

The result of having the host route for the VPN server is that all traffic that is sent to applications running on the VPN server is not sent across the VPN connection, but is instead sent in an unencrypted form across the network between the VPN client and VPN server.

For example, when a remote access VPN client creates a VPN connection with a VPN server and then accesses a shared file on the VPN server computer, that traffic is not sent using the VPN connection. The file sharing traffic is sent in plaintext over the network between the VPN client and VPN server.

Additionally, if packet filters are configured on the VPN server that only allow VPN connection traffic, all other traffic sent to the VPN server is discarded. In this situation, all attempts to connect to services running on the VPN server will fail because traffic attempting to connect to those services are not sent over the VPN connection.

The key to which address is used by the VPN client to access services running on the VPN server lies in the way that the name of the VPN server is resolved. Typical users and applications refer to network resources using names, rather than IP addresses. The name must be resolved to an IP address using either DNS or WINS. If the intranet DNS and WINS infrastructures never contain a record mapping the name of the VPN server to the public IP address of the VPN server, traffic to services running on the VPN server is always sent across the VPN connection.

To prevent the VPN server from dynamically registering the public IP address of its Internet interface in the intranet DNS, obtain properties of the **Internet Protocol (TCP/IP)** component of the Internet connection in the **Network Connections** folder. Click **Advanced**. In the **Advanced TCP/IP Settings** dialog box, click the **DNS** tab, and then clear the **Register this connection's addresses in DNS** check box.

To prevent the VPN server from registering the public IP address of its Internet interface with intranet WINS servers, obtain properties of the **Internet Protocol (TCP/IP)** component of the Internet connection in the **Network Connections** folder. Click **Advanced**. In the **Advanced TCP/IP Settings** dialog box, click the **WINS** tab, and then click **Disable NetBIOS over TCP/IP**.

Before the VPN connection is made, the VPN client uses the Internet DNS infrastructure to resolve the name of the VPN server computer to its public IP addresses. After the VPN connection is made, assuming that intranet DNS and WINS servers are configured either during the PPP connection process or through the relaying of the DHCPInform message, the VPN client uses the intranet DNS and WINS infrastructures to resolve the name of the VPN server computer to its intranet IP addresses.

**Preventing traffic routed through remote access clients**

Once a remote access client successfully establishes a PPTP or L2TP connection, by default any packet sent over the connection is received by the VPN server and forwarded. Packets sent over the connection can include:

- Packets originated from the remote access client computer.
- Packets sent to the remote access client computer by other computers.

When the remote access client computer makes the VPN connection, by default it creates a default route so that all traffic that matches the default route is sent over the VPN connection. If other computers are forwarding traffic to the remote access VPN client, treating the remote access client computer as a router, then that traffic may also be forwarded across the VPN connection. This is a security problem because the computer that is sending traffic to the remote access VPN client has not been authenticated by the VPN server. The computer sending traffic to the remote access VPN client computer has physical network access to the same resources as the authenticated remote access VPN client computer.

To prevent the VPN server from sending traffic across the VPN connection for computers other than authenticated remote access VPN client computers, configure the following remote access policy packet filters on the remote access policy that is used for your VPN connections:

- From client filter:

  Filter action set to **Deny all traffic except those listed below**.

| IP Packet Filter Field | Setting |
|---|---|
| Source Address | User's address |
| Source Network Mask | User's mask |
| Destination Address | Any |
| Destination Network Mask | Any |
| Protocol | Any |

- To client filter:

  Filter action set to **Deny all traffic except those listed below**.

| IP Packet Filter Field | Setting |
|---|---|
| Source Address | Any |
| Source Network Mask | Any |
| Destination Address | User's address |
| Destination Network Mask | User's mask |
| Protocol | Any |

This set of IP packet filters will cause the VPN server to discard all traffic sent across the VPN connection except those that either originated from or is sent to authenticated remote access VPN clients.

**Remote access policy profile packet filtering**

To define the specific types of IP traffic that are allowed for remote access VPN connections, you need to configure IP packet filters on the profile for the remote access policy that is used for your remote access VPN connections. With profile packet filters, you can configure the IP traffic that is allowed from remote access clients (**From client** filters) or to remote access clients (**To client** filters) on an exception basis: either all traffic except traffic specified by filters or no traffic except traffic specified by filters. Remote access policy profile filtering applies to all remote access connections that match the remote access policy. For more information, see Elements of a remote access policy and Configure IP options.

# Deploying Remote Access VPNs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying remote access VPNs**

This section covers:

- PPTP-based remote access VPN deployment
- L2TP-based remote access VPN deployment

# PPTP-based remote access VPN deployment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PPTP-based remote access VPN deployment**

You can use remote access with products in the Windows Server 2003 family to provide access to a corporate intranet for remote access clients who are making PPTP connections across the Internet. If you want your remote access server to support multiple PPTP connections, complete the following steps:

- Configure the connection to the Internet.
- Configure the connection to the intranet.
- Configure the remote access server as a corporate intranet router.
- Configure the VPN server.
- Configure firewall packet filters.
- Configure remote access policies.

The following illustration shows the elements of a remote access server running Windows Server 2003 that provides PPTP-based remote access to a corporate intranet.

For more information, see Remote access VPN connection and Point-to-Point Tunneling Protocol.

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

**Configuring the connection to the Internet**

The connection to the Internet from a computer running a Windows Server 2003 operating system is a dedicated connection--a WAN adapter installed in the computer. The WAN adapter is typically a DDS, T1, Fractional T1, or Frame Relay adapter. You must contract with a local telephone company to run the appropriate physical wiring to your premises. You need to verify that the WAN adapter is compatible with products in the Windows Server 2003 family. To verify compatibility, see the Compatible Hardware and Software section at Support resources.

The WAN adapter includes drivers that are installed in memobers of the Windows Server 2003 family so that the WAN adapter appears as a network adapter.

You need to configure the following TCP/IP settings on the WAN adapter:

- IP address and subnet mask assigned from the InterNIC or an Internet service provider (ISP).
- Default gateway of the ISP router.

So that VPN clients can connect to your VPN server by name (rather than IP address), you can request DNS registration of your VPN server by your ISP.

**Configuring the connection to the intranet**
The connection to the intranet from a computer running a Windows Server 2003 operating system is a LAN adapter that is installed in the computer. You need to verify that the LAN adapter is compatible with products in the Windows Server 2003 family. To verify compatibility, see the Compatible Hardware and Software section at Support resources.

You need to configure the following TCP/IP settings on the LAN adapter:

- IP address and subnet mask assigned from the network administrator.
- DNS and WINS name servers of corporate intranet name servers.

**Configuring the remote access server as a corporate intranet router**
In order for the remote access server to properly forward traffic on the corporate intranet, you must configure it as a router with either static routes or routing protocols so that all of the locations of the intranet are reachable from the remote access server. For information about routing concepts, see Routing Overview. For information about setting up the remote access server as a router, see Deploying Routing.

**Configuring the VPN server**
You can configure your VPN server by running the Routing and Remote Access Server Setup Wizard. You can configure the following settings using the wizard:

- A basic firewall on the public interface.
- The method by which the VPN server assigns addresses to remote access clients (either using addresses that the VPN server obtains from a DHCP server or using addresses from a specified range of addresses that you have configured on the VPN server).
- Forwarding of authorization and authentication messages to a Remote Access Dial-In User Service (RADIUS) server (configuration of the VPN server as a RADIUS client).

Once the wizard is run, these Routing and Remote Access settings are automatically configured:

- Network interfaces
- PPTP and L2TP ports (5 or 128 of each, depending on your choices when running the wizard)
- Multicast support using Internet Group Messaging Protocol (IGMP)
- IP routing
- Installation of the DHCP Relay Agent component.

For more information on enabling Routing and Remote Access and running the wizard, see Enable the Routing and Remote Access service.

**Configuring firewall packet filters**
If you are using a firewall, you need to configure PPTP packet filters on your firewall to allow PPTP traffic between Internet-based VPN clients and the VPN server computer. For more information, see VPN servers and firewall configuration.

**Configuring remote access policies**
For an access-by-user administrative model, you need to set the remote access permission to **Allow access** on the user accounts for those users who will be making VPN connections. For an access-by-policy model, make the appropriate changes to the remote access permission of the user accounts. For more information, see Introduction to remote access policies.

To configure a remote access policy to control the authentication and encryption options for VPN connections, you can create a remote access policy with the following settings:

- Set **Policy name** to **VPN Access** (example).
- For conditions, set the **NAS-Port-Type** condition to **Virtual (VPN)** and the **Tunnel-Type** condition to **Point-to-Point Tunneling Protocol**.
- Select the **Grant remote access permission** option.
- For profile settings, select the appropriate authentication and encryption options.

Then, either delete the default remote access policies or position them after the new policy. This remote access policy allows all users with remote access permission to create a VPN connection.

If you want to distinguish dial-up remote access users from VPN remote access users, do the following:

1. Create an Active Directory group whose members can create virtual private networking connections with the VPN server. For example, VPN_Users.
2. Add the appropriate user accounts to the new Active Directory group.
3. Create a new remote access policy with the following properties:
    - Set **Policy name** to **VPN Access if member of VPN_Users** (example).
    - For conditions, set the **Windows-Groups** condition to **VPN_Users** (example), set the **NAS-Port-Type** condition to **Virtual (VPN)**, and set the **Tunnel-Type** condition to **Point-to-Point Tunneling Protocol**.
    - Select the **Grant remote access permission** option.
4. Move the default remote access policies after the new policy.

The default encryption settings allow no encryption and all levels of encryption strength. To require encryption, clear the **No Encryption** option and select the appropriate encryption strengths on the **Encryption** tab of the remote access policy profile. The encryption strengths are:

- **Basic**

  You can use this option when communicating with older Microsoft dial-up networking clients. This option uses Microsoft Point-to-Point Encryption (MPPE) and a 40-bit encryption key.

- **Strong**

  You can use this option when communicating with dial-up networking clients running Windows 98, Windows 2000, or Windows XP. This option uses MPPE and a 56-bit encryption key.

- **Strongest**

  You can use this option when communicating with dial-up networking clients running Windows 98, Windows 2000, or Windows XP. This option uses MPPE and a 128-bit encryption key.

For more information, see Configure encryption.

# L2TP-based remote access VPN deployment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**L2TP-based remote access VPN deployment**

You can use remote access with products in the Windows Server 2003 family to provide access to a corporate intranet for remote access clients who are making Layer Two Tunneling Protocol over Internet Protocol security (L2TP/IPSec) connections across the Internet. If you want your remote access server to support multiple L2TP/IPSec connections, complete the following steps:

- Configure the connection to the Internet.
- Configure the connection to the intranet.
- Configure the remote access server as a corporate intranet router.
- Configure the VPN server.
- Install certificates.
- Configure firewall packet filters.
- Configure remote access policies.

The following illustration shows the elements of a remote access server running Windows Server 2003 that provides L2TP/IPSec remote access to a corporate intranet.

For more information, see Remote access VPN connection and Layer Two Tunneling Protocol.

### Notes

- The following configuration assumes that computer certificates, also known as machine certificates, are already installed on the VPN server and remote access client computers. For more information, see Computer certificates for L2TP/IPSec VPN connections and Network access authentication and certificates.
- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

**Configuring the connection to the Internet**

The connection to the Internet from a computer running a Windows Server 2003 family operating system is a dedicated connection--a WAN adapter installed in the computer. The WAN adapter is typically a DDS, T1, Fractional T1, or Frame Relay adapter. You must contract with a local telephone company to run the appropriate physical wiring to your premises. You need to verify that the WAN adapter is compatible with products in the Windows Server 2003 family. To verify compatibility, see the Compatible Hardware and Software section at Support resources.

The WAN adapter includes drivers that are installed in members of the Windows Server 2003 family so that the WAN adapter appears as a network adapter.

You need to configure the following TCP/IP settings on the WAN adapter:

- IP address and subnet mask assigned from the InterNIC or an Internet service provider (ISP).
- Default gateway of the ISP router.

To enable VPN clients to connect to your VPN server by name rather than by IP address, request that your ISP register your VPN server in DNS.

**Configuring the connection to the intranet**
The connection to the intranet from a computer running a Windows Server 2003 operating system is a LAN adapter that is installed in the computer. You need to verify that the LAN adapter is compatible with products in the Windows Server 2003 family. To verify compatibility, see the Compatible Hardware and Software section at Support resources.

You need to configure the following TCP/IP settings on the LAN adapter:

- IP address and subnet mask assigned from the network administrator.
- DNS and WINS name servers of corporate intranet name servers.

**Configuring the remote access server as a corporate intranet router**
In order for the remote access server to properly forward traffic on the corporate intranet, you must configure it as a router with either static routes or routing protocols so that all of the locations of the intranet are reachable from the remote access server. For information about routing concepts, see Routing Overview. For information about setting up the remote access server as a router, see Deploying Routing.

**Configuring the VPN server**
You can configure your VPN server by running the Routing and Remote Access Server Setup Wizard. You can use the wizard to configure the following settings:

- A basic firewall on the public interface.
- The method by which the VPN server assigns addresses to remote access clients (either using addresses that the VPN server obtains from a DHCP server or using addresses from a specified range of addresses that you configure).
- Forwarding of authorization and authentication messages to a Remote Authentication Dial-In User Service (RADIUS) server (configuration of the VPN server as a RADIUS client).

Once the wizard is run, the following Routing and Remote Access settings are automatically configured:

- Network interfaces
- PPTP and L2TP ports (five or 128 of each, depending on the choices you made when you ran the wizard)
- Multicast support using Internet Group Management Protocol (IGMP)
- IP routing
- Installation of the DHCP Relay Agent component.

For more information about enabling Routing and Remote Access and running the wizard, see Enable the Routing and Remote Access service.

**Installing certificates**
In order to create L2TP/IPSec remote access VPN connections using computer certificate authentication for IPSec, you must install computer certificates, also known as machine certificates, on the VPN client and the VPN server. For more information, see Network access authentication and certificates and Computer certificates for L2TP/IPSec VPN connections.

**Configuring firewall packet filters**

If you are using a firewall, you need to configure L2TP/IPSec packet filters on your firewall to allow L2TP/IPSec traffic between Internet-based VPN clients and the VPN server computer. For more information, see VPN servers and firewall configuration.

**Configuring remote access policies**

For an access-by-user administrative model, you need to set the remote access permission to **Allow access** on the user accounts for those users who will be making VPN connections. For an access-by-policy model, make the appropriate changes to the remote access permission of the user accounts. For more information, see Introduction to remote access policies.

To configure a remote access policy to control the authentication and encryption options for VPN connections, create a remote access policy with the following settings:

- Set **Policy name** to **VPN Access** (example).
- For conditions, set the **NAS-Port-Type** condition to **Virtual (VPN)** and the **Tunnel-Type** condition to **Layer Two Tunneling Protocol**.
- Select the **Grant remote access permission** option.
- For profile settings, select the appropriate authentication and encryption options.

Then, either delete the default remote access policies or position them after the new policy. This remote access policy allows all users with remote access permission to create a VPN connection.

If you want to distinguish dial-up remote access users from VPN remote access users, do the following:

1. Create an Active Directory group whose members can create virtual private networking connections with the VPN server. For example, VPN_Users.
2. Add the appropriate user accounts to the new Active Directory group.
3. Create a new remote access policy with the following properties:
    - Set **Policy name** to **VPN Access if member of VPN_Users** (example).
    - For conditions, set the **Windows-Groups** condition to **VPN_Users** (example), set the **NAS-Port-Type** condition to **Virtual (VPN)**, and set the **Tunnel-Type** condition to **Layer Two Tunneling Protocol**.
    - Select the **Grant remote access permission** option.
4. Move the default remote access policies after the new policy.

The default encryption settings allow no encryption and all levels of encryption strength. To require encryption, clear the **No Encryption** option and select the appropriate encryption strengths on the **Encryption** tab of the remote access policy profile. The encryption strengths are:

- **Basic**

  This option uses 56-bit DES encryption.

- **Strong**

  This option uses 56-bit DES encryption.

- **Strongest**

  This option uses triple DES (3DES) encryption.

For more information, see Configure encryption.

# Deploying Certificate-based Authentication for VPN Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying certificate-based authentication for VPN connections**
The use of certificates for authentication of VPN connections is the strongest form of authentication in the Windows Server 2003 family. You must use certificate-based authentication for Layer Two Tunneling Protocol over Internet Protocol security (L2TP/IPSec)-based VPN connections and with smart cards. With smart cards, you must use the Extensible Authentication Protocol (EAP) with the **Smartcard or other certificate (TLS)** EAP type, also known as EAP-Transport Level Security (EAP-TLS).

This section covers:

- Computer certificates for L2TP/IPSec VPN connections
- Smart cards and remote access VPN connections
- Deploying certificate-based authentication for demand-dial routing

# Computer certificates for L2TP/IPSec VPN connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Computer certificates for L2TP/IPSec VPN connections**
The Windows Server 2003 family supports two authentication methods for Layer Two Tunneling Protocol over Internet Protocol security (L2TP/IPSec)-based VPN connections: computer certificates, also known as machine certificates, and preshared keys.

In order to create an L2TP/IPSec connection using the computer certificate authentication method, you must install a certificate in the local computer certificate store on the VPN client and VPN server computer. To install a computer certificate, a certification authority must be present to issue certificates. Once the certification authority is configured, you can install a certificate in three different ways:

- By configuring the automatic enrollment, or auto-enrollment, of computer certificates to computers in a Windows Server 2003 domain.
- By using the Certificates snap-in to obtain a computer certificate.
- By using your browser to connect to the CA Web enrollment pages to install a certificate on the local computer or to a floppy disk for installation on another computer, such as a user's home computer.

Based on the certificate policies in your organization, you need to perform only one of these allocations.

Non-domain member computers cannot obtain certificates through auto-enrollment. For more information, see Network access authentication and certificates.

To configure a CA and install the computer certificate, perform the following steps:

1. If you do not already have an enterprise root CA:
   a. Promote the computer that will be a CA to a domain controller (DC), if necessary.
   b. Install the Certificate Services component as an enterprise root CA on a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition. For more information, see Install an enterprise root certification authority.
2. To auto-enroll computer certificates, configure Windows Server 2003 domain. For more information, see Configure automatic certificate allocation from an enterprise CA.

   To create a computer certificate for the VPN server that is a member of the domain for which auto-enrollment is configured (as well as other computers that are members of the domain), restart the computer or type **gpupdate /target:computer** from a Windows Server 2003 command prompt.
3. To manually enroll computer certificates, use the Certificates snap-in to install the CA root certificate. For more information, see Use Windows Server 2003 Certificate Services Web Pages, Manage certificates for a computer and Request a certificate.

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# Smart cards and remote access VPN connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Smart cards and remote access VPN connections**
The use of smart cards for user authentication is the strongest form of authentication in the Windows Server 2003 family. For remote access VPN connections, you must use Extensible Authentication Protocol (EAP) with the **Smart card or other certificate (TLS)** EAP type, also known as EAP-Transport Level Security (EAP-TLS).

To use smart cards for remote access VPN authentication, you must do the following:

- Configure the VPN server to provide remote access VPN services.
- Install a computer certificate on the VPN server.
- Enable a smart card logon process for the domain.
- Enable EAP and configure the **Smartcard or other certificate (TLS)** EAP type on the VPN server computer.
- Enable smart card authentication on the VPN connection on the remote access client computer.

**Configuring the VPN server to provide remote access VPN services**
Configure the VPN server running Windows Server 2003 as described in Deploying Remote Access VPNs.

**Installing a computer certificate on the VPN server**
In order to configure EAP-TLS on the VPN server computer, you must install a computer certificate, also known as a machine certificate. To install a computer certificate on the VPN server computer, a certification authority (CA) must be present to issue certificates. Once the CA is configured, you can install a certificate on the VPN server computer in one of three different ways:

- By configuring the automatic enrollment, or auto-enrollment, of computer certificates to computers in a Windows Server 2003 domain.
- By using the Certificates snap-in to request and install a computer certificate.
- By using your browser to connect to the CA Web enrollment pages to request and install a certificate on the local computer or to a floppy disk for installation on another computer, such as a user's home computer.

Based on the certificate policies in your organization, you need to perform only one of these enrollment methods.

For more information, see Network access authentication and certificates.

To configure a CA and install the computer certificate, perform the following steps:

1. If you do not already have an enterprise root CA:

   a. Promote the computer that will be a CA to a domain controller (DC), if necessary.

   b. Install the Certificate Services component on a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition; as an enterprise root CA. For more information, see Install an enterprise root certification authority.

2. To auto-enroll computer certificates, configure the Windows Server 2003 domain. For more information, see Configure automatic certificate allocation from an enterprise CA.

   To create a computer certificate for the VPN server that is a member of the domain for which auto-enrollment is configured (as well as other computers that are members of the domain), restart the computer or type **gpupdate**

**/target:computer** from a Windows Server 2003 command prompt.

3. To manually enroll computer certificates, use the Certificates snap-in to install the CA root certificate, or use your browser to connect to the CA Web enrollment pages. For more information, see Use Windows Server 2003 Certificate Services Web Pages, Manage certificates for a computer, and Request a certificate.

### Note

- VPN servers that terminate connections for remote users must have a certificate that contains the Server Authentication purpose in the Enhanced Key Usage extensions. VPN servers that are used for site-to-site VPN connections both originate and terminate connections. For this reason the certificate on these servers must contain both the Server Authentication purpose and the Client Authentication purpose in the Enhanced Key Usage extensions. For more information, see Network access authentication and certificates.

#### Enabling a smart card logon process for the domain

To enable a smart card logon process for the domain, complete the following procedures:

1. Prepare a certification authority to issue smart card certificates
2. Prepare a smart card certificate enrollment station
3. Set up a smart card for user logon

#### Configuring the VPN server for smart card remote access

To configure the VPN server running Windows Server 2003 for smart card remote access, see Configure smart card remote access.

#### Configuring the remote access client for smart card remote access

You need to install a smart card reader on the remote access client computer. For more information, see Install a smart card reader on a computer.

Once a smart card reader is installed on the computer running Windows XP, then you are prompted about whether you want to use the smart card for authentication when you create dial-up or VPN connections.

For existing dial-up or VPN connections, you can enable smart card authentication from the properties of the dial-up or VPN connection. For more information, see Enable smart card or other certificate authentication.

### Note

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# Deploying certificate-based authentication for demand-dial routing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying certificate-based authentication for demand-dial routing**

The use of certificates for authentication of calling routers is the strongest form of authentication in the Windows Server 2003 family. For certificate-based authentication of demand-dial connections, you must use the Extensible Authentication Protocol (EAP) with the **Smart card or other certificate (TLS)** EAP type, also known as EAP-Transport Level Security (EAP-TLS). EAP-TLS requires the use of user certificates for the calling router and machine certificates (also known as computer certificates) for the answering router.

The deployment of certificate-based authentication for demand-dial routing typically occurs in the following situations:

- Business partner demand-dial connection
- Branch office demand-dial connection

# Business partner demand-dial connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Business partner demand-dial connection**
To use certificates for a two-way initiated, mutually authenticated, demand-dial configuration between two business partners (in this example, Company A and Company B), you must perform the following:

- Configure the calling and answering routers for demand-dial routing.
- Install computer certificates on the calling router and answering router computers.
- Configure the domain for Web-based certificate enrollment.
- At Company A, create a user account for the Company B router and export a certificate for the user account.
- At Company B, create a user account for the Company A router and export a certificate for the user account.
- At Company A, import the certificate from Company B.
- Configure the Company A router to support certificate-based authentication as a calling router and as an answering router.
- At Company B, import the certificate from Company A.
- Configure the Company B router to support certificate-based authentication as a calling router and as an answering router.

**Configuring the calling and answering routers for demand-dial routing**
Configure the Routing and Remote Access calling and answering routers as described in Deploying demand-dial routing for dial-in demand-dial routing or Router-to-router VPN Deployment for VPN demand-dial routing.

**Installing computer certificates on the calling router and answering router computers**
To use EAP-TLS, a computer certificate (also known as a machine certificate) must be installed on the authenticating server and the remote access client. In order to install a computer certificate, a certification authority must be present to issue certificates. Once the certification authority is configured, you can install a certificate in three different ways:

- By configuring the automatic enrollment, or autoenrollment, of computer certificates to computers in a Windows Server 2003 domain.
- By using the Certificates snap-in to obtain a computer certificate.
- By using your browser to connect to the CA Web enrollment pages to install a certificate on the local computer or to a floppy disk for installation on another computer, such as non-domain member computers that cannot obtain a certificate through autoenrollment.

Based on the certificate policies in your organization, you only need to perform one of these allocations.

For more information, see Network access authentication and certificates.

To configure a certification authority and install the computer certificate, perform the following steps:

1. Install the Certificate Services component as an enterprise root certification authority (CA). This step is only necessary if you do not already have an enterprise root CA.

    a. If necessary, promote the computer that will be a CA to a domain controller (DC).

b. Install the Certificate Services component as an enterprise root CA. For more information, see Install an enterprise root certification authority.

2. Configure the CA to issue certificates that permit exportable keys. To do so, you must clone and rename the **router (offline request)** template, choose to make the keys exportable, and add the new template to the templates the CA can use to issue certificates. For more information, see To establish the certificate types that an enterprise certification authority can issue.

3. Do one of the following:

   - To auto-enroll computer certificates, configure the domain. For more information, see Configure automatic certificate allocation from an enterprise CA.

     To create a computer certificate for the calling or answering router that is a member of the domain for which auto-enrollment is configured (as well as other computers that are members of the domain), restart the computer or type **gpupdate /Target:Computer /Force** from the command prompt.

   - To manually enroll computer certificates, use the Certificates snap-in or the CA Web enrollment pages to install the CA root certificate. For more information, see Manage certificates for a computer and Request a certificate.

In order for the CA to issue certificates for the calling router, you must configure the domain for Web-based enrollment. For more information, see Set up certification authority Web enrollment support.

**Creating a user account and exporting its certificate for the Company B router**

To create a dial-in user account for the Company B router and export the user certificate of the user account, do the following:

1. Log on as a domain administrator.

2. Create a user account that the Company B router will use when it dials the Company A router. For more information, see Create a new user account.

3. Obtain a certificate that has an exportable key from the certification authority through Web-based enrollment. This certificate might be called **router (offline request)**, or have another name. For more information, see Install a router (offline request) certificate.

4. Export the exportable key certificate to a .cer file. For more information, see Export a certificate. Within the Certificates snap-in Export wizard, do not export the private key.

5. Map the newly created certificate (the .cer file) to the user account that was created for the Company B router. For more information, see Map a certificate to a user account.

6. Export the certificate to a .pfx file. For more information, see Export a certificate. Within the Certificates snap-in Export wizard, export the private key, select the **Delete the private key if the import is successful** check box, and click **Include all certificates in the certification path if possible**. Save this file to a floppy disk to send to the network administrator at Company B.

7. Send the floppy disk that contains the Company B dial-in account user certificate file to the network administrator at Company B.

**Creating a user account and exporting its certificate for the Company A router**

To create a dial-in user account for the Company A router and export the user certificate of the user account, do the following:

1. Log on as a domain administrator.

2. Create a user account that the Company A router will use when it dials the Company B router. For more information, see

Create a new user account.

3. Obtain a certificate that has exportable keys from the certification authority through Web-based enrollment. This certificate might be called **router (offline request)**, or it might have another name. For more information, see Install a router (offline request) certificate.

4. Export the certificate to a .cer file. For more information, see Export a certificate. Within the Certificates snap-in Export wizard, do not export the private key.

5. Map the newly created certificate (the .cer file) to the user account created for the Company A router. For more information, see Map a certificate to a user account.

6. Export the certificate to a .pfx file. For more information, see Export a certificate. Within the Certificates snap-in Export wizard, export the private key, select the **Delete the private key if the import is successful** check box, and click **Include all certificates in the certification path if possible**. Save this file to a floppy disk to send to the network administrator at Company A.

7. Send the floppy disk that contains the Company A dial-in account user certificate file to the network administrator at Company A.

**Importing the certificates from Company B**
Upon receipt at Company A of the floppy disk that contains the certificate file from Company B, on the Company A router, import the user certificate. For more information, see Import a certificate.

**Configuring the Company A router to support certificate-based authentication**
To configure the Company A router for certificate-based authentication as an answering router, see Configure the answering router for certificate-based EAP.

To configure the Company A router for certificate-based authentication as a calling router, see Configure the calling router for certificate-based EAP.

**Importing the certificates from Company A**
Upon receipt at Company B of the floppy disk that contains the certificate files from Company A, on the Company B router, import the user certificate. For more information, see Import a certificate.

**Configuring the Company B router to support certificate-based authentication**
To configure the Company B router for certificate-based authentication as an answering router, see Configure the answering router for certificate-based EAP.

To configure the Company B router for certificate-based authentication as a calling router, see Configure the calling router for certificate-based EAP.

# Branch office demand-dial connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Branch office demand-dial connection**
To use certificates for a two-way initiated, mutually authenticated, demand-dial configuration between two routers in the same organization (in this example, a branch office router and a corporate office router), you must perform the following:

- Configure the calling and answering routers for demand-dial routing.
- Install a computer certificate on the corporate office router.
- Configure the domain for Web-based certificate enrollment.
- Create user accounts and export certificates.
- Import the dial-out user certificate on the corporate office router.
- Configure the corporate office router to support certificate-based authentication as a calling router and as an answering router.
- Import the dial-in certificate on the branch office router.
- Configure the branch office router to support certificate-based authentication as a calling router.
- Connect to the corporate office and join the organization domain.

**Configuring the calling and answering routers for demand-dial routing**
Configure the calling and answering routers as described in Deploying demand-dial routing for dial-up demand-dial routing or Router-to-router VPN Deployment for VPN demand-dial routing.

**Installing a computer certificate on the corporate office router**
In order to configure EAP-TLS on the corporate office router, you must install a computer certificate (also known as a machine certificate). In order to install a computer certificate, a certification authority must be present to issue certificates. Once the certification authority is configured, you can install a certificate in three different ways:

- By configuring the automatic enrollment, or autoenrollment, of computer certificates to computers in a Windows Server 2003 domain.
- By using the Certificates snap-in to obtain a computer certificate.
- By using your browser to connect to the CA Web enrollment pages to install a certificate on the local computer or to a floppy disk for installation on another computer, such as non-domain member computers that cannot obtain a certificate through autoenrollment.

Based on the certificate policies in your organization, you only need to perform one of these allocations.

For more information, see Network access authentication and certificates.

To configure a certification authority and install the computer certificate, perform the following steps:

1. Install the Certificate Services component as an enterprise root certification authority. This step is only necessary if you do not already have an enterprise root certification authority (CA).
    a. If necessary, promote the computer that will be a CA to a domain controller (DC).
    b. Install the Certificate Services component as an enterprise root CA. For more information, see Install an enterprise root

certification authority.

2. Configure the CA to issue certificates with exportable keys. For more information, see To establish the certificate types that an enterprise certification authority can issue.

3. Do one of the following:

   - To auto-enroll computer certificates, configure the domain. For more information, see Configure automatic certificate allocation from an enterprise CA.

     To create a computer certificate for the calling or answering router that is a member of the domain for which autoenrollment has been configured (as well as other computers that are members of the domain), restart the computer or type **gpupdate /Target:***Computer***/Force** from the command prompt.

   - To manually enroll computer certificates, use the Certificates snap-in or the CA Web enrollment pages to install the CA root certificate. For more information, see Manage certificates for a computer and Request a certificate.

In order for the CA to issue certificates for the calling router, you must configure the domain for Web-based enrollment. For more information, see Set up certification authority Web enrollment support.

**Creating user accounts and exporting certificates**

To create dial-in and dial-out user accounts and export certificates, do the following:

1. Log on as a domain administrator.

2. Create a user account that the corporate office router will use when it dials the branch office router (the dial-out account). For more information, see Create a new user account.

3. Obtain a certificate that has exportable keys for the dial-out account from the certification authority through Web-based enrollment. This certificate might be called **router (offline request)**, or it might have another name. For more information, see Install a router (offline request) certificate.

4. Export the certificate for the dial-out account to a .cer file. For more information, see Export a certificate. Within the Certificates snap-in Export wizard, do not export the private key.

5. Map the newly created certificate (the .cer file) to the dial-out user account. For more information, see Map a certificate to a user account.

6. Export the certificate of the dial-out account to a .pfx file. For more information, see Export a certificate. Within the Certificates snap-in Export wizard, export the private key and click **Delete the private key if the import is successful** and select the option to **Include all certificates in the certification path if possible**.

7. Create a user account that the branch office router will use when it dials the corporate office router (the dial-in account). For more information, see Create a new user account.

8. Obtain a certificate that has exportable keys for the dial-in account from the certification authority through Web-based enrollment. This certificate might be called **router (offline request)**, or it might have another name. For more information, see Install a router (offline request) certificate.

9. Export the certificate for the dial-in account to a .cer file. For more information, see Export a certificate. Within the Certificates snap-in Export wizard, do not export the private key.

10. Map the newly created certificate (the .cer file) to the dial-in user account. For more information, see Map a certificate to a user account.

11. Export the certificate of the dial-in account to a .pfx file. For more information, see Export a certificate. Within the Certificates snap-in Export wizard, export the private key and click **Delete the private key if the import is successful**. Save this file to a floppy disk to send to the network administrator at the branch office.

12. Send the floppy disk that contains the dial-in account user certificate file to the network administrator at the branch office.

**Importing the dial-out certificate on the corporate office router**
On the corporate office router, import the user certificate for the dial-out account. For more information, see Import a certificate.

**Configuring the corporate office router to support certificate-based authentication**
To configure the corporate office router for certificate-based authentication as an answering router, see Configure the answering router for certificate-based EAP.

To configure the corporate office router for certificate-based authentication as a calling router, see Configure the calling router for certificate-based EAP.

**Importing the certificate on the branch office router**
Upon receipt at the branch office of the floppy disk that contains the certificate file from the corporate office, import the user certificate for the dial-in account. For more information, see Import a certificate.

**Configuring the branch office router to support certificate-based authentication**
To configure the branch office router for certificate-based authentication as a calling router, see Configure the calling router for certificate-based EAP.

**Connecting to the corporate office and joining the organization domain**
To connect to the corporate office and join the organization domain, do the following:

1. From the branch office, connect to the corporate office by right-clicking the demand-dial interface, and then clicking **Connect**.

2. Once connected, the branch office router joins the domain through the **Computer Name** tab (in the properties of My Computer).

3. After joining the domain, restart the branch office router.

4. After restarting the branch office router, connect to the corporate office router again.

5. Once connected, the branch office router receives domain policy and a computer certificate (if auto-enrollment of computer certificates is configured). If auto-enrollment of computer certificates is not configured, obtain a computer certificate through the Certificates snap-in. For more information, see Manage certificates for a computer and Request a certificate.

6. Once a computer certificate is obtained, configure the branch office router for certificate-based authentication as an answering router. For more information, see Configure the answering router for certificate-based EAP.

At this point, you can install a domain controller in the branch office by using the demand-dial connection to the corporate office. For more information on installing a domain controller, see Checklist: Installing a domain controller.

### Notes

- The ability of the branch office router to join the domain and the installation of a domain controller depends on DNS name resolution. Ensure that both the router and the domain controller computer are configured with the proper DNS server IP addresses.

- By default, an answering router checks the certificate revocation list when authenticating the calling router. Because the root CA computer is always reachable by the corporate office router, the certificate revocation list can always be checked. However, the root CA computer is not reachable by the branch office router until after the connection is made. If the root CA computer cannot be reached, then Active Directory is checked. In this case, the branch office router accesses its local domain controller for the revocation list. If the certificate revocation list is not published in Active Directory, then the branch office router acting as the answering router rejects the connection attempt. To prevent this problem, do one of the following:

    - Publish the certificate revocation list in Active Directory. For more information, see Schedule the publication of the certificate revocation list or Manually publish the certificate revocation list.

    - On the branch office router, set the following registry value to 1:

**HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\RasMan\PPP\EAP\13\IgnoreRevocationOffline**

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

# Virtual Private Network Implementation Examples

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Virtual private network implementation examples**
This section describes how common VPN scenarios are configured for a fictional company by using computers running Windows Server 2003 operating systems. While your network configuration may be different than those described here, you can apply the basic concepts.

Electronic, Inc. is an electronics design and manufacturing company with a main corporate campus in New York and branch offices and distribution business partners throughout the United States. Electronic, Inc. has implemented a VPN solution by using computers running Windows Server 2003, Standard Edition, that connect remote access users, branch offices, and business partners.

The VPN server at the corporate office provides both remote access and router-to-router PPTP and L2TP/IPSec VPN connections and the routing of packets to intranet and Internet locations. For more information, see Common configuration for the VPN server.

Based on the common configuration of the VPN server, the following virtual private network scenarios are described:

- Remote access for employees
- On-Demand Branch Office
- Persistent Branch Office
- Extranet for Business Partners
- Dial-up and VPNs with RADIUS

**Note**

- The example companies, organizations, products, people and events depicted herein are fictitious. No association with any real company, organization, product, person or event is intended or should be inferred.

# Common configuration for the VPN server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Common configuration for the VPN server**
To deploy a VPN solution for Electronic, Inc., the network administrator performs an analysis and makes design decisions regarding:

- The network configuration
- The remote access policy configuration
- The domain configuration
- The security configuration

**The network configuration**
The key elements of the network configuration are:

- The Electronic, Inc. corporate intranet uses the private networks of 172.16.0.0 with a subnet mask of 255.240.0.0 and 192.168.0.0 with a subnet mask of 255.255.0.0. The corporate campus network segments use subnets of 172.16.0.0 and the branch offices use subnets of 192.168.0.0.
- The VPN server computer is directly attached to the Internet by using a T3 (also known as a DS-3) dedicated WAN link.
- The IP address of the WAN adapter on the Internet is 207.209.68.1 as allocated by the Internet service provider (ISP) for Electronic, Inc. The IP address of the WAN adapter is referred to on the Internet by the domain name vpn.electronic.microsoft.com.
- The VPN server computer is directly attached to an intranet network segment that contains a RADIUS server, a file and Web server for business partner access, and a router that connects to the rest of the Electronic, Inc. corporate campus intranet. The intranet network segment has the IP network ID of 172.31.0.0 with the subnet mask of 255.255.0.0.
- The VPN server computer is configured with a static pool of IP addresses to allocate to remote access clients and calling routers. The static pool of IP addresses is a subset of the intranet network segment (an on-subnet address pool).

The following illustration shows the network configuration of the Electronic, Inc. VPN server.

**Note**

- While the illustration shows the RADIUS server and file and Web server, the RADIUS server is not discussed until Dial-up and VPNs with RADIUS, and the file and Web servers are not discussed until Extranet for Business Partners.

Based on the network configuration of the Electronic, Inc. corporate campus intranet, the VPN server computer is configured as follows.

**1. Install hardware in the VPN server**
The network adapter that is used to connect to the intranet segment and the WAN adapter that is used to connect to the Internet are installed according to the adapter manufacturer's instructions. Once drivers are installed and functioning, both adapters appear as local area connections in the Network Connections folder.

**2. Configure TCP/IP on the LAN and WAN adapter**
For the LAN adapter, an IP address of 172.31.0.1 with a subnet mask 255.255.0.0 is configured. For the WAN adapter, an IP address of 207.209.68.1 with a subnet mask 255.255.255.255 is configured. A default gateway is not configured for either adapter. DNS and WINS server addresses are also configured.

**3. Install the Routing and Remote Access service**
The Routing and Remote Access Server Setup Wizard is run. Within the wizard, the **Remote Access (dial-up or VPN)** option is selected. For more information, see Enable the Routing and Remote Access service.

While running the wizard, a static IP address pool with a starting IP address of 172.31.255.1 and an ending IP address of 172.31.255.254 is configured. This creates a static address pool for up to 253 VPN clients.

For more information, see Create a static IP address pool.

The default method of authenticating remote access and demand-dial connections is to use Windows authentication, which is appropriate in this configuration containing only one VPN server. For information on the use of RADIUS authentication for Electronic, Inc., see Dial-up and VPNs with RADIUS. For more information on the use of Windows and RADIUS authentication, see Authentication vs. authorization.

**4. Enable the EAP authentication method**
To enable the use of smart card-based remote access VPN clients and certificate-based calling routers, the network administrator enables Extensible Authentication Protocol (EAP) on the VPN server.

For more information, see Enable EAP.

**5. Configure static routes on the VPN server to reach intranet and Internet locations**
To reach intranet locations, a static route is configured with the following settings:

- Interface: The LAN adapter attached to the intranet
- Destination: 172.16.0.0
- Network mask: 255.240.0.0
- Gateway: 172.31.0.2
- Metric: 1

This static route simplifies routing by summarizing all destinations on the Electronic, Inc. intranet. This static route is used so that the VPN server does not need to be configured with a routing protocol.

To reach Internet locations, a static route is configured with the following settings:

- Interface: The WAN adapter attached to the Internet
- Destination: 0.0.0.0
- Network mask: 0.0.0.0
- Gateway: 0.0.0.0
- Metric: 1

This static route summarizes all destinations on the Internet. This route allows the VPN server to respond to a remote access client or demand-dial router VPN connection from anywhere on the Internet.

**Note**

- Because the WAN adapter creates a point-to-point connection to the ISP, any address can be entered for the gateway. The gateway address of 0.0.0.0 is an example. 0.0.0.0 is the unspecified IP address.

**Setting the phone number for the PPTP and L2TP devices**

To aid in the configuration of remote access policies to confine VPN connections from Internet users, the port properties for the **WAN Miniport (PPTP)** and **WAN Miniport (L2TP)** devices are modified with the IP address of the VPN server's Internet interface in the **Phone number for this device** field. For more information, see Set the phone number on a port.

**Configure a static route on the intranet router to reach all branch offices**

To reach branch office locations from the intranet router, a static route is configured with the following settings:

- Interface: The LAN adapter attached to the intranet
- Destination: 192.168.0.0
- Network mask: 255.255.0.0
- Gateway: 172.31.0.1
- Metric: 1

This static route simplifies routing by summarizing all destinations at branch offices of Electronic, Inc.

**The remote access policy configuration**

Electronic, Inc. has migrated to a Windows 2000 native domain and the network administrator for Electronic, Inc. decides on an access-by-policy administrative model. The remote access permission on all user accounts is set to **Control access through Remote Access Policy**. The granting of remote access permission to connection attempts is controlled by the remote access permission setting on the first matching remote access policy. Remote access policies are used to apply different VPN connection settings based on group membership, and the default remote access policies are deleted.

For more information, see Introduction to remote access policies.

**The domain configuration**

To take advantage of the ability to apply different connection settings to different types of VPN connections, the following Active Directory groups are created:

- VPN_Users

  Used for remote access VPN connections

- VPN_Routers

  Used for router-to-router VPN connections from Electronic, Inc. branch offices

- VPN_Partners

  Used for router-to-router VPN connections from Electronic, Inc. business partners

**Note**

- All users and groups in this implementation example are created in the electronic.microsoft.com Active Directory domain.

**The security configuration**

To enable L2TP/IPSec connections, the use of smart cards by remote access clients, and the use of EAP-TLS by routers, the

Electronic, Inc. domain is configured to auto-enroll computer certificates to all domain members.

For more information, see Deploying Certificate-based Authentication for VPN Connections.

**Notes**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

- The example companies, organizations, products, people and events depicted herein are fictitious. No association with any real company, organization, product, person or event is intended or should be inferred.

# Remote access for employees

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote access for employees**
Remote access for Electronic, Inc. employees is deployed by using remote access VPN connections across the Internet based on the settings configured in Common configuration for the VPN server and the following additional settings.

The following illustration shows the Electronic, Inc. VPN server that provides remote access VPN connections.

**Domain configuration**
For each employee that is allowed VPN access:

- The remote access permission on the dial-in properties of the user account is set to **Control access through Remote Access Policy**.
- The user account is added to the VPN_Users Active Directory group.

**Remote access policy configuration**
To define the authentication and encryption settings for remote access VPN clients, the following remote access policy is created:

- Policy name: Remote Access VPN Clients
- Conditions:
    - **NAS-Port-Type** is set to Virtual (VPN)
    - **Windows-Groups** is set to VPN_Users
    - **Called-Station-ID** is set to 207.209.68.1
- Permission is set to **Grant remote access permission**
- Profile settings:
    - **Authentication** tab: **Extensible Authentication Protocol** is enabled and **Smartcard or other certificate (TLS)** is configured to use the installed computer certificate (also known as the machine certificate). **Microsoft Encrypted Authentication version 2 (MS-CHAP v2)** and **Microsoft Encrypted Authentication (MS-CHAP)** are also enabled.
    - **Encryption** tab: **Strong** and **Strongest** are the only options that are selected.

### Note

- The **Called-Station-ID** condition is set to the IP address of the Internet interface for the VPN server. Only tunnels initiated from the Internet are allowed. Tunnels initiated from the Electronic, Inc. intranet are not permitted. Electronic, Inc. users that require Internet access from the Electronic, Inc. intranet must go through the Electronic, Inc. proxy server (not shown), where Internet access is controlled and monitored.

#### PPTP-based remote access client configuration

The New Connection Wizard is used on client computers to create a VPN connection with the following setting:

- Host name or IP address: vpn.electronic.microsoft.com

- On the **Networking** tab, **Type of dial-up server I am calling** is set to **Point-to-Point Tunneling Protocol (PPTP)**. This is done to provide better performance when connecting. When **Type of dial-up server I am calling** is set to **Automatic**, an Internet Protocol security (IPSec) security association (SA) for an Layer Two Tunneling Protocol (L2TP) connection is attempted first. By configuring the connection for PPTP, the IPSec SA for an L2TP connection is not attempted.

#### L2TP/IPSec remote access client configuration

The remote access computer logs on to the Electronic, Inc. domain using a LAN connection to the Electronic, Inc. intranet and receives a certificate through auto-enrollment. Then, the New Connection Wizard is used to create a VPN connection with the following setting:

- Host name or IP address: vpn.electronic.microsoft.com

The VPN connection settings are modified as follows:

- On the **Networking** tab, **Type of dial-up server I am calling** is set to **Layer-2 Tunneling Protocol (L2TP)**. When **Type of dial-up server I am calling** is set to **Automatic**, an IPSec SA for an L2TP connection is attempted first. If the IPSec SA is not successful, then a PPTP connection is attempted. In this case, the network administrator for Electronic, Inc. does not want remote access clients that are capable of establishing an L2TP connection to fall back to the PPTP connection.

### Notes

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

- The example companies, organizations, products, people and events depicted herein are fictitious. No association with any real company, organization, product, person or event is intended or should be inferred.

# On-Demand Branch Office

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**On-demand branch office**

The Portland and Dallas branch offices of Electronic, Inc. are connected to the corporate office by using on-demand router-to-router VPN connections. Both the Portland and Dallas offices contain a small number of employees who only need occasional connectivity with the corporate office. The routers running Windows Server 2003, Standard Edition, in the Portland and Dallas offices are equipped with an ISDN adapter that dials a local Internet service provider to gain access to the Internet, and then a router-to-router VPN connection is made across the Internet. When the VPN connection is not used for five minutes, the routers at the branch offices terminate the VPN connection.

The Dallas branch office uses the IP network ID of 192.168.28.0 with a subnet mask of 255.255.255.0. The Portland branch office uses the IP network ID of 192.168.4.0 with a subnet mask of 255.255.255.0.

To simplify the configuration, the VPN connection is a one-way initiated connection that is always initiated by the branch office router. For more information, see One-way initiated demand-dial connections.

The following illustration shows the Electronic, Inc. VPN server that provides on-demand branch office connections.

To deploy on-demand router-to-router VPN connections to connect the Portland and Dallas branch offices to the corporate office based on the settings configured in Common configuration for the VPN server, the following additional settings are configured.

**Domain configuration**

For the VPN connection to the Dallas office, the user account VPN_Dallas is created with the following settings:

- Password of nY7W{q8~=z3.
- For the dial-in properties on the VPN_Dallas account, the remote access permission is set to **Control access through Remote Access Policy**, and the static route is 192.168.28.0 with a subnet mask of 255.255.255.0 is added.
- For the account properties on the VPN_Dallas account, the **Password never expires** account option is enabled.
- The VPN_Dallas account is added to the VPN_Routers group.

For the VPN connection to the Portland office, the user account VPN_Portland is created with the following settings:

- Password of P*4s=wq!Gx1.
- For the dial-in properties on the VPN_Portland account, the remote access permission is set to **Control access through Remote Access Policy**, and the static route is 192.168.4.0 with a subnet mask of 255.255.255.0 is added.
- For the account properties on the VPN_Portland account, the **Password never expires** account option is enabled.
- The VPN_Portland account is added to the VPN_Routers group.

**Remote access policy configuration**

To define the authentication and encryption settings for the VPN routers, the following remote access policy is created:

- Policy name: VPN Routers
- Conditions:
  - **NAS-Port-Type** is set to Virtual (VPN)
  - **Windows-Groups** is set to VPN_Routers
  - **Called-Station-ID** is set to 207.209.68.1
- Permission is set to **Grant remote access permission**
- Profile settings:
  - **Authentication** tab: **Extensible Authentication Protocol** is enabled and **Smartcard or other certificate (TLS)** is configured to use the installed computer certificate (also known as the machine certificate). **Microsoft Encrypted Authentication version 2 (MS-CHAP v2)** is also enabled.
  - **Encryption** tab: **Strong** and **Strongest** are the only options that are selected.

**Note**

- The **Called-Station-ID** is set to the IP address of the Internet interface for the VPN server. Only tunnels initiated from the Internet are allowed. Tunnels initiated from the Electronic, Inc. intranet are not permitted. Electronic, Inc. users that require Internet access from the Electronic, Inc. intranet must go through the Electronic, Inc. proxy server (not shown), where Internet access is controlled and monitored.

For more information about the branch office router configuration, see:

- The Dallas office: PPTP-based on-demand branch office
- The Portland office: L2TP-based on-demand branch office

**Note**

- The example companies, organizations, products, people and events depicted herein are fictitious. No association with any real company, organization, product, person or event is intended or should be inferred.

# PPTP-based on-demand branch office

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PPTP-based on-demand branch office**

The Dallas branch office is a PPTP-based branch office that uses a router running Windows Server 2003, Standard Edition, to create an on-demand, router-to-router VPN connection with the corporate office router in New York as needed. When the connection is made and is idle for five minutes, the connection is terminated.

To deploy a PPTP, one-way initiated, on-demand, router-to-router VPN connection to the corporate office based on the settings configured in Common configuration for the VPN server and On-Demand Branch Office, the following settings are configured on the Dallas router.

**Demand-dial interface for the connection to the ISP**

To connect the Dallas office router to the Internet by using a local ISP, a demand-dial interface is created by using the Demand-Dial Interface Wizard with the following settings:

- **Interface name**

  ISP

- **Connection type**

  **Connect using a modem, ISDN adapter, or other physical device** is selected.

- **Select a device**

  The appropriate ISDN device is selected.

- **Phone number or address**

  Phone number of the ISP for the Dallas office.

- **Protocols and security**

  The **Route IP packets on this interface** check box is selected.

- **Static Routes for Remote Networks**

  Static route for Electronic, Inc. VPN server: To create the connection to the Dallas ISP when the router-to-router VPN connection needs to be made, the following static route is configured:

  - Interface: ISP
  - Destination: 207.209.68.1
  - Network mask: 255.255.255.255
  - Metric: 1

- **Dial-out credentials**

  - User name: Dallas office ISP account name.
  - Password: Dallas office ISP account password.

- Confirm password: Dallas office ISP account password.

For more information, see Add a demand-dial interface.

**Demand-dial interface for router-to-router VPN connection**
To connect the Dallas office router to the VPN server by using a router-to-router VPN connection over the Internet, a demand-dial interface is created by using the Demand-Dial Interface Wizard with the following settings:

- **Interface name**

  CorpHQ

- **Connection type**

  **Connect using virtual private networking (VPN)** is selected.

- **VPN type**

  **Point to Point Tunneling Protocol (PPTP)** is selected.

- **Destination address**

  207.209.68.1

- **Protocols and security**

  The **Route IP packets on this interface** check box is selected.

- **Static Routes for Remote Networks**

  To make all locations on the corporate intranet reachable, the following static route is configured:

  - Interface: CorpHQ
  - Destination: 172.16.0.0
  - Network mask: 255.240.0.0
  - Metric: 1

  To make all locations on Electronic, Inc. branch offices reachable, the following static route is configured:

  - Interface: CorpHQ
  - Destination: 192.168.0.0
  - Network mask: 255.255.0.0
  - Metric: 1

- **Dial-out credentials**

  - User name: VPN_Dallas
  - Domain: electronic.microsoft.com
  - Password: nY7W{q8~=z3

- Confirm password: nY7W{q8~=z3

**PPTP packet filters on the demand-dial interface that connects to the ISP**
To ensure that only PPTP-based traffic is allowed on the connection to the Internet, PPTP packet filters are configured on the ISP demand-dial interface. For more information, see Add PPTP Filters.

### Note

- The example companies, organizations, products, people and events depicted herein are fictitious. No association with any real company, organization, product, person or event is intended or should be inferred.

# L2TP-based on-demand branch office

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**L2TP-based on-demand branch office**

The Portland branch office is an L2TP/IPSec branch office that uses a router running Windows Server 2003, Standard Edition, to create an on-demand, router-to-router VPN connection with the corporate office router in New York as needed. When the connection is made and is idle for five minutes, the connection is terminated.

To deploy an L2TP, one-way initiated, on-demand, router-to-router VPN connection to the corporate office based on the settings configured in Common configuration for the VPN server and On-Demand Branch Office, the following settings are configured on the Portland router.

**Certificate configuration**

The Portland router was configured by the Electronic, Inc. network administrator while it was physically connected to the Electronic, Inc. intranet and then shipped to the Portland site. While the Portland router was connected to the Electronic, Inc. intranet, a computer certificate was installed through auto-enrollment.

**Demand-dial interface for the connection to the ISP**

To connect the Portland office router to the Internet by using a local ISP, a demand-dial interface is created by using the Demand-Dial Interface Wizard with the following settings:

- **Interface name**

  ISP

- **Connection type**

  **Connect using a modem, ISDN adapter, or other physical device** is selected.

- **Select a device**

  The appropriate ISDN device is selected.

- **Phone number or address**

  Phone number of the ISP for the Portland office.

- **Protocols and security**

  The **Route IP packets on this interface** check box is selected.

- **Static Routes for Remote Networks**

  The following static route for the Electronic, Inc. VPN server is added automatically when the wizard is run to create the connection to the Portland ISP:

  - Interface: ISP
  - Destination: 207.209.68.1
  - Network mask: 255.255.255.255
  - Metric: 1

- **Dial-out credentials**

- User name: Portland office ISP account name.
- Password: Portland office ISP account password.
- Confirm password: Portland office ISP account password.

**Demand-dial interface for router-to-router VPN connection**

To connect the Portland office router to the VPN server by using a router-to-router VPN connection over the Internet, a demand-dial interface is created by using the Demand-Dial Interface Wizard with the following settings:

- **Interface name**

  CorpHQ

- **Connection type**

  **Connect using virtual private networking (VPN)** is selected.

- **VPN type**

  **Layer-2 Tunneling Protocol (L2TP)** is selected.

- **Destination address**

  207.209.68.1

- **Protocols and security**

  The **Route IP packets on this interface** check box is selected.

- **Static Routes for Remote Networks**

  Static route for corporate headquarters and branch offices: To make all locations on the corporate intranet reachable, the following static route is configured:

  - Interface: CorpHQ
  - Destination: 172.16.0.0
  - Network mask: 255.240.0.0
  - Metric: 1

  To make all locations on Electronic, Inc. branch offices reachable, the following static route is configured:

  - Interface: CorpHQ
  - Destination: 192.168.0.0
  - Network mask: 255.255.0.0
  - Metric: 1

- **Dial-out credentials**

  - User name: VPN_Portland

- Domain: electronic.microsoft.com
- Password: P*4s=wq!Gx1
- Confirm password: P*4s=wq!Gx1

**Note**

- The example companies, organizations, products, people and events depicted herein are fictitious. No association with any real company, organization, product, person or event is intended or should be inferred.

# Persistent Branch Office

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Persistent branch office**

The Chicago and Phoenix branch offices of Electronic, Inc. are connected to the corporate office by using persistent router-to-router VPN connections that stay connected 24 hours a day. The routers running Windows Server 2003, Standard Edition, in the Chicago and Phoenix offices are equipped with T1 WAN adapters that have a permanent connection to a local Internet service provider to gain access to the Internet.

The Chicago branch office uses the IP network ID of 192.168.9.0 with a subnet mask of 255.255.255.0. The Chicago branch office router uses the public IP address of 131.107.0.1 for its Internet interface. The Phoenix branch office uses the IP network ID of 192.168.14.0 with a subnet mask of 255.255.255.0. The Phoenix branch office router uses the public IP address of 131.107.128.1 for its Internet interface.

The VPN connection is a two-way initiated connection. The connection is initiated from either the branch office router or the corporate office router. Two-way initiated connections require the creation of demand-dial interfaces, remote access policies, IP address pools, and packet filters on the routers on both sides of the connection.

The following illustration shows the Electronic, Inc. VPN server that provides persistent branch office connections.

To deploy persistent router-to-router VPN connections to connect the Chicago and Phoenix branch offices to the corporate office based on the settings configured in Common configuration for the VPN server, the following additional settings are configured.

**Domain configuration**

For the Chicago office VPN connection that is initiated by the Chicago router, the user account VPN_Chicago is created with the following settings:

- Password of U9!j5dP(%q1.
- For the dial-in properties on the VPN_Chicago account, the remote access permission is set to **Control access through Remote Access Policy**.
- For the account properties on the VPN_Chicago account, the **Password never expires** account option is enabled.
- The VPN_Chicago account is added to the VPN_Routers group.

For the Phoenix office VPN connection that is initiated by the Phoenix router, the user account VPN_Phoenix is created with the following settings:

- Password of z2F%s)bW$4f.
- For the dial-in properties on the VPN_Phoenix account, the remote access permission is set to **Control access through Remote Access Policy**.

- For the account properties on the VPN_Phoenix account, the **Password never expires** account option is enabled.
- The VPN_Phoenix account is added to the VPN_Routers group.

For the Chicago office VPN connection and the Phoenix office VPN connection that are initiated by the corporate headquarters router, the user account VPN_CorpHQ is created with the following settings:

- Password of o3\Dn6@`-J4.
- For the dial-in properties on the VPN_CorpHQ account, the remote access permission is set to **Control access through Remote Access Policy**.
- For the account properties on the VPN_CorpHQ account, the **Password never expires** account option is enabled.
- The VPN_CorpHQ account is added to the VPN_Routers group.

**Remote access policy configuration**
Remote access policies must be configured at the VPN server, the Chicago router, and the Phoenix router.

**Remote access policy configuration at the VPN server**
The remote access policy configuration for the VPN server is the same as described in On-Demand Branch Office.

**Remote access policy configuration at the Chicago router**
To define the authentication and encryption settings for the VPN connections, the default policies are deleted, and the following remote access policy is created:

- Policy name: VPN Routers
- Conditions:
    - **NAS-Port-Type** is set to Virtual (VPN)
    - **Windows-Groups** is set to VPN_Routers
    - **Called-Station-ID** is set to 131.107.0.1
- Permission is set to **Grant remote access permission**
- Profile settings:
    - **Authentication** tab: **Extensible Authentication Protocol** is enabled and **Smartcard or other certificate (TLS)** is configured to use the installed computer certificate (also known as the machine certificate). **Microsoft Encrypted Authentication version 2 (MS-CHAP v2) is also enabled.**
    - **Encryption** tab: **Strong** and **Strongest** are the only options that are selected.

**Note**

- The **Called-Station-ID** is set to the IP address of the Internet interface for the branch office router. Only tunnels initiated from the Internet are allowed. Tunnels initiated from the Electronic, Inc. branch office network are not permitted.

**Remote access policy configuration at the Phoenix router**
To define the authentication and encryption settings for the VPN connections, the default policies are deleted, and the following remote access policy is created:

- Policy name: VPN Routers

- Conditions:
    - **NAS-Port-Type** is set to Virtual (VPN)
    - **Windows-Groups** is set to VPN_Routers
    - **Called-Station-ID** is set to 131.107.128.1
- Permission is set to **Grant remote access permission**
- Profile settings:
    - **Authentication** tab: **Extensible Authentication Protocol** is enabled and **Smartcard or other certificate (TLS)** is configured to use the installed computer certificate (also known as the machine certificate). **Microsoft Encrypted Authentication version 2 (MS-CHAP v2)** is also enabled.
    - **Encryption** tab: **Strong** and **Strongest** are the only options that are selected.

### Note

- The **Called-Station-ID** is set to the IP address of the Internet interface for the branch office router. Only tunnels initiated from the Internet are allowed. Tunnels initiated from the Electronic, Inc. branch office network are not permitted.

#### IP address pool configuration

IP address pools must be configured at the VPN server, the Chicago router, and the Phoenix router.

#### IP address pool configuration at the VPN server

The IP address pool configuration for the VPN server is the same as described in Common configuration for the VPN server.

#### IP address pool configuration at the Chicago router

A static IP address pool with a starting IP address of 192.168.9.248 and an ending IP address of 192.168.9.253 is configured. This creates a static address pool for up to five VPN clients.

For more information, see Create a static IP address pool.

#### IP address pool configuration at the Phoenix router

A static IP address pool with a starting IP address of 192.168.14.248 and an ending IP address of 192.168.14.253 is configured. This creates a static address pool for up to five VPN clients.

For more information, see Create a static IP address pool.

For more information about the corporate router and branch office router configuration, see:

- The Chicago office: PPTP-based persistent branch office
- The Phoenix office: L2TP-based persistent branch office

### Note

- The example companies, organizations, products, people and events depicted herein are fictitious. No association with any real company, organization, product, person or event is intended or should be inferred.

# PPTP-based persistent branch office

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PPTP-based persistent branch office**
The Chicago branch office is a PPTP-based branch office that uses a router running Windows Server 2003, Standard Edition, to create a persistent, router-to-router VPN connection with the corporate office router in New York. The connection is never terminated even when idle.

To deploy a PPTP, two-way initiated, persistent, router-to-router VPN connection to the corporate office based on the settings configured in Common configuration for the VPN server and Persistent Branch Office, the following settings are configured on the corporate router and Chicago router.

**VPN server configuration**
The VPN server is configured with a demand-dial interface and a static route.

**Demand-dial interface for router-to-router VPN connection**
To connect the corporate office router to the Chicago router by using a router-to-router VPN connection over the Internet, a demand-dial interface is created by using the Demand-Dial Interface Wizard with the following settings:

- **Interface name**

  VPN_Chicago

- **Connection type**

  **Connect using virtual private networking (VPN)** is selected.

- **VPN type**

  **Point to Point Tunneling Protocol (PPTP)** is selected.

- **Destination address**

  131.107.0.1

- **Protocols and security**

  The **Route IP packets on this interface** check box is selected.

- **Static Routes for Remote Networks**

  Static route for Chicago office network: To make all locations on the Chicago network reachable, the following static route is configured:

  - Interface: VPN_Chicago
  - Destination: 192.168.9.0
  - Network mask: 255.255.255.0
  - Metric: 1

- **Dial-out credentials**

  - User name: VPN_CorpHQ

- Domain: electronic.microsoft.com
- Password: o3\Dn6@`-J4
- Confirm password: o3\Dn6@`-J4

Once the demand-dial interface is created, the following change is made:

- For the properties of the demand-dial interface, on the **Options** tab, under **Connection type**, the **Persistent connection** option is selected. To obtain properties of a demand-dial interface, click **Routing Interfaces**, right-click the desired demand-dial interface, and then click **Properties**.

**Chicago router configuration**
The Chicago router is configured with a demand-dial interface and a static route.

**Demand-dial interface for router-to-router VPN connection**
To connect the Chicago office router to the corporate office router by using a router-to-router VPN connection over the Internet, a demand-dial interface is created by using the Demand-Dial Interface Wizard with the following settings:

- **Interface name**

  VPN_CorpHQ

- **Connection type**

  **Connect using virtual private networking (VPN)** is selected.

- **VPN type**

  **Point to Point Tunneling Protocol (PPTP)** is selected.

- **Destination address**

  207.209.68.1

- **Protocols and security**

  The **Route IP packets on this interface** check box is selected.

- **Static Routes for Remote Networks**

  Static route for the Electronic, Inc. VPN server: To make the Electronic, Inc. VPN server on the Internet reachable, the following static route is configured:

  - Interface: The WAN adapter attached to the Internet
  - Destination: 207.209.68.1
  - Network mask: 255.255.255.255
  - Gateway: 0.0.0.0
  - Metric: 1

  Static routes for corporate intranet and branch offices: To make all locations on the corporate intranet reachable, the following static route is configured:

    - Interface: VPN_CorpHQ
    - Destination: 172.16.0.0
    - Network mask: 255.240.0.0
    - Metric: 1

  To make all locations on Electronic, Inc. branch offices reachable, the following static route is configured:

    - Interface: VPN_CorpHQ
    - Destination: 192.168.0.0
    - Network mask: 255.255.0.0
    - Metric: 1

- **Dial-out credentials**
    - User name: VPN_Chicago
    - Domain: electronic.microsoft.com
    - Password: U9!j5dP(%q1
    - Confirm password: U9!j5dP(%q1

Once the demand-dial interface is created, the following change is made:

- For the properties of the demand-dial interface, on the **Options** tab, under **Connection type**, the **Persistent connection** option is selected.

**Notes**

- Because the WAN adapter creates a point-to-point connection to the ISP, any address can be entered for the gateway. The gateway address of 0.0.0.0 is an example. 0.0.0.0 is the unspecified IP address.

- The example companies, organizations, products, people and events depicted herein are fictitious. No association with any real company, organization, product, person or event is intended or should be inferred.

# L2TP-based persistent branch office

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**L2TP-based persistent branch office**

The Phoenix branch office is an L2TP/IPSec branch office that uses a router running Windows Server 2003, Standard Edition, to create a persistent, router-to-router VPN connection with the corporate office router in New York. The connection is never terminated even when idle.

To deploy an L2TP, two-way initiated, persistent, router-to-router VPN connection to the corporate office based on the settings configured in Common configuration for the VPN server and Persistent Branch Office, the following settings are configured on the corporate router and Phoenix router.

**VPN server configuration**

The VPN server is configured with a demand-dial interface and a static route.

**Demand-dial interface for router-to-router VPN connection**

To connect the corporate office router to the Phoenix router by using a router-to-router VPN connection over the Internet, a demand-dial interface is created by using the Demand-Dial Interface Wizard with the following settings:

- **Interface name**

  VPN_Phoenix

- **Connection type**

  **Connect using virtual private networking (VPN)** is selected.

- **VPN type**

  **Layer-2 Tunneling Protocol (L2TP)** is selected.

- **Destination address**

  131.107.128.1

- **Protocols and security**

  The **Route IP packets on this interface** check box is selected.

- **Static Routes for Remote Networks**

  Static route for Phoenix office network: To make all locations on the Phoenix network reachable, the following static route is configured:

  - Interface: VPN_Phoenix
  - Destination: 192.168.14.0
  - Network mask: 255.255.255.0
  - Metric: 1

- **Dial-out credentials**

  - User name: VPN_CorpHQ

- Domain: electronic.microsoft.com
- Password: o3\Dn6@`-J4
- Confirm password: o3\Dn6@`-J4

Once the demand-dial interface is created, the following change is made:

- For the properties of the demand-dial interface, on the **Options** tab, under **Connection type**, the **Persistent connection** option is selected.

**Phoenix router configuration**

The Phoenix router was configured by the Electronic, Inc. network administrator while connected to the Electronic, Inc. intranet and then shipped to the Phoenix site. While the Phoenix router was connected to the Electronic, Inc. intranet, a computer certificate was installed through auto-enrollment. Additionally, the Phoenix router computer was configured with a demand-dial interface and a static route.

**Demand-dial interface for router-to-router VPN connection**

To connect the Phoenix office router to the corporate office router by using a router-to-router VPN connection over the Internet, a demand-dial interface is created by using the Demand-Dial Interface Wizard with the following settings:

- **Interface name**

  VPN_CorpHQ

- **Connection type**

  **Connect using virtual private networking (VPN)** is selected.

- **VPN type**

  **Layer-2 Tunneling Protocol (L2TP)** is selected.

- **Destination address**

  207.209.68.1

- **Protocols and security**

  The **Route IP packets on this interface** check box is selected.

- **Static Routes for Remote Networks**

  Static route for the Electronic, Inc. VPN server: To make the Electronic, Inc. VPN server on the Internet reachable, the following static route is configured:

  - Interface: The WAN adapter attached to the Internet
  - Destination: 207.209.68.1
  - Network mask: 255.255.255.255
  - Gateway: 0.0.0.0
  - Metric: 1

  **Note**

- Because the WAN adapter creates a point-to-point connection to the ISP, any address can be entered for the gateway. The gateway address of 0.0.0.0 is an example. 0.0.0.0 is the unspecified IP address.

Static route for corporate intranet and branch offices: To make all locations on the corporate intranet reachable, the following static route is configured:

- Interface: VPN_CorpHQ
- Destination: 172.16.0.0
- Network mask: 255.240.0.0
- Metric: 1

To make all locations on Electronic, Inc. branch offices reachable, the following static route is configured:

- Interface: VPN_CorpHQ
- Destination: 192.168.0.0
- Network mask: 255.255.0.0
- Metric: 1

- **Dial-out credentials**
  - User name: VPN_Phoenix
  - Domain: electronic.microsoft.com
  - Password: z2F%s)bW$4f
  - Confirm password: z2F%s)bW$4f

Once the demand-dial interface is created, the following change is made:

- For the properties of the demand-dial interface, on the **Options** tab, under **Connection type**, the **Persistent connection** option is selected.

**Note**

- The example companies, organizations, products, people and events depicted herein are fictitious. No association with any real company, organization, product, person or event is intended or should be inferred.

# Extranet for Business Partners

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Extranet for business partners**

The network administrator for Electronic, Inc. has created an extranet, a portion of the Electronic, Inc. private network that is available to business partners through secured VPN connections. The Electronic, Inc. extranet is the network attached to the Electronic, Inc. VPN server and contains a file server and a Web server. Parts distributors Tasmanian Traders and Parnell Aerospace are Electronic, Inc. business partners and connect to the Electronic, Inc. extranet by using on-demand, router-to-router VPN connections. An additional access policy is used to ensure that the business partners can only access the extranet file server and Web server.

The file server on the Electronic, Inc. extranet is configured with an IP address of 172.31.0.10, and the Web server is configured with an IP address of 172.31.0.11. Tasmanian Traders uses the public network ID of 131.107.254.0 with a subnet mask of 255.255.255.0. Parnell Aerospace uses the public network ID of 131.107.250.0 with a subnet mask of 255.255.255.0. To ensure that the extranet Web server and file server can reach the business partners, static routes are configured on the file server and Web server for each of the business partner networks that use the gateway address of 172.31.0.1

To simplify configuration, the VPN connection is a one-way initiated connection. The connection is always initiated by the business partner router. For more information, see One-way initiated demand-dial connections.

The following illustration shows the Electronic, Inc. VPN server that provides extranet connections for business partners.

To deploy business partner, on-demand, one-way initiated, router-to-router VPN connections to connect Tasmanian Traders and Parnell Aerospace to the Electronic, Inc. extranet based on the settings configured in Common configuration for the VPN server, the following additional settings are configured.

**Domain configuration**

For the VPN connection to Tasmanian Traders, the user account PTR_Tasmanian is created with the following settings:

- Password of Y8#-vR7?]fl.
- For the dial-in properties on the PTR_Tasmanian account, the remote access permission is set to **Control access through Remote Access Policy**.
- For the account properties on the PTR_Tasmanian account, the **Password never expires** account option is enabled.
- The PTR_Tasmanian account is added to the VPN_Partners group.

For the VPN connection to Parnell Aerospace, the user account PTR_Parnell is created with the following settings:

- Password of W@8c^4r-;2\.
- For the dial-in properties on the PTR_Parnell account, the remote access permission is set to **Control access through Remote Access Policy**.

- For the account properties on the PTR_Parnell account, the **Password never expires** account option is enabled.
- The PTR_Parnell account is added to the VPN_Partners group.

**Routing configuration**

In order for traffic to be sent back to the Tasmanian Traders and Parnell Aerospace business partners, additional routes are added to the routing tables on the file server and Web server computers. On both computers, the following commands were issued at the Windows Server 2003 command prompt.

- route -p add 131.107.254.0 mask 255.255.255.0 172.31.0.1
- route -p add 131.107.250.0 mask 255.255.255.0 172.31.0.1

**Remote access policy configuration**

To define the authentication and encryption settings for business partner VPN connections, the following remote access policy is created:

- Policy name: VPN Partners
- Conditions:
    - **NAS-Port-Type** is set to Virtual (VPN)
    - **Windows-Groups** is set to VPN_Partners
    - **Called-Station-ID** is set to 207.209.68.1
- Permission is set to **Grant remote access permission**
- Profile settings:
    - **Authentication** tab: **Extensible Authentication Protocol** is enabled and **Smartcard or other certificate (TLS)** is configured to use the installed computer certificate (also known as the machine certificate). **Microsoft Encrypted Authentication version 2 (MS-CHAP v2)** is also enabled.
    - **Encryption** tab: **Strong** and **Strongest** are the only options that are selected.

**Demand-dial interface configuration**

To connect the Tasmanian Traders router to the Electronic, Inc. VPN server by using a router-to-router VPN connection over the Internet, a demand-dial interface is created by using the Demand-Dial Interface Wizard with the following settings:

- **Interface name**

  PTR_Tasmanian

- **Connection type**

  **Connect using virtual private networking (VPN)** is selected.

- **VPN type**

  **Point to Point Tunneling Protocol (PPTP)** is selected.

- **Destination address**

  Leave blank.

- **Protocols and security**

  The **Route IP packets on this interface** check box is selected.

- **Dial-out credentials**

  - User name: none
  - Domain: none
  - Password: none
  - Confirm password: none

**Note**

- The destination address is left blank, and the user name is set to "none" because this demand-dial interface is never used to initiate the connection. The business partner always initiates the connection to the Electronic, Inc. VPN server.

To connect the Parnell Aerospace router to the Electronic, Inc. VPN server by using a router-to-router VPN connection over the Internet, a demand-dial interface is created by using the Demand-Dial Interface Wizard with the following settings:

- **Interface name**

  PTR_Parnell

- **Connection type**

  **Connect using virtual private networking (VPN)** is selected.

- **VPN type**

  **Point to Point Tunneling Protocol (PPTP)** is selected.

- **Destination address**

  Leave blank.

- **Protocols and security**

  The **Route IP packets on this interface** check box is selected.

- **Dial-out credentials**

  - User name: none
  - Domain: none Password: none
  - Confirm password: none

**Note**

- The destination address is left blank and the user name is set to "none" because this demand-dial interface is never used to initiate the connection. The business partner always initiates the connection to the Electronic, Inc. VPN server.

**Static route for Tasmanian Traders**
To make all locations at Tasmanian Traders reachable, the following static route is configured:

- Interface: PTR_Tasmanian
- Destination: 131.107.254.0
- Network mask: 255.255.255.0
- Metric: 1

**Static route for Parnell Aerospace**
To make all locations at Parnell Aerospace reachable, the following static route is configured:

- Interface: PTR_Parnell
- Destination: 131.107.250.0
- Network mask: 255.255.255.0
- Metric: 1

**IP packet filter configuration**
To confine the traffic from the Tasmanian Traders business partner to the file server and Web server, the following IP packet filters are configured on the PTR_Tasmanian demand-dial interface:

- Input filters
    - Filter action: **Deny all traffic except those listed below**
    - Filter 1: Destination network IP address of 172.31.0.10 and subnet mask of 255.255.255.255
    - Filter 2: Destination network IP address of 172.31.0.11 and subnet mask of 255.255.255.255
- Output filters
    - Filter action: **Deny all traffic except those listed below**
    - Filter 1: Source network IP address of 172.31.0.10 and subnet mask of 255.255.255.255
    - Filter 2: Source network IP address of 172.31.0.11 and subnet mask of 255.255.255.255

To confine the traffic from the Parnell Aerospace business partner to the file server and Web server, the following IP packet filters are configured on the PTR_Parnell demand-dial interface:

- Input filters
    - Filter action: **Deny all traffic except those listed below**
    - Filter 1: Destination network IP address of 172.31.0.10 and subnet mask of 255.255.255.255
    - Filter 2: Destination network IP address of 172.31.0.11 and subnet mask of 255.255.255.255
- Output filters
    - Filter action: **Deny all traffic except those listed below**

- Filter 1: Source network IP address of 172.31.0.10 and subnet mask of 255.255.255.255
- Filter 2: Source network IP address of 172.31.0.11 and subnet mask of 255.255.255.255

**Note**

- The **Called-Station-ID** is set to the IP address of the Internet interface for the VPN server. Only tunnels initiated from the Internet are allowed. Tunnels initiated from the Electronic, Inc. intranet are not permitted. Electronic, Inc. users that require Internet access from the Electronic, Inc. intranet must go through the Electronic, Inc. proxy server (not shown), where Internet access is controlled and monitored.

For more information about the business partner router configuration, see:

- Tasmanian Traders: PPTP-based extranet for business partners
- Parnell Aerospace: L2TP-based extranet for business partners

**Note**

- The example companies, organizations, products, people and events depicted herein are fictitious. No association with any real company, organization, product, person or event is intended or should be inferred.

# PPTP-based extranet for business partners

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PPTP-based extranet for business partners**

Tasmanian Traders is a business partner that uses a router running a Windows Server 2003 operating system to create an on-demand, PPTP-based, router-to-router VPN connection with the Electronic, Inc. corporate office router in New York as needed. When the connection is created and is idle for five minutes, the connection is terminated. The Tasmanian Traders router is connected to the Internet by using a permanent WAN connection.

To deploy a PPTP, one-way initiated, on-demand, router-to-router VPN connection to the corporate office based on the settings configured in Common configuration for the VPN server and Extranet for Business Partners, the following settings are configured on the Tasmanian Traders router:

**Demand-dial interface for router-to-router VPN connection**

To connect the Tasmanian Traders router to the Electronic, Inc. VPN server by using a router-to-router VPN connection over the Internet, a demand-dial interface is created by using the Demand-Dial Interface Wizard with the following settings:

- **Interface name**

  Electronic

- **Connection type**

  **Connect using virtual private networking (VPN)** is selected.

- **VPN type**

  **Point to Point Tunneling Protocol (PPTP)** is selected.

- **Destination address**

  207.209.68.1

- **Protocols and security**

  The **Route IP packets on this interface** check box is selected.

- **Static Routes for Remote Networks**

  Static route for Electronic, Inc. extranet: To make all locations on the Electronic, Inc. extranet reachable, the following static route is configured:

  - Interface: Electronic
  - Destination: 172.31.0.0
  - Network mask: 255.255.0.0
  - Metric: 1

- **Dial-out credentials**

  - User name: PTR_Tasmanian
  - Domain: electronic.microsoft.com

- Password: Y8#-vR7?]fI
- Confirm password: Y8#-vR7?]fI

**Notes**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

- The example companies, organizations, products, people and events depicted herein are fictitious. No association with any real company, organization, product, person or event is intended or should be inferred.

# L2TP-based extranet for business partners

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**L2TP-based extranet for business partners**

Parnell Aerospace is a business partner that uses a router running Windows Server 2003, Standard Edition, to create an on-demand, L2TP/IPSec, router-to-router VPN connection with the Electronic, Inc. corporate office router in New York as needed. When the connection is created and is idle for five minutes, the connection is terminated. The Parnell Aerospace router is connected to the Internet by using a permanent WAN connection.

To deploy an L2TP, one-way initiated, on-demand, router-to-router VPN connection to the corporate office based on the settings configured in Common configuration for the VPN server and Extranet for Business Partners, the following settings are configured on the Parnell Aerospace router.

**Certificate configuration**

The Parnell Aerospace router was configured by the Electronic, Inc. network administrator while physically connected to the Electronic, Inc. intranet and then shipped to the network administrator at Parnell Aerospace. While the Parnell Aerospace router was connected to the Electronic, Inc. intranet, a computer certificate was installed through auto-enrollment.

**Demand-dial interface for router-to-router VPN connection**

To connect the Parnell Aerospace router to the Electronic, Inc. VPN server by using a router-to-router VPN connection over the Internet, a demand-dial interface is created by using the Demand-Dial Interface Wizard with the following settings:

- **Interface name**

  Electronic

- **Connection type**

  **Connect using virtual private networking (VPN)** is selected.

- **VPN type**

  **Layer-2 Tunneling Protocol (L2TP)** is selected.

- **Destination address**

  207.209.68.1 (the IP address of the Electronic, Inc. VPN server's interface on the Internet)

- **Protocols and security**

  The **Route IP packets on this interface** check box is selected.

- **Static Routes for Remote Networks**

  Static route for Electronic, Inc. extranet: To make all locations on the Electronic, Inc. extranet reachable, the following static route is configured:

  - Interface: Electronic
  - Destination: 172.31.0.0
  - Network mask: 255.255.0.0
  - Metric: 1

- **Dial-out credentials**

- User name: PTR_Parnell
- Domain: electronic.microsoft.com
- Password: W@8c^4r-;2\
- Confirm password: W@8c^4r-;2\

**Notes**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

- The example companies, organizations, products, people and events depicted herein are fictitious. No association with any real company, organization, product, person or event is intended or should be inferred.

# Dial-up and VPNs with RADIUS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Dial-up and VPNs with RADIUS**
In addition to VPN-based remote access, the network administrator for Electronic, Inc. wants to provide modem-based dial-up remote access for employees of the New York office. All employees of the New York office belong to a Windows Server 2003 operating system group called NY_Employees. A separate remote access server running Windows Server 2003, Standard Edition, provides dial-up remote access at the phone number 555-0111. Rather than administer the remote access policies of both the VPN server and the remote access server separately, the network administrator is using a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition; with Internet Authentication Service (IAS) as a RADIUS server. The IAS server has an IP address of 172.31.0.9 on the Electronic, Inc. extranet and provides centralized remote access authentication, authorization, and accounting for both the remote access server and the VPN server.

The following illustration shows the Electronic, Inc. RADIUS server that provides authentication and accounting for the VPN server and the remote access server.

**Domain configuration**
For each New York office employee that is allowed dial-up access, the remote access permission for the dial-in properties of the user account is set to **Control access through Remote Access Policy**.

**Remote access policy configuration**
Remote access policies must be modified in two ways:

1. The existing remote access policies that are configured on the VPN server running Windows Server 2003 must be copied to the IAS server.

2. A new remote access policy is added for dial-up remote access clients on the IAS server.

**Copying the remote access policies**
Once the VPN server running Windows Server 2003 is configured to use RADIUS authentication, the remote access policies stored on the VPN server are no longer used. Instead, the remote access policies stored on the IAS server running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition. Therefore, the current set of remote access policies is copied to the IAS server.

For more information, see Copy the IAS configuration to another server.

**Creating a new remote access policy for dial-up remote access clients**
To define the authentication and encryption settings for dial-up connections by employees of the New York office, the following remote access policy is created on the RADIUS server computer:

- Policy name: Dial-Up for New York Employees

- Conditions:

    - **NAS-Port-Type** is set to all types *except* Virtual (VPN)

    - **Windows-Groups** is set to NY_Employees

- Permission is set to **Grant remote access permission**

- Profile settings:

    - **Authentication** tab: **Extensible Authentication Protocol** is enabled and **Smartcard or other certificate (TLS)** is configured to use the installed computer certificate (also known as the machine certificate). **Microsoft Encrypted Authentication version 2 (MS-CHAP v2)** and **Microsoft Encrypted Authentication (MS-CHAP)** are also enabled.

    - **Encryption** tab: All options are selected.

**RADIUS configuration**

To configure RADIUS authentication and accounting, the network administrator for Electronic, Inc. configures the following:

- The RADIUS server is a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition; and with IAS installed. IAS is configured for two RADIUS clients; the remote access server and the VPN server. For more information, see Internet Authentication Service and Add RADIUS clients.

- The remote access server running a member of the Windows Server 2003 family is configured to use RADIUS authentication and accounting at the IP address of 172.31.0.9 and a shared secret. For more information, see Use RADIUS authentication and Use RADIUS accounting.

- The VPN server running Windows Server 2003 is configured to use RADIUS authentication and accounting at the IP address of 172.31.0.9 and to use a shared secret. For more information, see Use RADIUS authentication and Use RADIUS accounting.

**Dial-up remote access client configuration**

The New Connection Wizard is used to create a dial-up connection with the following setting:

- Phone number: 555-0111

### Note

- The example companies, organizations, products, people and events depicted herein are fictitious. No association with any real company, organization, product, person or event is intended or should be inferred.

# Virtual Private Network Test Lab

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Virtual private network test lab**
This section provides detailed information about how you can use five computers to create a test lab with which to configure and test the virtual private network (VPN) features in the Windows Server 2003 family. These instructions are designed to take you through a set of tasks that expose you to VPN connections and their functionality. Beyond the set of tasks, you can use these instructions to create a functioning VPN configuration. You can then use this configuration to experiment with VPN features and functionality in the Windows Server 2003 family prior to deployment on your production network.

This section covers:

- Setting up the VPN test network infrastructure
- Virtual private network test lab tasks

**Note**

- The following instructions are for configuring a test lab using a minimum number of computers. Individual computers are needed to separate the services provided on the network and to clearly show the desired functionality. This configuration is neither designed to reflect best practices nor is it designed to reflect a desired or recommended configuration for a production network. The configuration, including IP addresses and all other configuration parameters, is designed only to work on a separate test lab network.

For more information about deploying VPN connections, see Deploying Virtual Private Networks. For configuration checklists, see VPN Checklists. For an example implementation of VPN connections, see Virtual Private Network Implementation Examples.

# Setting up the VPN test network infrastructure

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting up the infrastructure**

The infrastructure for the VPN test lab network consists of five computers performing the following services:

- A computer running Windows Server 2003, Standard Edition, named DC1 that is acting as a domain controller, a Domain Name System (DNS) server, and a certification authority (CA).
- A computer running Windows Server 2003, Standard Edition, named IAS1 that is acting as a Remote Authentication Dial-in User Service (RADIUS) server.
- A computer running Windows Server 2003, Standard Edition, named IIS1 that is acting as a Web server and file sharing server.
- A computer running Windows Server 2003, Standard Edition, named VPN1 that is acting as a VPN server. VPN1 has two network adapters installed.
- A computer running Windows XP Professional named CLIENT1 that is acting as a VPN client.

The following illustration shows the configuration of the VPN test lab.

There is a network segment representing a corporate intranet and a network segment representing the Internet. All computers on the corporate intranet are connected to a common hub or Layer 2 switch. All computers on the Internet are connected to a separate common hub or Layer 2 switch. Private addresses are used throughout the test lab configuration. The private network of 172.16.0.0/24 is used for the intranet. The private network of 10.0.0.0/24 is used for the simulated Internet.

Each computer is manually configured with the appropriate IP address, subnet mask, and DNS server IP address. There are no Dynamic Host Configuration protocol (DHCP) or Windows Internet Name Service (WINS) servers present.

The following sections describe the configuration for each of the computers in the test lab. To reconstruct this test lab, configure the computers in the order presented.

### Note

- The following instructions are for configuring a test lab using a minimum number of computers. Individual computers are needed to separate the services provided on the network and to clearly show the desired functionality. This configuration is neither designed to reflect best practices nor is it designed to reflect a desired or recommended configuration for a production network. The configuration, including IP addresses and all other configuration parameters, is designed only to work on a separate test lab network.

**DC1**

DC1 is a computer running Windows Server 2003, Standard Edition, that is providing the following services:

- A domain controller for the testlab.microsoft.com domain.
- A DNS server for the testlab.microsoft.com DNS domain.
- The enterprise root certification authority (CA) for the testlab.microsoft.com domain.

To configure DC1 for these services, perform the following steps.

1. Install Windows Server 2003, Standard Edition, as a stand-alone server.
2. Configure the TCP/IP protocol with the IP address of 172.16.0.1 and the subnet mask of 255.255.255.0. For more information, see Configure TCP/IP for static addressing.
3. Run Active Directory Installation Wizard for a new domain called testlab.microsoft.com in a new forest. Install the DNS service when prompted.
4. Install the Certificate Services component as an enterprise root CA. For more information, see Install an enterprise root certification authority.
5. Configure the testlab.microsoft.com domain for automatic enrollment of computer certificates. For more information, see Configure automatic certificate allocation from an enterprise CA.

**IAS1**

IAS1 is a computer running Windows Server 2003, Standard Edition, that is providing RADIUS authentication, authorization, and accounting for VPN1 (the VPN server computer).

To configure IAS1 as a RADIUS server, perform the following steps:

1. On DC1, add a computer account for the IAS1 computer. For more information, see Create a new computer account.
2. Install Windows Server 2003, Standard Edition, as a stand-alone server.
3. Configure the TCP/IP protocol with the IP address of 172.16.0.2, the subnet mask of 255.255.255.0, and the DNS server IP address of 172.16.0.1. For more information, see Configure TCP/IP for static addressing and Configure TCP/IP to use DNS.
4. Join IAS1 to the testlab.microsoft.com domain. For more information, see Join a domain.
5. Install Internet Authentication Service (IAS) and register it in the testlab.microsoft.com domain. For more information, see Install IAS and Enable the IAS server to read user accounts in Active Directory.

**IIS1**

IIS1 is a computer running Windows Server 2003, Standard Edition, and Internet Information Services (IIS). It is providing Web server services for intranet clients. To configure IIS1 as a Web server, perform the following steps:

1. On DC1, add a computer account for the IIS1 computer. For more information, see Create a new computer account.
2. Install Windows Server 2003, Standard Edition, as a stand-alone server, then install IIS.

   For more information, see Installing IIS.
3. Configure the TCP/IP protocol with the IP address of 172.16.0.3, the subnet mask of 255.255.255.0, and the DNS server IP address of 172.16.0.1. For more information, see Configure TCP/IP for static addressing and Configure TCP/IP to use DNS.

4. Join IIS1 to the testlab.microsoft.com domain. For more information, see Join a domain.

5. Install IIS.

6. To determine whether the Web server is working correctly, run your Web browser on IAS1. When prompted by the Internet Connection Wizard, configure the wizard for a LAN connection. In your Web browser, in **Address**, type **http://IIS1.testlab.microsoft.com/wnetStndS_v_s_rgb.gif**. You should see a Windows Server 2003, Standard Edition, graphic.

7. On IIS1, in Windows Explorer, share the root directory of **Local Disk (C:)** using the share name **ROOT** to the group **Everyone** with full access. For more information, see Share a folder or drive.

**VPN1**

VPN1 is a computer running Windows Server 2003, Standard Edition, that is providing VPN server services for Internet-based VPN clients. To configure VPN1 as a VPN server, perform the following steps:

1. On DC1, add a computer account for VPN1. For more information, see Create a new computer account.

2. Install Windows Server 2003, Standard Edition, as a stand-alone server.

3. For the intranet local area connection, configure the TCP/IP protocol with the IP address of 172.16.0.4, the subnet mask of 255.255.255.0, and the DNS server IP address of 172.16.0.1. For more information, see Configure TCP/IP for static addressing and Configure TCP/IP to use DNS.

4. For the Internet local area connection, configure the TCP/IP protocol with the IP address of 10.0.0.2 and the subnet mask of 255.255.255.0. For more information, see Configure TCP/IP for static addressing.

5. Join VPN1 to the testlab.microsoft.com domain. For more information, see Join a domain.

6. Configure and enable the Routing and Remote Access service. For more information, see Enable the Routing and Remote Access service. In the Routing and Remote Access server Setup Wizard, select **Virtual private network (VPN) server** from the list of common configurations. When prompted for IP address assignment, select **From a specified range of addresses** and configure the range 172.16.0.248 to 172.16.0.255. Do not configure RADIUS authentication.

**CLIENT1**

CLIENT1 is a computer running Windows XP Professional that is acting as a VPN client and gaining remote access to intranet resources across the simulated Internet. To configure CLIENT1 as a VPN client, perform the following steps:

1. On DC1, add a computer account for CLIENT1. For more information, see Create a new computer account.

2. Connect CLIENT1 to the intranet network segment.

3. On CLIENT1, install Windows XP Professional as a workgroup computer.

4. Configure the TCP/IP protocol with the IP address of 172.16.0.5, the subnet mask of 255.255.255.0, and the DNS server IP address of 172.16.0.1. For more information, see Configure TCP/IP for static addressing and Configure TCP/IP to use DNS.

5. Join CLIENT1 to the testlab.microsoft.com domain. For more information, see Join a domain.

6. Configure the TCP/IP protocol with the IP address of 10.0.0.1, the subnet mask of 255.255.255.0, and no DNS server IP address. For more information, see Configure TCP/IP for static addressing and Configure TCP/IP to use DNS.

7. Shut down the CLIENT1 computer.

8. Disconnect the CLIENT1 computer from the intranet network segment, and connect it to the simulated Internet network

segment.

9. Restart the CLIENT computer and log on using the cached credentials of the testlab.microsoft.com administrator account.

# Virtual private network test lab tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Virtual private network test lab tasks**
The following tasks are designed to take you through the most common elements of setting up VPN support with the Windows Server 2003 family:

- PPTP-based remote access
- L2TP/IPSec remote access
- RADIUS authentication and accounting
- Remote access policies for both PPTP and L2TP connections

### Note

- The following instructions are for configuring a test lab using a minimum number of computers. Individual computers are needed to separate the services provided on the network and to clearly show the desired functionality. This configuration is neither designed to reflect best practices nor is it designed to reflect a desired or recommended configuration for a production network. The configuration, including IP addresses and all other configuration parameters, is designed only to work on a separate test lab network.

**PPTP-based remote access**
To create a PPTP-based remote access VPN connection between CLIENT1 and VPN1 and test whether intranet resources are available, perform the following steps:

**1. Create a user account.**

1. On DC1, use Active Directory Users and Computers to create a user account called **PPTPUser** and set the password. For more information, see Create a new computer account.
2. Set the remote access permission on the **Dial-in** tab to **Allow access**. For more information, see Configure remote access permission for a user.

**2. Create the PPTP connection.**

1. On CLIENT1, use the New Connection Wizard to create a new PPTP-based connection named **PPTPtoCorpnet**, using the IP address of 10.0.0.2. For more information, see Make a virtual private network (VPN) connection.
2. Obtain properties on the newly created **PPTPtoCorpnet** connection, and click the **Networking** tab.
3. Under **Type of VPN server I am calling**, select **PPTP VPN**, and click **OK**.

**3. Make the PPTP connection.**

1. On CLIENT1, double-click the **PPTPtoCorpnet** connection.
2. When prompted for credentials, type **PPTPUser** as the user name, **testlab.microsoft.com** as the domain name, and the password.

**4. Access Web server and file share on the intranet.**

1. On CLIENT1, run your Web browser.

2. When prompted by the Internet Connection Wizard, configure it for a LAN connection. In your Web browser, type **http://IIS1.testlab.microsoft.com/wnetStndS_v_s_rgb.gif**.

   You should see a Windows Server 2003, Standard Edition, graphic.

3. On CLIENT1, click **Start**, click **Run**, type **\\IIS1\ROOT**, and then click **OK**.

   You should see the contents of the Local Drive (C:) on IIS1.

**5. Disconnect the PPTP connection.**

- On CLIENT1, right-click the **PPTPtoCorpnet** connection, and then click **Disconnect**.

**L2TP/IPSec remote access**

To create an L2TP/IPSec remote access VPN connection between CLIENT1 and VPN1 and test whether intranet resources are available, perform the following steps:

**1. Create a user account.**

1. On DC1, use Active Directory Users and Computers to create a user account called **L2TPUser**, and set the password. For more information, see Create a new computer account.

2. Set the remote access permission on the **Dial-in** tab to **Allow access**. For more information, see Configure remote access permission for a user.

**2. Create the L2TP connection.**

1. On CLIENT1, use the New Connection Wizard to create a new L2TP/IPSec connection named **L2TPtoCorpnet**, using the IP address of 10.0.0.2. For more information, see Make a virtual private network (VPN) connection.

2. Obtain properties on the newly created **L2TPtoCorpnet** connection, and click the **Networking** tab.

3. Under **Type of VPN server I am calling**, select **L2TP IPSec VPN**, and click **OK**.

**3. Make the L2TP connection.**

1. On CLIENT1, double-click the **L2TPtoCorpnet** connection.

2. When prompted for credentials, type **L2TPUser** as the user name, **testlab.microsoft.com** as the domain name, and the password.

**4. Access Web server and file share on the intranet.**

1. On CLIENT1, run your Web browser.

2. When prompted by the Internet Connection Wizard, configure it for a LAN connection. In your Web browser, type **http://IIS1.testlab.microsoft.com/wnetStndS_v_s_rgb.gif**.

   You should see a Windows Server 2003, Standard Edition, graphic.

3. On CLIENT1, click **Start**, click **Run**, type **\\IIS1\ROOT**, and then click **OK**.

   You should see the contents of the Local Drive (C:) on IIS1.

**5. Disconnect the L2TP connection.**

- On CLIENT1, right-click the **L2TPtoCorpnet** connection, and then click **Disconnect**.

**RADIUS authentication and accounting**

To configure RADIUS authentication and accounting for VPN connections, perform the following steps:

**1. Configure IAS1 for VPN1 as a RADIUS client.**

- On IAS1, add VPN1 as a RADIUS client with the Microsoft Client-Vendor, at the IP address of 172.16.0.4, and set the shared secret. For more information, see Add RADIUS clients.

**2. Configure IAS1 to log authentication events.**

- On IAS1, enable the logging of accounting and authentication requests in the Internet Authentication Service console, in the **Remote Access Logging** folder, in the properties of the **Local File** object, on the **Settings** tab.

**3. Configure VPN1 for IAS1 as a RADIUS server.**

- On VPN1, add IAS1 as a RADIUS server for both the authentication and accounting provider, at the IP address of 172.16.0.2, and set the shared secret. For more information, see Use RADIUS authentication and Use RADIUS accounting.

**4. Make a PPTP connection.**

1. On CLIENT1, create a PPTP connection with VPN1 using the **PPTPtoCorpnet** connection.
2. Disconnect the connection. For more information, see Disconnect from a remote network.

**5. Make an L2TP connection.**

1. On CLIENT1, create an L2TP connection with VPN1 using the **L2TPtoCorpnet** connection.
2. Disconnect the connection. For more information, see Disconnect from a remote network.

**6. Check the system event log for RADIUS events.**

- On IAS1, use Event Viewer to view IAS events in the system event log for the PPTP and L2TP connections that were recently created using CLIENT1.

**7. Check RADIUS authentication and accounting logs.**

- On IAS1, use Windows Explorer to open the *systemroot*\System32\Logfiles\Iaslog.log file. Note the authentication and accounting entries for the PPTP and L2TP connection. For more information on the IAS log file format, see Interpreting IAS-formatted log files.

**Remote access policies for both PPTP and L2TP connections**

To create separate remote access policies for PPTP and L2TP connections, perform the following steps:

**1. On IAS1, create a new remote access policy with the following settings:**

- **Policy name**: PPTP connections
- **Policy Conditions**:
    - **NAS-Port-Type** matches **Virtual (VPN)**

- **Tunnel-Type** matches **Point-to-Point Tunneling Protocol (PPTP)**

- **If a connection request matches the specified conditions**: Grant remote access permission

- Profile settings, **IP** tab, output packet filter:

  Filter action: **Deny all traffic except those listed below**

  Destination network, IP address: 172.16.0.1

  Destination network, Subnet mask: 255.255.255.255

  Protocol: Any

- Profile settings, **IP** tab, input packet filter:

  Filter action: **Deny all traffic except those listed below**

  Source network, IP address: 172.16.0.1

  Destination network, Subnet mask: 255.255.255.255

  Protocol: Any

**2. On IAS1, create a new custom remote access policy with the following settings:**

- **Policy name**: L2TP connections

- **Policy Conditions**:

  **NAS-Port-Type** matches **Virtual (VPN)**

  **Tunnel-Type** matches **Layer Two Tunneling Protocol (L2TP)**

- **If a connection request matches the specified conditions**: Grant remote access permission

- Profile settings, **IP** tab, output packet filter:

  Filter action: **Deny all traffic except those listed below**

  Destination network, IP address: 172.16.0.2

  Destination network, Subnet mask: 255.255.255.255

  Protocol: Any

- Profile settings, **IP** tab, input packet filter:

  Filter action: **Deny all traffic except those listed below**

  Source network, IP address: 172.16.0.2

  Destination network, Subnet mask: 255.255.255.255

  Protocol: Any

**3. Make a PPTP connection and test connectivity.**

1. On CLIENT1, make a VPN connection with VPN1 using the **PPTPtoCorpnet** connection.

2. Use the **ping** command to ping DC1 at its IP address of 172.16.0.1.

3. Use the **ping** command to ping IAS1 at its IP address of 172.16.0.2. This command fails because packet filtering for all connections that match the **PPTP connections** policy allows only traffic sent to and from the IP address of 172.16.0.1.

4. Disconnect the **PPTPtoCorpnet** connection.

**4. Make an L2TP connection and test connectivity.**

1. On CLIENT1, make a VPN connection with VPN1 using the **L2TPtoCorpnet** connection.

2. Use the **ping** command to ping IAS1 at its IP address of 172.16.0.2.

3. Use the **ping** command to ping DC1 at its IP address of 172.16.0.1. This command fails because packet filtering for all connections that match the L2TP connections policy allows only traffic sent to and from the IP address of 172.16.0.2.

4. Disconnect the **L2TPtoCorpnet** connection.

**5. Check the system event log for IAS events.**

- On IAS1, use Event Viewer to view the IAS events in the system event log for the PPTP and L2TP connections that were recently created by CLIENT1. Note that the authentication event message text contains the name of the remote access policy that accepted the connection.

# VPN Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

The Microsoft Windows Server 2003 Deployment Kit contains advanced information about virtual private networks (VPNs).

- For more information about configuring, administering, and optimizing VPNs, see "Internetworking Guide" at the Microsoft Windows Resource Kits Web site.
- For more information about designing remote access solutions, see "Designing Network Services" at the Microsoft Windows Resource Kits Web site.
- For additional information, see VPN Technical White Papers at the Microsoft Web site.

For additional information about troubleshooting with the remote access server, see Remote Access Troubleshooting tools.

# Remote Access Troubleshooting tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting tools**
To help you gather information to troubleshoot problems with the remote access server, the following troubleshooting tools are available:

- Authentication and accounting logging. For more information see Logging.
- Event logging records errors, warnings, and events in the system event log.
- PPP logging creates a log file of the PPP control messages that are sent and received during a PPP connection.
- Tracing records the sequence of programming functions called during a process to a file. For more information, see Using tracing.
- Network Monitor captures traffic sent between a remote access server and dial-up client during the PPP connection process and during data transfer.
- Netsh commands for remote access configure and display remote access settings for a server running Routing and Remote Access. For more information, see Netsh commands for remote access (ras).

**Remote Access Diagnostics**
You can use the Remote Access diagnostic functions available in the Windows Server 2003 family to collect detailed logs and information about a remote access connection. Diagnostics can be set from the **Diagnostics** tab of the properties of the connection in the Network Connection folder, or you can run specific diagnostics by typing the **netsh ras diagnostics** command at the command line.

**Audit logging and Oakley logging for L2TP/IPSec connections**
You can use the Audit Logging feature to monitor IPSec-related events. This is the fastest and simplest method to troubleshoot unsuccessful L2TP/IPSec connections. You can also enable the Oakley log to record all ISAKMP main mode or quick mode negotiations. For more information, see IPSec troubleshooting tools.

**Event logging**
You can use event logging to record remote access server errors, warnings, and other detailed information in the system event log. You can enable event logging on the **Event Logging** tab on the properties of a remote access server. For more information, see View properties of the remote access server.

**PPP logging**
PPP logging records the series of programming functions and PPP control messages during a PPP connection and is a valuable source of troubleshooting information when you are troubleshooting the failure of a PPP connection. To enable PPP logging, select the **Enable Point-to-Point Protocol (PPP) logging** option on the **PPP** tab on the properties of a remote access server. For more information, see View properties of the remote access server.

The PPP log in Windows NT 4.0 has been replaced by the tracing function. To duplicate the PPP log, you need to enable file tracing for the PPP key. By default, the PPP log is stored as the ppp.log file in the *systemroot*\Tracing folder. For more information on tracing options, see Using tracing.

**Network Monitor**
Network Monitor can capture the network traffic between a dial-up networking client and the remote access server. By analyzing remote access traffic, you can find answers to remote access problems and possible solutions or workarounds. For more information, see Install and Configure Network Monitor.

### Note

- The proper interpretation of remote access traffic with Network Monitor requires an in-depth understanding of PPP and other protocols. You can save Network Monitor traces as files and send them to Microsoft Product Support Services for analysis.

# VPN Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
This section covers:

- Troubleshooting remote access VPNs
- Troubleshooting router-to-router VPNs

# Troubleshooting remote access VPNs

Updated: August 28, 2006

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting remote access VPNs**
What problem are you having?

- I received error 800, which says the VPN server is unreachable
- I received error 721, which says the remote computer is not responding
- I received error 741/742, which says there is an encryption mismatch error
- I am unable to establish a remote access VPN connection
- VPN clients are unable to access resources beyond the VPN server

**I received error 800, which says the VPN server is unreachable.**

- **Cause:** PPTP/L2TP packets from the VPN client cannot reach the VPN server.
- **Solution:**
  - Assuming ping is allowed (that is, not blocked) between the VPN client and the VPN server, ping the VPN server. Confirm that you have network connectivity and that packet filters configured on the VPN server are not preventing communication.
  - By default, when you configure the Routing and Remote Access service for the VPN server role, only PPTP and L2TP/IPsec packets are allowed on the Internet interface of the VPN server. Internet Control Message Protocol (ICMP) packets used by the ping command are filtered out. To enable ping on the VPN server, add an input filter and an output filter that allow ICMP traffic.
  - To allow PPTP traffic, configure the network firewall to open TCP port 1723 and to forward IP protocol 47 for Generic Routing Encapsulation (GRE) traffic to the VPN server. Some firewalls refer to IP protocol 47 as VPN or PPTP pass-through. Not all firewalls support IP protocol 47. You may need to upgrade the firmware.
  - To allow L2TP traffic, configure the network firewall to open UDP port 1701 and to allow IPsec ESP formatted packets (IP protocol 50).
  - Check that the VPN server is listening for PPTP traffic on TCP port 1723 and is listening for L2TP traffic on UDP port 1701. On the VPN server, from the command line, type:

    **netstat -aon**

    You should see the following:

    | | | | |
    |---|---|---|---|
    | TCP | 0.0.0.0:1723 | 0.0.0.0:0 | LISTENING |
    | UDP | 0.0.0.0:1701 | *:* | |

  - You can use the Portqry command-line tool to determine if PPTP and L2TP packets are being dropped between the VPN client and VPN server. For more information, see Description of the Portqry.exe command-line utility on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=71609).

To query the PPTP port, use the following command: `portqry.exe -n <server_IP_address> -e 1723`

To query the L2TP port, use the following command: `portqry.exe -n <server_IP_address> -e 1701 -p UDP`

If the query output includes "NOT LISTENING/FILTERED", check the port configuration on the RRAS server.

**I received error 721, which says the remote computer is not responding.**

- **Cause:** This issue can occur if the network firewall does not permit GRE traffic (IP protocol 47). PPTP uses GRE for tunneled data.

- **Solution:** Configure the network firewall between the VPN client and the server to permit GRE. In addition, make sure that the network firewall permits TCP traffic on port 1723. Both of these conditions must be met to establish VPN connectivity by using PPTP. For more information, see article 888201, "You receive an "Error 721" error message when you try to establish a VPN connection through your Windows Server-based remote access server" in the Microsoft Knowledge Base.

| **Note** |
| --- |
| The firewall might be on or in front of the VPN client or in front of the VPN server. |

**I received error 741/742, which says there is an encryption mismatch error.**

- **Cause:** These errors occur if the VPN client requests an encryption level that is not valid or if the VPN server does not support an encryption type requested by the client.

- **Solution:**

  - Check the properties (**Security** tab) of the VPN connection on the VPN client. If **Require data encryption (disconnect if none)** is selected, clear the selection and retry the connection.

  - If you are using Internet Authentication Service (IAS), check the encryption level in the remote access policy in the IAS console or policies on other RADIUS servers. Ensure that the encryption level requested by the VPN client is selected on the VPN server.

**I am unable to establish a remote access VPN connection.**

- **Cause:** The user account used by the remote access client is locked out, expired, disabled, or the time the connection is being made does not correspond to the configured logon hours.

- **Solution:** Modify the account properties of the user account.

**See also:** Manage Users, Groups, and Computers

**Cause:** The Routing and Remote Access service is not started on the VPN server.

**Solution:** Verify the state of the Routing and Remote Access service on the VPN server.

**See also:** Monitor the Routing and Remote Access service; Start and stop the Routing and Remote Access service

**Cause:** Remote access is not enabled on the VPN server.

**Solution:** Enable remote access on the VPN server.

**See also:** Enable the remote access server

**Cause:** PPTP or L2TP ports are not enabled for inbound remote access requests.

**Solution:** Enable PPTP ports, L2TP ports, or both, for inbound remote access requests.

**See also:** Configure ports for remote access

**Cause:** The LAN protocols being used by the VPN clients are not enabled for remote access on the VPN server.

**Solution:** Enable the LAN protocols being used by the VPN clients for remote access on the VPN server.

**See also:** View properties of the remote access server

**Cause:** All of the PPTP or L2TP ports on the VPN server are already being used by currently connected remote access clients or demand-dial routers.

**Solution:** Verify that all of the PPTP or L2TP ports on the VPN server are not already being used by clicking **Ports** in Routing and Remote Access. If necessary, change the number of PPTP or L2TP ports to allow more concurrent connections.

**See also:** Add PPTP or L2TP ports

**Cause:** The tunneling protocol of the VPN client is not supported by the VPN server.

By default, remote access VPN clients running Windows XP or a Windows Server 2003 operating system use the **Automatic** server type option, which means that they try to establish a PPTP-based VPN connection first, and then they try an L2TP/IPSec-based VPN connection. If VPN clients use either the **Point-to-Point Tunneling Protocol (PPTP)** or **Layer Two Tunneling Protocol (L2TP)** server type option, verify that the selected tunneling protocol is supported by the VPN server.

By default, a computer running a Windows Server 2003 operating system and the Routing and Remote Access service is a PPTP and L2TP server with five L2TP ports and five PPTP ports. To create a PPTP-only server, set the number of L2TP ports to 0. To create an L2TP-only server, set the number of PPTP ports to 1 and disable remote access inbound connections and demand-dial connections.

**Solution:** Verify that the appropriate number of PPTP or L2TP ports is configured.

**See also:** Add PPTP or L2TP ports

**Cause:** The VPN client and the VPN server in conjunction with a remote access policy are not configured to use at least one common authentication method.

**Solution:** Configure the VPN client and the VPN server in conjunction with a remote access policy to use at least one common authentication method.

**See also:** Configure authentication

**Cause:** The VPN client and the VPN server in conjunction with a remote access policy are not configured to use at least one common encryption method.

**Solution:** Configure the VPN client and the VPN server in conjunction with a remote access policy to use at least one common encryption method.

**See also:** Configure encryption

**Cause:** The VPN connection does not have the appropriate permissions through dial-in properties of the user account and remote access policies.

**Solution:** Verify that the VPN connection has the appropriate permissions through dial-in properties of the user account and remote access policies.

In order for the connection to be established, the settings of the connection attempt must:

- Match all of the conditions of at least one remote access policy.
- Be granted remote access permission through the user account (set to **Allow access**) or through the user account (set to **Control access through Remote Access Policy**) and the remote access permission of the matching remote access policy (set to **Grant remote access permission**).
- Match all the settings of the profile.
- Match all the settings of the dial-in properties of the user account.

**See also:** Introduction to remote access policies; Accepting a connection attempt

**Cause:** The settings of the remote access policy profile are in conflict with properties of the VPN server.

The properties of the remote access policy profile and the properties of the VPN server both contain settings for:

- Multilink
- Bandwidth allocation protocol
- Authentication protocols

If the settings of the profile of the matching remote access policy are in conflict with the settings of the VPN server, the connection attempt is rejected. For example, if the matching remote access policy profile specifies that the EAP-TLS authentication protocol must be used, and EAP is not enabled on the VPN server, the connection attempt is rejected.

**Solution:** Verify that the settings of the remote access policy profile are not in conflict with properties of the VPN server.

**See also:** Enable authentication protocols; Configure authentication

**Cause:** The credentials of the VPN client (user name, password, and domain name) are incorrect and cannot be validated by the VPN server.

**Solution:** Verify that the credentials of the VPN client (user name, password, and domain name) are correct and can be validated by the VPN server.

**Cause:** There are not enough addresses in the static IP address pool.

**Solution:** If the VPN server is configured with a static IP address pool, verify that there are enough addresses in the pool. If all of the addresses in the static pool have been allocated to connected VPN clients, the VPN server is unable to allocate an IP address, and the connection attempt is rejected. Modify the static IP address pool if needed.

**See also:** Create a static IP address pool

**Cause:** The VPN client is configured to request its own IPX node number, and the VPN server is not configured to allow IPX clients to request their own IPX node number.

**Solution:** Configure the VPN server to allow IPX clients to request their own IPX node number.

**Cause:** The VPN server is configured with a range of IPX network numbers that are being used elsewhere on your IPX internetwork.

**Solution:** Configure the VPN server with a range of IPX network numbers that is unique to your IPX internetwork.

**Cause:** The authentication provider of the VPN server is improperly configured.

**Solution:** Verify the configuration of the authentication provider. You can configure the VPN server to use either Windows or RADIUS to authenticate the credentials of the VPN client.

**See also:** Use RADIUS authentication

**Cause:** The VPN server cannot access Active Directory.

**Solution:** For a VPN server that is a member server in a Windows 2000 mixed domain or a Windows 2000 native domain that is configured for Windows authentication, verify that:

- The **RAS and IAS Servers** security group exists. If not, then create the group and set the group type to **Security** and the group scope to **Domain local**.
- The **RAS and IAS Servers** security group has Read permission to the **RAS and IAS Servers Access Check** object.
- The computer account of the VPN server computer is a member of the **RAS and IAS Servers** security group. You can use the **netsh ras show registeredserver** command to view the current registration. You can use the **netsh ras add registeredserver** command to register the server in a specified domain.

If you add the VPN server computer to (or remove the VPN server computer from) the **RAS and IAS Servers** security group, the change does not take effect immediately (due to the way that Active Directory information is cached). For the change to take effect immediately, you need to restart the VPN server computer.

- For a Windows 2000 native domain, the VPN server has joined the domain.

**See also:** Create a new group; Verify permissions for the RAS and IAS security group; Netsh commands for remote access; Domain and forest functionality

**Cause:** A Windows NT 4.0 VPN server cannot validate connection requests.

**Solution:** If VPN clients are dialing in to a VPN server running Windows NT 4.0 that is a member of a Windows 2000 mixed domain, verify that the Everyone group is added to the Pre-Windows 2000 Compatible Access group with the **net localgroup "Pre-Windows 2000 Compatible Access"** command. If not, type **net localgroup "Pre-Windows 2000 Compatible Access" everyone /add** at a command prompt on a domain controller computer and then restart the domain controller computer.

**See also:** Domain and forest functionality

**Cause:** The VPN server is unable to communicate with the configured RADIUS server.

**Solution:** If your RADIUS server is only reachable through your Internet interface, add an input filter and output filter to the Internet interface for UDP port 1812 (based on RFC 2138, "Remote Authentication Dial-In User Service (RADIUS)") or UDP port 1645 (for older RADIUS servers) for RADIUS authentication and UDP port 1813 (based on RFC 2139, "RADIUS Accounting") or UDP port 1646 (for older RADIUS servers) for RADIUS accounting.

**See also:** Add a packet filter

**Cause:** Cannot ping the VPN server from the Internet.

**Solution:** Due to the PPTP and L2TP/IPSec packet filtering that is configured on the Internet interface of the VPN server, Internet Control Message Protocol (ICMP) packets used by the **ping** command are filtered out. To enable ping capability on the VPN server, you need to add an input filter and an output filter that allow traffic for IP protocol 1 (ICMP traffic).

**See also:** Add a packet filter

**VPN clients are unable to access resources beyond the VPN server.**
**Cause:** The LAN protocols used by remote access VPN clients are not enabled to allow access to the network to which the VPN server is attached.

**Solution:** Configure the LAN protocols used by the remote access VPN clients to allow access to the network to which the VPN server is attached.

**See also:** View properties of the remote access server

**Cause:** A static IP address pool is configured but there are no routes back to the remote access VPN clients.

**Solution:** If the VPN server is configured to use a static IP address pool, verify that the routes to the ranges of addresses defined by the static IP address pool are reachable by the hosts and routers of the intranet. If not, then IP routes consisting of the address ranges of the static IP address pool, as defined by the IP address and mask of each range, must be added to the routers of the intranet, or the routing protocol of your routed infrastructure on the VPN server must be enabled. If the routes to the remote access VPN client subnets are not present, remote access VPN clients cannot receive traffic from locations on the intranet. A route for the network is implemented either through static routing entries or through a routing protocol, such as Open Shortest Path First (OSPF) or Routing Information Protocol (RIP).

If the VPN server is configured to use DHCP for IP address allocation, and no DHCP server is available, the VPN server allocates addresses from the Automatic Private IP Addressing (APIPA) address range from 169.254.0.1 through 169.254.255.254. Allocating APIPA addresses for remote access clients works only if the network to which the VPN server is attached is also using APIPA addresses.

If the VPN server is using APIPA addresses when a DHCP server is available, verify that the proper adapter is selected from which to obtain DHCP-allocated IP addresses. By default, the VPN server randomly chooses the adapter to use to obtain IP addresses through DHCP. If there is more than one LAN adapter, then the Routing and Remote Access service may choose a LAN adapter for which there is no DHCP server available.

If the static IP address pool consists of ranges of IP addresses that are a subset of the range of IP addresses for the network to

which the VPN server is attached, verify that the ranges of IP addresses of the static IP address pool are not assigned to other TCP/IP nodes, either through static configuration or through DHCP.

**See also:** Create a static IP address pool

**Cause:** Packet filters on the remote access policy profile are preventing the flow of IP traffic.

**Solution:** Verify that there are no configured TCP/IP packet filters on the profile properties of the remote access policies on the VPN server (or the RADIUS server if Internet Authentication Service is used) that are preventing the sending or receiving of TCP/IP traffic.

You can use remote access policies to configure TCP/IP input and output packet filters that control the exact nature of TCP/IP traffic allowed on the VPN connection. Verify that the profile TCP/IP packet filters are not preventing the flow of needed traffic.

**See also:** Configure IP options

For more information about troubleshooting remote access connections, see Remote Access Troubleshooting.

**Note**

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling Protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling Protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

# Troubleshooting router-to-router VPNs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting router-to-router VPNs**
What problem are you having?

- Unable to establish a router-to-router VPN connection.
- Unable to send and receive data.

**Unable to establish a router-to-router VPN connection.**
**Cause:** The user account used by the calling router is locked out, expired, disabled, or the time the connection is being made does not correspond to the configured logon hours.

**Solution:** Modify the account properties of the user account.

**See also:** Manage Users, Groups, and Computers

**Cause:** The Routing and Remote Access service is not started on the VPN client (the calling router) and the VPN server (the answering router).

**Solution:** Verify the state of the Routing and Remote Access service on the VPN client and the VPN server.

**See also:** Monitor the Routing and Remote Access service; Start and stop the Routing and Remote Access service

**Cause:** LAN and WAN routing is not enabled on the calling router and the answering router.

**Solution:** Enable **Local and remote routing (LAN and WAN router)** on the calling router and the answering router.

**See also:** Enable LAN and WAN routing

**Cause:** PPTP or L2TP ports are not enabled for inbound and outbound demand-dial routing connections.

**Solution:** Enable PPTP ports, L2TP ports, or both, for inbound and outbound demand-dial routing connections.

**See also:** Enable routing on ports

**Cause:** All of the PPTP or L2TP ports on the calling or answering router are already being used by currently connected remote access clients or demand-dial routers.

**Solution:** Verify that all of the PPTP or L2TP ports on the VPN server are not already being used by clicking **Ports** in Routing and Remote Access. If necessary, change the number of PPTP or L2TP ports to allow more concurrent connections.

**See also:** Add PPTP or L2TP ports

**Cause:** The tunneling protocol of the calling router is not supported by the answering router.

By default, demand-dial interfaces on a computer running a Windows Server 2003 operating system use the **Automatic** server type option, which means that they try to establish an L2TP/IPSec-based VPN connection first, and then they try a PPTP-based VPN connection. If calling routers use either the **Point-to-Point Tunneling Protocol (PPTP)** or **Layer-2 Tunneling Protocol (L2TP)** server type option, verify that the selected tunneling protocol is supported by the answering router.

By default, a computer running a Windows Server 2003 operating system and the Routing and Remote Access service is a PPTP and L2TP-capable demand dial router with five L2TP ports and five PPTP ports. To create a PPTP-only router, set the number of L2TP ports to 0. To create an L2TP-only router, set the number of PPTP ports to 1 and disable remote access inbound connections and demand-dial connections.

**Solution:** Verify that the appropriate number of PPTP or L2TP ports is configured on the calling router and answering router.

**See also:** Add PPTP or L2TP ports

**Cause:** The calling router and the answering router in conjunction with a remote access policy are not configured to use at least one common authentication method.

**Solution:** Configure the calling router and the answering router in conjunction with a remote access policy to use at least one common authentication method.

**See also:** Configure authentication

**Cause:** The calling router and the answering router in conjunction with a remote access policy are not configured to use at least one common encryption method.

**Solution:** Configure the calling router and the answering router in conjunction with a remote access policy to use at least one common encryption method.

**See also:** Configure encryption

**Cause:** The VPN connection does not have the appropriate permissions through dial-in properties of the user account and remote access policies.

**Solution:** Verify that the VPN connection has the appropriate permissions through dial-in properties of the user account and remote access policies.

In order for the connection to be established, the settings of the connection attempt must:

- Match all of the conditions of at least one remote access policy.
- Be granted remote access permission through the user account (set to **Allow access**) or through the user account (set to **Control access through Remote Access Policy**) and the remote access permission of the matching remote access policy (set to **Grant remote access permission**).
- Match all the settings of the profile.
- Match all the settings of the dial-in properties of the user account.

**See also:** Introduction to remote access policies; Accepting a connection attempt

**Cause:** The settings of the remote access policy profile are in conflict with properties of the answering router.

The properties of the remote access policy profile and the properties of the answering router both contain settings for:

- Multilink
- Bandwidth allocation protocol
- Authentication protocols

If the settings of the profile of the matching remote access policy are in conflict with the settings of the answering router, the connection attempt is rejected. For example, if the matching remote access policy profile specifies that the EAP-TLS authentication protocol must be used, and EAP is not enabled on the answering router, the connection attempt is rejected.

**Solution:** Verify that the settings of the remote access policy profile are not in conflict with properties of the VPN server.

**See also:** Enable authentication protocols; Configure authentication

**Cause:** The credentials of the calling router (user name, password, and domain name) are incorrect and cannot be validated by the answering router.

**Solution:** Verify that the credentials of the calling router (user name, password, and domain name) are correct and can be validated by the answering router.

**Cause:** There are not enough addresses in the static IP address pool.

**Solution:** If the answering router is configured with a static IP address pool, verify that there are enough addresses in the pool. If all of the addresses in the static pool have been allocated to connected remote access clients or demand-dial routers, the answering router is unable to allocate an IP address, and the connection attempt is rejected. Modify the static IP address pool if needed.

**See also:** Create a static IP address pool

**Cause:** The authentication provider of the answering router is improperly configured.

**Solution:** Verify the configuration of the authentication provider. You can configure the answering router to use either Windows or RADIUS to authenticate the credentials of the VPN client.

**See also:** Use RADIUS authentication

**Cause:** The answering router cannot access Active Directory.

**Solution:** For an answering router that is a member server in a Windows 2000 mixed domain or a Windows 2000 native domain that is configured for the Windows authentication provider, verify that:

- The **RAS and IAS Servers** security group exists. If not, then create the group and set the group type to **Security** and the group scope to **Domain local**.

- The **RAS and IAS Servers** security group has Read permission to the **RAS and IAS Servers Access Check** object.

- The computer account of the answering router computer is a member of the **RAS and IAS Servers** security group. You can use the **netsh ras show registeredserver** command to view the current registration. You can use the **netsh ras add registeredserver** command to register the server in a specified domain.

  If you add the answering router computer to (or remove the answering router from) the **RAS and IAS Servers** security group, the change does not take effect immediately (due to the way that Active Directory information is cached). For the change to take effect immediately, you need to restart the answering router computer.

- For a Windows 2000 native domain, the answering router has joined the domain.

**See also:** Create a new group; Verify permissions for the RAS and IAS security group; Netsh commands for remote access; Domain and forest functionality

**Cause:** An answering router running Windows NT 4.0 with the Routing and Remote Access Service (RRAS) cannot validate connection requests.

**Solution:** If calling routers are dialing in to a answering router running Windows NT 4.0 with RRAS that is a member of a Windows 2000 mixed domain, verify that the Everyone group is added to the Pre-Windows 2000 Compatible Access group with the **net localgroup "Pre-Windows 2000 Compatible Access"** command. If not, type **net localgroup "Pre-Windows 2000 Compatible Access" everyone /add** at a command prompt on a domain controller computer and then restart the domain controller computer.

**See also:** Domain and forest functionality

**Cause:** The answering router is unable to communicate with the configured RADIUS server.

**Solution:** If your RADIUS server is only reachable through your Internet interface, add an input filter and output filter to the Internet interface for UDP port 1812 (based on RFC 2138, "Remote Authentication Dial-In User Service (RADIUS)") or UDP port 1645 (for older RADIUS servers) for RADIUS authentication and UDP port 1813 (based on RFC 2139, "RADIUS Accounting") or UDP port 1646 (for older RADIUS servers) for RADIUS accounting.

**See also:** Add a packet filter

**Cause:** Cannot ping the answering router from the Internet.

**Solution:** Due to the PPTP and L2TP/IPSec packet filtering that is configured on the Internet interface of the answering router, Internet Control Message Protocol (ICMP) packets used by the **ping** command are filtered out. To enable ping capability on the answering router, you need to add an input filter and an output filter that allow traffic for IP protocol 1 (ICMP traffic).

**See also:** Add a packet filter

**Unable to send and receive data.**
**Cause:** The appropriate demand-dial interface has not been added to the protocol being routed.

**Solution:** Add the appropriate demand-dial interface to the protocol being routed.

**See also:** Add a routing interface

**Cause:** There are no routes on both sides of the router-to-router VPN connection that support the two-way exchange of traffic.

**Solution:** Unlike a remote access VPN connection, a router-to-router VPN connection does not automatically create a default route. You need to create routes on both sides of the router-to-router VPN connection so that traffic can be routed to and from the other side of the router-to-router VPN connection.

You can manually add static routes to the routing table, or you can add static routes through routing protocols. For persistent VPN connections, you can enable Open Shortest Path First (OSPF) or Routing Information Protocol (RIP) across the VPN connection. For on-demand VPN connections, you can automatically update routes through an auto-static RIP update.

**See also:** Add an IP routing protocol; Add a static route; Perform Auto-Static Updates

**Cause:** A two-way initiated, router-to-router VPN connection is being interpreted by the answering router as a remote access connection.

**Solution:** If the user name in the credentials of the calling router appears under **Dial-In Clients** in Routing and Remote Access, the answering router interpreted the calling router as a remote access client. Verify that the user name in the credentials of the calling router matches the name of a demand-dial interface on the answering router.

If the incoming caller is a router, the port on which the call was received shows a status of **Active** and the corresponding demand-dial interface is in a **Connected** state.

**See also:** Check the status of the port on the answering router; Check the status of the demand-dial interface

**Cause:** Packet filters on the demand-dial interfaces of the calling router and answering router are preventing the flow of traffic.

**Solution:** Verify that there are no packet filters on the demand-dial interfaces of the calling router and answering router that prevent the sending or receiving of traffic.

You can configure each demand-dial interface with IP input and output filters to control the exact nature of TCP/IP traffic that is allowed into and out of the demand-dial interface.

**See also:** Manage Packet Filters

**Cause:** Packet filters on the remote access policy profile are preventing the flow of IP traffic.

**Solution:** Verify that there are no configured TCP/IP packet filters on the profile properties of the remote access policies on the VPN server (or the RADIUS server if Internet Authentication Service is used) that are preventing the sending or receiving of TCP/IP traffic.

You can use remote access policies to configure TCP/IP input and output packet filters that control the exact nature of TCP/IP traffic allowed on the VPN connection. Verify that the profile TCP/IP packet filters are not preventing the flow of needed traffic.

**See also:** Configure IP options

For more information on troubleshooting demand-dial connections, see Troubleshooting demand-dial routing.

# Internet Authentication Service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet Authentication Service**
Internet Authentication Service (IAS) in Microsoft® Windows Server® 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition is the Microsoft implementation of a Remote Authentication Dial-in User Service (RADIUS) server and proxy. As a RADIUS server, IAS performs centralized connection authentication, authorization, and accounting for many types of network access including wireless, authenticating switch, and remote access dial-up and virtual private network (VPN) connections. As a RADIUS proxy, IAS forwards authentication and accounting messages to other RADIUS servers. RADIUS is an Internet Engineering Task Force (IETF) standard. For more detailed information, see Features of IAS.

- Before installing an IAS server, see IAS checklists.
- For tips about using IAS, see IAS Best Practices.
- For help with specific tasks, see IAS How To....
- For general background information, see IAS Concepts.
- For problem-solving instructions, see IAS Troubleshooting.

**Notes**

- This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.
- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# IAS checklists

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklists**

- Checklist: Configuring IAS for dial-up and VPN access
- Checklist: Configuring IAS to outsource dial-up access
- Checklist: Configuring IAS to forward requests
- Checklists: Configuring IAS for Wireless Access
- Checklists: Configuring IAS for Authenticated Switch Access

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Checklist: Configuring IAS for dial-up and VPN access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Configuring IAS for dial-up and VPN access**

| Step | Reference |
|---|---|
| Review RADIUS and IAS concepts. | IAS Overview; Understanding IAS |
| Review IAS implementation best practices. | IAS Best Practices |
| Review IAS security issues. | Security information for IAS |
| Install IAS on the servers to be used as IAS servers. (One server is configured first, and then the configuration is copied to the other server or servers.) | Install IAS |
| Configure the properties of one IAS server, including the ports used and event log settings. | Configure IAS Properties |
| Add the access servers (the dial-up network access servers and VPN servers) as clients on the same IAS server. | Configure RADIUS Clients |
| Set up the remote access policies that reflect your dial-up and VPN connection requirements on the same IAS server. | Introduction to remote access policies; Configure Remote Access Policies |
| Configure logging methods for user authentication and accounting requests. | Configure Logging for User Authentication and Accounting |
| Copy the IAS configuration from the first IAS server to additional IAS servers. | Copy the IAS configuration to another server |
| Register the IAS servers in the appropriate Active Directory domains. | Enable the IAS server to read user accounts in Active Directory |
| Verify the configuration of RADIUS accounting and authentication on the access servers, ensuring that IAS is configured on all access servers as the authentication and accounting provider. | IAS as a RADIUS server design considerations; Use RADIUS authentication; Use RADIUS accounting;Remote Access; Manufacturer's documentation |
| Verify that the access servers are properly configured for dial-up and VPN connections. | Routing and Remote Access; Manufacturer's documentation |

**Notes**

- For more information about how to deploy IAS with Routing and Remote Access, see Dial-up and VPN remote access.
- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Checklist: Configuring IAS to outsource dial-up access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Configuring IAS to outsource dial-up access**

| Step | Reference |
|---|---|
| Review RADIUS and IAS concepts. | IAS Overview; Understanding IAS |
| Review IAS implementation best practices. | IAS Best Practices |
| Review IAS security issues. | Security information for IAS |
| Configure the firewall to support the IAS servers in the perimeter network. | IAS and firewalls |
| Install IAS on the servers to be used as primary and backup IAS servers. | Install IAS |
| Add the Internet service provider (ISP) RADIUS proxies and the VPN servers as clients on the primary IAS server. | Configure RADIUS Clients; Contact the Internet service provider (ISP) |
| Configure the remote access policies that reflect your dial-up and VPN connection requirements on the primary IAS server. | Introduction to remote access policies; Configure Remote Access Policies |
| Configure logging methods for user authentication and accounting requests. | Configure Logging for User Authentication and Accounting |
| Copy the IAS configuration from the primary IAS server to the backup and remote IAS servers. | Copy the IAS configuration to another server |
| Register the primary and backup IAS servers in the appropriate Active Directory domains. | Enable the IAS server to read user accounts in Active Directory |
| Verify the configuration of RADIUS accounting and authentication on the VPN servers. Ensure that IAS is configured on all VPN servers as the authentication and accounting provider. | IAS as a RADIUS server design considerations; Use RADIUS authentication; Use RADIUS accounting; Remote Access; Manufacturer's documentation |
| Verify that the VPN servers are correctly configured for VPN connections. | Virtual Private Networks;Routing and Remote Access; Manufacturer's documentation |
| Verify the configuration of the RADIUS proxies at the ISP. | Contact the ISP |
| Verify that Connection Manager service profiles have been configured to support access to the corporate network, and that they work correctly (with Connection Point Services support, as required). | Connection Manager Administration Kit |

**Notes**

- For information about how to deploy IAS with outsourced dial-up access, see Outsourced VPN remote access.
- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Checklist: Configuring IAS to forward requests

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Configuring IAS to forward requests**

| Step | Reference |
|---|---|
| Review RADIUS and IAS concepts. | IAS Overview; Understanding IAS |
| Review IAS implementation best practices. | IAS Best Practices |
| Review IAS security issues. | Security information for IAS |
| Install IAS on the computer that will be used as the IAS proxy server. | Install IAS |
| Configure the properties of the IAS proxy server, including the ports used and event log settings. | Configure IAS Properties |
| Add the RADIUS clients on the IAS proxy server. Configure the shared secret that is common to both the IAS proxy server and the RADIUS client (from which requests are received). | Add RADIUS clients |
| On the IAS proxy server, use the New Remote RADIUS Server Group Wizard to create a remote server group with one or more RADIUS servers to which RADIUS messages are forwarded. Configure RADIUS ports and shared secrets that are common to both the IAS proxy server and the RADIUS servers (to which requests are forwarded). | Add a remote RADIUS server group |
| On the IAS proxy server, use the New Connection Request Policy Wizard to create a connection request policy to forward connection requests and accounting information to the remote RADIUS server group. | Add a connection request policy |
| Configure logging methods for user authentication and accounting requests. | Configure Logging for User Authentication and Accounting |
| Optional. Copy the IAS proxy configuration from the IAS proxy server to additional IAS proxy servers. | Copy the IAS configuration to another server |
| Register the IAS proxy servers in the appropriate Active Directory domains. | Enable the IAS server to read user accounts in Active Directory |
| Verify the configuration of RADIUS accounting and authentication on the RADIUS clients. | IAS as a RADIUS server design considerations; Use RADIUS authentication; Use RADIUS accounting;Remote Access; Manufacturer's documentation |
| Configure the IAS servers as RADIUS clients on the RADIUS servers (to which requests are forwarded). | Add RADIUS clients; Manufacturer's documentation |

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Checklists: Configuring IAS for Wireless Access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklists: Configuring IAS for wireless access**
You can use the following checklists to configure both the IAS server and wireless access points, and to install user certificates on wireless clients.

- Checklist: Configuring the IAS server and wireless access points for wireless access
- Checklist: Installing a user certificate on a wireless client over a wireless connection
- Checklist: Installing a user certificate on a wireless client over an unauthenticated Ethernet connection
- Checklist: Installing a user certificate from floppy disk on a wireless client

### Note

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Checklist: Configuring the IAS server and wireless access points for wireless access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Configuring the IAS server and wireless access points for wireless access**

| Step | Reference |
|---|---|
| Review RADIUS and IAS concepts. | IAS Overview; Understanding IAS |
| Review IAS implementation best practices. | IAS Best Practices |
| Review IAS security issues. | Security information for IAS |
| If you are using certificates to authenticate wireless clients, install a computer certificate on the IAS server computers. | Computer certificates for certificate-based authentication |
| Install IAS on the servers to be used as primary and backup IAS servers. | Install IAS |
| Configure the properties of the primary IAS server, including the ports used and event log settings. | Configure IAS Properties |
| Configure logging methods for user authentication and accounting requests. | Configure Logging for User Authentication and Accounting |
| Add the wireless access points as RADIUS clients on the primary IAS server. | Add RADIUS clients |
| Use the New Remote Access Policy Wizard to create a common policy for wireless access. | Add a remote access policy |
| If you are using secure password authentication through Protected Extensible Authentication Protocol (PEAP), also called PEAP-EAP-MS-CHAP v2, configure authentication methods for the remote access policy. | Configure PEAP and EAP methods; PEAP |
| If you want client and server certificate authentication using Protected Extensible Authentication Protocol (PEAP), also called PEAP-EAP-TLS, configure authentication methods for the remote access policy. | Configure PEAP and EAP methods; PEAP |
| If you want client and server certificate authentication using PEAP-EAP-TLS, install a certificate on the wireless client from floppy disk, or deploy smart cards. | Checklist: Installing a user certificate from floppy disk on a wireless client; Checklist: Deploying smart cards for logging on to Windows; PEAP; Network access authentication and certificates |
| If you are using certificate authentication with EAP-TLS and initially installing a user certificate on your wireless clients over a wireless connection, enable guest authentication. | Guest authentication |
| If you are using certificate authentication with EAP-TLS and initially installing a user certificate on your wireless clients over a wireless connection, create a group named Guests and add the Guest account as a member. | Create a new group; Add a member to a group |

| | |
|---|---|
| If you are using certificate authentication with EAP-TLS and initially installing a user certificate on your wireless clients over a wireless connection, use the New Remote Access Policy Wizard to create a custom policy for new wireless clients (clients that do not have user certificates). Set the **NAS-Port-Type** condition to **Wireless-IEEE 802.11** and **Wireless-Other**, and the **Windows-Groups** condition to **Guests**. On the **Dial-in Constraints** tab of the profile, restrict the maximum session time to 10 minutes. On the **Advanced** tab of the profile, add the **Tunnel-Type** attribute with the value of **Virtual LANs (VLAN)**, and then add the **Tunnel-Pvt-Group-ID** attribute with the VLAN ID value that corresponds to guest wireless clients. | Add a remote access policy |
| Copy the IAS configuration from the primary IAS server to the backup IAS server. | Copy the IAS configuration to another server |
| Register the primary and backup IAS servers in the appropriate Active Directory domains. | Enable the IAS server to read user accounts in Active Directory |
| Verify the configuration of the wireless access points. Ensure that the RADIUS servers used for authentication and accounting for the wireless access point are the IAS server computers. | Manufacturer's documentation |
| Optional. Install a user certificate on wireless clients over a wireless connection. | Checklist: Installing a user certificate on a wireless client over a wireless connection |
| Optional. Install user certificates on wireless clients over an unauthenticated Ethernet connection. | Checklist: Installing a user certificate on a wireless client over an unauthenticated Ethernet connection |
| Optional. Install user certificates from floppy disk on wireless clients. | Checklist: Installing a user certificate from floppy disk on a wireless client |

For more information, see Wireless access and Outsourced wireless access.

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Checklist: Installing a user certificate on a wireless client over a wireless connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Installing a user certificate on a wireless client over a wireless connection**

| Step | Reference |
|---|---|
| Configure the IAS server and wireless access points for wireless access. | Checklist: Configuring the IAS server and wireless access points for wireless access |
| Configure the network connection that corresponds to your wireless network adapter for EAP-TLS authentication. | Right-click the network connection, and then click **Properties**. Click the **Authentication** tab. Select **Smart Card or other Certificate** as the Extensible Authentication Protocol (EAP) type. Click **Properties**, and then click **Use a certificate on this computer**. Click **OK** three times to save changes to the network connection. |
| Move your wireless client computer within range of the configured wireless access point. | |
| After your wireless client computer has guest access, join the domain. | Join a domain |
| Restart the computer when prompted and log on to the domain. You will still have a guest connection. | |
| Install a user certificate on the wireless client computer. | Request a certificate;<br><br>Submit a user certificate request via the Web |
| After 10 minutes, your wireless client computer is disconnected because of the dial-in constraint in the new wireless client remote access policy that has been configured on the IAS server. When the wireless client computer reconnects, it will authenticate with the new user certificate and receive an authenticated connection to the wireless access point. | |

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Checklist: Installing a user certificate on a wireless client over an unauthenticated Ethernet connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Installing a user certificate on a wireless client over an unauthenticated Ethernet connection**

| Step | Reference |
|---|---|
| Configure the IAS server and wireless access points for wireless access. | Checklist: Configuring the IAS server and wireless access points for wireless access |
| Connect your wireless client computer to the organization network using an unauthenticated Ethernet connection. | |
| Join the domain. | Join a domain |
| Restart the computer when prompted and log on to the domain. | |
| Install a user certificate on the wireless client computer. | Request a certificate;<br><br>Submit a user certificate request via the Web |
| Configure the network connection that corresponds to your wireless network adapter for EAP-TLS authentication. | Right-click the network connection, and then click **Properties**. Click the **Authentication** tab. Select **Smart Card or other Certificate** as the Extensible Authentication Protocol (EAP) type. Click **Properties**, and then click **Use a certificate on this computer**. Click **OK** three times to save changes to the network connection. |
| Move your wireless client computer within range of the configured wireless access point. | |
| When the wireless client computer connects, it will authenticate with the new user certificate and receive an authenticated connection to the wireless access point. | |

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. In addition, you can configure RADIUS clients by specifying an IP address range.

# Checklists: Configuring IAS for Authenticated Switch Access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklists: Configuring IAS for authenticated switch access**
You can use the following checklists to configure both the IAS server and Ethernet switch clients, and to install user certificates on Ethernet clients.

- Checklist: Configuring the IAS server for authenticated switch access
- Checklist: Configuring a first-time Ethernet switch client for authenticated access
- Checklist: Installing a computer certificate on an Ethernet client over an unauthenticated Ethernet connection
- Checklist: Installing a user certificate from floppy disk on an Ethernet client

### Note

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Checklist: Configuring the IAS server for authenticated switch access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Configuring the IAS server for authenticated switch access**

| Step | Reference |
|---|---|
| Review RADIUS and IAS concepts. | IAS Overview; Understanding IAS |

| Verify the configuration of the Ethernet switches. Ensure that the RADIUS servers used for the Ethernet switch authentication and accounting are the IAS server computers. | Manufacturer's documentation |
| Optional. Configure first-time Ethernet switch clients for authenticated access. | Checklist: Configuring a first-time Ethernet switch client for authenticated access |
| Optional. Install a computer certificate on Ethernet clients over an unauthenticated Ethernet connection. | Checklist: Installing a computer certificate on an Ethernet client over an unauthenticated Ethernet connection |
| Optional. Install user certificates from floppy disk on Ethernet clients. | Checklist: Installing a user certificate from floppy disk on an Ethernet client |

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Checklist: Configuring a first-time Ethernet switch client for authenticated access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Configuring a first-time Ethernet switch client for authenticated access**
This checklist applies only to Ethernet client computers that use EAP-TLS authentication.

| Step | Reference |
|---|---|
| Configure the IAS server for authenticated switch access. | Checklist: Configuring the IAS server for authenticated switch access |
| Configure the network connection that corresponds to your Ethernet network adapter for EAP-TLS authentication. | Right-click the network connection, and then click **Properties**. Click the **Authentication** tab, and then select **Smart Card or other Certificate** as the Extensible Authentication Protocol (EAP) type. Click **Properties**, and then click **Use a certificate on this computer**. Click **OK** three times to save changes to the network connection. |
| Connect your Ethernet client computer to the Ethernet switch. | |
| After your Ethernet client computer has unauthenticated access, join the domain. | Join a domain |
| Restart the computer when prompted and log on to the domain. Although you will still have a guest connection, the Ethernet client computer is issued a computer certificate during the startup and domain logon process. | |
| After 10 minutes, your Ethernet client computer is disconnected because of the dial-in constraint in the first-time Ethernet client remote access policy that has been configured on the IAS server. When the Ethernet client computer reconnects, it will authenticate with the new computer certificate and receive an authenticated connection to the Ethernet switch. | |

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

In addition, you can configure RADIUS clients by specifying an IP address range.

# IAS Best Practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS Best Practices**
This topic provides best practices for implementing and configuring IAS and is based on recommendations from Microsoft Product Support Services.

**Installation suggestions**
Before installing IAS, do the following:

- Install and test each of your access servers using local authentication methods before making them RADIUS clients.

- After you install and configure IAS, save the configuration by using the **netsh aaaa show config** > *path**file.txt* command. For more information, see Netsh commands for AAAA. Save the IAS configuration with the **netsh aaaa show config** > *path**file.txt* command each time a change is made.

- Do not install Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition on the same partition as Windows 2000. These operating systems use common files in the *systemroot*\Program Files folder to access the IAS database. If you decide to install Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition on the same partition as Windows 2000, IAS in Windows 2000 can no longer access remote access policies or remote access logging.

- Do not configure a server running IAS or Routing and Remote Access and Windows Server 2003 as a member of a Windows NT Server 4.0 domain if your user accounts database is stored on a Windows Server 2003 domain controller in another domain. Doing this will cause Lightweight Directory Access Protocol (LDAP) queries from the IAS server to the Windows Server 2003 domain controller to fail.

- Instead, configure your server running IAS or Routing and Remote Access and Windows Server 2003 as a member of a Windows Server 2003 domain. Alternately, you can configure a server running IAS and Windows Server 2003 as a proxy server that forwards authentication and accounting requests to another server running IAS and Windows Server 2003 that can access the user accounts database on the Windows Server 2003 domain controller. For more information, see Deploying IAS as a RADIUS Proxy.

**Security issues**
When you are administering an IAS server remotely, do not send sensitive or confidential data (for example shared secrets or passwords) over the network in plaintext. There are two recommended methods for remote administration of IAS servers:

- Use Terminal Services to access the IAS server.

  When you use Terminal Services, data is not sent between client and server. Only the user interface of the server (for example, the operating system desktop and IAS console image) is sent to the Terminal Services client, which is named Remote Desktop Connection in Windows XP. The client sends keyboard and mouse input, which is processed locally by the server that has Terminal Services enabled. When Terminal Services users log on, they can view only their individual client sessions, which are managed by the server and are independent of each other. In addition, Remote Desktop Connection provides 128-bit encryption between client and server. For more information, see Terminal Services.

- Use IPSec to encrypt confidential data.

  You can use IPSec to encrypt communication between the IAS server and the remote client computer that is being used to administer it. In order to administer the server remotely, the Windows Server 2003 Administration Tools Pack must be installed on the client computer, and the IAS snap-in must be added to the Microsoft Management Console (MMC). For more information, see IPSec Policy Rules.

Your IAS server provides authentication, authorization, and accounting for connection attempts to your organization network. You can protect your IAS server and RADIUS messages from unwanted internal and external intrusion. For more information about how to secure your IAS server, see Securing IAS.

For additional information about securing RADIUS traffic when IAS is used as a RADIUS server, see IAS as a RADIUS server security considerations. For additional information about securing RADIUS traffic when IAS is used as a RADIUS proxy, see IAS as a RADIUS proxy security considerations.

**Use the Runas command to administer local IAS servers**

You can use the **Runas** command to perform administrative tasks when you are logged on as a member of a group that does not have the required administrative credentials (such as the Users group or the Power Users group). Logging onto your server without administrative credentials is recommended because it protects the computer from a variety of possible security attacks, such as the accidental installation of a computer virus.

**Logging**

There are two types of logging in IAS:

1. Event logging for IAS You can use event logging to record IAS events in the system event log. This is used primarily for auditing and troubleshooting connection attempts.

2. Logging user authentication and accounting requests You can log user authentication and accounting requests to log files in text format or database format, or you can log to a stored procedure in a SQL Server 2000 database. Request logging is used primarily for connection analysis and billing purposes, and is also useful as a security investigation tool, providing you with a method of tracking down the activity an attacker.

To make the most effective use of IAS logging:

- Turn on logging (initially) for both authentication and accounting records. Modify these selections after you have determined what is appropriate for your environment.

- Ensure that event logging is configured with a capacity that is sufficient to maintain your logs.

- Back up all log files on a regular basis, since they cannot be recreated when they are damaged or deleted.

- Use the RADIUS Class attribute to both track usage and simplify the identification of which department or user to charge for usage. Although the automatically generated Class attribute is unique for each request, duplicate records might exist in cases where the reply to the access server is lost and the request is resent. You might need to delete duplicate requests from your logs to accurately track usage.

- To provide failover and redundancy with SQL Server logging, place two computers running SQL Server on different subnets. Use the SQL Server Create Publication Wizard to set up database replication between the two servers. For more information, see SQL Server 2000 documentation.

You can use the Iasparse.exe tool in the \Support\Tools folder on the Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition compact disc to view IAS logs.

For more information, see Remote Access Logging.

**Performance-tuning IAS**

- To optimize IAS authentication and authorization response times and minimize network traffic, install IAS on a domain controller.

- When universal principal names (UPNs) or Windows Server 2003 domains are used, IAS uses the global catalog to authenticate users. To minimize the time it takes to do this, install IAS on either a global catalog server or a server that is on the same subnet. For more information, see The role of the global catalog. For more information about domain functionality, see Domain and forest functionality.

- When you have remote RADIUS server groups configured and, in IAS **Connection Request Policies**, you clear the **Record accounting information on the servers in the following remote RADIUS server group** check box, these

groups are still sent network access server (NAS) start and stop notification messages. This creates unnecessary network traffic. To eliminate this traffic, disable NAS notification forwarding for individual servers in each remote RADIUS server group by clearing the **Forward network start and stop notifications to this server** check box. For more information, see Configure the authentication and accounting settings of a group member and Configure accounting.

#### Using IAS in large organizations

- If you are using remote access policies to restrict access for all but certain groups, create a universal group for all of the users for whom you want to allow access, and then create a remote access policy that grants access for this universal group. Do not put all of your users directly into the universal group, especially if you have a large number of them on your network. Instead, create separate groups that are members of the universal group, and add users to those groups. For more information about universal groups, see Group scope. For more information about restricting or granting access to a group, see Allow dial-up connection using group membership.

- Use a user principal name to refer to users whenever possible. A user can have the same user principal name regardless of domain membership. This practice provides scalability that might be required in organizations with a large number of domains.

- If the IAS server is on a computer other than a domain controller and it is receiving a very large number of authentication requests per second, you can improve performance by increasing the number of concurrent authentications between the IAS server and the domain controller.

  To do this, edit the following registry key: **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Netlogon\Parameters**. Add a new value named **MaxConcurrentApi** and assign to it a value from 2 through 5.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

### Notes

- If you assign a value to **MaxConcurrentApi** that is too high, your IAS server might place an excessive load on your domain controller.

- To effectively balance the load of either a large number of authorizations or a large volume of RADIUS authentication traffic (such as a large wireless implementation using certificate-based authentication), install IAS as a RADIUS server on all of your domain controllers. Next, configure two or more IAS proxies to forward the authentication requests between the access servers and the RADIUS servers. Next, configure your access servers to use the IAS proxies as RADIUS servers. For more information, see Using IAS proxy for load balancing.

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# IAS How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install IAS
- Manage a remote IAS server
- Copy the IAS configuration to another server
- Enable the IAS server to read user accounts in Active Directory
- Start or stop IAS
- Configure IAS Properties
- Configure RADIUS Clients
- Configure Remote Access Policies
- Configure Connection Request Processing
- Configure Logging for User Authentication and Accounting

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Install IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To install IAS

1. Open Add or Remove Programs in Control Panel.
2. Click **Add/Remove Windows Components**.
3. In the **Windows Components Wizard** dialog box, click **Networking Services**, and then click **Details**.
4. In the **Networking Services** dialog box, select **Internet Authentication Service**, click **OK**, and then click **Next**.
5. If prompted, insert your Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition compact disc.
6. After IAS is installed, click **Finish**, and then click **Close**.

### Notes

- You must be logged on as an administrator or a member of the Administrators group in order to complete this procedure. If your computer is connected to a network, network policy settings might prevent you from completing this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage a remote IAS server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manage a remote IAS server**

1. Click **Start**, click **Run**, type **MMC**, and then click **OK**.
2. In the MMC console, click **File**, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Internet Authentication Service (IAS)**, and then click **Add**.
4. Select the computer for which you want to manage IAS:

| To | Do this |
|---|---|
| Manage IAS on the computer on which this console is running | Click **Local computer (the one this console is running on)**. |
| Manage IAS on a remote computer | Click **Another computer**, and then type the name or IP address of the remote IAS server. |

5. Click **Finish**, click **Close**, and then click **OK**.

### Note

- You must be logged on as an administrator or a member of the Administrators group in order to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Start or stop IAS

# Copy the IAS configuration to another server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To copy the IAS configuration to another server**

1. Open **Command Prompt**.
2. At the command prompt, type **netsh aaaa show config >***path\file.txt*.

   This stores configuration settings (including registry settings) in a text file. The path can be relative or absolute, or it can be a UNC path.
3. Copy the file you created to the destination computer.
4. At a command prompt on the destination computer, type **netsh exec** *path\file.txt*.

   A message appears indicating whether the update was successful.

## Notes

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- You do not need to stop IAS on the destination computer to run the **netsh exec** command. When the command is run, IAS is automatically refreshed with the updated configuration settings.
- Because IAS configurations are not encrypted in the text file, sending it over a network might pose a security risk.
- Do not use this procedure if the source IAS database is a higher version number than the version number of the destination IAS database. You can view the version number of the IAS database from the display of the **netsh aaaa show config** command.
- This procedure replicates the entire IAS, remote access policy, connection request policy, registry, and logging configuration.
- You can copy a remote access configuration from a server running Routing and Remote Access and Windows 2000 or Windows Server 2003 to an IAS server. Use the **netsh aaaa dump** command at the remote access server to create a file that contains the configuration, copy it to the IAS server, and then use the **netsh exec** command to import the configuration to the IAS server. Next, configure RADIUS clients on the IAS server.
- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable the IAS server to read user accounts in Active Directory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable the IAS server to read user accounts in Active Directory**
**To register the IAS server in the default domain using Internet Authentication Service:**

1. Log on to the IAS server with an account that has administrative credentials for the domain.
2. Open Internet Authentication Service.
3. Right-click **Internet Authentication Service**, and then click **Register Server in Active Directory**. When the **Register Internet Authentication Service in Active Directory** dialog box appears, click **OK**.

**To register the IAS server in the default domain using the netsh command:**

1. Log on to the IAS server with an account that has administrative credentials for the domain.
2. Open Command Prompt.
3. At the command prompt, type: **netsh ras add registeredserver**

**To register the IAS server in the default domain using Active Directory Users and Computers:**

1. Log on to the IAS server with an account that has administrative credentials for the domain.
2. Open Active Directory Users and Computers.
3. In the console tree, click the **Users** folder in the appropriate domain.
4. In the details pane, right-click **RAS and IAS Servers**, and then click **Properties**.
5. In the **RAS and IAS Servers Properties** dialog box, on the **Members** tab, add each of the IAS servers.

**To register the IAS server in another domain using Active Directory Users and Computers:**

1. Log on to the IAS server with an account that has administrative credentials for the domain.
2. Open Active Directory Users and Computers.
3. In the console tree, click the **Users** folder in the appropriate domain.
4. In the details pane, right-click **RAS and IAS Servers**, and then click **Properties**.
5. In the **RAS and IAS Servers Properties** dialog box, on the **Members** tab, add each of the IAS servers.

**To register the IAS server in another domain using the netsh command:**

1. Log on to the IAS server with an account that has administrative credentials for the domain.
2. Open Command Prompt.
3. At the command prompt, type **netsh ras add registeredserver** *Domain IASServer*, where *Domain* is the DNS domain name of the domain and *IASServer* is the name of the IAS server computer.

## Notes

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- After you register the service in Active Directory, you can verify the security settings. For more information, see Related Topics.

- You can add the IAS server to the **RAS and IAS Servers** group with the Dsmod tool.

- For more information about how to use IAS or Routing and Remote Access servers as stand-alone servers or member servers in Windows NT 4.0 domains, Windows 2000 mixed domains, Windows 2000 native domains, and Windows Server 2003 domains, see the links below.

### Information about functional differences

# Start or stop IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To start or stop IAS

1. Open Internet Authentication Service.
2. In the console tree, right-click **Internet Authentication Service**, and then click **Start Service**.

   Or, to stop the service, click **Stop Service**.

### Note

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure IAS Properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure IAS properties**

- Configure IAS port information
- Configure event logging for IAS

# Configure IAS port information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure IAS port information**

1. Open Internet Authentication Service.

2. Right-click **Internet Authentication Service**, and then click **Properties**.

3. Click the **Ports** tab, and then examine the settings for ports. If your RADIUS authentication and RADIUS accounting UDP ports vary from the default values provided (1812 and 1645 for authentication, and 1813 and 1646 for accounting), type your port settings in **Authentication** and **Accounting**.

   To use multiple port settings for authentication or accounting requests, separate the port numbers with commas.

## Notes

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

- To configure a remote IAS server, you must have administrative credentials on the remote server.

- The values of 1812 for authentication and 1813 for accounting are RADIUS standard ports defined in RFCs 2865 and 2866. However, many access servers use ports 1645 for authentication requests and 1646 for accounting requests by default. Whatever port numbers you decide to use, make sure that IAS and your access server are configured to use the same ones.

- You can specify an IP address to which the RADIUS messages must be sent with the following syntax: *IPAddress***:***UDPPort*. For example, if you have multiple network adapters and you only want to receive RADIUS authentication messages sent to the IP address of 10.0.0.99 and UDP port 1812, you would type **10.0.0.99:1812** in **Authentication**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure event logging for IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure event logging for IAS**

1. Open Internet Authentication Service.
2. Right-click **Internet Authentication Service (IAS)**, and then click **Properties**.
3. On the **General** tab, select each required option, and then click **OK**.

## Notes

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- Rejected, discarded, and successful authentication requests are logged by default.
- Selecting **Successful authentication requests** can result in logging extremely large volumes of data. Before selecting this option, verify that the Event Viewer is configured with a maximum log size that will accommodate this type of event logging.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure RADIUS Clients

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure RADIUS clients**

- Add RADIUS clients
- Delete a RADIUS client
- Edit RADIUS client configuration
- Configure the Message Authenticator attribute and shared secret

### Note

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Add RADIUS clients

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add RADIUS clients**

1. Open Internet Authentication Service.
2. Right-click **RADIUS Clients**, and then click **New RADIUS Client**.
3. Use the New RADIUS Client Wizard to both add and configure a client.

## Notes

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- If the client is a network access server (NAS) and you are planning to use NAS-specific remote access policies for configuration (for example, a remote access policy that contains vendor-specific attributes), in the New RADIUS Client Wizard, click **Client Vendor**, and then select the name of the manufacturer. If you do not know the name of the manufacturer or it is not in the list, click **RADIUS Standard**. If the RADIUS client is a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition and the Routing and Remote Access service, click **Microsoft**.
- When you have a number of RADIUS clients on the same subnet (such as, numerous wireless access points), you can simplify RADIUS client administration by specifying an address range while running the wizard, instead of specifying the IP address or DNS name of a single RADIUS client. All of the RADIUS clients in the range must use the same configuration and shared secret. The address range for RADIUS clients is expressed in the network prefix length notation *w.x.y.z/p*, where *w.x.y.z* is the dotted decimal notation of the address prefix and *p* is the prefix length (the number of high order bits that define the network prefix). This is also known as Classless Inter-Domain Routing (CIDR) notation. An example is 192.168.21.0/24. To convert from subnet mask notation to network prefix length notation, p is the number of high order bits set to one in the subnet mask.
- If your access server supports use of the Message Authenticator attribute (also known as the signature attribute), in the New RADIUS Client Wizard, click **Request must contain the Message Authenticator attribute**. If the access server does not support the Message Authenticator attribute, do not select this option.
- If IAS receives an access request from a RADIUS proxy, it cannot detect the manufacturer of the NAS that originated the request. This can cause problems if you plan to use remote access policy conditions that are based on the client vendor and have at least one client that is defined as a RADIUS proxy. Requests from the proxy might not match any of the remote access policies and be denied.
- Shared secrets are case-sensitive. Verify that the client's shared secret and the shared secret you type in **Shared secret** are identical. For more information, see Related Topics.
- If the client address cannot be resolved when you click **Verify**, make sure that the DNS name that you typed is correct.
- You can use the friendly name that you provide for your RADIUS clients with the **Client-Friendly-Name** condition in remote access policies. For more information, see Related Topics.
- Enabling the use of the Message Authenticator attribute provides additional security when PAP, CHAP, MS-CHAP, and MS-CHAP v2 are used for authentication. EAP uses the Message Authenticator attribute by default and does not require that you enable it. For more information, see Related Topics.
- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum

of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Edit RADIUS client configuration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To edit RADIUS client configuration**

1. Open Internet Authentication Service.
2. In the console tree, click **RADIUS Clients**.
3. In the details pane, double-click the client for which you want to edit the configuration.
4. Make changes to the RADIUS client configuration.
5. Click **OK** to save your changes.

## Notes

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- If IAS receives an access request from a RADIUS proxy server, IAS cannot detect the manufacturer of the NAS that originated the request. This can cause problems if you plan to use remote access policy conditions that are based on the client vendor and have at least one client that is defined as a RADIUS proxy server. Requests from the proxy might not match any of the remote access policies and be denied.
- Shared secrets are case-sensitive. Verify that the client's shared secret and the shared secret that you type in **Shared secret** are identical. For more information, see Related Topics.
- If the client address cannot be resolved when you click **Verify**, make sure the DNS name that you typed is correct.
- You can use the friendly name that you provide for your RADIUS clients with the **Client-Friendly-Name** condition in remote access policies. For more information, see Related Topics.
- Enabling the use of the Message Authenticator attribute provides additional security when PAP, CHAP, MS-CHAP, and MS-CHAP v2 are used for authentication. EAP uses the Message Authenticator attribute by default and does not require that you enable it. For more information, see Related Topics.
- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. # Configure the Message Authenticator attribute and shared secret

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure the Message Authenticator attribute and shared secret**

1. Open Internet Authentication Service.
2. In the console tree, click **RADIUS Clients**.
3. In the details pane, double-click the client for which you want to edit the configuration.
4. To enable or disable use of the Message Authenticator attribute, click **Request must contain the Message Authenticator attribute**.
5. In **Shared secret**, type a shared secret. In **Confirm shared secret**, retype the shared secret.
6. Click **OK** to save your changes.

## Notes

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- When you enable the Message Authenticator attribute, the entire RADIUS message is encrypted and the shared secret is used as the key. Shared secrets are case-sensitive. Verify that the client's shared secret and the shared secret that you type in **Shared secret** are identical. For more information, see Related Topics.
- Enabling the use of the Message Authenticator attribute provides additional security when PAP, CHAP, MS-CHAP, and MS-CHAP v2 are used for authentication. EAP uses the Message Authenticator attribute by default and does not require that you enable it. For more information, see the topics listed below.
- Shared secrets should be comprised of a 22-character or longer random sequence of letters, numbers, and punctuation and should be changed often to protect your IAS server and your RADIUS clients from online dictionary attacks. For more information, see the topics listed below.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Elements of a remote access policy

# Configure Remote Access Policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure remote access policies**

- Add a remote access policy
- Configure a remote access policy to grant or deny access
- Configure a condition of a remote access policy
- Change the policy evaluation order
- Rename a remote access policy
- Delete a remote access policy
- Recreate the default remote access policy
- Configure a Profile for a Remote Access Policy

# Add a remote access policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a remote access policy**

1. Do one of the following:

    - Open Routing and Remote Access and, if necessary, double-click **Routing and Remote Access** and the server name.
    - Open Internet Authentication Service and, if necessary, double-click **Internet Authentication Service**.

2. In the console tree, right-click **Remote Access Policies**, and then click **New Remote Access Policy**.
3. Use the New Remote Access Policy Wizard to create a policy.

For a common policy, you must choose the following:

- An access method:
    - VPN access
    - Dial-up access
    - Wireless access
    - Ethernet
- Whether to grant access permissions by user or by group.
- Authentication methods.
- Levels of allowed encryption (depending on the access method selected).

  For a custom policy, you must configure the following:

- A set of policy conditions.
- Whether remote access permission for the policy is granted or denied.
- Remote access policy profile settings.

**Notes**

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.
- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

- You cannot use this procedure to configure a remote access policy unless a remote access server is already installed on your network. After installing one or more remote access servers, use this procedure and the New Remote Access Policy Wizard to configure a new remote access policy.

- When you use the New Remote Access Policy Wizard to create a common policy:

    - The access method is used to automatically configure the NAS Port Type condition.

    - If you choose to grant access by group, the Windows Groups condition is automatically set to the selected groups.

    - The authentication settings are used to set the profile settings on the **Authentication** tab.

    - The encryption levels are used to set the profile settings on the **Encryption** tab.

    - The remote access permission is always set to **Grant remote access permission**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure a remote access policy to grant or deny access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure a remote access policy to grant or deny access**

1. Do one of the following:

   - Open Routing and Remote Access and, if necessary, double-click **Routing and Remote Access** and the server name.
   - Open Internet Authentication Service and, if necessary, double-click **Internet Authentication Service**.

2. In the console tree, click **Remote Access Policies**.
3. In the details pane, double-click the policy that you want to configure.
4. Under **If a connection request matches the specified conditions**:

   - To grant dial-up permission for these users, click **Grant remote access permission**.
   - To deny dial-up permission for these users, click **Deny remote access permission**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.
- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- The **Remote Access Permission** setting on the dial-in properties of the user or computer account overrides this setting if it is set to either **Allow access** or **Deny access**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure a condition of a remote access policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure a condition of a remote access policy**

1. Do one of the following:
   - Open Routing and Remote Access, double-click **Routing and Remote Access**, and then double-click the server name to expand the console tree.
   - Open Internet Authentication Service and, if necessary, double-click **Internet Authentication Service**.
2. In the console tree, click **Remote Access Policies**.
3. In the details pane, double-click the policy that you want to configure.
4. To configure a new condition, click **Add**, and then do the following:
   - In the **Select Attribute** dialog box, click the attribute to add, and then click **Add**.
   - In the attribute dialog box, configure the attribute, and then click **OK**.
5. To change the configuration of an existing condition:
   - Click the condition, and then click **Edit**.
   - In the attribute dialog box, specify the required settings, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.
- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the policy evaluation order

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the policy evaluation order**

1. Do one of the following:

    - Open Routing and Remote Access and, if necessary, double-click **Routing and Remote Access** and the server name.

    - Open Internet Authentication Service and, if necessary, double-click **Internet Authentication Service**.

2. In the console tree, click **Remote Access Policies**.

3. In the details pane, right-click the policy that you want to move, and then click either **Move Up** (to move the policy up one level) or **Move Down** (to move the policy down one level).

**Notes**

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Rename a remote access policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To rename a remote access policy**

1. Do one of the following:

    - Open Routing and Remote Access and, if necessary, expand **Routing and Remote Access** and the server name.
    - Open Internet Authentication Service and, if necessary, expand **Internet Authentication Service**.

2. In the console tree, click **Remote Access Policies**.
3. In the details pane, right-click the policy that you want to rename, and then click **Rename**.
4. Type a new name for the policy, and then press ENTER.

## Notes

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.
- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

# Delete a remote access policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a remote access policy**

1. Do one of the following:

    - Open Routing and Remote Access and, if necessary, double-click **Routing and Remote Access** and the server name.

    - Open Internet Authentication Service and, if necessary, double-click **Internet Authentication Service**.

2. In the console tree, click **Remote Access Policies**.

3. In the details pane, right-click the policy that you want to delete, and then click **Delete**.

## Notes

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

# Recreate the default remote access policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To recreate the default remote access policy**

1. Do one of the following:

   - Open Routing and Remote Access and, if necessary, double-click both **Routing and Remote Access** and the server name.
   - Open Internet Authentication Service and, if necessary, double-click **Internet Authentication Service**.

2. Right-click **Remote Access Policies** and then click **New Remote Access Policy**.

3. In the Add Remote Access Policy Wizard, create a custom remote access policy with the following settings:

   - In **Policy name**, type a default name, and then click **Next**.
   - In **Conditions**, click **Add**, click **Day-and-Time-Restrictions**, click **Add**, and then configure the attribute to permit all times on all days.
   - Click **OK**, and then click **Next**.
   - In **Permissions**, click **Deny remote access permission**, and then click **Next**.
   - In **Profile**, click **Next**. Do not make any changes to the profile.
   - Click **Finish**.

## Notes

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure a Profile for a Remote Access Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure a profile for a remote access policy**

- Configure dial-in constraints
- Configure IP options
- Configure multilink options
- Configure authentication
- Configure PEAP and EAP methods
- Configure encryption
- Configure Attributes for a Profile

# Configure dial-in constraints

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To configure dial-in constraints

1. Do one of the following:

    - Open Routing and Remote Access, double-click **Routing and Remote Access**, and then double-click the server name to expand the console tree.

    - Open Internet Authentication Service and, if necessary, double-click **Internet Authentication Service**.

2. In the console tree, click **Remote Access Policies**.

3. In the details pane, double-click the remote access policy that you want to configure.

4. Click **Edit Profile**.

5. On the **Dial-in Constraints** tab, specify any required settings.

### Notes

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

- Dial-in constraints should work with most network access servers, however, some network access servers might not support the RADIUS attributes that are required to enable dial-in constraints. For more information, see your NAS documentation.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure IP options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To configure IP options

1. Do one of the following:

    - Open Routing and Remote Access and, if necessary, double-click **Routing and Remote Access** and the server name.

    - Open Internet Authentication Service and, if necessary, double-click **Internet Authentication Service**.

2. In the console tree, click **Remote Access Policies**.

3. In the details pane, double-click the remote access policy that you want to configure.

4. Click **Edit Profile**.

5. On the **IP** tab, specify any required settings.

### Notes

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure multilink options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To configure multilink options

1. Do one of the following:

    - Open Routing and Remote Access and, if necessary, double-click **Routing and Remote Access** and the server name.

    - Open Internet Authentication Service and, if necessary, double-click **Internet Authentication Service**.

2. In the console tree, click **Remote Access Policies**.

3. In the details pane, double-click the remote access policy that you want to configure.

4. Click **Edit Profile**.

5. On the **Multilink** tab, specify any required settings.

### Notes

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure authentication**

1. Do one of the following:

   - Open Routing and Remote Access and, if necessary, double-click **Routing and Remote Access** and the server name.

   - Open Internet Authentication Service and, if necessary, double-click **Internet Authentication Service**.

2. In the console tree, click **Remote Access Policies**.

3. In the details pane, double-click the policy that you want to configure.

4. Click **Edit Profile**.

5. On the **Authentication** tab, specify any required settings.

## Notes

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

- When using the EAP-TLS authentication method with certificates, TLS uses cached certificate properties instead of reading the certificate from the certificate store. If a certificate is either changed or deleted and replaced by a new certificate, TLS continues using outdated cached certificate information until the cache expires or is refreshed. If you change or replace a certificate, you can refresh the TLS cache by restarting the server computer.

- For information about configuring specific authentication protocols, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure PEAP and EAP methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure PEAP and EAP methods**

1. Open Internet Authentication Service and, if necessary, double-click **Internet Authentication Service**.
2. In the console tree, click **Remote Access Policies**.
3. In the details pane, double-click the policy that you want to configure.
4. Click **Edit Profile**.
5. On the **Authentication** tab, click **EAP Methods**.
6. In **Select EAP providers**, click **Add**. Select the authentication methods that you want to use, and then click **OK**.
7. In **Select EAP providers**, click the EAP type that you want to configure, and then click **Edit**. Depending on the EAP type selected, one of the following dialog boxes is displayed:
   - If **Protected EAP (PEAP)** is selected, the **Protected EAP Properties** dialog box opens. In **Certificate Issued**, select the certificate that the server uses to identify itself to client computers. To enable PEAP fast reconnect for 802.11 wireless client computers, click **Enable Fast Reconnect**. Secure password user authentication with EAP-MSCHAPv2 is the default in **EAP Types**. To configure EAP-MSCHAPv2 properties, click **Edit**. To configure certificate or smart card user authentication click **Add**. In **Authentication methods,** click **Smart Card or other certificate**, and then click **OK**.
   - If **Smart Card or other Certificate Properties** is selected, the **Smart Card or other Certificate Properties** dialog box opens. In **Certificate issued to**, select the certificate that the server uses to authenticate to client computers.
8. In **Select EAP providers**, click **Move Up** or **Move Down** to specify the negotiation order of EAP methods. The server starts negotiation with the client according to the order specified in **EAP types**.

**Notes**

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- If the EAP types displayed in the **Select EAP Providers** dialog box are selected as **(Server-Configured)**, then the configuration of the EAP type is common to the server and applies to all remote access policies that are configured on the server. Otherwise, the EAP type configuration is specific to the current remote access policy, in which case the EAP method must be configured for each policy to which you want it to apply.
- PEAP is used as an authentication method for 802.11 wireless client computers, but is not supported for virtual private network (VPN) or other remote access clients. Because of this, you can only configure PEAP as the authentication method for a remote access policy when you are using IAS.
- When using the PEAP-EAP-TLS and EAP-TLS authentication methods with certificates, TLS uses cached certificate properties instead of reading the certificate from the certificate store. If a certificate is either changed or deleted and

replaced by a new certificate, TLS continues using outdated cached certificate information until the cache expires or is refreshed. If you change or replace a certificate, you can refresh the TLS cache by restarting the server computer.

- EAP-TLS is not supported if the IAS or remote access server is not a member of the domain.

- If you have issued a certificate to your IAS server that has a blank Subject, the certificate is not available to authenticate your IAS server. To change this, you can use Certificate Templates to create a new certificate for enrollment on your IAS server. In the certificate properties, on the **Subject Name** tab, in **Subject name format**, select a value other than **None**.

- For information about configuring specific authentication protocols, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure encryption

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To configure encryption

1. Do one of the following:

    - Open Routing and Remote Access and, if necessary, double-click **Routing and Remote Access** and the server name.

    - Open Internet Authentication Service and, if necessary, double-click **Internet Authentication Service**.

2. In the console tree, click **Remote Access Policies**.

3. In the details pane, double-click the remote access policy that you want to configure.

4. Click **Edit Profile**.

5. On the **Encryption** tab, specify any required settings.

### Notes

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Attributes for a Profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure attributes for a profile**

- Add RADIUS attributes to a remote access policy
- Configure vendor-specific attributes for a remote access policy

# Add RADIUS attributes to a remote access policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add RADIUS attributes to a remote access policy**

1. Open Internet Authentication Service.
2. In the console tree, click **Remote Access Policies**.
3. Right-click the policy for which you want to configure a RADIUS attribute, and then click **Properties**.
4. Click **Edit Profile**, click the **Advanced** tab, and then click **Add**.
5. In the list of available RADIUS attributes, double-click the attribute that you want to add to the profile. If the **Multivalued Attribute Information** dialog box appears, click **Add**.
6. In **Attribute**, supply a value from the following table, and then click **Add**. If you want to add another value to the attribute, click **Add** again, and then configure the attribute.

| If the attribute format is | In Attribute value | Attributes in this format include |
|---|---|---|
| Integer | Type the value specified in your access server documentation. | Acct-Interim-Interval |
| Enumerator | Select the value from the list. | Framed-Protocol |
| InetAddr | Type the IP address to be specified in the attribute. | Framed-IP-Netmask |
| Octet String | Type the string or the hexadecimal value that you provide. | Tunnel-Password |
| String | Type the string that you provide. | Reply-Message |
| Boolean | Select either **True** or **False**. | Ignore-User-Dialin-Properties |

**Notes**

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- You can only use the Generate-Session-Timeout attribute if your user account database is either a Security Accounts Manager (SAM) database or the user account database for an Active Directory domain. When the value of **Generate-Session-Timeout** is set to **True**, the ForceLogoff value for a SAM database should be set to **0** (zero). In Local Security Settings, ForceLogoff is set to **0** when **Network security: Force logoff when logon hours expire** is enabled. For more information, see Edit security settings on a Group Policy object. For information about changing the ForceLogoff value for the SAM database at the command prompt, see Net accounts.
- You can configure wireless connection policy so that wireless clients periodically reauthenticate. This ensures that the client Wired Equivalent Privacy (WEP) encryption keys are changed often enough to provide adequate security for the wireless connection. To configure reauthentication, set the session timeout in your remote access policy or connection request policy for wireless connections (using the Session-Timeout attribute) to the interval you prefer (for example, 10 minutes). Additionally, configure the Termination-Action attribute with **Attribute value** set to **RADIUS-Request**. If the Termination-Action attribute is not set to **RADIUS-Request**, wireless access points might end the connection during reauthentication. For more information, see your hardware documentation.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Configure vendor-specific attributes for a remote access policy

# Configure vendor-specific attributes for a remote access policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure vendor-specific attributes for a remote access policy**

1. Open Internet Authentication Service.
2. In the console tree, click **Remote Access Policies**.
3. Right-click the policy for which you want to configure a vendor-specific attribute (VSA), and then click **Properties**.
4. Click **Edit Profile**, click the **Advanced** tab, and then click **Add**.
5. Look at the list of available RADIUS attributes to determine whether your vendor-specific attribute is already in it. If it is, double-click it, and then configure it as specified in your NAS documentation.

If the vendor-specific attribute is not in the list of available RADIUS attributes:

1. Double-click **Vendor-Specific**, and then click **Add**.
2. Specify the vendor for your network access server.

   To specify the NAS vendor by selecting the name from the list, click **Select from list**, and then select the vendor of the NAS for which you are configuring the VSA. If you are using Routing and Remote Access as your NAS, click **Microsoft**.

   If the vendor is not listed, you can specify the vendor by typing the vendor code. To do this, click **Enter Vendor Code**, and then type the vendor code in the space provided. If you do not know the vendor code for your NAS, see IETF RFC 1007 for a list of SMI Network Management Private Enterprise Codes.
3. Specify whether the attribute conforms to the RADIUS RFC VSA specification. If you are not sure, see your NAS documentation.
4. If your attribute conforms, click **Yes. It conforms**, and then click **Configure Attribute**.
   - In **Vendor-assigned attribute number**, type the number that is assigned to the attribute (the numbers available are 0 through 255).
   - In **Attribute format**, specify the format for the attribute, and then in **Attribute value**, type the value that you are assigning to the attribute.
5. If the attribute does not conform, click **No. It does not conform**, and then click **Configure Attribute**. In **Hexadecimal attribute value**, type the value for the attribute.

**Notes**

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- To see configuration examples for vendor-specific attributes that both conform and do not conform to the RADIUS RFC, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Connection Request Processing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure connection request processing**

- Configure Connection Request Policies
- Configure Remote RADIUS Server Groups

# Configure Connection Request Policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure connection request policies**

- Add a connection request policy
- Configure a condition of a connection request policy
- Change the policy evaluation order
- Delete a connection request policy
- Configure a Profile for a Connection Request Policy

# Add a connection request policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a connection request policy**

1. Open Internet Authentication Service.
2. In the console tree, right-click **Connection Request Policies**, and then click **New Connection Request Policy**.

   **Where?**

   - Internet Authentication Service (Local)/Connection Request Processing/Connection Request Policies

3. Use the New Connection Request Policy Wizard to configure your connection request policy.

## Notes

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- You are not required to configure a remote RADIUS server group before you create a connection request policy that forwards authentication or accounting messages. You can create a remote RADIUS server group in the New Connection Request Policy Wizard.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure a condition of a connection request policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure a condition of a connection request policy**

1. Open Internet Authentication Service.
2. In the console tree, click **Connection Request Policies**.

   **Where?**

   - Internet Authentication Service (Local)/Connection Request Processing/Connection Request Policies

3. In the details pane, double-click the policy that you want to configure.
4. To configure a new condition, click **Add**, and then do the following:

   - In the **Select Attribute** dialog box, click the attribute to add, and then click **Add**.
   - In the attribute dialog box, configure the attribute, and then click **OK**.

5. To change the configuration of an existing condition:

   - Click the condition, and then click **Edit**.
   - In the attribute dialog box, specify your required settings, and then click **OK**.

**Note**

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the connection request policy evaluation order

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the policy evaluation order**

1. Open Internet Authentication Service.
2. In the console tree, click **Connection Request Policies**.

   **Where?**

   - Internet Authentication Service (Local)/Connection Request Processing/Connection Request Policies

3. In the details pane, right-click the policy that you want to move, and then click either **Move Up** (to move the policy up one level) or **Move Down** (to move the policy down one level).

**Note**

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a connection request policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a connection request policy**

1. Open Internet Authentication Service.
2. In the console tree, click **Connection Request Policies**.

   **Where?**

   - Internet Authentication Service (Local)/Connection Request Processing/Connection Request Policies

3. In the details pane, right-click the policy that you want to delete, and then click **Delete**.

### Note

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure a Profile for a Connection Request Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure a profile for a connection request policy**

- Configure authentication
- Configure accounting
- Configure attribute manipulation
- Configure advanced attributes

# Configure authentication in a connection request policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure authentication**

1. Open Internet Authentication Service.
2. In the console tree, click **Connection Request Policies**.

   **Where?**

   - Internet Authentication Service (Local)/Connection Request Processing/Connection Request Policies

3. In the details pane, right-click the policy that you want to configure, and then click **Properties**.
4. Click **Edit Profile**.
5. On the **Authentication** tab, specify authentication settings.

**Note**

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure accounting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure accounting**

1. Open Internet Authentication Service.
2. In the console tree, click **Connection Request Policies**.

   **Where?**

   - Internet Authentication Service (Local)/Connection Request Processing/Connection Request Policies

3. In the details pane, right-click the policy that you want to configure, and then click **Properties**.
4. Click **Edit Profile**.
5. On the **Accounting** tab, specify accounting settings.

## Notes

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- When you have remote RADIUS server groups configured and, in RADIUS proxy server **Connection Request Policies**, you clear the **Record accounting information on the servers in the following remote RADIUS server group** check box, these groups are still sent network access server (NAS) start and stop notification messages. This creates unnecessary network traffic. To eliminate this traffic, disable NAS notification forwarding for individual servers in each remote RADIUS server group by clearing the **Forward network start and stop notifications to this server** check box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure attribute manipulation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure attribute manipulation**

1. Open Internet Authentication Service.
2. In the console tree, click **Connection Request Policies**.

   **Where?**

   - Internet Authentication Service (Local)/Connection Request Processing/Connection Request Policies

3. In the details pane, right-click the policy that you want to configure, and then click **Properties**.
4. Click **Edit Profile**.
5. On the **Attribute** tab, specify find and replace rules for RADIUS attributes.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- When the user name does not contain a domain name, IAS supplies one. By default, the domain name supplied is that of which the IAS server is a member. You can specify this domain name through the following registry setting:

  **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\RasMan\PPP\ControlProtocols\BuiltIn\DefaultDomain**

- Some third party network access servers delete or modify the domain name as specified by the user. As the result, the network access request is authenticated against the default domain, which might not be the domain for the user's account. To resolve this problem, configure your RADIUS servers to change the user name into the correct format with the accurate domain name.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure advanced attributes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure advanced attributes**

1. Open Internet Authentication Service.
2. In the console tree, click **Connection Request Policies**.

   **Where?**

   - Internet Authentication Service (Local)/Connection Request Processing/Connection Request Policies

3. In the details pane, right-click the policy that you want to configure, and then click **Properties**.
4. Click **Edit Profile**.
5. On the **Advanced** tab, specify connection attributes.

**Note**

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure the Members of a Remote RADIUS Server Group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure the members of a remote RADIUS server group**

- Add a member to a remote RADIUS server group
- Remove a member from a remote RADIUS server group
- Configure the name of a group member
- Configure the authentication and accounting settings of a group member
- Configure the load balancing properties of a group member

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Add a member to a remote RADIUS server group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a member to a remote RADIUS server group**

1. Open Internet Authentication Service.
2. In the console tree, click **Remote RADIUS Server Groups**.

   **Where?**

   - Internet Authentication Service (Local)/Connection Request Processing/Remote RADIUS Server Groups

3. In the details pane, right-click the remote RADIUS server group that you want to configure, and then click **Properties**.
4. Click **Add**, and then configure address, authentication, accounting, and load balancing settings.

## Notes

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. # Configure the name of a group member

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure the name of a group member**

1. Open Internet Authentication Service.
2. In the console tree, click **Remote RADIUS Server Groups**.

   **Where?**

   - Internet Authentication Service (Local)/Connection Request Processing/Remote RADIUS Server Groups

3. In the details pane, right-click the remote RADIUS server group that you want to configure, and then click **Properties**.
4. On the **General** tab, click the server that you want to configure, and then click **Properties**.
5. On the **Address** tab, type the name or IP address of the server.

## Notes

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. # Configure the authentication and accounting settings of a group member

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure the authentication and accounting settings of a group member**

1. Open Internet Authentication Service.
2. In the console tree, click **Remote RADIUS Server Groups**.

   **Where?**

   - Internet Authentication Service (Local)/Connection Request Processing/Remote RADIUS Server Groups

3. In the details pane, right-click the remote RADIUS server group that you want to configure, and then click **Properties**.
4. On the **General** tab, click the server that you want to configure, and then click **Properties**.
5. On the **Authentication/Accounting** tab, specify authentication and accounting settings.

## Notes

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- When you have remote RADIUS server groups configured and, in RADIUS proxy server **Connection Request Policies**, you clear the **Record accounting information on the servers in the following remote RADIUS server group** check box, these groups are still sent network access server (NAS) start and stop notification messages. This creates unnecessary network traffic. To eliminate this traffic, disable NAS notification forwarding for individual servers in each remote RADIUS server group by clearing the **Forward network start and stop notifications to this server** check box. For more information, see Configure the authentication and accounting settings of a group member and Configure accounting.

# Configure Logging for User Authentication and Accounting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure logging for user authentication and accounting**

- Select requests to be logged
- Configure log file properties

# Select requests to be logged

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To select requests to be logged**

1. Open Internet Authentication Service.
2. In the console tree, click **Remote access logging**.
3. In the details pane, right-click **Local File** or **SQL Server**, and then click **Properties**.
4. On the **Settings** tab, select one or more check boxes for recording authentication and accounting requests in the IAS log files:
   - To capture accounting requests and responses, select **Accounting requests**.
   - To capture authentication requests, Access-Accept messages, and Access-Reject messages, select **Authentication requests**.
   - To capture periodic status updates, such as interim accounting packets, select **Periodic status**.

**Notes**

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
- It is recommended that you initially select **Accounting requests** and **Authentication requests**. You can change your selections as your requirements change.
- To use SQL Server logging, you must have a computer running an XML-compliant version of SQL Server.
- The **Authentication requests** option alerts you to both problems with transaction volume and unauthorized attempts to access resources.
- Interim accounting messages, recorded when you select **Periodic status**, are sent by the access server only when:
  1. You have added and configured the **Acct-Interim-Interval** RADIUS accounting attribute on the **Advanced** tab of the appropriate remote access policy.
  2. The access server supports the Acct-Interim-Interval attribute and the sending of interim accounting messages.
- Logging of client certificate validation failures is a secure channel (Schannel) event, and is not enabled on the IAS server by default. You can enable additional Schannel events (including logging of the client certificate validation failure) by changing the following registry key value from **1** (**REG_DWORD** type, data **0x00000001**) to **3** (**REG_DWORD** type, data **0x00000003**):

  **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\SecurityProviders\SCHANNEL\EventLogging**

  **Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure log file properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure log file properties**

1. Open Internet Authentication Service.
2. In the console tree, click **Remote Access Logging**.
3. In the details pane, choose **Local File** or **SQL Server**, and then follow the appropriate directions below:
   - Local File
   - SQL Server

**Local File**

1. In the details pane, right-click **Local File**, and then click **Properties**.
2. On the **Log File** tab, in **Directory**, type the location where log files are to be stored. The default location is the *systemroot*\System32\LogFiles folder.
3. In **Format**, click **Database-compatible**. Or, to keep your log files in IAS format, click **IAS**.
4. To open new log files at specific intervals, click the interval that you want to use:
   - For heavy transaction volume and logging activity, click **Daily**.
   - For lesser transaction volumes and logging activity, click **Weekly** or **Monthly**.
   - To store all transactions in one log file, click **Never (unlimited file size)**.
   - To limit the size of each log file, click **When log file reaches this size**, and then type a file size--after which a new log is created. The default size is 10 MB.
5. To automatically delete log files when the disk is full, click **When disk is full delete older log files.** If the oldest log file is the current log file, it is not deleted.

**SQL Server**

1. In the details pane, right-click **SQL Server**, and then click **Properties**.
2. In **Log the following information**, select the information that you want to log:
   - To log all accounting requests, click **Accounting requests**.
   - To log authentication requests, click **Authentication requests**.
   - To log periodic status, such as interim accounting requests, click **Periodic status**.

3. To configure the number of concurrent sessions allowed between the IAS server and the SQL Server database, type a number in **Maximum number of concurrent sessions**.

4. To configure the SQL Server data source, click **Configure**, and then, on the **Connection** tab, specify the following:

   - To specify the name of the server on which the database is stored, type or select a name in **Select or enter a server name**.

   - To specify the authentication method with which to log on to the server, click **Use Windows NT integrated security**. Or, click **Use a specific user name and password**, and then type credentials in **User name** and **Password**.

   - To allow a blank password, click **Blank password**.

   - To store the password, click **Allow saving password**.

   - To specify which database to connect to on the computer running SQL Server, click **Select the database on the server**, and then select a database name from the list.

5. To test the connection between the IAS server and the computer running SQL Server, click **Test Connection**.

### Notes

- To open Internet Authentication Service, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.

- To prevent the log files from filling the hard drive on which you are storing them, it is strongly recommended that you keep them on a partition that is separate from the system partition.

- To send the log file data for collection by another process, you can configure IAS to write to a named pipe. To use named pipes, set the log file folder to **\\.\pipe** or *****ComputerName***\pipe**. The named pipe server program creates a named pipe called **\\.\pipe\iaslog.log** to accept the data. In the **Local file properties** dialog box, in **Create a new log file**, select **Never (unlimited file size)** when you use named pipes.

- The log file directory can be created by using system environment variables (instead of user variables), such as %systemdrive%, %systemroot%, and %windir%. For example, the following path, using the environment variable %windir%, locates the log file at the system directory in the subfolder \System32\Logs (that is, %windir%\System32\Logs\).

- Switching log file formats does not cause a new log to be created. If you change log file formats, the file that is active at the time of the change will contain a mixture of the two formats (records at the start of the log will have the previous format, and records at the end of the log will have the new format).

- If you are administering an IAS server remotely, you cannot browse the directory structure. If you need to log accounting information to a remote server, specify the log file name by typing a Universal Naming Convention (UNC) name, such as *MyLogServer**LogShare*.

- If you do not supply a full path statement in **Log File Directory**, the default path is used. For example, if you type **IASLogFile** in **Log File Directory**, the file is located at *systemroot*\System32\IASLogFile.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Security information for IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security information for IAS**

It is important to follow best practices for security when using IAS servers on your network. For more information, see Best practices for security.

Following is security information for IAS and related protocols:

- **Deployments of PEAP and EAP unprotected by PEAP should not use the same authentication type**

  When you deploy both PEAP and EAP unprotected by PEAP, do not use the same EAP authentication type with and without PEAP. For example, if you deploy PEAP with EAP-TLS (PEAP-EAP-TLS), do not also deploy EAP-TLS without PEAP. Deploying authentication methods with the same type -- one with and the other without the protection of PEAP -- creates a security vulnerability.

- **The RADIUS User-Password hiding mechanism might not provide sufficient security for passwords.**

  The RADIUS hiding mechanism uses the RADIUS shared secret, the Request Authenticator, and the use of the MD5 hashing algorithm to encrypt the User-Password and other attributes, such as Tunnel-Password and MS-CHAP-MPPE-Keys. RFC 2865 notes the potential need for evaluating the threat environment and determining whether additional security should be used.

  You can provide additional protection for hidden attributes by using Internet Protocol Security (IPSec) with Encapsulating Security Payload (ESP) and an encryption algorithm, such as Triple DES (3DES), to provide data confidentiality for the entire RADIUS message.

  **Recommendations:**

  - Use IPSec to provide additional security for RADIUS clients and servers. For more information, see Securing RADIUS traffic with IPSec.
  - If you are using IPSec with ESP and an encryption algorithm is not available, do the following:

1. Require the use of the Message Authenticator attribute for all Access-Request messages. For more information, see Message Authenticator attribute and Configure the Message Authenticator attribute and shared secret.
2. Use cryptographically strong Request Authenticators.
3. Require the use of strong user passwords.
4. Use authentication counting and account lockout to help prevent a dictionary attack against a user password.
5. Use a long shared secret with a random sequence of letters, numbers, and punctuation. Change it often to help protect your IAS server and your RADIUS clients from dictionary attacks. For more information, see Shared secrets.

- **Many authentication methods are too weak to provide adequate security for most organizations.**

  Many organizations use authentication methods that expose their network to a variety of security attacks. The most secure method of authentication is Extensible Authentication Protocol-Transport Level Security (EAP-TLS) when used in conjunction with smart cards. However, EAP-TLS and smart cards require a public key infrastructure (PKI), which can be complicated to deploy.

  **Recommendations:**

  - When you use password-based authentication, enforce strong password policies on your network to make dictionary attacks more difficult.
  - Make sure that Password Authentication Protocol (PAP), Shiva Password Authentication Protocol (SPAP), and Challenge Handshake Authentication Protocol (CHAP) are disabled. PAP, SPAP, and CHAP are disabled by default on the profile of a remote access policy.
  - Disable Microsoft Challenge Handshake Authentication Protocol (MS-CHAP). MS-CHAP is enabled by default on the profile of a remote access policy. Before you disable MS-CHAP, ensure that all of the clients of your access server are capable of using MS-CHAP version 2 (MS-CHAP v2). If your server is not running Windows Server 2003 , you will need the latest service packs and dial-up networking updates in order to support MS-CHAP v2.
  - If you do not disable MS-CHAP, disable Microsoft LAN Manager authentication for MS-CHAP. LAN Manager authentication for MS-CHAP is enabled by default on clients running earlier versions of Windows.

    To disable LAN Manager authentication, set the registry value **Allow LM Authentication** to **0** at the following registry key:

    **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RemoteAccess\Policy**

**Caution**

Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

- **Remote access account lockout can cause authorized users to be denied network access.**

  If a malicious user attempts a dictionary attack with an authorized user logon name when remote access account lockout is enabled, both the malicious user and the authorized user are locked out of the account until the configured **Account lockout threshold** is reached.

  **Recommendations:**

  - When the lockout count for a user account is reset to zero, due to either a successful authentication or an automatic reset, the registry subkey for the user account is deleted. To manually unlock a user account (before the **Account lockout threshold** is automatically reset), you can delete the following registry subkey that corresponds to the user's account name:

    **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\AccountLockout***DomainName***:***UserName*

    **Caution**

  - Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. You can also use the **Last Known Good Configuration** startup option if problems are encountered after manual changes have been applied.

  **Notes**

  - Remote access account lockout is not related to the **Account locked out** setting on the **Account** tab in the properties of a user account.

  - With remote access account lockout, there is no distinction between malicious users who attempt to access your intranet and authentic users who attempt remote access but have forgotten or repeatedly mistyped their current passwords. Depending on the number of attempts and the MaxDenials setting in the registry, these users might have their accounts locked out.

- **Moving IAS log files from the default location results in unprotected log files.**

  When IAS logging is enabled, log files are located by default in the *systemroot*\System32\LogFiles folder. By default, the access control list on the LogFiles folder provides the best security for the IAS log files. The access control list is a list of users and groups that can access the folder. In addition, each user or group is assigned specific permissions that determine what actions the user or group can take with the folder. For more information, see Access Control.

  If you change the location of the IAS log files, however, the new folder location is not protected with the usual access control list by default. This creates a security risk.

  **Recommendations:**

  - If you move the IAS log files to another folder, create an access control list that contains only the Local System account and the Administrators group. In addition, ensure that the new log file folder does not inherit permissions from any other folder.

  - Do not store IAS log files in any personal folders, in My Documents, or in any subfolder of My Documents.

  - Store IAS log files on a computer that is physically secured and protected from unauthorized access.

  - Use file-level auditing for individual IAS log files to track the users and groups that access them. For more information, see Apply or modify auditing policy settings for a local file or folder.

  - Do not move or map the IAS log files to a remote storage device or an external drive for which no access control list can be created. Also do not move or copy IAS log files to an anonymous FTP site or any other unprotected location.

- **IAS server log data is sent in plaintext to remote computers running SQL server**

  If your IAS server is configured to log user authentication and accounting requests to a remote computer running SQL Server, the log data is sent unencrypted over the network, posing a high security risk.

  **Recommendations:**

  - Establish an encrypted connection at the computer running SQL Server for communication with the IAS server. For more information, see the SQL Server documentation.

  For more information about logging IAS data to a SQL Server database, see SQL Server database logging and Configure log file properties.

For additional information about security considerations and best practices, consult the following resources:

- Securing IAS
- IAS as a RADIUS server security considerations
- IAS Best Practices
- IAS as a RADIUS proxy security considerations
- Remote Access Logging
- Event Viewer
- Security issues for VPN
- Security information for remote access
- Security information for routing

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Introducing IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Introducing IAS**

Internet Authentication Service (IAS) in Microsoft® Windows Server® 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition is the Microsoft implementation of a Remote Authentication Dial-In User Service (RADIUS) server and proxy. As a RADIUS server, IAS performs centralized connection authentication, authorization, and accounting for many types of network access, including wireless, authenticating switch, dial-up and virtual private network (VPN) remote access, and router-to-router connections. As a RADIUS proxy, IAS forwards authentication and accounting messages to other RADIUS servers. IAS supports the Internet Engineering Task Force (IETF) standards for RADIUS described in RFCs 2865 and 2866.

IAS enables the use of a heterogeneous set of wireless, switch, remote access, or VPN equipment. You can use IAS with the Routing and Remote Access service, which is available in Microsoft Windows 2000, Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition.

When an IAS server is a member of an Active Directory® domain, IAS uses the directory service as its user account database and is part of a single sign-on solution. The same set of credentials is used for network access control (authenticating and authorizing access to a network) and to log on to an Active Directory domain.

Internet service providers (ISPs) and organizations that maintain network access have the increased challenge of managing all types of network access from a single point of administration, regardless of the type of network access equipment used. The RADIUS standard supports this functionality in both homogeneous and heterogeneous environments. RADIUS is a client-server protocol that enables network access equipment (used as RADIUS clients) to submit authentication and accounting requests to a RADIUS server.

A RADIUS server has access to user account information and can check network access authentication credentials. If the user's credentials are authentic and the connection attempt is authorized, the RADIUS server authorizes the user's access on the basis of specified conditions and logs the network access connection in an accounting log. The use of RADIUS allows the network access user authentication, authorization, and accounting data to be collected and maintained in a central location, rather than on each access server.

With IAS, organizations can also outsource remote access infrastructure to a service provider while retaining control over user authentication, authorization, and accounting.

Different IAS configurations can be created for the following solutions:

- Wireless access
- Organization dial-up or virtual private network (VPN) remote access
- Outsourced dial-up or wireless access
- Internet access
- Authenticated access to extranet resources for business partners

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Features of IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Features of IAS**

IAS includes support for the following features:

- A variety of authentication methods

  IAS supports a number of authentication protocols and allows you to add custom methods that meet your authentication requirements. The supported authentication methods are:

  - Password-based Point-to-Point Protocol (PPP) authentication protocols

    Password-based PPP authentication protocols, such as Password Authentication Protocol (PAP), Challenge Handshake Authentication Protocol (CHAP), Microsoft Challenge Handshake Authentication Protocol (MS-CHAP), and MS-CHAP version 2 (MS-CHAP v2), are supported. For more information, see Authentication methods.

  - Extensible Authentication Protocol (EAP)

    An Internet standards-based infrastructure that allows the addition of arbitrary authentication methods, such as smart cards, certificates, one-time passwords, and token cards. A specific authentication method that uses the EAP infrastructure is an EAP type. IAS includes support for EAP-Message Digest 5 (MD5) and EAP-Transport Level Security (EAP-TLS). For more information, see EAP.

- A variety of authorization methods

  IAS supports a number of authorization methods and allows you to add custom methods that meet your authorization requirements. The supported authorization methods are:

  - Dialed Number Identification Service (DNIS)

    The authorization of a connection attempt that is based on the number called. DNIS supplies the number that was called to the call receiver and is provided by most standard telephone companies.

  - Automatic Number Identification/Calling Line Identification (ANI/CLI)

    The authorization of a connection attempt that is based on the phone number of the caller. ANI/CLI service supplies the number of the caller to the call receiver and is provided by most standard telephone companies.

  - Guest authorization

    The use of the Guest account as the identity of the user when the connection is made without user credentials (user name and password).

    For more information, see Unauthenticated access.

- Heterogeneous access servers

  IAS supports access servers that support RADIUS RFCs 2865 and 2866. In addition to dial-up access servers (also known as network access servers), IAS also supports the following:

  - Wireless access points

    By using remote access policies and the Wireless-IEEE 802.11 port type condition, IAS can be used as a RADIUS server for wireless access points that use RADIUS for authentication and authorization of wireless nodes. For

more information, see New features for IAS.

- Authenticating switches

  By using remote access policies and the Ethernet port type condition, IAS can be used as a RADIUS server for Ethernet network switches that use RADIUS for authentication and authorization of switch nodes. For more information, see New features for IAS.

- Integration with the Routing and Remote Access service

  Both IAS and the Routing and Remote Access service share remote access policies and log file capabilities. This integration provides a consistent implementation for both IAS and the Routing and Remote Access service. It enables you to deploy Routing and Remote Access in small sites without the requirement of a separate, centralized IAS server. It also provides the ability to scale to a centralized remote access management model, whenever you have multiple Routing and Remote Access servers in your organization. IAS, in conjunction with Routing and Remote Access servers, implements a single point of administration for remote access to your network for outsourced-dial, demand-dial, and VPN access. The policies within IAS at a central and large site can be exported to the independent Routing and Remote Access server in a small site.

- RADIUS proxy

  IAS allows an incoming RADIUS request to be forwarded to another RADIUS server for the processing of authentication and authorization, or accounting. As a RADIUS proxy, IAS can be used whenever the RADIUS request must be routed to another RADIUS server. IAS can forward requests based on user name, access server IP address, access server identifier, and other conditions. For more information, see New features for IAS.

- Outsourced dial-up and wireless network access

  Outsourced dialing (also known as wholesale dialing) provides a contract between an organization (the customer) and an Internet service provider (ISP). The ISP allows organization employees to connect to its network before the VPN tunnel to the organization’s private network is established. When an organization employee connects to the ISP's NAS, the authentication and usage records are forwarded to the IAS server at the organization. The IAS server enables the organization to control user authentication, track usage, and determine which employees are allowed to access the ISP's network.

  The advantage of outsourced dialing is the potential savings. By using an ISP's routers, network access servers, and wide area network (WAN) links instead of purchasing your own, you might save a great deal on hardware (infrastructure) costs. By dialing into the ISP with worldwide connections, you might significantly decrease your long-distance phone bill. And, by moving support requirements to the provider, you might eliminate administrative costs.

  You can also outsource wireless access. A vendor can provide wireless access in a remote location and use your user name to forward the connection request to a RADIUS server that is under your control for authentication and authorization. A good example is wireless Internet access in an airport.

- Centralized user authentication and authorization

  To authenticate a connection request, IAS validates the connection credentials against user accounts in the local Security Accounts Manager (SAM), a Microsoft® Windows NT® Server 4.0 domain, or an Active Directory® domain. For an Active Directory domain, IAS supports the use of Active Directory user principal names (UPNs) and universal groups.

  To authorize a connection request, IAS uses the dial-in properties of the user account that correspond to both the connection credentials and remote access policies. Although it is relatively easy to manage remote access permission for each user account, this approach does not scale well as an organization grows. Remote access policies provide a more powerful and flexible way to manage remote access permission. You can authorize network access based on various conditions, including:

  - User account membership in a group.

- The time of day or day of the week.
- The type of media through which the user is connecting (for example, wireless, Ethernet switch, modem, or VPN).
- The phone number that the user calls.
- The access server from which the request arrives.

  By configuring profile settings on remote access policies, you can control many connection parameters, including:

- The use of specific authentication methods.
- The idle timeout.
- The maximum time of a single session.
- The number of links in a multilink session.
- The use of encryption and its strength.
- The use of packet filters to control what the remote access user can access when connected to the network. For example, you can use filters to control which IP addresses, hosts, and ports the user is allowed to use in sending or receiving packets.
- The creation of a compulsory tunnel that forces all packets from that connection to be securely tunneled through the Internet and terminated in a private network.
- The virtual local area network identifier (VLAN ID) for wireless or Ethernet connections.

- Centralized administration for all of your access servers

  Support for the RADIUS standard allows IAS to control connection parameters for any access server that implements RADIUS. The RADIUS standard also allows individual remote access vendors to create proprietary extensions called vendor-specific attributes (VSAs). IAS has incorporated the extensions from a number of vendors in its dictionary. Additional VSAs can be added to the profile of individual remote access policies. For more information, see Vendor-specific attribute overview.

- Centralized auditing and usage accounting

  Support for the RADIUS standard allows IAS to collect, at a central location, the usage (accounting) records sent by all access servers. IAS stores audit information (for example, authentication accepts and rejects) and usage information (for example, connect and disconnect records) in log files. IAS supports a log file format that can be directly imported into a database. The data can then be analyzed with any standard data analysis application. For more information, see Logging user authentication and accounting requests.

- Snap-in-based management tool

  IAS provides an administration tool named the Internet Authentication Service snap-in. You can run Internet Authentication Service from Administrative Tools to administer IAS on a local computer. Or, you can add the Internet Authentication Service snap-in to the Microsoft Management Console (MMC) to administer IAS running on either a local computer or a remote computer.

- Local or remote monitoring with tools provided in Microsoft® Windows Server® 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition

  You can monitor IAS locally or on a remote computer with tools provided in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition, including Event Viewer, System

Monitor, and Simple Network Management Protocol (SNMP). You can also use Network Monitor to capture RADIUS messages for detailed traffic analysis and troubleshooting.

- Scalability

  You can use IAS in a variety of network configurations of varying size, from stand-alone servers for small networks to large organization and ISP networks.

- Support for multiple IAS servers

  The synchronization of the configuration of multiple IAS servers can be performed with the Netsh command-line tool. For more information see Copy the IAS configuration to another server.

- Extensibility

  The Windows Server 2003 Platform Software Development Kit (SDK) contains two smaller networking SDKs--the IAS SDK and the EAP SDK.

  You can use the IAS SDK to:

  - Return custom attributes to the access server in addition to those returned by IAS. For example, you can create a customized module to assign IP addresses.
  - Control the number of user network sessions.
  - Import usage and audit data directly into an Open Database Connectivity (ODBC)-compliant database.
  - Create customized authorization modules.
  - Create customized authentication modules (non-EAP).

You can use the EAP SDK to create EAP types. For more information, see EAP.

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# RADIUS protocol

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**RADIUS protocol**

Remote Authentication Dial-In User Service (RADIUS) is an industry standard protocol described in RFC 2865, "Remote Authentication Dial-in User Service (RADIUS)," and RFC 2866, "RADIUS Accounting." RADIUS is used to provide authentication, authorization, and accounting services. A RADIUS client (typically a dial-up server, VPN server, or wireless access point) sends user credentials and connection parameter information in the form of a RADIUS message to a RADIUS server. The RADIUS server authenticates and authorizes the RADIUS client request, and sends back a RADIUS message response. RADIUS clients also send RADIUS accounting messages to RADIUS servers. Additionally, the RADIUS standards support the use of RADIUS proxies. A RADIUS proxy is a computer that forwards RADIUS messages between RADIUS-enabled computers.

RADIUS messages are sent as User Datagram Protocol (UDP) messages. UDP port 1812 is used for RADIUS authentication messages and UDP port 1813 is used for RADIUS accounting messages. Some network access servers might use UDP port 1645 for RADIUS authentication messages and UDP port 1646 for RADIUS accounting messages. By default, IAS supports receiving RADIUS messages destined to both sets of UDP ports. For information about changing the UDP ports that are used by IAS, see Configure IAS port information. Only one RADIUS message is included in the UDP payload of a RADIUS packet.

RFCs 2865 and 2866 define the following RADIUS message types:

- Access-Request

  Sent by a RADIUS client to request authentication and authorization for a connection attempt.

- Access-Accept

  Sent by a RADIUS server in response to an Access-Request message. This message informs the RADIUS client that the connection attempt is authenticated and authorized.

- Access-Reject

  Sent by a RADIUS server in response to an Access-Request message. This message informs the RADIUS client that the connection attempt is rejected. A RADIUS server sends this message if either the credentials are not authentic or the connection attempt is not authorized.

- Access-Challenge

  Sent by a RADIUS server in response to an Access-Request message. This message is a challenge to the RADIUS client that requires a response.

- Accounting-Request

  Sent by a RADIUS client to specify accounting information for a connection that was accepted.

- Accounting-Response

  Sent by the RADIUS server in response to the Accounting-Request message. This message acknowledges the successful receipt and processing of the Accounting-Request message.

A RADIUS message consists of a RADIUS header and zero or more RADIUS attributes. Each RADIUS attribute specifies a piece of information about the connection attempt. For example, there are RADIUS attributes for the user name, the user password, the type of service requested by the user, and the IP address of the access server. RADIUS attributes are used to convey information between RADIUS clients, RADIUS proxies, and RADIUS servers. For example, the list of attributes in the Access-Request message includes information about the user credentials and the parameters of the connection attempt. In contrast, the Access-Accept message includes information about the type of connection that can be made, connection constraints, and any vendor-specific attributes (VSAs).

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# New features for IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New features for IAS**

The following are new features for IAS in Microsoft® Windows Server® 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition:

- Support for RADIUS proxy
- Support for mapping network authentication and authorization for IAS proxy
- Support for IEEE 802.1x wireless and authenticating switches
- Support for Protected Extensible Authentication Protocol (PEAP) for 802.11 wireless clients
- Enhanced EAP configuration for remote access policies
- Support for IAS Network Access Quarantine Control
- Support for logging to an XML-compliant SQL server database
- Ignoring the dial-in properties of user accounts
- Support for configuring RADIUS clients by IP address range
- Support for computer authentication
- Support for checking user certificate purposes
- Improved attribute manipulation
- Support for the Authentication Type remote access policy condition
- Improved support for the Class attribute

Each of these new features is described below.

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

**Support for RADIUS proxy**

Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition include RADIUS proxy support in addition to RADIUS server support. With RADIUS proxy support, you can use IAS as a RADIUS message router or forwarder. Based on attributes in the incoming RADIUS message, the RADIUS proxy forwards the message to a specific RADIUS server or client.

IAS implements RADIUS proxy support through connection request processing and remote RADIUS server groups. Connection

request processing is a set of rules that determine how an incoming connection request is processed: It is either authenticated and authorized by the IAS server (when the IAS server is being used as a RADIUS server), or it is forwarded to another RADIUS server for authentication and authorization (when the IAS server is being used as a RADIUS proxy). When IAS is being used as a proxy, it forwards the connection request to a member of a remote RADIUS server group.

By correctly configuring connection request processing rules and remote RADIUS server groups, an IAS server can be used as a RADIUS server for some requests and a RADIUS proxy for others. The IAS proxy also provides the ability to balance RADIUS requests across multiple RADIUS servers, to detect both which RADIUS servers are no longer available and when they become available again. For more information about how RADIUS proxies are used and when to use IAS as a RADIUS proxy, see IAS as a RADIUS proxy.

For more information about configuring IAS as a RADIUS proxy, see Deploying IAS as a RADIUS Proxy and Checklist: Configuring IAS to forward requests.

**Support for mapping network authentication and authorization for IAS proxy**
The proxy component of IAS supports the ability to separate the authentication and authorization of connection requests from access servers. The IAS proxy can forward password-based user credentials to an external RADIUS server for authentication, and perform authorization against a user account in an Active Directory® domain and a locally configured remote access policy. Alternate user authentication databases can be used but connection authorization and restrictions are still determined through local administration.

For example, a visitor from a partner company can be authenticated by using the partner company RADIUS server and user database. Authorization to access your network is accomplished based on connection request policy settings on your IAS server and a Windows account user database in an Active Directory domain that is established for visitor accounts.

You can configure the proxy component with the **Remote-RADIUS-to-Windows-User-Mapping** attribute in the advanced properties of a connection request policy.

For more information, see Mapping network authentication and authorization and Connection request policies.

**Support for IEEE 802.1x wireless and authenticating switches**
IAS provides authentication, authorization, and accounting for connections that use the link-layer standard IEEE 802.1x for wireless and switch access.

**Wireless access point support**
Wireless networking technology has become more widely used since the adoption of wireless industry standards such as IEEE 802.11 and 802.11b. You can use wireless networking to roam within a building or area and connect automatically to a network when you are in the vicinity of a wireless access point.

While providing convenience, wireless networking technologies and wireless access points have the following security risks:

- Anyone who has a compatible wireless network adapter can gain access to the network.
- Wireless networking signals use radio waves to send and receive information. Anyone within an appropriate distance to a wireless access point can detect and receive all data sent to and from the wireless access point.

To counter the first security risk, wireless access points must require authentication and authorization of the wireless node before data can be sent to and received from the network that is attached to the wireless access point. To provide their own authentication and authorization, each wireless access point should require a user account database with each user's authentication credentials and a set of rules by which authorization is granted. Because this is difficult to manage, some wireless access points are RADIUS clients that use the industry standard RADIUS protocol to send connection request and accounting messages to a central RADIUS server. The RADIUS server has access to a user account database and a set of rules for granting authorization. The RADIUS server processes the wireless access point's connection request and either accepts or rejects the connection request.

To counter the second security risk, the data sent between the wireless nodes and the wireless access points must be encrypted. Because of this, the authentication method that is used by the wireless node must allow for the determination of encryption keys that are used to encrypt data.

IAS supports wireless access authentication through the following:

- The use of Extensible Authentication Protocol-Transport Level Security (EAP-TLS) to provide certificate-based authentication and the management of encryption keys that are used to encrypt data sent between wireless access points and wireless nodes.

- The use of the Wireless-IEEE 802.11 port types when configuring the NAS-Port-Type condition of remote access policies.

  By using these port types, you can create a separate remote access policy that contains connection parameters and encryption settings that are specifically designed for wireless nodes.

- By providing a means to grant guest access for a wireless client that does not have a certificate installed.

For more information about configuring IAS for wireless access authentication, see Checklist: Configuring the IAS server and wireless access points for wireless access and Wireless access.

For an example of a remote access policy for wireless clients, see Wireless access example.

**Authenticating switch support**
Network switches are a commonly used technology. A network switch provides selective filtering of the traffic received on each port of the switch and allows better traffic management by segmenting a network. A typical switch, however, sends and receives packets to any node that is connected to the switch. This can be a problem for switch ports in a conference room within an organization. A person from another organization can simply connect their network adapter to the switch port and gain instant access to the network.

To prevent physical layer access to the network, newer switches can be configured to require switch node authentication and authorization before data can be sent to and received from the network that is attached to the switch. To provide their own authentication and authorization, each switch is required to have a user account database with each user's authentication credentials and a set of rules by which authorization is granted. Because this is difficult to manage, newer switches can be RADIUS clients, using the industry standard RADIUS protocol to send connection request and accounting messages to a central RADIUS server. The RADIUS server has access to a user account database and a set of rules for granting authorization. The RADIUS server processes the switch's connection request and either grants the connection request or rejects it.

As the data sent to and from the switch node travels on the wire between the switch node and the switch, encryption of the sent data is neither required nor typically implemented.

IAS supports switch access authentication through the following:

- EAP-TLS is used to provide computer or user certificate-based authentication.

- The Ethernet port type is used when configuring the NAS-Port-Type condition of remote access policies. By using this port type, you can create a separate remote access policy containing connection parameters that are specifically designed for switch nodes.

- Virtual local area network (VLAN) switching is used on the basis of whether or not the switch access client is authenticated.

For more information about configuring IAS for switch access authentication, see Checklist: Configuring the IAS server for authenticated switch access and Ethernet switch access.

**Support for Protected Extensible Authentication Protocol (PEAP) for 802.11 wireless clients**
Protected Extensible Authentication Protocol (PEAP) provides protection for clients and authenticators (IAS or RADIUS servers) that are using EAP. The next generation of EAP, PEAP uses Transport Level Security (TLS) to create end-to-end communication between client and authenticator after the identity of the authenticator is verified.

PEAP creates a session key that is used to derive keys for the encryption of data traffic between the wireless client and the wireless access point. It also provides smooth and efficient roaming between wireless access points that are configured as RADIUS clients on the same IAS server. You can use PEAP with two different authentication types: EAP-MS-CHAPv2 or EAP-TLS. PEAP with EAP-MS-CHAPv2 (also known as PEAP-EAP-MS-CHAPv2), provides secure password authentication for wireless and authenticated switch clients. PEAP-EAP-MS-CHAPv2 can be used to complement the security of MS-CHAPv2 and does not require deployment of user or computer certificates. You can also use PEAP with EAP-TLS (also known as PEAP-EAP-TLS), which provides strong security through a public key infrastructure (PKI) with certificates, which is used for server authentication, and either smart cards or certificates for client and user authentication. When you use PEAP-EAP-TLS, client certificate information is encrypted, providing improved security over the use of EAP-TLS without PEAP.

The following table shows the strengths of PEAP-EAP-MS-CHAPv2 and how it compares to MS-CHAPv2:

| Feature/function | MS-CHAPv2 | PEAP-EAP-MS-CHAPv2 |
|---|---|---|
| Provides client authentication using passwords | Yes | Yes |
| Ensures that the server has access to credentials | Yes | Yes |
| Authenticates the server | No | Yes |
| Prevents wireless access point spoofing | No | Yes |
| Prevents an unauthorized server from negotiating the least secure authentication method | No | Yes |
| Uses TLS keys generated with a public key | No | Yes |
| Provides end-to-end encryption | No | Yes |
| Prevents dictionary or brute force attacks | No | Yes |
| Prevents replay | No | Yes |
| Allows chaining of authentication methods | No | Yes |
| Requires client trust of certificates provided by the server | No | Yes |

For more information, see PEAP.

**Enhanced EAP configuration for remote access policies**

In Microsoft Windows 2000 Server, you can select only a single EAP type for a remote access policy. All connections matching the conditions of the policy must use this single EAP type, which is selected in the policy profile settings. Additionally, the configuration of an EAP type is global for all of the remote access policies configured on the IAS server. This can cause problems when you want to either individually configure the properties for EAP types for each policy or select multiple EAP types by group or for a specific kind of network connection.

In Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition; these limitations are removed for IAS. For example, you can select different computer certificates for VPN connections and EAP-TLS authentication for wireless connections, or you can select multiple EAP types for wireless connections in the circumstance where some of your wireless clients use EAP-TLS authentication and some of them use PEAP with EAP-MS-CHAPv2.

For more information, see Configure PEAP and EAP methods, PEAP, and EAP.

**Support for IAS Network Access Quarantine Control**

IAS Network Access Quarantine Control provides phased network access, which restricts the access of remote clients to quarantine mode until each client is either verified as meeting or configured according to organization network access policy. After the client computer configuration is verified as meeting organization network policy, the quarantine restrictions, which consist of Quarantine IP-Filters and Session Timers, are removed and standard remote access policy is applied to the connection.

For more information, see IAS Network Access Quarantine Control.

**Support for logging to an XML-compliant SQL server database**

You can use an XML-compliant database, such as Microsoft SQL server™ 2000, to log user authentication and accounting requests, which are received from one or more access servers, to a central data source. Log data is passed from IAS to a procedure stored in a database that supports both structured query language (SQL) and extensible markup language (XML).

For more information, see SQL Server database logging.

**Ignoring the dial-in properties of user accounts**

You can configure a RADIUS attribute on the profile properties of a remote access policy to ignore the dial-in properties of user accounts. The dial-in properties of the user account contain the following:

- Remote access permission

- Caller-ID
- Callback options
- Static IP address
- Static routes

To support multiple types of connections for which IAS provides authentication and authorization, it might be necessary to disable the processing of user account dial-in properties. This can be done to support scenarios in which specific dial-in properties are not required.

For example, the caller-ID, callback, static IP address, and static routes properties are designed for a client that is dialing into a network access server (NAS), not for wireless access points. A wireless access point that receives these settings in a RADIUS message might not be able to process them, which could cause the wireless client to be disconnected. When IAS provides authentication and authorization for users who are both dialing in and accessing the organization network through wireless technology, the dial-in properties must be configured to support either dial-in connections (by setting dial-in properties) or wireless connections (by not setting dial-in properties).

You can use IAS to enable dial-in properties processing for the user account in some scenarios (such as dial-in) and to disable dial-in properties processing for user account dial-in properties in other scenarios (such as wireless and authenticating switch). This is accomplished by configuring the **Ignore-User-Dialin-Properties** attribute on the **Advanced** tab of the profile settings for a remote access policy. For more information, see Add RADIUS attributes to a remote access policy.

The **Ignore-User-Dialin-Properties** attribute is set to the following:

- To enable user account dial-in properties processing, delete the **Ignore-User-Dialin-Properties** attribute or set it to **False**. For example, for a remote access policy that is designed for dial-in connections, no additional configuration is required.
- To disable user account dial-in properties processing, set the **Ignore-User-Dialin-Properties** attribute to the value of **True**. For example, this is set for the remote access policy that is designed for wireless or authenticating switch connections. When the dial-in properties of the user account are ignored, remote access permission is determined by the remote access permission setting in the remote access policy.

You can also use this attribute to manage network access control through groups and the remote access permission on the remote access policy. By setting the **Ignore-User-Dialin-Properties** attribute to the value of **True**, the remote access permission on the user account is ignored. The disadvantage to using the **Ignore-User-Dialin-Properties** attribute in this way is that you cannot use the additional dial-in properties of caller-ID, callback, static IP address, and static routes.

For more information about setting advanced attributes, see Add RADIUS attributes to a remote access policy.

**Note**

- The **Ignore-User-Dialin-Properties** attribute disables the use of all dial-in properties for the user account. Specific dial-in properties cannot be selectively disabled.

**Support for configuring RADIUS clients by IP address range**

For IAS in Windows 2000, you must specify a RADIUS client by IP address or by Domain Name System (DNS) name. In addition, you must configure each RADIUS client separately, even if you have a number of RADIUS clients on the same subnet. While this is not an issue for typical dial-in or VPN access server configurations, numerous wireless access points can be placed on the same subnet. To simplify administration of RADIUS clients for this type of network configuration, IAS in Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition allows you to specify a RADIUS client by using an address range. All of the RADIUS clients in the range must use the same configuration and shared secret.

The address range for RADIUS clients is expressed in the network prefix length notation *w.x.y.z/p*, where *w.x.y.z* is the dotted decimal notation of the address prefix and *p* is the prefix length (the number of high order bits that define the network prefix). This is also known as Classless Inter-Domain Routing (CIDR) notation. An example is 192.168.21.0/24. To convert from subnet mask notation to network prefix length notation, *p* is the number of high order bits set to one in the subnet mask.

For more information, see Configure RADIUS Clients.

**Support for computer authentication**
Active Directory and IAS in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition support the authentication of computer accounts by using standard user authentication methods such as Point-to-Point Protocol (PPP). This allows a computer and its computer certificate to be authenticated for wireless or authenticating switch access clients.

**Support for checking user certificate purposes**
To enforce the use of specific types of user certificates for specific connection types, you can configure IAS to check the purposes (also known as object identifiers or OIDs) of certificates in their Enhanced Key Usage (EKU) extensions. When EAP-TLS is used, the access client can send a smart card certificate or a user certificate from the client computer certificate store during the authentication process. Because smart card certificates are more secure than certificates from the client computer certificate store, you might want to ensure that remote access VPN connections use a smart card certificate for user authentication instead of a locally-installed user certificate. In this case, you can configure a remote access policy to require that the user certificate EKU extensions contain the Smart Card Logon purpose (the object identifier is 1.3.6.1.4.1.311.20.2.2). When the VPN client offers the smart card certificate for user authentication, the IAS server checks the EKU extensions according to remote access policy. Because the Smart Card Logon purpose is present in the VPN client certificate, authentication succeeds. For more information, see Network access authentication and certificates.

You can configure a list of object identifiers that are required to be present in the user certificate (which is offered by the access client). To do this, use the **Allow certificates with these OIDs** attribute on the **Advanced** tab in the properties of a remote access policy profile. No required object identifiers are specified by default. For more information, see Add RADIUS attributes to a remote access policy.

**Improved attribute manipulation**
In Windows 2000, you can use IAS to manipulate the contents of the User-Name RADIUS attribute. Using connection request policies in IAS for Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition; you can manipulate the User-Name, Called-Station-ID, and Calling-Station-ID RADIUS attributes. For more information, see Connection request policies.

**Support for the Authentication Type remote access policy condition**
In IAS for Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition; you can create remote access policies by using the Authentication Type condition. You can use it to specify connection constraints that are based on the authentication protocol or method that is used by the access client. For more information, see Elements of a remote access policy.

**Improved support for the Class attribute**
In Windows 2000, IAS automatically generates a value for the Class attribute and appends it to the existing value of the Class attribute received in the RADIUS request message. The result is the Class attribute in the RADIUS response message. In Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition:

1. You can disable the automatic generation of a value for the Class attribute by using **Generate-Class-Attribute** on the **Advanced** tab in the properties of a remote access policy profile. Automatic generation of a value for the Class attribute is disabled by default. For more information, see Add RADIUS attributes to a remote access policy.

2. Instead of appending the generated value of the Class attribute to the existing Class attribute, IAS creates a separate Class attribute. The RADIUS response message contains both the original Class attribute and the second Class attribute that is generated by IAS.

# Differences in IAS implementations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Differences in IAS implementations**

A previous version of IAS was released with the Microsoft® Windows NT® 4.0 Option Pack. The following table describes the differences between this version and the one available in Microsoft® Windows Server® 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition.

| **Windows NT 4.0 IAS** | **IAS in Microsoft® Windows Server™ 2003 operating systems** |
|---|---|
| If a domain name is not specified during authentication, the IAS server authenticates the user against only the local SAM database. | IAS resolves a user name without a specified domain name by using the following sequence:<br>1. IAS determines a default domain from the registry, if one is specified.<br>2. If the IAS server is a member of a domain, IAS authenticates the user against that domain.<br>3. If the IAS server is not a member of a domain, IAS authenticates the user against the local SAM database. |
| IAS does not use callback permissions for all user objects. | IAS uses callback permissions for all user objects. |
| IAS log files are written in ASCII. | IAS log files are multilanguage and are written in UTF-8. |

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# IAS as a RADIUS server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS as a RADIUS server**

Internet Authentication Service (IAS) can be used as a RADIUS server to perform authentication, authorization, and accounting for RADIUS clients. A RADIUS client can be either an access server or a RADIUS proxy. When Internet Authentication Service (IAS) is used as a RADIUS server, it provides the following:

- A central authentication and authorization service for all access requests that are sent by RADIUS clients.

  IAS uses either a Microsoft® Windows NT® Server 4.0 domain, an Active Directory® domain, or the local Security Accounts Manager (SAM) to authenticate user credentials for a connection attempt. IAS uses the dial-in properties of the user account and remote access policies to authorize a connection.

- A central accounting recording service for all accounting requests that are sent by RADIUS clients.

  Accounting requests are stored in a local log file for analysis.

The following illustration shows IAS as a RADIUS server for a variety of access clients and a RADIUS proxy. IAS uses an Active Directory domain for user credential authentication of incoming RADIUS Access-Request messages.

When IAS is used as a RADIUS server, RADIUS messages provide authentication, authorization, and accounting for network access connections in the following way:

1. Access servers, such as dial-up network access servers, VPN servers, and wireless access points, receive connection requests from access clients.

2. The access server, configured to use RADIUS as the authentication, authorization, and accounting protocol, creates an Access-Request message and sends it to the IAS server.

3. The IAS server evaluates the Access-Request message.

4. If required, the IAS server sends an Access-Challenge message to the access server. The access server processes the challenge and sends an updated Access-Request to the IAS server.

5. The user credentials are checked and the dial-in properties of the user account are obtained by using a secure connection to a domain controller.

6. The connection attempt is authorized with both the dial-in properties of the user account and remote access policies.

7. If the connection attempt is both authenticated and authorized, the IAS server sends an Access-Accept message to the access server.

   If the connection attempt is either not authenticated or not authorized, the IAS server sends an Access-Reject message to the access server.

8. The access server completes the connection process with the access client and sends an Accounting-Request message to the IAS server, where the message is logged.

9. The IAS server sends an Accounting-Response to the access server.

**Note**

- The access server also sends Accounting-Request messages for the following:

  - During the time in which the connection is established.

  - When the access client connection is closed.

  - When the access server is started and stopped.

You can use IAS as a RADIUS server when:

- You are using a Windows NT Server 4.0 domain, an Active Directory domain, or the local Security Accounts Manager (SAM) as your user account database for access clients.

- You are using the Microsoft® Windows Server® 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; or Windows 2000 Routing and Remote Access service on multiple dial-up servers, VPN servers, or demand-dial routers and you want to centralize both the configuration of remote access policies and connection logging for accounting.

- You are outsourcing your dial-in, VPN, or wireless access to a service provider. The access servers use RADIUS to authenticate and authorize connections that are made by members of your organization.

- You want to centralize authentication, authorization, and accounting for a heterogeneous set of access servers.

For more information, see Deploying IAS as a RADIUS Server.

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# IAS as a RADIUS proxy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS as a RADIUS proxy**

Internet Authentication Service (IAS) can be used as a RADIUS proxy to provide the routing of RADIUS messages between RADIUS clients (access servers) and RADIUS servers that perform user authentication, authorization, and accounting for the connection attempt. When used as a RADIUS proxy, IAS is a central switching or routing point through which RADIUS access and accounting messages flow. IAS records information in an accounting log about the messages that are forwarded.

The following illustration shows IAS as a RADIUS proxy between RADIUS clients (access servers) and either RADIUS servers or another RADIUS proxy.

When IAS is used as a RADIUS proxy between a RADIUS client and a RADIUS server, RADIUS messages for network access connection attempts are forwarded in the following way:

1. Access servers, such as dial-up network access servers, VPN servers, and wireless access points, receive connection requests from access clients.

2. The access server, configured to use RADIUS as the authentication, authorization, and accounting protocol, creates an Access-Request message and sends it to the IAS server that is being used as the IAS RADIUS proxy.

3. The IAS RADIUS proxy receives the Access-Request message and, based on the locally configured connection request policies, determines where to forward the Access-Request message.

4. The IAS RADIUS proxy forwards the Access-Request message to the appropriate RADIUS server.

5. The RADIUS server evaluates the Access-Request message.

6. If required, the RADIUS server sends an Access-Challenge message to the IAS RADIUS proxy, where it is forwarded to the access server. The access server processes the challenge with the access client and sends an updated Access-Request to the IAS RADIUS proxy, where it is forwarded to the RADIUS server.

7. The RADIUS server authenticates and authorizes the connection attempt.

8. If the connection attempt is both authenticated and authorized, the RADIUS server sends an Access-Accept message to the IAS RADIUS proxy, where it is forwarded to the access server.

   If the connection attempt is either not authenticated or not authorized, the RADIUS server sends an Access-Reject message to the IAS RADIUS proxy, where it is forwarded to the access server.

9. The access server completes the connection process with the access client and sends an Accounting-Request message to the IAS RADIUS proxy. The IAS RADIUS proxy logs the accounting data and forwards the message to the RADIUS server.

10. The RADIUS server sends an Accounting-Response to the IAS RADIUS proxy, where it is forwarded to the access server.

You can use IAS as a RADIUS proxy when:

- You are a service provider that offers outsourced dial, virtual private network (VPN), or wireless network access services to multiple customers. Your network access servers send connection requests to the IAS RADIUS proxy. Based on the realm portion of the user name in the connection request, the IAS RADIUS proxy forwards the connection request to a RADIUS server that is maintained by the customer and can authenticate and authorize the connection attempt. For more information, see Realm names.

- You want to provide authentication and authorization for user accounts that are not members of either the domain in which the IAS server is a member or another domain that has a two-way trust with the domain in which the IAS server is a member. This includes accounts in untrusted domains, one-way trusted domains, and other forests. Instead of configuring your access servers to send their connection requests to an IAS RADIUS server, you can configure them to send their connection requests to an IAS RADIUS proxy. The IAS RADIUS proxy uses the realm name portion of the user name and forwards the request to an IAS server in the correct domain or forest. Connection attempts for user accounts in one domain or forest can be authenticated for network access servers in another domain or forest.

  IAS supports authentication across forests without a RADIUS proxy when the two forests contain only domains that consist of domain controllers running Microsoft® Windows Server® 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition. The forest functional level must be Windows Server 2003 , and there must be a two-way trust relationship between forests. If you use EAP-TLS with certificates as your authentication method, however, you must use a RADIUS proxy for authentication across forests that consist of Windows Server 2003 domains.

- You want to perform authentication and authorization by using a database that is not a Windows account database. In this case, connection requests that match a specified realm name are forwarded to a RADIUS server, which has access to a different database of user accounts and authorization data. Examples of other user databases include Novell Directory Services (NDS) and Structured Query Language (SQL) databases.

- You want to process a large number of connection requests. In this case, instead of configuring your RADIUS clients to attempt to balance their connection and accounting requests across multiple RADIUS servers, you can configure them to send their connection and accounting requests to an IAS RADIUS proxy. The IAS RADIUS proxy dynamically balances the load of connection and accounting requests across multiple RADIUS servers and increases the processing of large numbers of RADIUS clients and authentications per second.

- You want to provide RADIUS authentication and authorization for outsourced service providers and minimize intranet firewall configuration. An intranet firewall is between your perimeter network (the network between your intranet and the Internet) and intranet. By placing an IAS server on your perimeter network, the firewall between your perimeter network and intranet must allow traffic to flow between the IAS server and multiple domain controllers. When replacing the IAS server with an IAS proxy, the firewall must allow only RADIUS traffic to flow between the IAS proxy and one or multiple IAS servers within your intranet.

For more information, see Deploying IAS as a RADIUS Proxy.

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Understanding IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding IAS**
This section covers:

- Components of a RADIUS infrastructure
- Realm names
- IAS and tunnels
- Managing multiple IAS servers
- Network access authentication and certificates
- Securing IAS
- Vendor-Specific Attributes
- Authentication methods
- Remote Access Policies
- Connection Request Processing
- Remote Access Logging

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Components of a RADIUS infrastructure

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Components of a RADIUS infrastructure**
A RADIUS authentication, authorization, and accounting infrastructure consists of the following components:

- Access clients
- Access servers (RADIUS clients)
- RADIUS proxies
- RADIUS servers
- User account databases

These components are shown in the following illustration.

**Access clients**
An access client is a device that requires some level of access to a larger network. Examples of access clients are dial-up or virtual private network (VPN) clients, wireless clients, or LAN clients connected to a switch.

**Access servers (RADIUS clients)**
An access server is a device that provides some level of access to a larger network. An access server using a RADIUS infrastructure is also a RADIUS client, sending connection requests and accounting messages to a RADIUS server. Examples of access servers are:

- Network access servers (NASs) that provide remote access connectivity to an organization network or the Internet. An example is a Windows 2000 computer running the Routing and Remote Access service and providing either traditional dial-up or virtual private network (VPN) remote access services to an organization's intranet.
- Wireless access points that provide physical layer access to an organization's network, using wireless-based transmission and reception technologies.
- Switches that provide physical layer access to an organization's network, using traditional LAN technologies such as Ethernet.

**RADIUS proxies**
A RADIUS proxy is a device that forwards or routes RADIUS connection requests and accounting messages between RADIUS clients (and RADIUS proxies) and RADIUS servers (or RADIUS proxies). The RADIUS proxy uses information within the RADIUS message, such as the User-Name or Called-Station-ID RADIUS attributes, to route the RADIUS message to the appropriate

RADIUS server.

A RADIUS proxy can be used as a forwarding point for RADIUS messages when the authentication, authorization, and accounting must occur at multiple RADIUS servers in different organizations.

**RADIUS servers**
A RADIUS server is a device that receives and processes connection requests or accounting messages sent by RADIUS clients or RADIUS proxies. In the case of connection requests, the RADIUS server processes the list of RADIUS attributes in the connection request. Based on a set of rules and the information in the user account database, the RADIUS server either authenticates and authorizes the connection and sends back an Access-Accept message or sends back an Access-Reject message. The Access-Accept message can contain connection restrictions that are implemented by the access server for the duration of the connection.

**User account databases**
The user account database is the list of user accounts and their properties that can be checked by a RADIUS server to verify authentication credentials and user account properties containing authorization and connection parameter information.

The user account databases that IAS can use are the local Security Accounts Manager (SAM), a Microsoft Windows NT 4.0 domain, or the Active Directory directory service. For Active Directory, IAS can provide authentication and authorization for user or computer accounts in the domain in which the IAS server is a member, two-way trusted domains, and trusted forests with domain controllers running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition.

If the user accounts for authentication reside in a different type of database, IAS can be configured as a RADIUS proxy to forward the authentication request to a RADIUS server that does have access to the user account database. Different databases for Active Directory include untrusted forests, untrusted domains, or one-way trusted domains.

### Note

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Realm names

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Realm names**

When an access client sends user credentials, a user name is often included. Within the user name are two elements:

1. Identification of the user account name
2. Identification of the user account location

For example, for the user name user1@microsoft.com, user1 is the user account name and microsoft.com is the location of the user account. The identification of the location of the user account is known as a realm. There are different forms of realm names:

- The realm name can be a prefix.

  For example, Microsoft\user1, where Microsoft is the name of a Windows NT 4.0 domain.

- The realm name can be a suffix.

  For example, user1@microsoft.com, where microsoft.com is either a DNS domain name or the name of an Active Directory domain.

You can require users to specify the realm name by using the correct syntax when they connect. For example, you can require that the user type the user name (including the user account name and the realm) in **User name** in the **Connect** dialog box when making a dial-up or VPN connection in Network Connections. You can also add the realm name automatically to the user account name. For example, you can specify a realm name and syntax when you create a custom dialing package with the Connection Manager Administration Kit, so that the user has to specify only the user account name. For more information, see Connection Manager Administration Kit.

The user name is passed from the access client to the access server during the authentication phase of the connection attempt. This user name becomes the User-Name RADIUS attribute in the Access-Request message that is sent by the access server to its RADIUS server.

If the RADIUS server is an IAS server, the Access-Request message is evaluated against the set of configured connection request policies. Conditions on the connection request policy can include the specification of the contents of User-Name attribute. You can configure a set of connection request policies that are specific to the realm name within the User-Name attribute of incoming messages. This allows to you create routing rules that forward RADIUS messages with a specific realm name to a specific set of RADIUS servers when IAS is used as a RADIUS proxy.

Before the RADIUS message is either processed locally (when IAS is being used as a RADIUS server) or forwarded to another RADIUS server (when IAS is being used as a RADIUS proxy), the User-Name attribute in the message might be modified by attribute manipulation rules that are configured on the profile of the first matching connection request policy. Attribute manipulation rules for the User-Name attribute might change the following:

- Remove the realm name from the user name (also known as realm stripping).

  For example, the user name user1@microsoft.com is changed to user1.

- Change the realm name but not its syntax.

  For example, the user name user1@microsoft.com is changed to user1@wcoast.microsoft.com.

- Change the syntax of the realm name.

  For example, the user name microsoft\user1 is changed to user1@microsoft.com.

Attribute manipulation rules are configured in the **Attribute** tab on the profile of a connection request policy. For more information, see Configure attribute manipulation. IAS attribute manipulation rules use regular expression syntax. For more

information about this syntax and examples, see Pattern matching syntax.

After the User-Name attribute is modified according to attribute manipulation rules, additional settings on the profile of the first matching connection request policy are used to determine whether:

- The IAS server processes the Access-Request message locally (when IAS is being used as a RADIUS server).
- The IAS server forwards the message to another RADIUS server (when IAS is being used as a RADIUS proxy).

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**Notes**

- When the user name does not contain a domain name, IAS supplies one. By default, the IAS-supplied domain name is the domain of which the IAS server is a member. You can specify the IAS-supplied domain name through the following registry setting:

  **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\RasMan\PPP\ControlProtocols\BuiltIn\DefaultDomain**

- Some third party network access servers delete or modify the domain name as specified by the user. As the result, the network access request is authenticated against the default domain, which might not be the domain for the user's account. To resolve this problem, configure your RADIUS servers to change the user name into the correct format with the accurate domain name.

# IAS and tunnels

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS and tunnels**

Tunneling, also known as encapsulation, is a method of using an internetwork infrastructure of one protocol to transfer a payload. Sometimes, the payload consists of the frames (or packets) of another protocol. Instead of being sent as the originating host produces it, the frame is encapsulated with an additional header. The additional header provides routing information so that the encapsulated payload can traverse an intermediate internetwork (also known as a transit internetwork). The encapsulated packets are then routed between tunnel endpoints over the transit internetwork. After the encapsulated payload packets reach their destination on the transit internetwork, the frame is de-encapsulated and forwarded to its final destination.

The entire process of the encapsulation, transmission, and de-encapsulation of packets is called tunneling. The logical path in the transit internetwork through which the encapsulated packets travel is called a tunnel.

With remote access virtual private network (VPN) connections, there are two types of tunneling:

1. Voluntary tunneling

2. Compulsory tunneling

**Voluntary tunneling**

A user or client computer can issue a VPN request to configure and create a voluntary tunnel. In this case, the user's computer is a tunnel endpoint that acts as the tunnel client. Voluntary tunneling occurs when a workstation or router uses tunneling client software to create a VPN connection to the target tunnel server. In order to accomplish this, the appropriate tunneling protocol must be installed on the client computer. In a dial-up situation, which is the most common use, the client must establish a dial-up connection to the internetwork before the client can set up a tunnel. A good example of this is the dial-up Internet user, who must dial an ISP and obtain an Internet connection before a tunnel over the Internet is created.

Voluntary tunneling is not different from other types of network access, and IAS can be used for authentication, authorization, and accounting.

**Compulsory tunneling**

Compulsory tunneling is the creation of a secure tunnel by another computer or network device on the client computer's behalf. Compulsory tunnels are configured and created automatically for users without their knowledge or intervention. With a compulsory tunnel, the user's computer is not a tunnel endpoint. Another device between the user's computer and the tunnel server is the tunnel endpoint, which acts as the tunnel client.

Some vendors that sell dial-up access servers provide for the creation of a tunnel on behalf of a dial-up client. The computer or network device that provides the tunnel for the client computer is known as a front-end processor (FEP) in PPTP, an L2TP access concentrator (LAC) in L2TP, or an IP Security gateway in IPSec. The term FEP is used to describe tunnel creation functionality, regardless of the protocol used. To perform its function, the FEP must have the appropriate tunneling protocol installed and must be capable of establishing the tunnel when the client computer attempts a connection. The Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; and Windows 2000 Routing and Remote Access service cannot be used as a FEP.

An organization can contract with an ISP to deploy a nationwide set of FEPs. These FEPs can establish tunnels across the Internet to a VPN server that is connected to the organization private network, thereby consolidating calls from geographically diverse locations into a single Internet connection at the organization network.

There are two types of compulsory tunneling. In the first type, the tunnel is created before the access client is authenticated. Based on the realm name or the caller ID of the access client, the FEP sends an Access-Request to an IAS server. The IAS server sends back an immediate Access-Accept with RADIUS attributes for the tunnel creation without performing authentication and authorization. After the tunnel is created, the access client authenticates against the tunnel server.

In the second type of compulsory tunneling, the tunnel is created after the access client is authenticated by the FEP. In this case, the FEP sends the Access-Request message with the client credentials to an IAS server. The IAS server authenticates and authorizes the connection attempt and returns RADIUS attributes in the Access-Accept message, which specify to the NAS how to initiate a tunnel to a VPN server. The tunnel-endpoint (the VPN server at which the tunnel is terminated), can be changed on

the basis of conditions in a remote access policy. For example, the tunnel-endpoint can be changed on the basis of the user name or the user account group membership. Controlling compulsory tunnels with remote access policies provides more flexibility than static tunneling (which requires a dedicated network access server) or realm-based tunneling (which requires that all users in a given realm use the same tunnel settings).

**RADIUS attributes used with compulsory tunneling**

The following is a list of RADIUS attributes that are used to carry compulsory tunneling information from the IAS server to the FEP. The same set of attributes is used regardless of the type of compulsory tunnel.

- Attributes used only for authorization:
    - Tunnel-Preference
    - Tunnel-Password

      This attribute should not be used with RADIUS proxies.
- Attributes used in authorization and accounting:
    - Tunnel-Type (for example, PPTP and L2TP)
    - Tunnel-Medium-Type (for example, X.25, ATM, Frame Relay, and IP)
    - Tunnel-Client-Endpoint
    - Tunnel-Server-Endpoint
    - Tunnel-Private-Group-ID
    - Tunnel-Assignment-ID
    - Tunnel-Client-Auth-ID
    - Tunnel-Server-Auth-ID
- Attributes used only for accounting:
    - Acct-Tunnel-Connection-ID

**Compulsory tunneling example**

The following table lists the set of compulsory tunneling RADIUS attributes that specify a compulsory tunnel. This tunnel uses the Layer Two Tunneling Protocol (L2TP) with a VPN server at the IP address of 131.107.9.41, and a tunnel password of og*37y#cW@95?4xT.

| Attribute | Value |
|---|---|
| Framed-Protocol | PPP |
| Service-Type | Outbound-User |
| Tunnel-Medium-Type | IP (IP version 4) |
| Tunnel-Password | og*37y#cW@95?4xT |
| Tunnel-Server-Endpt | 131.107.9.41 |
| Tunnel-Type | Layer Two Tunneling Protocol (L2TP) |

To configure IAS, add your versions of all of these attributes and their appropriate values on the **Advanced** tab in the profile

properties of the applicable remote access policy. For more information, see Add RADIUS attributes to a remote access policy.

**Notes**

- You can use a RADIUS Access-Accept packet to send tunnel attributes that describe multiple tunnels. However, IAS only returns information for a single tunnel.

- IAS only supports one compulsory tunnel for each connection request and remote access policy.

# Managing multiple IAS servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing multiple IAS servers**

To prevent a single IAS server from becoming a single point of failure for authentication, authorization, and accounting, IAS servers are often deployed either in pairs (a primary and a backup) to provide fault tolerance, or in multiples to balance the load of large numbers of authentication and accounting requests.

When you deploy more than one IAS server computer to provide the same authentication, authorization, and accounting service to RADIUS clients and proxies, you must synchronize the configuration of the IAS server computers. You can do this through the following:

- Internet Authentication Service snap-in

  You can use the Internet Authentication Service snap-in to manage both local and remote IAS server computers. If you make a configuration change to one IAS server, you must make the same configuration change to all of the IAS servers that provide the same service. For information about managing a remote IAS server computer, see Manage a remote IAS server. This method might be acceptable for a small number of servers and minor configuration changes.

- Copying the configuration of one IAS server computer to another

  With this method, you can use the **netsh aaaa show config** to export the configuration of one IAS server to a Netsh script file. Next, you can use the **netsh exec** command to import the IAS server configuration on another IAS server. For more information, see Copy the IAS configuration to another server. This method is recommended for a large number of configuration changes or a larger number of servers. You can use this method to centrally manage RADIUS and remote access policy configuration in a large enterprise network.

When you type **netsh aaaa show config**, it creates a Netsh script file that is designed to be used with the **netsh exec** command. The contents of the display of the **netsh aaaa show config** command includes:

- IAS settings
- RADIUS clients
- Remote access policies
- Connection request policies
- Remote access logging settings

For more information, see Netsh commands for AAAA.

The Routing and Remote Access service uses the same database as IAS. There are no settings, however, for IAS, RADIUS clients, or connection request policies. If settings are present, they are ignored by the Routing and Remote Access service. Because of this, it is possible to copy the configuration of an IAS server computer to a Routing and Remote Access server. For example, you can update the remote access policies of a branch office demand-dial router computer.

**Notes**

- The **netsh aaaa show config** and **netsh exec** commands can be run without stopping the Internet Authentication Service or the Routing and Remote Access service.
- The version number of the IAS database from which the configuration was exported, should be less than or equal to the version of the IAS database to which the configuration is being imported. To view the version of the IAS database from which the configuration was exported, view the Netsh command script file, which is created with the **netsh aaaa show config** command. To view the version of the IAS database on the IAS server computer on which the Netsh script is being

run, use the **netsh aaaa show version** command.

- The **netsh aaaa show config** and **netsh exec** commands are used to export and import the entire database. You cannot specify which elements of the IAS database to export or import.

- Do not copy the configuration from a Routing and Remote Access server to an IAS server. By default, the Routing and Remote Access service version of the IAS database does not contain all of the configuration items contained in the full IAS database.

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Network access authentication and certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network access authentication and certificates**
This topic contains the following sections:

- Overview
- Certificate requirements for EAP
- Computer authentication by IPSec
- Certificate-based authentication and wireless clients
- Certificate enrollment methods and domain membership
- Choosing a certificate enrollment method
- CA Web enrollment services

**Overview**
Certificates are used for network access authentication because they provide strong security for authenticating users and computers and eliminate the need for less secure password-based authentication methods. This topic describes how Internet Authentication Service (IAS) and virtual private network (VPN) servers use Extensible Authentication protocol-Transport Level Security (EAP-TLS), protected Extensible Authentication protocol (PEAP), or Internet protocol security (IPSec) to perform certificate-based authentication for many types of network access, including VPN and wireless connections. Additionally, this topic describes certificate enrollment methods to help you determine the best certificate enrollment method for your use.

When discussing authentication, a server is defined as a VPN or IAS server that is a TLS end point. You can configure VPN servers to perform network access authentication without IAS, or you can use IAS for authentication when you have multiple Remote Access Dial-In User Service (RADIUS) clients (such as VPN servers and wireless access points) on your network.

Two authentication methods use certificates: Extensible Authentication protocol-Transport Level Security (EAP-TLS) and protected Extensible Authentication protocol (PEAP). Both methods always use certificates for server authentication. Depending on the authentication type configured with the authentication method, certificates might be used for user authentication and client authentication. For more information, see EAP and PEAP.

The use of certificates for authentication of VPN connections is the strongest form of authentication available with the Windows Server 2003 family. You must use certificate-based authentication for VPN connections based on Layer Two Tunneling protocol over Internet protocol security (L2TP/IPSec). Point-To-Point Tunneling protocol (PPTP) connections do not require certificates, although you can configure PPTP connections to use certificates for computer authentication when you use EAP-TLS as the authentication method. For wireless clients (computing devices with wireless network adapters, such as your portable computer or personal digital assistant), PEAP with EAP-TLS and smart cards or certificates is the recommended authentication method. For more information, see Layer Two Tunneling Protocol, Point-to-Point Tunneling Protocol, and Wireless Networking.

**Notes**

- During authentication attempts for PPTP connections, computer authentication does not occur. When EAP-TLS is used as the authentication method with PPTP connections, user authentication is performed with a certificate from the certificate store on the local computer or from a smart card.

- On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

In order to deploy certificates to users and computers, you must first do the following:

- Design a public key infrastructure (PKI).
- Deploy a certification authority (CA) using Certificate Services.
- Design and publish one or more certificates using Certificate Templates, which is installed with Certificate Services.
- Select one or more distribution methods (also known as certificate enrollment methods) to install the certificates on computers and distribute them to users.

### Notes

- This topic assumes that you have designed and deployed a PKI according to the guidelines provided in Certificate Services Best practices. For more information, see Public Key Infrastructure.
- PEAP is not supported for VPN or dial-up connections.

#### Example certificate deployments

- Remote access VPN connections

  L2TP/IPSec or PPTP connections between VPN server and VPN client with EAP-TLS used as the authentication method. IPSec uses computer certificates between the client and the server for authentication, and EAP-TLS uses a certificate (from a smart card or the user's local certificate store) for user authentication. The IAS or VPN server certificate must contain the server Authentication purpose, and the client computer or user certificate must contain the Client Authentication purpose in the Enhanced Key Usage (EKU) extensions of the certificate.

  For more information, see L2TP-based remote access VPN deployment and PPTP-based remote access VPN deployment.

- Router-to-router VPN connections

  L2TP/IPSec connections for dedicated or dial-on-demand connections between servers with EAP-TLS as the authentication method. Both servers must have certificates that contain the server Authentication and Client Authentication purposes in EKU extensions.

  For more information, see Deploying Router-to-Router VPNs.

- IEEE 802.1X wireless or switch clients

  PEAP-EAP-MS-CHAPv2 is configured as the authentication method, and the **Validate server certificate** option is enabled on the client computers. The IAS server certificate EKU extensions contain the server Authentication purpose, and the certificate is used to identify the server to the client. User authentication is accomplished with user name and password.

  For more information, see Enable smart card or other certificate authentication and Configuring wireless network settings on client computers.

- IEEE 802.1X wireless or switch clients

  L2TP/IPSec is used, and EAP-TLS with certificates is configured as the authentication method. The IAS server certificate contains the server Authentication purpose in EKU extensions to identify itself to the client, and the client uses a certificate (from a smart card or the user's local certificate store) to identify itself to the IAS server. (The wireless access points are configured as RADIUS clients on the IAS server, which is the EAP authenticator.)

**Note**

- User authentication and network access authorization are performed by either the VPN server or a RADIUS server, such as Internet Authentication Service (IAS), as configured on the VPN gateway. For more information, see Use RADIUS authentication.

**Certificate requirements for EAP**

When you use EAP with a strong EAP type (such as TLS with smart cards or certificates), both the client and the server use certificates to verify their identities to each other. Certificates must meet specific requirements in order to allow the server and the client to use them for successful authentication.

One such requirement is that the certificate is configured with one or more purposes in EKU extensions that correlate to the certificate use. For example, a certificate used for the authentication of a client to a server must be configured with the Client Authentication purpose. Similarly, a certificate used for the authentication of a server must be configured with the server Authentication purpose. When certificates are used for authentication, the authenticator examines the client certificate, seeking the correct purpose object identifier in EKU extensions. For example, the object identifier for the Client Authentication purpose is 1.3.6.1.5.5.7.3.2.

Certificate Templates allow customization of the certificates issued by Certificate Services, including both how certificates are issued and what they contain, including their purposes. In Certificate Templates, you can use a default template, such as the Computer template, to define the template that the CA uses to assign certificates to computers. You can also create a certificate template and assign purposes in EKU extensions to the certificate. By default, the Computer template includes the Client Authentication purpose and the server Authentication purpose in EKU extensions.

The certificate template that you create can include any purpose for which the certificate will be used. For example, if you use smart cards for authentication, you can include the Smart Card Logon purpose in addition to the Client Authentication purpose.

When using IAS, you can configure IAS to check certificate purposes before granting network authorization. IAS can check additional EKUs and Issuance Policy purposes (also known as Certificate Policies).

Some non-Microsoft CA software might contain a purpose named All, which represents all possible purposes. This is indicated by a blank (or null) EKU extension. Although All means all possible purposes, the All purpose cannot be substituted for the Client Authentication purpose, the server authentication purpose, or any other purpose related to network access authentication.

For more information, see Certificate Templates and Manage Certificate Templates for an Enterprise Certification Authority.

You can view certificates and their purposes by using the Certificates console to open the certificate store. Certificate stores can be viewed in Logical Store mode or in Purpose mode. For information about how to view certificate purposes, see Display certificate stores in Purpose mode.

**Minimum certificate requirements**

All certificates that are used for network access authentication must meet the requirements for X.509 certificates and work for connections that use Secure Sockets Layer-Transport Level Security (SSL/TLS). After this minimum requirement is met, both client and server certificates have additional requirements.

**Client certificate requirements**

With EAP-TLS or PEAP-EAP-TLS, the server accepts the client authentication attempt when the certificate meets the following requirements:

- The client certificate is issued by an enterprise CA or mapped to a user or computer account in Active Directory.

- The user or computer certificate on the client chains to a trusted root CA, includes the Client Authentication purpose in EKU extensions (the object identifier for Client Authentication is 1.3.6.1.5.5.7.3.2), and fails neither the checks that are performed by CryptoAPI and specified in the remote access policy nor the Certificate object identifier checks that are

specified in IAS remote access policy.

- The 802.1X client does not use registry-based certificates that are either smart card-logon or password-protected certificates.

- For user certificates, the Subject Alternative Name (SubjectAltName) extension in the certificate contains the user principal name (UPN). To configure the UPN name in a certificate template:

1. Open Certificate Templates.

2. In the details pane, right-click the certificate template that you want to change, and then click **properties**.

3. Click the **Subject Name** tab, and then click **Build from this Active Directory information**.

4. In **Include this information in alternate subject name**, select **User principal name (UPN)**.

- For computer certificates, the Subject Alternative Name (SubjectAltName) extension in the certificate must contain the client's fully qualified domain name (FQDN), which is also called the DNS name. To configure this name in the certificate template:

1. Open Certificate Templates.

2. In the details pane, right-click the certificate template that you want to change, and then click **properties**.

3. Click the **Subject Name** tab, and then click **Build from this Active Directory information**.

4. In **Include this information in alternate subject name**, select **DNS name**.

With PEAP-EAP-TLS and EAP-TLS, clients display a list of all installed certificates in the Certificates snap-in, with the following exceptions:

- Wireless clients do not display registry-based and smart card-logon certificates.

- Wireless clients and VPN clients do not display password-protected certificates.

- Certificates that do not contain the Client Authentication purpose in EKU extensions are not displayed.

**Server certificate requirements**

Clients can be configured to validate server certificates by using the **Validate server certificate** option. With PEAP-EAP-MS-CHAPv2, PEAP-EAP-TLS, or EAP-TLS as the authentication method, the client accepts the server's authentication attempt when the certificate meets the following requirements:

- The Subject name contains a value. If you issue a certificate to your IAS server that has a blank Subject, the certificate is not available to authenticate your IAS server. To configure the certificate template with a Subject name:

1. Open Certificate Templates.

2. In the details pane, right-click the certificate template that you want to change, and then click **properties**.

3. Click the **Subject Name** tab, and then click **Build from this Active Directory information**.

4. In **Subject name format**, select a value other than **None**.

- The computer certificate on the server chains to a trusted root CA and does not fail any of the checks that are performed by CryptoAPI and specified in the remote access policy.

- The IAS or VPN server computer certificate is configured with the server Authentication purpose in EKU extensions (the object identifier for server Authentication is 1.3.6.1.5.5.7.3.1).

- The server certificate is configured with a required cryptographic service provider (CSP) value of **Microsoft RSA SChannel Cryptographic provider**. To configure the required CSP:

1. Open Certificate Templates.

2. In the details pane, right-click the certificate template that you want to change, and then click **properties**.

3. Click the **Request Handling** tab, and then click **CSPs**.

4. In **CSP Selection**, select **Requests must use one of the following CSPs**.

5. In **CSPs**, select the **Microsoft RSA SChannel Cryptographic provider** checkbox. Clear all other checkboxes in **CSPs**.

- The Subject Alternative Name (SubjectAltName) extension, if used, must contain the DNS name of the server. To configure the certificate template with the DNS name of the enrolling server:

1. Open Certificate Templates.

2. In the details pane, right-click the certificate template that you want to change, and then click **properties**.

3. Click the **Subject Name** tab, and then click **Build from this Active Directory information**.

4. In **Include this information in alternate subject name**, select **DNS name**.

With PEAP and EAP-TLS, servers display a list of all installed certificates in the computer's certificate store, with the following exceptions:

- Certificates that do not contain the server Authentication purpose in EKU extensions are not displayed.

- Certificates that do not contain a Subject name are not displayed.

- Servers do not display registry-based and smart card-logon certificates.

**Note**

- You can designate which certificate is used by the IAS or VPN server in the remote access policy profile. When you configure EAP and PEAP authentication methods that require a certificate for server authentication and you do not select a specific certificate in the **Smart Card or other Certificate properties** dialog box, the IAS or VPN server automatically selects a certificate from the computer certificate store. If the server obtains a newer certificate, it uses the new certificate. This might cause the IAS or VPN server to use a certificate that is not correctly configured for authentication, causing authentication to fail as the result. To prevent this, always select a server certificate when configuring PEAP and EAP authentication methods that require one. For more information, see Configure PEAP and EAP methods.

**Computer authentication by IPSec**

Computer authentication is first performed during L2TP/IPSec connection attempts between remote access client and server. When a secure channel is established between the client and the server, the user authentication and authorization attempt proceeds.

Computer authentication by IPSec is performed using preshared keys or computer certificates. The recommended method of authentication is the use of a PKI and certificates. If certificates are used, a computer certificate is required to establish IPSec trust during the Internet Key Exchange (IKE) negotiation in L2TP/IPSec-based VPN connections.

In order for a VPN server running Windows Server 2003 and a VPN client running Windows 2000 or Windows XP to establish trust for an L2TP/IPSec VPN connection, both computers must have a computer certificate that was issued by the same trusted enterprise root CA. When both computers have and exchange certificates that were issued by the trusted root CA during IPSec negotiation, they extend trust to each other, and the security association is made.

**How VPN servers use certificates**

When an L2TP/IPSec VPN connection is attempted between VPN client and server, computer authentication fails if the VPN client certificate (from a smart card or the certificate store on the local computer) is not configured with the Client Authentication purpose in EKU extensions, and the VPN server certificate is not configured with the server Authentication purpose in EKU extensions. IPSec checks the EKU extensions for the client certificate to determine whether the Client Authentication purpose object identifier is present. When the EKU extension includes the Client Authentication purpose object identifier, IPSec can use the certificate for authentication. Similarly, the client checks the VPN server certificate for the server Authentication purpose object identifier in EKU extensions.

Although VPN servers that end connections for remote users need a certificate configured with the server Authentication purpose in EKU extensions only, a VPN servers that is used as an end point for a VPN connection with another VPN server originates (as a client) and ends (as a server) VPN connections. For this reason, the certificate on these servers must contain both the server Authentication purpose and the Client Authentication purpose in EKU extensions. In addition, due to the way in which automatic certificate selection functions, both purposes (server Authentication and Client Authentication) must be contained in the same certificate.

Automatic certificate selection can provide IPSec with any certificate in the certificate store that chains to the trusted enterprise root CA, regardless of the purposes contained in the certificate. If two certificates are installed on the server--one that contains the Client Authentication purpose and one that contains the server Authentication purpose--it is possible that automatic certificate selection could use the wrong certificate for authentication. For example, the certificate with the Client Authentication purpose might be required, but the certificate provided through automatic certificate selection contains the server Authentication purpose. In this and similar instances, computer authentication fails.

**Certificate-based authentication and wireless clients**

IEEE 802.1X authentication provides authenticated access to 802.11 wireless networks and to wired Ethernet networks. 802.1X provides support for secure EAP types, such as TLS with smart cards or certificates. You can configure 802.1X with EAP-TLS in a variety of ways. If the **Validate server certificate** option is configured on the Windows XP Professional client, the client authenticates the server by using its certificate. Client computer and user authentication can be accomplished using certificates from the client certificate store or a smart card, providing mutual authentication.

With wireless clients, PEAP-EAP-MS-CHAPv2 can be used as the authentication method. PEAP-EAP-MS-CHAPv2 is a password-based user authentication method that uses TLS with server certificates. During PEAP-EAP-MS-CHAPv2 authentication, the IAS or RADIUS server supplies a certificate to validate its identity to the client (if the **Validate server certificate** option is configured on the Windows XP Professional client). Client computer and user authentication is accomplished with passwords, which eliminates some of the difficulty of deploying certificates to wireless client computers.

802.1X wireless and switch clients can also use PEAP-EAP-TLS, which provides strong security. PEAP-EAP-TLS uses a public key infrastructure (PKI) with certificates used for server authentication and either smart cards or certificates for client computer and user authentication. For more information, see PEAP.

For more information about 802.1X authentication, see Understanding 802.1X authentication for wireless networks.

**Certificate enrollment methods and domain membership**

The domain membership of computers for which you want to enroll certificates affects the certificate enrollment method that you can choose. Certificates for domain member computers can be enrolled automatically (also known as auto-enrollment), while an administrator must enroll certificates for non-domain member computers using the Web or a floppy disk. The certificate enrollment method for non-domain member computers is known as a trust bootstrap process, through which certificates are created and then manually requested or distributed securely by administrators, to build common trust.

**Domain member certificate enrollment**

If your VPN server, IAS server, or client running Windows 2000 or Windows XP is a member of a domain running Windows Server 2003 and Active Directory, you can configure the auto-enrollment of computer and user certificates. After auto-enrollment is configured and enabled, all domain member computers receive computer certificates when Group Policy is refreshed next, whether the refresh is triggered manually with the **gpupdate** command, or by logging on to the domain.

If your computer is a member of a domain where Active Directory is not installed, you can install computer certificates

manually by requesting them through Certificates.

For more information, see Computer certificates for L2TP/IPSec VPN connections.

**Note**

- Computers running Windows 2000 can auto-enroll computer certificates only.

**Non-domain member certificate enrollment**

Certificate enrollment for computers that are not domain members cannot be done with auto-enrollment. When a computer is joined to a domain, a trust is established that allows auto-enrollment to occur without administrator intervention. When a computer is not joined to a domain, trust is not established and a certificate is not issued. Trust must be established using one of the following methods:

- An administrator (who is, by definition, trusted) must request a computer or user certificate using the CA Web enrollment tool.

- An administrator must save a computer or user certificate to a floppy disk and install it on the non-domain member computer. Or, when the computer is not accessible to the administrator (for example, a home computer connecting to an organization network with an L2TP/IPSec VPN connection), a domain user whom the administrator trusts can install the certificate.

- An administrator can distribute a user certificate on a smart card (computer certificates are not distributed on smart cards).

Many network infrastructures contain VPN and IAS servers that are not domain members. For example, a VPN server in a perimeter network might not be a domain member for security purposes. In this case, a computer certificate with the server Authentication purpose contained in the EKU extensions must be installed on the non-domain member VPN server before it can successfully negotiate L2TP/IPSec-based VPN connections with clients. Note that if the non-domain member VPN server is used as an end point for a VPN connection with another VPN server, EKU extensions must contain both the server Authentication and Client Authentication purposes.

**Choosing a certificate enrollment method**

If you are running an enterprise certification authority (CA) on a computer running Windows Server 2003, Standard Edition, you can use the following table to determine the best certificate enrollment method for your requirements:

| Object and domain membership | Certificate template | Certificate purposes | Preferred certificate enrollment method | Alternate certificate enrollment method |
|---|---|---|---|---|
| VPN or IAS server, domain member | Computer | Server Authentication | Auto-enrollment | Request a certificate with the Certificates snap-in |
| VPN server with site-to-site connection, domain member | Computer | Server Authentication and Client Authentication | Auto-enrollment | Request a certificate with the Certificates snap-in |
| Windows XP client, domain member | Computer | Client Authentication | Auto-enrollment | Request a certificate with the Certificates snap-in |
| VPN or IAS server, non-domain member | Computer | Server Authentication | CA Web enrollment tool | Install from a floppy disk |
| VPN server with site-to-site connection, non-domain member | Computer | Server Authentication and Client Authentication | CA Web enrollment tool | Install from a floppy disk |
| Windows XP client, non-domain member | Computer | Client Authentication | CA Web enrollment tool | Install from a floppy disk |
| User, domain user | User | Client Authentication | Auto-enrollment | Use a smart card or the CA Web enrollment tool |

If your certification authority is on a computer running one of the following operating systems, the RAS and IAS servers and Workstation Authentication templates are available for use:

- Windows Server 2003, Enterprise Edition
- Windows Server 2003, Datacenter Edition
- Windows Server 2003, Enterprise Edition for Itanium-based Systems
- Windows Server 2003, Datacenter Edition for Itanium-based Systems
- Windows Server 2003, Enterprise x64 Edition
- Windows Server 2003, Datacenter x64 Edition

Use the following table to determine when to use these templates.

| Object and domain membership | Certificate template | Certificate purpose | Preferred certificate enrollment method | Alternate certificate enrollment method |
|---|---|---|---|---|
| VPN or IAS server, domain member | RAS and IAS server | Server Authentication | Auto-enrollment | Request a certificate with the Certificates snap-in |
| Windows XP client, domain member | Workstation Authentication | Client Authentication | Auto-enrollment | Request a certificate with the Certificates snap-in |
| VPN or IAS server, non-domain member | RAS and IAS server | Server Authentication | CA Web enrollment tool | Install from a floppy disk |
| Windows XP client, non-domain member | Workstation Authentication | Client Authentication | CA Web enrollment tool | Install from a floppy disk |

**Important**

If your server running IAS is not a domain controller but is a member of a domain with a Windows 2000 mixed functional level, you must add the server to the access control list (ACL) of the **RAS and IAS server** certificate template. You must also configure the correct permissions for autoenrollment. There are different procedures for adding single servers and groups of servers to the ACL.

To add an individual server to the ACL for the **RAS and IAS server** certificate template:

In Certificate Templates, select the template **RAS and IAS server**, and then add the IAS server to the template **Security** properties. For more information, see Allow subjects to request a certificate that is based on the template. After you have added your IAS server to the ACL, grant **Read**, **Enroll**, and **Autoenroll** permissions.

To manage a group of servers, add the servers to a new global or universal group, and then add the group to the ACL of the certificate template:

1. In Active Directory Users and Computers, create a new global or universal group for IAS servers. For more information, see Create a new group. Next, add to the group all computers that are IAS servers, are not domain controllers, and are members of a domain with a Windows 2000 mixed functional level. For more information, see Add a member to a group.

2. In Certificate Templates, select the **RAS and IAS server** template, and then add the group you created to the template **Security** properties by completing the steps in Allow subjects to request a certificate that is based on the template. After you have added your new group, grant **Read**, **Enroll**, and **Autoenroll** permissions.

For more information, see Domain and forest functionality.

**CA Web enrollment services**

A set of CA Web pages is provided with Certificate Services in the Windows Server 2003 family. These Web enrollment pages allow you to connect to the CA through a Web browser and perform common tasks, such as requesting certificates from a CA.

For more information, see Certification authority Web enrollment services and Set up certification authority Web enrollment support.

After your PKI has been designed and deployed and you are assigned the required permissions on the certificate templates, you can request certificates for computers by using the CA Web enrollment pages. You can request a certificate for a non-domain member computer using the CA Web enrollment tool by completing the following steps. You must be an administrator on the local computer to complete these steps.

**Install a computer certificate on the local computer**

1. Use your Web browser to log onto the Web enrollment tool at **http://***serverName***/certsrv**, where *serverName* is the name of the server hosting the CA, the CA Web pages, or both. Click **Request a certificate**.

2. In **Request a certificate**, click **Advanced Certificate Request**.

3. In **Advanced Certificate Request**, click **Create and submit a request to this CA**. A Web form that contains the sections **Certificate Template**, **Key Options**, and **Additional Options** becomes available. Select the following:

   - **Certificate template:** Administrator
   - **Key options:** Create new key set
   - **CSP:** Microsoft Enhanced Cryptographic provider v1.0
   - **Key usage:** Exchange
   - **Key size:** 1024
   - **Automatic key container name:** Selected
   - **Mark keys as exportable:** Selected
   - **Use local machine store:** Selected
   - **Request format:** PKCS 10
   - **Hash:** SHA-1
   - **Friendly name:** VPN server name

4. Click **Submit**.

5. Click **Install this certificate**

   The certificate you requested is installed on your local computer.

**Save a computer certificate to floppy disk**

1. Use your Web browser to log onto the Web enrollment tool at **http://***serverName***/certsrv**, where *serverName* is the name of the server hosting the CA, the CA Web pages, or both. Click **Request a certificate**.

2. In **Request a certificate**, click **Advanced Certificate Request**.

3. In **Advanced Certificate Request**, click **Create and submit a request to this CA**. A Web form that contains the sections **Certificate Template**, **Key Options**, and **Additional Options** becomes available. Select the following:

   - **Certificate template:** Administrator

- **Key options:** Create new key set
- **CSP:** Microsoft Enhanced Cryptographic provider v1.0
- **Key usage:** Exchange
- **Key size:** 1024
- **Automatic key container name:** Selected
- **Mark keys as exportable:** Selected
- **Export keys to file:** Selected
- **Full path name:** The path location where you want to save the file and the file name (for example, *\\serverName\ShareName\FileName.pvk*.).
- **Request format:** PKCS 10
- **Hash:** SHA-1
- **Friendly name:** VPN server name

4. Click **Submit**.
5. Create and confirm your private key password.
6. In **Certificate Issued**, select **DER encoded** and **Download certificate chain**.
7. Insert a floppy disk in your disk drive.
8. When prompted by your browser, select **Save this file to disk**, and then click **OK**.
9. Browse to your floppy drive, and then click **OK**.

   The certificate you requested is downloaded and saved to floppy disk.

For more information, see Submit an advanced certificate request via the Web.

For information about installing a certificate from floppy to the certificate store of a local computer, see Import a certificate.

**Note**

- If you have issued a certificate to your IAS server that has a blank Subject, the certificate is not available to authenticate your IAS server. To change this, you can use Certificate Templates to create a new certificate for enrollment on your IAS server. In the certificate properties, on the **Subject Name** tab, in **Subject name format**, select a value other than **None**.

# Securing IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Securing IAS**

This section covers:

- IAS and firewalls
- Shared secrets
- Message Authenticator attribute
- Remote access account lockout
- IAS Network Access Quarantine Control
- Securing RADIUS traffic with IPSec

# IAS and firewalls

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS and firewalls**
In the most common configuration, the firewall is connected to the Internet and the IAS server is another intranet resource that is connected to the perimeter network.

To reach the domain controller within the intranet, the IAS server might have:

- An interface on the perimeter network and an interface on the intranet (IP routing is not enabled).

- A single interface on the perimeter network. In this configuration, IAS communicates with intranet domain controllers through another firewall that connects the perimeter network to the intranet. This configuration is shown in the following drawing.

**Configuring the Internet firewall**
The firewall that is connected to the Internet must be configured with input and output filters on its Internet interface (and, optionally, its network perimeter interface), to allow the forwarding of RADIUS messages between the IAS server and RADIUS clients or proxies on the Internet. Additional filters can be used to allow the passing of traffic to Web servers, VPN servers, and other types of servers on the perimeter network.

Separate input and output packet filters can be configured on the Internet interface and the perimeter network interface.

**Filters on the Internet interface**
Configure the following input packet filters on the Internet interface of the firewall to allow the following types of traffic:

- Destination IP address of the IAS server's perimeter network interface and UDP destination port of 1812 (0x714).

  This filter allows RADIUS authentication traffic from Internet-based RADIUS clients to the IAS server. This is the default UDP port that is used by IAS, as defined in RFC 2865. If you are using a different port, substitute that port number for 1812, which is used in this example.

- Destination IP address of the IAS server's perimeter network interface and UDP destination port of 1813 (0x715).

  This filter allows RADIUS accounting traffic from Internet-based RADIUS clients to the IAS server. This is the default UDP port that is used by IAS, as defined in RFC 2866. If you are using a different port, substitute that port number for 1813, which is used in this example.

- (Optional) Destination IP address of the IAS server's perimeter network interface and UDP destination port of 1645 (0x66D).

  This filter allows RADIUS authentication traffic from Internet-based RADIUS clients to the IAS server. This is the UDP port that is used by older RADIUS clients.

- (Optional) Destination IP address of the IAS server's perimeter network interface and UDP destination port of 1646 (0x66E).

  This filter allows RADIUS accounting traffic from Internet-based RADIUS clients to the IAS server. This is the UDP port that is used by older RADIUS clients.

Configure the following output filters on the Internet interface of the firewall to allow the following types of traffic:

- Source IP address of the IAS server's perimeter network interface and UDP source port of 1812 (0x714).

  This filter allows RADIUS authentication traffic from the IAS server to Internet-based RADIUS clients. This is the default UDP port that is used by IAS, as defined in RFC 2865. If you are using a different port, substitute that port number for 1812, which is used in this example.

- Source IP address of the IAS server's perimeter network interface and UDP source port of 1813 (0x715).

  This filter allows RADIUS accounting traffic from the IAS server to Internet-based RADIUS clients. This is the default UDP port that is used by IAS, as defined in RFC 2866. If you are using a different port, substitute that port number for 1813, which is used in this example.

- (Optional) Source IP address of the IAS server's perimeter network interface and UDP source port of 1645 (0x66D).

  This filter allows RADIUS authentication traffic from the IAS server to Internet-based RADIUS clients. This is the UDP port that is used by older RADIUS clients.

- (Optional) Source IP address of the IAS server's perimeter network interface and UDP source port of 1646 (0x66E).

  This filter allows RADIUS accounting traffic from the IAS server to Internet-based RADIUS clients. This is the UDP port that is used by older RADIUS clients.

**Filters on the perimeter network interface**

Configure the following input filters on the perimeter network interface of the firewall to allow the following types of traffic:

- Source IP address of the IAS server's perimeter network interface and UDP source port of 1812 (0x714).

  This filter allows RADIUS authentication traffic from the IAS server to Internet-based RADIUS clients. This is the default UDP port that is used by IAS, as defined in RFC 2865. If you are using a different port, substitute that port number for 1812, which is used in this example.

- Source IP address of the IAS server's perimeter network interface and UDP source port of 1813 (0x715).

  This filter allows RADIUS accounting traffic from the IAS server to Internet-based RADIUS clients. This is the default UDP port that is used by IAS, as defined in RFC 2866. If you are using a different port, substitute that port number for 1813, which is used in this example.

- (Optional) Source IP address of the IAS server's perimeter network interface and UDP source port of 1645 (0x66D).

  This filter allows RADIUS authentication traffic from the IAS server to Internet-based RADIUS clients. This is the UDP port that is used by older RADIUS clients.

- (Optional) Source IP address of the IAS server's perimeter network interface and UDP source port of 1646 (0x66E).

  This filter allows RADIUS accounting traffic from the IAS server to Internet-based RADIUS clients. This is the UDP port that is used by older RADIUS clients.

Configure the following output packet filters on the perimeter network interface of the firewall to allow the following types of traffic:

- Destination IP address of the IAS server's perimeter network interface and UDP destination port of 1812 (0x714).

  This filter allows RADIUS authentication traffic from Internet-based RADIUS clients to the IAS server. This is the default UDP port that is used by IAS, as defined in RFC 2865. If you are using a different port, substitute that port number for 1812, which is used in this example.

- Destination IP address of the IAS server's perimeter network interface and UDP destination port of 1813 (0x715).

  This filter allows RADIUS accounting traffic from Internet-based RADIUS clients to the IAS server. This is the default UDP port that is used by IAS, as defined in RFC 2866. If you are using a different port, substitute that port number for 1813, which is used in this example.

- (Optional) Destination IP address of the IAS server's perimeter network interface and UDP destination port of 1645 (0x66D).

  This filter allows RADIUS authentication traffic from Internet-based RADIUS clients to the IAS server. This is the UDP port that is used by older RADIUS clients.

- (Optional) Destination IP address of the IAS server's perimeter network interface and UDP destination port of 1646 (0x66E).

  This filter allows RADIUS accounting traffic from Internet-based RADIUS clients to the IAS server. This is the UDP port that is used by older RADIUS clients.

For added security, you can use the IP addresses of each RADIUS client that sends the packets through the firewall to define specific filters for traffic between the client and the IP address of the IAS server on the perimeter network.

**Configuring the intranet firewall**
The firewall that is connected to the intranet must be configured with input and output filters on its perimeter network interface (and, optionally, its intranet interface), to allow the forwarding of RADIUS messages between the IAS server on the perimeter network and domain controllers in the intranet. Additional filters can allow the passing of traffic to Web, VPN, and other types of servers on the perimeter network.

Separate input and output packet filters can be configured on the perimeter network interface and the intranet interface.

**Filters on the perimeter network interface**
Configure the following input packet filters on the perimeter network interface of the intranet firewall to allow the following types of traffic:

- Source IP address of the IAS server's perimeter network interface.

  This filter allows traffic from the IAS server on the perimeter network.

Configure the following output filters on the perimeter network interface of the intranet firewall to allow the following types of traffic:

- Destination IP address of the IAS server's perimeter network interface.

  This filter allows traffic to the IAS server on the perimeter network.

**Filters on the intranet interface**
Configure the following input filters on the intranet interface of the firewall to allow the following types of traffic:

- Destination IP address of the IAS server's perimeter network interface.

  This filter allows traffic to the IAS server on the perimeter network.

Configure the following output packet filters on the intranet interface of the firewall to allow the following types of traffic:

- Source IP address of the IAS server's perimeter network interface.

  This filter allows traffic from the IAS server on the perimeter network.

# Shared secrets

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shared secrets**

A shared secret is a text string that serves as a password between:

- A RADIUS client and RADIUS server.
- A RADIUS client and a RADIUS proxy.
- A RADIUS proxy and a RADIUS server.

For a configuration that uses a RADIUS client, a RADIUS proxy, and a RADIUS server, the shared secret that is used between the RADIUS client and the RADIUS proxy can be different than the shared secret used between the RADIUS proxy and the RADIUS server.

Shared secrets are used to verify that RADIUS messages, with the exception of the Access-Request message, are sent by a RADIUS-enabled device that is configured with the same shared secret. Shared secrets also verify that the RADIUS message has not been modified in transit (message integrity). The shared secret is also used to encrypt some RADIUS attributes, such as User-Password and Tunnel-Password. To provide verification for Access-Request messages, you can enable use of the RADIUS Message Authenticator attribute for both the RADIUS client configured on the IAS server and the access server. For more information, see Message Authenticator attribute and Configure the Message Authenticator attribute and shared secret.

When creating and using a shared secret:

- You must use the same case-sensitive shared secret on both RADIUS devices.
- Use a different shared secret for each RADIUS server-RADIUS client pair.
- To ensure a random shared secret, generate a random sequence at least 22 characters long.
- You can use any standard alphanumeric and special characters.
- You can use a shared secret of up to 128 characters in length. To protect your IAS server and your RADIUS clients from brute force attacks, use long shared secrets (more than 22 characters).
- Make the shared secret a random sequence of letters, numbers, and punctuation and change it often to protect your IAS server and your RADIUS clients from dictionary attacks. Shared secrets should contain characters from each of the following three groups:

| Group | Examples |
|---|---|
| Letters (uppercase and lowercase) | A, B, C and a, b, c |
| Numerals | 0, 1, 2, 3 |
| Symbols (all characters not defined as letters or numerals) | Exclamation point (!), asterisk (*), colon (:) |

The stronger your shared secret, the more secure are the attributes (for example, those used for passwords and encryption keys) that are encrypted with it. An example of a strong shared secret is 8d#>9fq4bV)H7%a3-zE13sW.

**Notes**

- When Password Authentication Protocol (PAP) is used between an access client and an access server (a RADIUS client), the access server encrypts the PAP password by using the shared secret and sends it in an Access-Request packet. If the access server sends the Access-Request message to a RADIUS proxy, the RADIUS proxy must first decrypt the PAP

password with the shared secret that was used between the RADIUS proxy and the access server. Next, it encrypts the PAP password with the shared secret that was used between the RADIUS proxy and the RADIUS server before forwarding the Access-Request message. Because a malicious user or process at a RADIUS proxy can record user names and passwords for PAP connections after they are decrypted but before they are encrypted, the use of PAP is highly discouraged.

- If you specify RADIUS clients by using an IP address range, all RADIUS clients within the address range must use the same shared secret.

- If you are using a password-based authentication method, it is strongly recommended that you use MS-CHAP v2, MS-CHAP, or CHAP with strong passwords to provide password protection from dictionary attacks.

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Message Authenticator attribute

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Message Authenticator attribute**

When you configure IAS for a RADIUS client, you configure the IP address of the client. If an incoming RADIUS Access-Request message does not originate from at least one of the IP addresses of configured clients, IAS automatically discards the message, providing protection for an IAS server. However, source IP addresses can be spoofed (substituted with other IP addresses).

To provide protection from spoofed Access-Request messages and RADIUS message tampering, each RADIUS message can be additionally protected with the RADIUS Message Authenticator attribute, which is described in RFC 2869, "RADIUS Extensions."

The RADIUS Message Authenticator attribute is a Message Digest 5 (MD5) hash of the entire RADIUS message. The shared secret is used as the key. If the RADIUS Message Authenticator attribute is present, it is verified. If it fails verification, the RADIUS message is discarded. If the client settings require the Message Authenticator attribute and it is not present, the RADIUS message is discarded.

For information about how to configure the use of the Message Authenticator attribute for RADIUS clients of an IAS server, see Configure the Message Authenticator attribute and shared secret. For information about how to configure the use of the Message Authenticator attribute for the Routing and Remote Access service, see Use RADIUS authentication.

# Remote access account lockout

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote access account lockout**

You can use the remote access account lockout feature to specify how many times a remote access authentication fails against a valid user account before the user is denied access. Remote access account lockout is especially important for remote access virtual private network (VPN) connections over the Internet. An attacker on the Internet can attempt to access an organization intranet by sending credentials (valid user name, guessed password) during the VPN connection authentication process. During a dictionary attack, the attacker sends hundreds or thousands of credentials by using a list of passwords based on common words or phrases.

With remote access account lockout enabled, a dictionary attack is thwarted after a specified number of failed attempts. As the network administrator, you must decide on two remote access account lockout variables:

1. The number of failed attempts before future attempts are denied.

   After each failed attempt, a failed attempts counter for the user account is incremented. If the user account's failed attempts counter reaches the configured maximum, future attempts to connect are denied.

   A successful authentication resets the failed attempts counter when its value is less than the configured maximum. In other words, the failed attempts counter does not accumulate beyond a successful authentication.

2. How often the failed attempts counter is reset.

   The failed attempts counter is periodically reset to 0. If an account is locked out after the maximum number of failed attempts, the failed attempts counter is automatically reset to 0 after the reset time.

You enable the remote access account lockout feature by changing settings in the registry on the computer that provides the authentication. If the remote access server is configured for Windows Authentication, modify the registry on the remote access server computer. If the remote access server is configured for RADIUS authentication and Internet Authentication Service (IAS) is being used, modify the registry on the IAS server.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

To enable remote access account lockout, you must set the **MaxDenials** entry in the registry to **1** or greater. **MaxDenials** is the maximum number of failed attempts before the account is locked out. You set the **MaxDenials** entry in the following registry subkey:

**HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\AccountLockout**

By default, **MaxDenials** is set to **0**, which means that remote access account lockout is disabled.

To modify the amount of time before the failed attempts counter is reset, you must set the **ResetTime (mins)** entry in the registry to the required number of minutes. You set the **ResetTime (mins)** entry in the following registry subkey:

**HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\AccountLockout**

By default, **ResetTime (mins)** is set to **0xb40**, or 2,880 minutes (48 hours).

**Manually resetting an account that is locked out**

To manually reset a user account that has been locked out before the failed attempts counter is automatically reset, delete the following registry subkey that corresponds to the user's account name:

**HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\AccountLockout\ *domain name:user name***

When the lockout count for a user account is reset to 0 due to either a successful authentication or an automatic reset, the registry subkey for the user account is deleted.

**Notes**

- Remote access account lockout is not related to the **Account locked out** setting on the **Account** tab on the properties of a user account.

- The remote access account lockout feature does not distinguish between malicious users who attempt to access your intranet and authentic users who attempt remote access but have forgotten their current passwords. Users who have forgotten their current password typically try the passwords that they remember and, depending on the number of attempts and the **MaxDenials** setting, may have their accounts locked out.

- If you enable the remote access account lockout feature, a malicious user can deliberately force an account to be locked out by attempting multiple authentications with the user account until the account is locked out, thereby preventing the authentic user from being able to log on.

# IAS Network Access Quarantine Control

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS Network Access Quarantine Control**

IAS Network Access Quarantine Control provides phased network access for remote client computers by restricting them to a quarantine mode. After the client computer configuration is either brought into or determined to be in accordance with your organization's network policy, quarantine restrictions, which consist of Quarantine IP-Filters and Session Timers, are removed and standard remote access policy is applied to the connection.

Network Access Quarantine Control provides protection when users in your organization accidentally reconfigure key settings and do not restore them before connecting to your network. For example, a user might disable antivirus software that is required while connected to your network. Although Network Access Quarantine Control does not protect against attackers, computer configurations for authorized users can be verified and, if necessary, corrected before they can access the network. A timer setting is also available, which you can use to specify an interval at which the connection is dropped if the client fails to meet configuration requirements.

You can use the Routing and Remote Access service to process the specific RADIUS options sent by IAS, complete any required client configuration work, and remove the quarantine condition (or drop the connection) based on success or failure.

**Quarantine mode**

Quarantine mode is a set of network restrictions that are configured in IAS and implemented by the remote access server for each connection. You can use a Quarantine IP Filter to restrict access to a specific set of servers (for example, servers on a specified virtual Local Area Network) and a Quarantine Session Timer to restrict the amount of time the client can remain connected in quarantine mode. You can set these filters in the IAS console.

**Configuring Network Access Quarantine Control**

You can implement Network Access Quarantine Control with one or more servers running Windows Server 2003 and remote access, one or more servers running Windows Server 2003 and IAS, a Connection Manager (CM) profile created with Connection Manager Administration Kit (CMAK), an administrator-provided script, and two additional components: the notifier component and the listener component.

The notifier component is included in the CM profile and installed on the client computer. The notifier component sends notification to the remote access server when the administrator-provided script has run successfully on the client.

The listener component is installed on the remote access server, and receives notification from the notifier component that the script on the client has successfully performed all configuration checks. After the listener component receives notification, it removes the client from quarantine mode, and the remote access server applies standard remote access policy to the client.

You can create your own notifier and listener components, or you can use Rqs.exe (a listener component also called the Remote Access Quarantine Service) and Rqc.exe (a notifier component), which are available in the Windows Deployment and Resource Kits. For more information, see Windows Resource Kit Tools Help.

If you are running Windows Server 2003 with Service Pack 1, you can install the Remote Access Quarantine Service (Rqs.exe) using the Windows Components Wizard. In the wizard, the Remote Access Quarantine Service is available in Networking Services. In addition, you can use the Windows Components Wizard to install CMAK. After you install CMAK, Rqc.exe is located on your hard drive at *%systemroot%\Program Files\cmak\support*.

When you create the CM profile, you can include the administrator-provided script and Rqc.exe, which are distributed to and installed on remote access client computers. This profile can be installed on the following client operating systems:

- Windows XP Professional
- Windows XP Home Edition
- Windows 2000 Professional
- Windows Millennium Edition
- Windows 98 Second Edition

For more information about CMAK, see Connection Manager Administration Kit.

**Caution**

- Placing all remote access clients in quarantine mode without a way to remove quarantine policy and apply full access policy might prevent all remote access clients from establishing network connections.

Before you implement a remote access policy with Quarantine IP-Filters and Session Timers on your network, you must complete the following steps:

1. Create a client-side script that validates client configuration information.

2. Create a notification component that provides verification to the remote access server that the script has successfully run. If you do not want to create a notification component, you can use Rqc.exe.

3. Create a listener component to install on remote access servers (that can receive information from the notification component), and then remove the client from quarantine mode, applying the full access policy. If you do not want to create a listener component, you can use Rqs.exe.

4. Create a CM profile with CMAK. Include the client-side script and the notification component in the profile.

5. Distribute the CM profile for installation on remote access client computers.

**Configure two remote access policies on remote access or IAS servers**

On your remote access servers or IAS servers, use the **New Remote Access Policy Wizard** to create these remote access policies:

- A full access policy

- A quarantine policy

The notification and listener components of Network Access Quarantine Control use port 7250 by default. When you create the quarantine policy, you must configure **Inbound Filters** (also called **Input Filters**) to allow network traffic on port 7250, or the notification component (Rqc.exe), which runs on client computers, cannot notify the remote access server listener component (Rqs.exe) that the script has run successfully. You can specify another port, but you must also configure the listener and notification components to use this new port.

When you use the **New Remote Access Policy Wizard** to create quarantine policy, do the following to add quarantine IP filters and session timers:

1. On the **profile** page, click **Edit profile**.

2. In **Edit Dial-In profile**, click the **Advanced** tab, and then click **Add**.

**To add a quarantine IP filter**

1. In **Attribute**, select **MS-Quarantine-IPFilter**, and then click **Add**.

2. In **IP Filter Attribute Information**, click **Input Filters**.

3. In **Inbound Filters**, click **New**.

4. In **Add IP Filter**, click **Destination network**, and then type values in **IP address** and **Subnet mask** that match your network configuration.

5. In **protocol**, select **TCP**.

6. In **Source port**, type **7250**.

7. In **Destination port**, type **7250**, and then click **OK**.

8. In **Inbound Filters**, for **Filter action**, click **Permit only the packets listed below**, and then click **OK**.

**To add a quarantine session timer**

- In **Attribute**, select **MS-Quarantine-Session-Timeout**, and then click **Add**.

- In **Attribute value**, type the number of seconds that represents the maximum amount of time (in seconds) that you want client computers to remain connected in quarantine mode, and then click **OK**.

After you have configured both the full access and quarantine policies, make sure that the quarantine policy is first in the list of remote access policies.

For more information about the **New Remote Access Policy Wizard**, see Add a remote access policy.

### Notes

- IAS Network Access Quarantine Control must be used in combination with remote access policy (user-based authentication and access control) to provide security for your network. The quarantine filters and timers can be defined in a remote access policy on either the remote access server or the IAS server. When the connection is made, the access server implements the restrictions (Quarantine IP Filters and Quarantine Session Timers) that are returned by IAS.

- Notification by the client (to the server) that the administrator-provided script has successfully run is not secure and can be spoofed by a malicious user or attacker. Network Access Quarantine Control is only intended to help verify a managed client computer configuration.

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Securing RADIUS traffic with IPSec

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Securing RADIUS traffic with IPSec**

Internet Protocol security (IPSec) provides you with the ability to secure RADIUS servers against unwanted traffic by filtering on specific network adapters (allowing or blocking specific protocols) and enabling you to choose source IP addresses from which traffic is allowed. For organizational units, you can create IPSec policies, which are stored in Active Directory. Or, you can create local policies on RADIUS servers, and apply these policies to specific computers. If you create IPSec policies for an organizational unit, the policy is applied through Group Policy.

For more information about organizational units and Group Policy, see Organizational units, Group Policy integration, and Create a new organizational unit.

Before you create IPSec filters, determine the type of traffic that you want to allow for each RADIUS server. Filters that are too strict might block acceptable network traffic. For example, if IAS is installed on a domain controller and all IP traffic, except RADIUS traffic, is blocked on all ports, user queries for Active Directory objects (such as printers) on default global catalog port 3268 will fail. Conversely, IP filters that are too general expose the RADIUS server to unwanted traffic. For more information, see Special IPSec considerations and Filter list.

RADIUS messages are sent with the User Datagram Protocol (UDP). UDP port 1812 is used for RADIUS authentication messages and UDP port 1813 is used for RADIUS accounting messages. When you create inbound and outbound filters with IPSec, UDP traffic must be allowed on these ports. However, some network access servers might use UDP port 1645 for RADIUS authentication messages and UDP port 1646 for RADIUS accounting messages. By default, IAS supports both sets of ports. If your network access servers use UDP ports 1645 and 1646, you can create IPSec filters that allow traffic on these ports. For information about changing the UDP ports that IAS uses, see Configure IAS port information. For more information about defining IP filter lists, see Internet Protocol Security (IPSec) and Define IP Filter Lists.

You can use the IP Security Policies snap-in and Group Policy to configure IPSec policy for organizational units. For more information, see Group Policy.

You can use the Local Security Policy console to configure IPSec policy for individual RADIUS servers. For more information, see Local Security Policy.

For information about how to create IP filters for remote access clients, see IAS Network Access Quarantine Control.

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Vendor-Specific Attributes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Vendor-specific attributes**
This section covers:

- Vendor-specific attribute overview
- Sample VSA for a Cisco NAS
- Sample VSA for a US Robotics NAS

# Vendor-specific attribute overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Vendor-specific attribute overview**

IAS provides the ability to specify RADIUS attributes that are returned with a RADIUS response message. These RADIUS attributes can be specified for each remote access policy and are configured on the **Advanced** tab in the properties of a profile for a remote access policy. For more information, see Configure Attributes for a Profile.

In addition to the standard RADIUS attributes, which are described in RFCs 2865 and 2866, you might also need to configure vendor-specific attributes (VSAs). VSAs allow vendors to support their own proprietary RADIUS attributes that are not included in RFCs 2865 and 2866. IAS includes VSAs from a number of vendors in its dictionary; however, the VSAs provided with IAS in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition do not include VSAs for all vendors. There is no process for centrally updating and distributing new versions of the IAS dictionary. Instead, you can manually create new VSAs for each remote access policy profile.

Some network access server (NAS) manufacturers use vendor-specific attributes (VSAs) to provide functionality that is not supported in standard attributes. IAS enables you to create or edit VSAs to take advantage of proprietary functionality supported by some NAS vendors. For more information about vendor-specific functionality and the VSAs that you can configure, see your access server documentation.

Before adding a VSA, check the list of attributes in the IAS dictionary. If the required VSA is present, use it. If not, you must add a VSA to the profile. VSAs are added by specifying the **Vendor-Specific** attribute on the **Advanced** tab in the properties of a profile for a remote access policy. For more information, see Configure vendor-specific attributes for a remote access policy.

If you want to add VSAs to the remote access policy profile to support proprietary functionality for your access point, you must determine whether the VSA conforms to the format recommended in RFC 2865.

- If it does, you must specify:
    - A network access vendor by either name or vendor code.
    - A vendor-assigned attribute number.
    - The attribute format (that is, the type of data, such as string or hexadecimal).
    - The attribute value.
- If it does not, you must specify:
    - A network access vendor by either name or vendor code.
    - A hexadecimal attribute value that represents the attribute data.

**Ordering of multiple VSAs**

If you need to configure more than one VSA, you should arrange them in the appropriate order in the **Multivalued Attribute Information** dialog box. For example, if you are using a filtering VSA that automatically disconnects users who do not meet specific criteria, you should ensure that the attribute appears at the top of the list. Use the **Move Up** and **Move Down** buttons in the **Multivalued Attribute Information** dialog box to arrange the attributes in the correct order.

# Sample VSA for a Cisco NAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Sample VSA for a Cisco NAS**

This sample Cisco vendor-specific attribute conforms to the format for vendor-specific attributes (type 26) that is specified in RFC 2865.

The following table lists the information used to configure a Cisco VSA to specify a primary DNS server with an IP address of 10.10.10.10.

| Information | Description |
|---|---|
| Vendor ID | This is the unique ID for Cisco. When you select Cisco as the network access server vendor, this ID (9) is automatically supplied. |
| Cisco-assigned attribute number | This is the vendor-type number (1) for vendor-specific attributes that take the attribute-value pair form, specified in Cisco documentation as cisco-avpair. |
| Syntax | If the attribute is mandatory, the syntax is *Protocol***:***Attribute* **=** *Value*. If the attribute is optional, the attribute-value pair is separated by an asterisk (*****) instead of an equal sign (**=**). In this example, *Protocol* is a value of the Cisco protocol attribute for a specific type of authorization. *Attribute* and *Value* represent an appropriate attribute/value (AV) pair defined in the Cisco TACACS+ specification. This allows the full set of features available for TACACS+ authorization to be used for RADIUS. The Cisco format, used to specify a primary DNS server, is **ip:dns-servers=10.10.10.10**. |

To specify the primary DNS server of 10.10.10.10, configure an RFC-compliant VSA:

1. Open the IAS console. To open the IAS console, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Authentication Service**.
2. In the console tree, click **Remote Access Policies**.
3. Right-click the policy for which you want to configure a vendor-specific attribute (VSA), and then click **Properties**.
4. Click **Edit Profile**, click the **Advanced** tab, and then click **Add**.
5. In the **Add Attribute** dialog box, scroll the **Attribute** list and double-click **Vendor-Specific**. The **Multivalued Attribute Information** dialog box opens. Click **Add**.
6. The **Vendor-Specific Attribute Information** dialog box opens. In **Select from list**, select **Cisco** as the network access server vendor, and then click **Yes, it conforms**.
7. Click **Configure Attribute**. The **Configure VSA (RFC-compliant)** dialog box opens.
8. In **Vendor-assigned attribute number**, type **1**.
9. In **Attribute format**, select **String**.
10. In **Attribute Value**, type **ip:dns-servers=10.10.10.10**.

For more information, see Configure vendor-specific attributes for a remote access policy. For more information about Cisco VSAs, see your Cisco documentation.

# Sample VSA for a US Robotics NAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Sample VSA for a US Robotics NAS**

This sample US Robotics vendor-specific attribute does not conform to the format for vendor-specific attributes (VSAs) that is specified in RFC 2865. Therefore, this US Robotics VSA must be entered in hexadecimal format.

The following table lists the information that is used to configure a US Robotics VSA to specify a primary DNS/NBNS server with an IP address of 10.10.10.10.

| Information | Description |
|---|---|
| Vendor ID | This is the unique ID for US Robotics. When you select US Robotics as the network access server vendor, this ID (429) is automatically supplied. |
| US Robotics VSA Indicator | The VSA indicator for the primary DNS/NBNS server is 0x900F. |
| String | The hexadecimal encoding of the string 10.10.10.10. (the IP address of a primary DNS/NBNS server) is 0x31302E31302E31302E31302E. |

To specify an IP address of 10.10.10.10 for a primary DNS/NBNS server:

- Configure a non-RFC-compliant VSA.

  For more information, see Configure vendor-specific attributes for a remote access policy.

  - Select **US Robotics** as the network access server vendor.
  - In **Hexadecimal attribute value**, in the **Configure VSA (non-RFC-compliant)** dialog box, type **0x900f31302E31302E31302E31302E**.

For more information about US Robotics VSAs, see your US Robotics documentation.

# Authentication Methods for use with IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authentication methods**
The authentication of access clients is an important security concern. Authentication methods typically use an authentication protocol that is negotiated during the connection establishment process. IAS also supports unauthenticated connections.

For information about using authentication methods, see the following:

- PEAP
- EAP
- MS-CHAP
- MS-CHAP version 2
- CHAP
- PAP
- Unauthenticated access

Each authentication method has advantages and disadvantages in terms of security, usability, and breadth of support. The authentication method used is determined by the configuration of both the access server and client. Consult your access server documentation to determine which authentication methods are supported.

You can configure IAS to accept multiple authentication methods. You can also configure your access servers to attempt to negotiate a connection by using the most secure protocol first, and then the next most secure, and so on down to the least secure. For example, the Routing and Remote Access service tries to negotiate a connection using EAP first, then MS-CHAP v2, then MS-CHAP, then CHAP, then SPAP, and then PAP. When EAP is chosen as the authentication method, the negotiation of the EAP type occurs between the access client and the IAS server.

In addition, you can use remote access policies for various authentication methods, depending on the type of client being authenticated. For example, you can create two remote access policies, one for virtual private network (VPN) clients and one for wireless clients--each of which uses a different authentication method. The remote access policy for VPN clients can be configured to use EAP-TLS with smart cards or certificates as the authentication method and authentication type, while the remote access policy for wireless clients can be configured to use PEAP-EAP-MS-CHAP v2, which provides secure password authentication.

**Certificate deployments and Active Directory replication**
Some authentication methods, such as PEAP and EAP, can use certificates for authentication of computers and users. Latency in Active Directory replication might temporarily affect the ability of a client or server to obtain a certificate from a certification authority (CA). If a computer configured to use certificates for authentication cannot enroll a certificate, authentication fails.

For example, if a new computer running IAS is joined to the domain by a local domain controller, the IAS server is rebooted and Group Policy is applied. After Group Policy is applied and certificate autoenrollment is configured, the IAS server attempts to enroll a certificate with a CA. The CA queries Active Directory to determine whether the IAS server has the security permissions required to enroll a certificate. If the domain controller that joined the IAS server to the domain has replicated IAS server domain membership information across the domain, the CA can verify that the IAS server should receive a certificate. The CA then enrolls a certificate to the IAS server. You can manually refresh Group Policy by logging onto the domain or by running the **gpupdate** command.

When information about the IAS server domain membership has not replicated to other domain controllers and the CA queries a domain controller that does not yet have information about the IAS server, the CA cannot verify that the IAS server is running on a computer that is a domain member. Because the CA cannot verify that the IAS server has the security permissions to enroll a certificate, the CA does not enroll a certificate for the IAS server. As the result, authentication fails and the server cannot log on to the network.

For more information, see Network access authentication and certificates and Remote Access Policies.

**Notes**

- IEEE 802.1x authentications for wireless and switch clients use only the PEAP and EAP authentication methods.
- IAS also supports authentication for computer accounts.
- When using the EAP-TLS authentication method with certificates, TLS uses cached certificate properties instead of reading the certificate from the certificate store. If a certificate is either changed or deleted and replaced by a new certificate, TLS continues using outdated cached certificate information until the cache expires or is refreshed. If you change or replace a certificate, you can refresh the TLS cache by restarting the server computer.

# PEAP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PEAP**

Protected Extensible Authentication Protocol (PEAP) is a new member of the family of Extensible Authentication Protocol (EAP) protocols. PEAP uses Transport Level Security (TLS) to create an encrypted channel between an authenticating PEAP client, such as a wireless computer, and a PEAP authenticator, such as an Internet Authentication Service (IAS) or Remote Authentication Dial-In User Service (RADIUS) server. PEAP does not specify an authentication method, but provides additional security for other EAP authentication protocols, such as EAP-MSCHAPv2, that can operate through the TLS encrypted channel provided by PEAP. PEAP is used as an authentication method for 802.11 wireless client computers, but is not supported for virtual private network (VPN) or other remote access clients.

To enhance both the EAP protocols and network security, PEAP provides:

- Protection for the EAP method negotiation that occurs between client and server through a TLS channel. This helps prevent an attacker from injecting packets between the client and the network access server (NAS) to cause the negotiation of a less secure EAP method. The encrypted TLS channel also helps prevent denial of service attacks against the IAS server.
- Support for the fragmentation and reassembly of messages, allowing the use of EAP types that do not provide this.
- Wireless clients with the ability to authenticate the IAS or RADIUS server. Because the server also authenticates the client, mutual authentication occurs.
- Protection against the deployment of an unauthorized wireless access point (WAP) when the EAP client authenticates the certificate provided by the IAS server. In addition, the TLS master secret created by the PEAP authenticator and client is not shared with the access point. Because of this, the access point cannot decrypt the messages protected by PEAP.
- PEAP fast reconnect, which reduces the delay in time between an authentication request by a client and the response by the IAS or RADIUS server, and allows wireless clients to move between access points without repeated requests for authentication. This reduces resource requirements for both client and server.

**PEAP authentication process**

There are two stages in the PEAP authentication process between PEAP client and authenticator. The first stage sets up a secure channel between the PEAP client and the authenticating server. The second stage provides EAP authentication between the EAP client and authenticator.

**TLS encrypted channel**

The wireless client associates with a wireless access point. An IEEE 802.11-based association provides an Open System or Shared Key Authentication before a secure association is created between the client and access point. After the IEEE 802.11-based association is successfully established between the client and access point, the TLS session is negotiated with the access point. After authentication is successfully completed between the wireless client and the server (for example, an IAS server), the TLS session is negotiated between them. The key that is derived during this negotiation is used to encrypt all subsequent communication.

**EAP-authenticated communication**

Complete EAP communication, including EAP negotiation, occurs through the TLS channel. The IAS server authenticates the user and client computer with the method that is determined by the EAP type and selected for use within PEAP (either EAP-TLS or EAP-MS-CHAPv2). The access point only forwards messages between wireless client and RADIUS server--the access point (or a person monitoring it) cannot decrypt these messages because it is not the TLS end point.

**802.11 wireless deployments using PEAP**

You can choose between two EAP types for use with PEAP: EAP-MS-CHAPv2 or EAP-TLS. EAP-MS-CHAPv2 uses credentials (user name and password) for user authentication, and a certificate in the server computer certificate store for server authentication. EAP-TLS uses either certificates installed in the client computer certificate store or a smart card for user and client computer authentication, and a certificate in the server computer certificate store for server authentication.

**PEAP with EAP-MS-CHAPv2**

PEAP with EAP-MS-CHAPv2 (PEAP-EAP-MS-CHAPv2) is easier to deploy than EAP-TLS because user authentication is accomplished with password-based credentials (user name and password) instead of certificates or smart cards--only the IAS or RADIUS server is required to have a certificate. Additionally, the server certificate can be issued by a public certification authority (CA) that is trusted by the client computer (that is, the public CA certificate already exists in the Trusted Root Certification Authority folder on the client computer certificate store). In this case, the server certificate is not downloaded and added to the client trusted root certificate store, and the user is not prompted to make a decision about whether to trust the server.

PEAP-EAP-MS-CHAPv2 provides improved security over MS-CHAPv2 by using mutual authentication, preventing an unauthorized server from negotiating the least secure authentication method, and providing key generation with TLS. PEAP-EAP-MS-CHAPv2 requires that the client trust certificates provided by the server.

For server and client computer certificate requirements, see Network access authentication and certificates. For an example wireless access policy using PEAP-EAP-MS-CHAPv2, see Wireless access with secure password authentication.

**PEAP with EAP-TLS**

Public Key certificates provide a much stronger authentication method than those that use password-based credentials. PEAP with EAP-TLS (PEAP-EAP-TLS) uses certificates for server authentication and either certificates or smart cards for user and client computer authentication. To use PEAP-EAP-TLS, you must deploy a public key infrastructure (PKI).

For more information, see Network access authentication and certificates.

**PEAP fast reconnect**

PEAP fast reconnect enables wireless clients to move between wireless access points on the same network without being reauthenticated each time they associate with a new access point.

Wireless access points are configured as RADIUS clients to RADIUS servers. If a wireless client roams between access points that are configured as clients to the same RADIUS server, the client is not required to be authenticated with each new association. When a client moves to an access point that is configured as a RADIUS client to a different RADIUS server, although the client is reauthenticated, this process occurs much more efficiently.

PEAP fast reconnect reduces the response time for authentication between client and authenticator because the authentication request is forwarded from the new server to the original server. Because both the PEAP client and authenticator use previously cached TLS connection properties (the collection of which is named the TLS handle), the authenticator can quickly determine that the client connection is a reconnect.

If the original PEAP authenticator is unavailable, full authentication must occur between the client and the new authenticator. The new PEAP authenticator's TLS handle is cached by the client. The client can cache TLS handles for multiple PEAP authenticators. For smart carts or PEAP-EAP-MSCHAPv2 authentication, the user is asked to supply the PIN or credentials, respectively.

With PEAP-EAP-MS-CHAPv2 authentication:

| **When the new access point is a client to the same RADIUS server** | **When the new access point is a client to a new RADIUS server** |
|---|---|
| The user is not prompted for credentials each time the client computer associates with a new access point. | The user is prompted for credentials on this initial association. The next time the client computer associates with an access point that is a client to this server, user credentials are not required. |
| The RADIUS server is not required to provide a certificate. | The RADIUS server provides a certificate on this initial association so that the wireless client can authenticate to the RADIUS server. The next time the client computer associates with an access point that is a client to this server, the server is not required to be reauthenticated. |

With PEAP-EAP-TLS authentication:

| **When the new access point is a client to the same RADIUS server** | **When the new access point is a client to a new RADIUS server** |
|---|---|

| | |
|---|---|
| The client and server are not required to exchange certificates. | The client and server exchange certificates on this initial association. The next time the client computer associates with an access point that is a client to this server, certificates are not exchanged. |
| The user is not prompted for a smart card personal identification number (PIN) each time the client computer associates with a new access point. | The user is prompted for a smart card PIN on this initial association. The next time the client computer associates with an access point that is a client to this server, the user is not prompted for the PIN. |

For more information about RADIUS clients, see Components of a RADIUS infrastructure.

For more information about RADIUS proxy servers, see IAS as a RADIUS proxy.

To enable PEAP fast reconnect:

- Both the PEAP client (802.11 wireless client) and PEAP authenticator (RADIUS server) must have fast reconnect enabled.
- All access points to which the PEAP client roams must be configured as RADIUS clients to a RADIUS server (the PEAP authenticator) for which PEAP is configured as the authentication method for wireless connections.
- All access points to which the PEAP client associates must be configured to prefer the same RADIUS server (PEAP authenticator) in order to avoid being prompted for credentials from every RADIUS server. If the access point cannot be configured to prefer a RADIUS server, you can configure an IAS RADIUS proxy with a preferred RADIUS server.

For more information, see Configure PEAP and EAP methods.

**Notes**

- When using the PEAP-EAP-TLS and EAP-TLS authentication methods with certificates, TLS uses cached certificate properties instead of reading the certificate from the certificate store. If a certificate is either changed or deleted and replaced by a new one, TLS continues using outdated cached certificate information until the cache expires or is refreshed. If you change or replace a certificate, you can refresh the TLS cache by restarting the server computer.
- PEAP does not support guest authentication, which has a blank user name and password.
- When you deploy both PEAP and EAP unprotected by PEAP, do not use the same EAP authentication type with and without PEAP. For example, if you deploy PEAP with EAP-TLS (PEAP-EAP-TLS), do not also deploy EAP-TLS without PEAP. Deploying authentication methods with the same type -- one with and the other without the protection of PEAP -- creates a security vulnerability.
- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# EAP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**EAP**

With the Extensible Authentication Protocol (EAP), an arbitrary authentication mechanism authenticates a remote access connection. The exact authentication scheme to be used is negotiated by the remote access client and the authenticator (either the remote access server or the Remote Authentication Dial-In User Service [RADIUS] server). Routing and Remote Access includes support for EAP-TLS and MD5-Challenge by default. You can plug in other EAP modules to the server running Routing and Remote Access to provide other EAP methods.

EAP allows for an open-ended conversation between the remote access client and the authenticator. The conversation consists of authenticator requests for authentication information and the responses by the remote access client. For example, when EAP is used with security token cards, the authenticator can separately query the remote access client for a name, PIN, and card token value. As each query is asked and answered, the remote access client passes through another level of authentication. When all questions have been answered satisfactorily, the remote access client is authenticated.

A specific EAP authentication scheme is known as an EAP type. Both the remote access client and the authenticator must support the same EAP type for successful authentication to occur.

The Windows Server 2003 family includes an EAP infrastructure, two EAP types, and the ability to pass EAP messages to a RADIUS server (EAP-RADIUS).

**EAP infrastructure**

EAP is a set of internal components that provide architectural support for any EAP type in the form of a plug-in module. For successful authentication, both the remote access client and authenticator must have the same EAP authentication module installed. The Windows Server 2003 family provides two EAP types: MD5-Challenge and EAP-TLS. EAP-TLS is only available for members of a domain. You can also install additional EAP types. The components for an EAP type must be installed on every remote access client and every authenticator.

**MD5-Challenge**

Message Digest 5 Challenge (MD5-Challenge) is a required EAP type that uses the same challenge handshake protocol as PPP-based CHAP, but the challenges and responses are sent as EAP messages.

A typical use for MD5-Challenge is to authenticate the credentials of remote access clients by using user name and password security systems. You can also use MD5-Challenge to test EAP interoperability.

**EAP-TLS**

EAP-Transport Level Security (EAP-TLS) is an EAP type that is used in certificate-based security environments. If you are using smart cards for remote access authentication, you must use the EAP-TLS authentication method. The EAP-TLS exchange of messages provides mutual authentication, negotiation of the encryption method, and encrypted key determination between the remote access client and the authenticator. EAP-TLS provides the strongest authentication and key determination method.

EAP-TLS is supported only on servers that are running Routing and Remote Access, that are configured to use Windows Authentication or RADIUS, and that are members of a domain. A remote access server running as a stand-alone server or a member of a workgroup does not support EAP-TLS.

For information about configuring smart cards for remote access clients, see Using smart cards for remote access.

**EAP-RADIUS**

EAP-RADIUS is not an EAP type, but the passing of EAP messages of *any* EAP type by an authenticator to a RADIUS server for authentication. For example, for a remote access server that is configured for RADIUS authentication, the EAP messages sent between the remote access client and remote access server are encapsulated and formatted as RADIUS messages between the remote access server and the RADIUS server.

EAP-RADIUS is used in environments where RADIUS is used as the authentication provider. An advantage of using EAP-RADIUS is that EAP types do not need to be installed at each remote access server, only at the RADIUS server. In the case of an IAS server, you only need to install EAP types on the IAS server.

In a typical use of EAP-RADIUS, a server running Routing and Remote Access is configured to use EAP and to use an IAS server for authentication. When a connection is made, the remote access client negotiates the use of EAP with the remote access server. When the client sends an EAP message to the remote access server, the remote access server encapsulates the EAP

message as a RADIUS message and sends it to its configured IAS server. The IAS server processes the EAP message and sends a RADIUS-encapsulated EAP message back to the remote access server. The remote access server then forwards the EAP message to the remote access client. In this configuration, the remote access server is only a pass-through device. All processing of EAP messages occurs at the remote access client and the IAS server.

Routing and Remote Access can be configured to authenticate locally, or to a RADIUS server. If Routing and Remote Access is configured to authenticate locally, all EAP methods will be authenticated locally. If Routing and Remote Access is configured to authenticate to a RADIUS server, all EAP messages will be forwarded to the RADIUS server with EAP-RADIUS.

For more information about configuring a server running Routing and Remote Access for EAP-RADIUS, see Configure EAP-RADIUS.

**Enabling EAP**

To enable EAP-based authentication, you must do the following:

1. Enable EAP as an authentication protocol on the remote access server. For more information, see Enable EAP.

2. Enable EAP and, if needed, configure the EAP type on the appropriate remote access policy. For more information, see Introduction to remote access policies and Configure authentication.

3. Enable and configure EAP on the remote access client. For more information, see Extensible Authentication Protocol (EAP).

**Note**

- Make sure your network access server (NAS) supports EAP before you enable it on a remote access policy on an IAS server. For more information, see your NAS documentation.

# MS-CHAP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MS-CHAP**
The Windows Server 2003 family includes support for the Microsoft Challenge Handshake Authentication Protocol (MS-CHAP), also known as MS-CHAP version 1. MS-CHAP is a nonreversible, encrypted password authentication protocol. The challenge handshake process works as follows:

1. The authenticator (the remote access server or the IAS server) sends a challenge to the remote access client that consists of a session identifier and an arbitrary challenge string.

2. The remote access client sends a response that contains the user name and a nonreversible encryption of the challenge string, the session identifier, and the password.

3. The authenticator checks the response and, if valid, the user's credentials are authenticated.

If you use MS-CHAP as the authentication protocol, then you can use Microsoft Point-to-Point Encryption (MPPE) to encrypt the data sent on the PPP or PPTP connection.

The Windows Server 2003 family also includes support for MS-CHAP version 2. MS-CHAP version 2 provides stronger security for remote access connections than MS-CHAP. You should consider using MS-CHAP version 2 instead of MS-CHAP. For more information, see MS-CHAP version 2.

**Enabling MS-CHAP**
To enable MS-CHAP-based authentication, you must do the following:

1. Enable MS-CHAP as an authentication protocol on the remote access server. For more information, see Enable authentication protocols. MS-CHAP is enabled by default.

2. Enable MS-CHAP on the appropriate remote access policy. For more information, see Introduction to remote access policies and Configure authentication. MS-CHAP is enabled by default.

3. Enable MS-CHAP on the remote access client. For more information, see Microsoft Challenge Handshake Authentication Protocol (MS-CHAP).

### Notes

- MS-CHAP (version 1 and version 2) is the only authentication protocol provided with the Windows Server 2003 family that supports password change during the authentication process.

- By default, the Windows Server 2003 family implementation of MS-CHAP v1 does not support LAN Manager authentication. If you want to allow the use of LAN Manager authentication with MS-CHAP v1 for older operating systems such as Windows NT 3.5x and Windows 95, you must set the following registry value to 1 on the authenticating server:

  **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\RemoteAccess\Policy\Allow LM Authentication**

  Windows 2000 Server supports LAN Manager authentication by default. Upgrading a computer running Windows 2000 Server to a member of the Windows Server 2003 family preserves the existing **Allow LM Authentication** setting.

- If MS-CHAP v1 is used as the authentication protocol, a 40-bit encrypted connection cannot be established if the user's password is larger than 14 characters. This behavior affects both dial-up and virtual private network-based remote access and demand dial connections.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

# MS-CHAP version 2

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MS-CHAP version 2**

The Windows Server 2003 family includes support for version 2 of the Microsoft Challenge Handshake Authentication Protocol (MS-CHAP v2), which provides stronger security for remote access connections. MS-CHAP v2 solves some issues of MS-CHAP version 1, as shown in the following table.

| MS-CHAP version 1 issue | MS-CHAP version 2 solution |
|---|---|
| LAN Manager encoding of the response used for backward compatibility with older Microsoft remote access clients is cryptographically weak. | MS-CHAP v2 no longer allows LAN Manager encoded responses. |
| LAN Manager encoding of password changes is cryptographically weak. | MS-CHAP v2 no longer allows LAN Manager encoded password changes. |
| Only one-way authentication is possible. The remote access client cannot verify that it is dialing in to its organization's remote access server or a masquerading remote access server. | MS-CHAP v2 provides two-way authentication, also known as mutual authentication. The remote access client receives verification that the remote access server that it is dialing in to has access to the user's password. |
| With 40-bit encryption, the cryptographic key is based on the user's password. Each time the user connects with the same password, the same cryptographic key is generated. | With MS-CHAP v2, the cryptographic key is always based on the user's password and an arbitrary challenge string. Each time the user connects with the same password, a different cryptographic key is used. |
| A single cryptographic key is used for data sent in both directions on the connection. | With MS-CHAP v2, separate cryptographic keys are generated for transmitted and received data. |

MS-CHAP v2 is a one-way encrypted password, mutual authentication process that works as follows:

1. The authenticator (the remote access server or the IAS server) sends a challenge to the remote access client that consists of a session identifier and an arbitrary challenge string.

2. The remote access client sends a response that contains:

   - The user name.

   - An arbitrary peer challenge string.

   - A one-way encryption of the received challenge string, the peer challenge string, the session identifier, and the user's password.

3. The authenticator checks the response from the client and sends back a response containing:

   - An indication of the success or failure of the connection attempt.

   - An authenticated response based on the sent challenge string, the peer challenge string, the encrypted response of the client, and the user's password.

4. The remote access client verifies the authentication response and, if correct, uses the connection. If the authentication response is not correct, the remote access client terminates the connection.

**Enabling MS-CHAP v2**

To enable MS-CHAP v2-based authentication, you must do the following:

1. Enable MS-CHAP v2 as an authentication protocol on the remote access server. For more information, see Enable authentication protocols. MS-CHAP v2 is enabled by default.

2. Enable MS-CHAP v2 on the appropriate remote access policy. For more information, see Introduction to remote access policies and Configure authentication. MS-CHAP v2 is enabled by default.

3. Enable MS-CHAP v2 on the remote access client. For more information, see Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAP v2).

## Notes

- Windows 95 with the Windows Dial-Up Networking 1.3 Performance & Security Upgrade for Windows 95 supports MS-CHAP v2 for virtual private network (VPN) connections but not for dial-up connections.

- MS-CHAP (version 1 and version 2) is the only authentication protocol provided with the Windows Server 2003 family that supports password change during the authentication process.

- Make sure your network access server (NAS) supports MS-CHAP v2 before you enable it on a remote access policy on an IAS server. For more information, see your NAS documentation.

# CHAP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CHAP**

The Challenge Handshake Authentication Protocol (CHAP) is a challenge-response authentication protocol that uses the industry-standard Message Digest 5 (MD5) hashing scheme to encrypt the response. CHAP is used by various vendors of network access servers and clients. A server running Routing and Remote Access supports CHAP so that remote access clients that require CHAP are authenticated. Because CHAP requires the use of a reversibly encrypted password, you should consider using another authentication protocol such as MS-CHAP version 2.

To enable CHAP-based authentication, you must do the following:

1. Enable CHAP as an authentication protocol on the remote access server. For more information, see Enable authentication protocols. CHAP is disabled by default.

2. Enable CHAP on the appropriate remote access policy. For more information, see Introduction to remote access policies and Configure authentication.

3. Enable storage of a reversibly encrypted form of the user's password.

   You can enable storage of a reversibly encrypted form of the user's password per user account or enable storage for all accounts in a domain. For more information, see Enable reversibly encrypted passwords in a domain.

4. Force a reset of the user's password so that the new password is in a reversibly encrypted form.

   When you enable passwords to be stored in a reversibly encrypted form, the current passwords are not in a reversibly encrypted form and are not automatically changed. You must either reset user passwords or set user passwords to be changed the next time each user logs on. For more information, see Reset a user password. Once the password is changed, it is stored in a reversibly encrypted form.

   If you set user passwords to be changed the next time a user logs on, the user must log on by using a LAN connection and change the password before they attempt to log on with a remote access connection by using CHAP. You cannot change passwords during the authentication process by using CHAP--the logon attempt fails. One workaround for the remote access user is to temporarily log on by using MS-CHAP to change the password.

5. Enable CHAP on the remote access client. For more information, see Challenge Handshake Authentication Protocol (CHAP).

**Notes**

- If your password expires, CHAP cannot change passwords during the authentication process.

- Make sure your network access server (NAS) supports CHAP before you enable it on a remote access policy on an IAS server. For more information, see your NAS documentation.

- You cannot use Microsoft Point-to-Point Encryption (MPPE) with CHAP.

# PAP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PAP**
Password Authentication Protocol (PAP) uses plaintext passwords and is the least secure authentication protocol. It is typically negotiated if the remote access client and remote access server cannot negotiate a more secure form of validation.

To enable PAP-based authentication, you must do the following:

1. Enable PAP as an authentication protocol on the remote access server. For more information, see Enable authentication protocols. PAP is disabled by default.

2. Enable PAP on the appropriate remote access policy. For more information, see Configure authentication. PAP is disabled by default.

3. Enable PAP on the remote access client. For more information, see Password Authentication Protocol (PAP).

### Important

- When you enable PAP as an authentication protocol, user passwords are sent in plaintext form. Anyone capturing the packets of the authentication process can easily read the password and use it to gain unauthorized access to your intranet. The use of PAP is highly discouraged, especially for virtual private network connections.

### Notes

- By disabling the support for PAP on the remote access server, plaintext passwords are never sent by the dial-up client. Disabling support for PAP increases authentication security, but remote access clients who only support PAP cannot connect.

- If your password expires, PAP cannot change passwords during the authentication process.

- Make sure your network access server (NAS) supports PAP before you enable it on a remote access policy on an IAS server. For more information, see your NAS documentation.

- You cannot use Microsoft Point-to-Point Encryption (MPPE) with PAP.

# Unauthenticated access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Unauthenticated access**
The Windows Server 2003 family supports unauthenticated access, which means that user credentials (a user name and password) are not required. There are some situations where unauthenticated access is useful. This section covers:

- DNIS authorization
- ANI/CLI authentication
- Guest authentication

**Important**

- When you enable unauthenticated access, remote access users are connected without sending user credentials. An unauthenticated remote access client does not negotiate the use of a common authentication protocol during the connection establishment process and does not send a user name or password.

  Unauthenticated access with remote access clients could occur when the authentication protocols configured by the remote access client do not match those configured on the remote access server. In this case, the use of a common authentication protocol is not negotiated and the remote access client does not send a user name and password.

# DNIS authorization

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DNIS authorization**

Dialed Number Identification Service (DNIS) enables authorization of a connection attempt based on the number called. DNIS identifies the number that was called to the receiver of the call and is provided by most standard telephone companies. For example, you could allow all connections that connect through a specific toll-free number. To identify DNIS-based connections and apply the appropriate connection settings, you must do the following:

1. Enable unauthenticated access on the remote access server. For more information, see Enable authentication protocols.

2. Create a remote access policy on the authenticating server (remote access server or IAS server) for DNIS-based authorization with the Called-Station-Id condition set to the phone number. For more information, see Introduction to remote access policies and Add a remote access policy.

3. Enable unauthenticated access on the remote access policy for DNIS-based authorization. For more information, see Configure authentication.

### Notes

- If your phone service or hardware does not support DNIS, the passing of the number that was called, you can manually set the phone number of the port. For more information, see Set the phone number on a port.

- IAS does not support proxied DNIS access requests.

# ANI/CLI authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ANI/CLI authentication**
Automatic Number Identification/Calling Line Identification (ANI/CLI) authentication is the authentication of a connection attempt based on the phone number of the caller. ANI/CLI service returns the number of the caller to the receiver of the call and is provided by most standard telephone companies.

ANI/CLI authentication is different from caller ID authorization. In caller ID authorization, the caller sends a valid user name and password. The caller ID that is configured for the dial-in property on the user account must match the connection attempt; otherwise, the connection attempt is rejected. In ANI/CLI authentication, a user name and password are not sent.

To identify ANI/CLI-based connections and apply the appropriate connection settings, you must do the following:

1. Enable unauthenticated access on the remote access server. For more information, see Enable authentication protocols.

2. Enable unauthenticated access on the appropriate remote access policy for ANI/CLI-based authentication. For more information, see Introduction to remote access policies and Configure authentication.

3. Create a user account for each number that will be calling for which you want to provide ANI/CLI authentication. The name of the user account must match the number that the user is dialing from. For example, if a user is dialing in from 555-0100, create a "5550100" user account.

4. Set the following registry value to 31 on the authenticating server (either the remote access server or the IAS server):

   **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\RemoteAccess\Policy\User Identity Attribute**

   This registry setting tells the authenticating server to use the calling number (RADIUS attribute 31, Calling-Station-ID) as the identity of the calling user. The user identity is set to the calling number only when there is no user name being supplied in the connection attempt.

   To always use the calling number as the user identity, set the following registry value to 1 on the authenticating server:

   **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\RemoteAccess\Policy\Override User-Name**

   However, if you set **Override User-Name** to 1 and the **User Identity Attribute** to 31, the authenticating server can only perform ANI/CLI-based authentication. Normal authentication by using authentication protocols such as MS-CHAP, CHAP, and EAP is disabled.

### Note

- Changes to the registry settings will not take effect until the Routing and Remote Access service or the Internet Authentication Service are restarted.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

# Guest authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Guest authentication**
By default, the Windows Server 2003 family includes a user account called Guest. With guest authentication, during the authentication process, the caller does not send a user name or password. If unauthenticated access is enabled, by default the Guest account is used as the identity of the caller.

To enable Guest account access, you must do the following:

1. Enable unauthenticated access on the remote access server. For more information, see Enable authentication protocols.

2. Enable unauthenticated access on the appropriate remote access policy. For more information, see Configure authentication.

3. Enable the Guest account. For more information, see To enable a disabled user account.

4. Set the remote access permission on the Guest account to either **Allow access** or **Control access through Remote Access Policy** depending on your remote access policy administrative model. For more information, see Remote Access Policies Examples and Configure remote access permission for a user.

If you want to enable a guest account that is not named **Guest**, create a user account and set the remote access permission to either **Allow access** or **Control access through Remote Access Policy**. Then, set the following registry value on the authenticating server (either the remote access server or the IAS server) to the name of the account:

**HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\RemoteAccess\Policy\Default User Identity**

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**Notes**

- Changes to the registry setting will not take effect until the Routing and Remote Access service or the Internet Authentication Service are restarted.

- For more information about how to modify registry keys and set values, see "Remote Access Server" at the Microsoft Windows Resource Kits Web site.

# Remote Access Policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote access policies**
This section covers:

- Introduction to remote access policies
- Dial-in properties of a user account
- Elements of a remote access policy
- Accepting a connection attempt
- Remote Access Policies Examples

# Introduction to remote access policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Introduction to remote access policies**

In Windows NT versions 3.5, 3.51, and 4.0, authorization was based on a **Grant dial-in permission to user** option in either User Manager or the Remote Access Admin utility. An individual user configured callback options. For the Routing and Remote Access service and Internet Authentication Service (IAS) in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; and Windows 2000, network access authorization is granted on the basis of user account dial-in properties and remote access policies.

Remote access policies are an ordered set of rules that define how connections are either authorized or rejected. For each rule, there are one or more conditions, a set of profile settings, and a remote access permission setting.

If a connection is authorized, the remote access policy profile specifies a set of connection restrictions. The dial-in properties of the user account also provide a set of restrictions. Where applicable, user account connection restrictions override the remote access policy profile connection restrictions.

For information about connection restrictions that can be configured on a user account, see Dial-in properties of a user account. For information about connection restrictions that can be configured through a remote access policy profile, see Elements of a remote access policy.

Remote access policies validate a number of connection settings before authorizing the connection, including the following:

- Remote access permission
- Group membership
- Type of connection
- Time of day
- Authentication methods
- Advanced conditions:
    - Access server identity
    - Access client phone number or MAC address
    - Whether user account dial-in properties are ignored
    - Whether unauthenticated access is allowed

After the connection is authorized, remote access policies can also be used to specify connection restrictions, including the following:

- Idle timeout time
- Maximum session time
- Encryption strength
- IP packet filters
- Advanced restrictions:

- IP address for PPP connections
- Static routes

Additionally, you can vary connection restrictions based on the following settings:

- Group membership
- Type of connection
- Time of day
- Authentication methods
- Identity of the access server
- Access client phone number or MAC address
- Whether unauthenticated access is allowed

For example, you can have policies that specify different maximum session times for different types of connections or groups. Additionally, you can specify restricted access for business partners or unauthenticated connections.

**Authorizing access**
There are two ways to use remote access policies to grant authorization:

1. By user
2. By group

**Authorization by user**
If you are managing authorization by user, set the remote access permission on the user or computer account to either **Grant access** or **Deny access** and, optionally, create different remote access policies based on different types of connections. For example, you might want to have one remote access policy that is used for dial-up connections and a different remote access policy that is used for wireless connections. Managing authorization by user is recommended only when you have a small number of user or computer accounts to manage.

If you are managing authorization by user, the basic process for authorizing a connection attempt occurs as follows:

- If the connection attempt matches all policy conditions, check the remote access permission setting of the account.
    - If the remote access permission is set to **Grant access**, apply the connection settings of the policy profile and user account.
    - If the remote access permission is set to **Deny access**, reject the connection attempt.
- If the connection attempt does not match all policy conditions, process the next remote access policy.

If the connection attempt does not match all conditions of any remote access policy, reject the connection attempt.

**Authorization by group**
If you are managing authorization by group, set the remote access permission on the user account to **Control access through Remote Access Policy** and create remote access policies that are based on different types of connections and group membership. For example, you might want to have one remote access policy for dial-up connections for employees (members of the Employees group) and a different remote access policy for dial-up connections for contractors (members of the Contractors group).

If you are managing authorization by group, the basic process for authorizing a connection attempt occurs as follows:

- If the connection attempt matches all policy conditions, check the remote access permission of the remote access policy.
    - If the remote access permission is set to **Grant remote access permission**, apply the connection settings of the policy profile and user account.
    - If the remote access permission is set to **Deny remote access permission**, reject the connection attempt.
- If the connection attempt does not match all policy conditions, process the next remote access policy.

If the connection attempt does not match all conditions of any remote access policy, reject the connection attempt.

**Notes**

- Setting the remote access permission on user accounts to **Control access through Remote Access Policy** and not using groups to manage network access is not recommended.
- For more information about how connection attempts are processed, see Remote Access Policies Examples

**Remote access policies and the Routing and Remote Access service**

For servers running the Routing and Remote Access service that are configured for the Windows authentication provider, remote access policies are administered from Routing and Remote Access and apply only to the connections of the Routing and Remote Access service server. For servers running the Routing and Remote Access service that are configured for the RADIUS authentication provider, you can no longer configure remote access policies using Routing and Remote Access. If the RADIUS server is an IAS server, remote access policies are administered from Internet Authentication Service.

To centrally manage a single set of remote access policies for multiple remote access or VPN servers using an IAS server, you must do the following:

1. Install the Internet Authentication Service (IAS) as a Remote Authentication Dial-In User Service (RADIUS) server. For more information, see Checklist: Configuring IAS for dial-up and VPN access.
2. Configure IAS with RADIUS clients that correspond to each of the Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition remote access or VPN servers. For more information, see Add RADIUS clients.
3. On the IAS server, create the central set of policies that will be used by all servers running the Routing and Remote Access service. For more information, see Add a remote access policy.
4. Configure each of the servers running the Routing and Remote Access service as RADIUS clients to the IAS server. For more information, see Use RADIUS authentication.

For more information about deploying IAS for centralized remote access policy management, see Using RADIUS for multiple remote access servers.

Centralized management of remote access policies is also used when you have remote access servers that are running Windows NT 4.0 and the Routing and Remote Access Service (RRAS). You can configure this server as a RADIUS client to an IAS server. However, a remote access server running Windows NT 4.0 without RRAS cannot be configured to use centralized remote access policies.

# Dial-in properties of a user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Dial-in properties of a user account**

In Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition; the user account for a stand-alone server or server running Active Directory contains a set of dial-in properties that are used when allowing or denying a connection attempt made by a user. On a stand-alone server, you can set the dial-in properties on the **Dial-in** tab in the user account in Local Users and Groups. On a server running Active Directory, you can set the dial-in properties on the **Dial-in** tab in the user account in Active Directory Users and Computers. On these servers, you cannot use the Windows NT 4.0 User Manager for Domains administrative tool.

The dial-in properties for a user account are:

- **Remote Access Permission (Dial-in or VPN)**

  You can use this property to set remote access permission to be explicitly allowed, denied, or determined through remote access policies. In all cases, remote access policies are used to authorize the connection attempt. If access is explicitly allowed, remote access policy conditions, user account properties, or profile properties can still deny the connection attempt. The **Control access through Remote Access Policy** option is only available on user accounts in a Windows 2000 native domain, a Windows server 2003 domain, or for local accounts on stand-alone servers running Windows 2000, Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition.

  By default, the Administrator and Guest accounts on a stand-alone server or in a Windows 2000 native domain are set to **Control access through Remote Access Policy**. In a Windows 2000 mixed domain, they are set to **Deny access**. New accounts that are created on a stand-alone server or in a Windows 2000 native domain are set to **Control access through Remote Access Policy**. New accounts that are created in a Windows 2000 mixed domain are set to **Deny access**.

  For more information, see Domain and forest functionality.

- **Verify Caller ID**

  If this property is enabled, the server verifies the caller's phone number. If the caller's phone number does not match the configured phone number, the connection attempt is denied.

  Caller ID must be supported by the caller, the phone system between the caller and the remote access server, and the remote access server. On a computer running the Routing and Remote Access service, caller ID support consists of call answering equipment that provides caller ID information and the appropriate Windows Server 2003, Standard Edition ; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition driver to pass the information to the Routing and Remote Access service.

  If you configure a caller ID phone number for a user, and you do not have support for the passing of caller ID information from the caller to the Routing and Remote Access service, the connection attempt is denied.

- **Callback Options**

  If this property is enabled, the server calls the caller back during the connection process. The phone number that is used by the server is set by either the caller or the network administrator.

- **Assign a Static IP Address**

  You can use this property to assign a specific IP address to a user when a connection is made.

- **Apply Static Routes**

You can use this property to define a series of static IP routes that are added to the routing table of the server running the Routing and Remote Access service when a connection is made. This setting is designed for user accounts that a router running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition uses for demand-dial routing. For more information, see One-way initiated demand-dial connections.

For information about configuring dial-in properties for a user account, see Configure dial-in user properties.

**Support for ignoring the dial-in properties of user accounts**
In Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition; you can configure a RADIUS attribute to ignore the dial-in properties of user and computer accounts in the profile properties of a remote access policy. To support multiple types of connections for which IAS provides authentication and authorization, it might be necessary to disable the processing of user account dial-in properties. This can be done to support scenarios in which specific dial-in properties are not required.

For example, the caller-ID, callback, static IP address, and static routes properties are designed for a client that is dialing into a network access server (NAS). These settings are not designed for wireless access points. A wireless access point that receives these settings in the RADIUS message from the IAS server might be unable to process them, which could cause the wireless client to become disconnected. When IAS provides authentication and authorization for users who are both dialing in and accessing the organization network through wireless technology, the dial-in properties must be configured to support either dial-in connections (by setting dial-in properties) or wireless connections (by not setting dial-in properties).

You can use IAS to enable the processing of dial-in properties for user and computer accounts in some scenarios (such as dial-in), and to disable the processing of dial-in properties for user and computer accounts in other scenarios (such as wireless and authenticating switch). This is done by configuring the **Ignore-User-Dialin-Properties** attribute on the **Advanced** tab of the profile settings for a remote access policy. For more information, see Add RADIUS attributes to a remote access policy.

The **Ignore-User-Dialin-Properties** attribute is set to the following:

- To enable the processing of dial-in properties for a user account, delete the **Ignore-User-Dialin-Properties** attribute or set it to **False**. For example, for a remote access policy that is designed for dial-in connections, no additional configuration is required.

- To disable the processing of dial-in properties for a user account, set the **Ignore-User-Dialin-Properties** attribute to the value of **True**. For example, this is set for the remote access policy that is used for wireless or authenticating switch connections. When the dial-in properties of the user account are ignored, remote access permission is determined by the setting in the remote access policy.

### Notes

- For a user account in a Windows NT 4.0 domain or a Windows 2000 mixed domain:

    - Only the dial-in properties named **Remote Access Permission (Dial-in or VPN)** (**Allow access** and **Deny access** options) and **Callback Options** are available.

    - You can use the Windows NT 4.0 User Manager for Domains administrative tool to grant or deny dial-in access and set callback options.

- If a user account is in a Windows 2000 native domain, the callback number can be up to 128 characters in length. If a user account is on a stand-alone remote access server, in a Windows NT 4.0 domain, or in a Windows 2000 mixed domain, the callback number can contain 24 through 48 characters. This is due to the compressed format for storing callback numbers.

- When a remote access server running Windows NT 4.0 uses a Windows 2000 native domain to obtain the dial-in properties of a user account, the **Control access through Remote Access Policy** remote access permission setting is retrieved as **Deny access**. Callback settings are retrieved correctly.

  For more information, see Domain and forest functionality.

- A remote access server running Windows NT 4.0 cannot use remote access policies. If you upgrade this remote access server with the Routing and Remote Access Service (RRAS) and configure it for RADIUS authentication, you can use the remote access policies of an IAS server. Alternately, you can upgrade this remote access server with a member of the Windows 2000 server family; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition.

- User accounts upgraded to Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition that were configured with dial-in permission enabled are set to **Allow access**. Those that were configured with dial-in permission disabled are set to **Deny access**.

- It is possible to ignore all of the user or computer account properties. For more information, see the section "Ignoring the dial-in properties of user accounts" in New features for IAS.

- In Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition; computer accounts also have dial-in properties and are similar to user accounts. This new feature allows computers to be authenticated as if they were users, and is used when an IEEE 802.1x Ethernet client uses EAP-TLS and an installed computer certificate to authenticate itself to an Ethernet switch.

- The **Ignore-User-Dialin-Properties** attribute disables the use of all dial-in properties for the user account. Specific dial-in properties cannot be selectively disabled.

# Elements of a remote access policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Elements of a remote access policy**

A remote access policy is a named rule that consists of the following elements:

- Conditions
- Remote access permission
- Profile

**Conditions**

Remote access policy conditions are one or more attributes that are compared to the settings of the connection attempt. If there are multiple conditions, then all of the conditions must match the settings of the connection attempt in order for it to match the policy.

The following table shows the condition attributes that you can set for a remote access policy.

| Attribute name | Description |
|---|---|
| Authentication Type | The type of authentication that is being used by the access client. Authentication types include CHAP, EAP, MS-CHAP, and MS-CHAP v2. |
| Called Station ID | The phone number of the network access server (NAS). This attribute is a character string. You can use pattern matching syntax to specify area codes. For more information, see Pattern matching syntax. In order to receive called station ID information during a call, the phone line, the hardware, and the Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition driver for the hardware must support passing the called ID. Otherwise, the called station ID is manually set for each port. To manually set phone numbers on ports, see Set the phone number on a port. |
| Calling Station ID | The phone number used by the caller. This attribute is a character string. You can use pattern matching syntax to specify area codes. For more information, see Pattern matching syntax. For more information about obtaining the calling station ID, see Caller ID and callback. |
| Client Friendly Name | The name of the RADIUS client that is requesting authentication. This name is configured in **Friendly name** on the **Settings** tab in the properties of a RADIUS client in Internet Authentication Service. This attribute is a character string. You can use pattern matching syntax to specify client names. For more information, see Pattern matching syntax. This attribute is used by the IAS server. |
| Client IP Address | The IP address of the RADIUS client. This can be the IP address of either the originating RADIUS client or an intermediate RADIUS proxy. This attribute is a character string. You can use pattern matching syntax to specify IP networks. For more information, see Pattern matching syntax. This attribute is used by the IAS server. |
| Client Vendor | The vendor of the network access server (NAS) that is requesting authentication. The Routing and Remote Access service is the **Microsoft** NAS manufacturer. You can use this attribute to configure separate policies for different NAS manufacturers who are RADIUS clients to an IAS server. This attribute is used by the IAS server. Ensure that you configure the NAS as a RADIUS client on the IAS server. For more information, see Add RADIUS clients. |
| Day and Time Restrictions | The day of the week and the time of day of the connection attempt. The day and time is relative to the day and time of the server providing the authorization. |
| Framed Protocol | The type of framing for incoming packets. Examples are PPP, SLIP, Frame Relay, and X.25. This attribute is used by the IAS server. |

| | |
|---|---|
| NAS Identifier | The name of the network access server (NAS). This attribute is a character string. You can use pattern matching syntax to specify multiple NASs. For more information, see Pattern matching syntax. This attribute is used by the IAS server. |
| NAS IP Address | The IP address of the NAS (the RADIUS client) that sent the message. This attribute is a character string. You can use pattern matching syntax to specify IP networks. For more information, see Pattern matching syntax. This attribute is used by the IAS server. |
| NAS Port Type | The type of media that is used by the access client. Examples include analog phone lines (known as async), ISDN, tunnels or virtual private networks (known as virtual), IEEE 802.11 wireless, and Ethernet switches. |
| Service Type | The type of service that is being requested. Examples include framed (such as PPP connections) and login (such as Telnet connections). For more information about RADIUS service types, see RFC 2865, "Remote Authentication Dial-in User Service (RADIUS)." This attribute is used by the IAS server. |
| Tunnel Type | The type of tunnel that is being created by the requesting client. Tunnel types include the Point-to-Point Tunneling Protocol (PPTP) and the Layer Two Tunneling Protocol (L2TP), which are used by Windows XP; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; and Windows 2000, remote access clients and demand-dial routers. You can use this condition to specify profile settings, such as authentication methods or encryption strengths for a specific type of tunneling technology. |
| Windows Groups | The names of the groups to which the user or computer account that is attempting the connection belongs. There is no condition attribute for a specific user or computer name. It is not necessary to have a separate remote access policy for each group. Instead, you can use multiple groups or nested groups to consolidate and delegate the administration of group membership. For a remote access or IAS server in a Windows 2000 native domain, you can use universal groups. For more information, see Domain and forest functionality. |

**Notes**

- If conditions that use an IAS server attribute are evaluated against a Routing and Remote Access service server that is configured for Windows authentication, they do not match and the policy is not applied.
- Not all access servers send all of the IAS server-specific attributes.
- You cannot use the built-in local or domain groups for the Windows Groups attribute.

**Remote access permission**

If all conditions of a remote access policy are met, remote access permission is either granted or denied. You can use either the **Grant remote access permission** option or the **Deny remote access permission** option to set remote access permission for a policy.

Remote access permission is also granted or denied for each user account. The user remote access permission overrides the policy remote access permission. When remote access permission on a user account is set to the **Control access through Remote Access Policy** option, the policy remote access permission determines whether the user is granted access.

Granting access through either the user account permission setting or the policy permission setting is only the first step in accepting a connection. The connection attempt is subject to the settings of both the user account dial-in properties and policy profile properties. If the connection attempt does not match the settings of the user account or policy profile properties, the connection attempt is rejected.

**Profile**

A remote access policy profile is a set of properties that are applied to a connection when it is authorized--either through the user account or policy permission settings. A profile consists of the following groups of properties:

- Dial-in constraints
- IP
- Multilink

- Authentication
- Encryption
- Advanced

**Dial-in constraints**

You can set the following dial-in constraints:

- **Minutes server can remain idle before it is disconnected**

  The time after which a connection is disconnected when there is no activity. By default, this property is not set. Additionally, the Routing and Remote Access service does not disconnect an idle connection.

- **Minutes client can be connected**

  The maximum amount of time that a connection is connected. The connection is disconnected by the access server after the maximum session length. By default, this property is not set and there is no maximum session limit.

- **Allow access only on these days and at these times**

  The days of the week and hours of each day that a connection is allowed. If the day and time of the connection attempt do not match the configured day and time limits, the connection attempt is rejected. By default, this property is not set and there are no day or time limits. The Routing and Remote Access service does not disconnect active connections that were previously connected at a time when connection attempts were allowed.

- **Allow access to this number only**

  The specific phone number that a caller must call in order for a connection to be allowed. If the dial-in number of the connection attempt does not match the configured dial-in number, the connection attempt is rejected. By default, this property is not set and all dial-in numbers are allowed.

- **Allow access only through these media**

  The specific types of media, such as modem (also known as async), ISDN, virtual private network (known as virtual), or 802.11 wireless that a caller must use in order for a connection to be allowed. If the dial-in medium of the connection attempt does not match the configured dial-in media, the connection attempt is rejected. By default, this property is not set and all media types are allowed.

For information about setting dial-in constraints on a profile, see Configure dial-in constraints.

**IP**

You can set IP properties that specify IP address assignment behavior. You have the following options:

- The access server must supply an IP address.
- The access client can request an IP address.
- IP address assignment is determined by the access server (this is the default setting).
- A static IP address is assigned. A static IP address assigned to the user account overrides this setting. The IP address assigned is typically used to accommodate vendor-specific attributes for IP addresses.

You can also use the **IP** tab to define IP packet filters that apply to remote access connection traffic. This is intended for use with the Routing and Remote Access service. You can configure IP traffic that is allowed to remote access clients (output filters) or from remote access clients (input filters) on an exception basis. Either all traffic is allowed, except traffic specified by filters; or all traffic is blocked, except traffic specified by filters . Remote access policy profile filtering applies to all remote access

connections that match the remote access policy.

Filters configured on the **IP** tab are applied to client connections on a Windows Server 2003 remote access server, but are not applied to dial-on-demand connections.

For information about setting IP options on a profile, see Configure IP options.

**Multilink**
You can set Multilink properties that both enable Multilink and determine the maximum number of ports that a Multilink connection can use. Additionally, you can set Bandwidth Allocation Protocol (BAP) policies that both determine BAP usage and specify when extra BAP lines are dropped. The Multilink and BAP properties are specific to the Routing and Remote Access service. By default, Multilink and BAP are disabled.

The Routing and Remote Access service must have Multilink and BAP enabled in order for the Multilink properties of the profile to be enforced. For more information about enabling Multilink and BAP for the Routing and Remote Access service, see Enable Multilink and Enable BAP and BACP.

For information about setting Multilink options on a profile, see Configure multilink options.

**Authentication**
You can set authentication properties to both enable the authentication types that are allowed for a connection and specify the EAP type that must be used. Additionally, you can configure the EAP type. By default, Microsoft Encrypted Authentication (MS-CHAP) and Microsoft Encrypted Authentication version 2 (MS-CHAP v2) are enabled. With Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition; you can specify whether users can change their expired passwords using MS-CHAP and MS-CHAP v2 (enabled by default). For more information, see Authentication methods.

The Routing and Remote Access service must have the corresponding authentication types enabled in order for the authentication properties of the profile to be enforced. For more information about enabling authentication methods for the Routing and Remote Access service, see Enable authentication protocols.

For information about setting authentication options on a profile, see Configure authentication.

**Encryption**
You can set encryption properties for the following encryption strengths:

- **No Encryption**

  This option allows a nonencrypted connection. To require encryption, clear this option.

- **Basic**

  For dial-up and PPTP-based VPN connections, Microsoft Point-to-Point Encryption (MPPE) is used with a 40-bit key. For L2TP/IPSec VPN connections, 56-bit Data Encryption Standard (DES) encryption is used.

- **Strong**

  For dial-up and PPTP VPN connections, MPPE is used with a 56-bit key. For L2TP/IPSec VPN connections, 56-bit DES encryption is used.

- **Strongest**

  For dial-up and PPTP VPN connections, MPPE is used with a 128-bit key. For L2TP/IPSec VPN connections, triple DES (3DES) encryption is used.

These settings are intended to be used with Routing and Remote Access. When other access servers are used, select **No Encryption** and clear all encryption strengths.

For information about setting encryption options on a profile, see Configure encryption.

**Advanced**
You can set advanced properties to specify the series of RADIUS attributes that are sent back by the IAS server to be evaluated by the RADIUS client. RADIUS attributes are specific to performing RADIUS authentication, and are ignored by a server that is

running the Routing and Remote Access service and is configured for Windows authentication. By default, **Framed-Protocol** is set to **PPP** and **Service-Type** is set to **Framed**.

The only advanced attributes that are used by the Routing and Remote Access service are **Account-Interim-Interval**, **Framed-Protocol**, **Framed-MTU**, **Reply-Message**, and **Service-Type**.

For information about setting advanced options on a profile, see Add RADIUS attributes to a remote access policy.

**Notes**

- Some elements of a remote access policy correspond to RADIUS attributes that are used during RADIUS-based authentication. For remote access policies on an Internet Authentication Service (IAS) server, verify that the access servers used are sending RADIUS attributes that correspond to the configured remote access policy conditions and profile settings. If a NAS does not send a RADIUS attribute that corresponds to a remote access policy condition or profile setting, then all RADIUS authentications from that NAS are denied.

- You can only use the Generate-Session-Timeout attribute if your user account database is a Security Accounts Manager (SAM) database or is the user account database for an Active Directory domain. When the value of **Generate-Session-Timeout** is set to **True**, the **ForceLogoff** value for a SAM database should be set to **0**. In the Local Security Settings console, ForceLogoff is changed to zero when **Network security: Force logoff when logon hours expire** is enabled. For information about how to change the ForceLogoff value for the SAM database at the command prompt, see Net accounts.

- You can configure wireless connection policy so that wireless clients periodically reauthenticate. This ensures that the client Wired Equivalent Privacy (WEP) encryption keys are changed often enough to provide adequate security for the wireless connection. To configure reauthentication, set the session timeout in your remote access policy or connection request policy for wireless connections (using the Session-Timeout attribute) to the required interval (for example, 10 minutes). Additionally, configure the Termination-Action attribute with the **Attribute value** set to **RADIUS-Request**. If the Termination-Action attribute is not set to **RADIUS-Request**, wireless access points might end the connection during reauthentication. For more information, see your hardware documentation.

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Accepting a connection attempt

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accepting a connection attempt**

When a user attempts a connection, the connection attempt is accepted or rejected, based on the following logic:

1. The first policy in the ordered list of remote access policies is checked. If there are no policies, reject the connection attempt.

2. If all conditions of the policy do not match the connection attempt, go to the next policy. If there are no more policies, reject the connection attempt.

3. If all conditions of the policy match the connection attempt, check the value of the **Ignore-User-Dialin-Properties** attribute.

4. If the **Ignore-User-Dialin-Properties** attribute is set to **False**, check the remote access permission setting for the user attempting the connection.

   - If **Deny access** is selected, reject the connection attempt.

   - If **Allow access** is selected, apply the user account and profile properties. If the connection attempt does not match the settings of the user account and profile properties, reject the connection attempt. If the connection attempt matches the settings of the user account and profile properties, accept the connection attempt.

   - If the remote access permission is not set to **Allow access** or **Deny access**, the remote access permission must be set to **Control access through Remote Access Policy**. Check the remote access permission setting of the policy.

     If **Deny remote access permission** is selected, reject the connection attempt.

     If **Grant remote access permission** is selected, apply the user account and profile properties. If the connection attempt does not match the settings of the user account and profile properties, reject the connection attempt. If the connection attempt matches the settings of the user account properties and profile, accept the connection attempt.

5. If the **Ignore-User-Dialin-Properties** attribute is set to **True**, check the remote access permission setting of the policy.

   - If **Deny remote access permission** is selected, reject the connection attempt.

   - If **Grant remote access permission** is selected, apply the profile properties. If the connection attempt does not match the settings of the profile properties, reject the connection attempt. If the connection attempt matches the settings of the profile properties, accept the connection attempt. The following illustration shows the logic of remote access policies.

**Notes**

- The profile and user account settings for the first matching policy are applied to the connection. If a connection does not match the profile or user account settings of the remote access policy, the additional remote access policies are not tried.

- A connection attempt might not match any of the remote access policies. If this is the case, the connection attempt is rejected regardless of the remote access permission setting on the user account.

- The remote access polices are tried in order. The more specific remote access policies are typically placed in order ahead of the more general remote access policies.

- The **Ignore-User-Dialin-Properties** attribute is a new feature for Windows Server 2003, Standard Edition ; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition that allows you to ignore all of the dial-in properties of a user account. For more information, see New features for IAS.

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

For examples of how different connection attempts are processed, see Remote Access Policies Examples.

# Remote Access Policies Examples

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote access policies examples**

Remote access policies provide a tremendous amount of flexibility in accepting connections based on policy evaluation order, policy conditions, user and policy dial-in permissions, and both policy profile and user account properties.

This section describes some examples in which remote access policies are used:

- Grant remote access per user
- Allow dial-up connection using group membership
- Restrict connections to a maximum session time
- Wireless access example
- Wireless access with secure password authentication
- Ethernet switch access
- Force VPN clients to use strongest encryption
- Apply packet filters for business partner extranet
- Send NAS-specific RADIUS attributes to a RADIUS client

# Grant remote access per user

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Grant remote access per user**

In this example, the network administrator wants to maintain the same administrative model as used in Windows NT 4.0. Dial-in access is granted on a per-user basis by modifying the remote access permission setting of the user account dial-in properties. The remote access permission is set to either **Allow access** or **Deny access**. This is the default behavior for remote access policies.

You can create a policy named **Allow access if dial-in permission is enabled**. The settings on this policy are configured as follows:

- A single condition that consists of the **Day-And-Time-Restrictions** attribute is set for all times on all days.
- The **Deny remote access permission** option is selected.
- The profile is set to the default settings.

When a user attempts a remote access connection, the following logic is used to accept or reject the attempt (assuming that the default settings are set for all the other user account dial-in properties):

1. The policy **Allow access if dial-in permission is enabled** is evaluated.
2. The settings of the connection attempt match the conditions of the policy (the connection attempt occurs on any day or at any time).
3. On the user account, the setting in **Remote Access Permission (Dial-in or VPN)** is evaluated.
    - If **Allow access** is selected, the connection is accepted, subject to the settings of the user account dial-in and profile properties.
    - If **Deny access** is selected, the connection is rejected.

# Allow dial-up connection using group membership

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Allow dial-up connection using group membership**
In this example, the network administrator is managing authorization by using groups. All user accounts have the **Remote Access Permission (Dial-in or VPN)** option set to **Control access through Remote Access Policy**.

The network administrator wants to allow dial-up connections for only those user accounts that belong to a specific set of groups. After remote access permission is set for all user accounts, the administrator completes the following steps:

1. Use the New Remote Access Policy Wizard to create a common dial-up policy with the following settings:

   - Policy name: Dial-up access for allowed groups
   - Access Method: Dial-up access
   - User or Group: Select **Group**, and then specify the set of groups for which dial-up access is allowed.
   - Authentication methods: Select **Microsoft Encrypted Authentication version 2 (MS-CHAP v2)** and **Microsoft Encrypted Authentication**.
   - Policy Encryption Level: Select all check boxes.

     For more information, see Add a remote access policy.

2. Delete the default policies.

   For more information, see Delete a remote access policy.

**Notes**

- It is not necessary to have a separate remote access policy for each group. You can specify multiple groups or you can use nested groups to both delegate administration of and consolidate group membership. For a remote access or IAS server in a Windows 2000 native domain or a Windows Server 2003 domain, you can use universal groups. For more information, see Domain and forest functionality.
- You cannot use built-in or local domain groups when specifying group names.

# Restrict connections to a maximum session time

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Restrict connections to a maximum session time**
In this example, the network administrator is managing authorization by using groups. All user accounts have the **Remote Access Permission (Dial-in or VPN)** option set to **Control access through Remote Access Policy**.

To conserve limited remote access server connection resources, the network administrator wants to limit the maximum session time for all dial-up users (members of the DialUpUsers group) to 20 minutes.

To implement this restriction through a remote access policy, the administrator completes the following steps:

**Use the New Remote Access Policy Wizard to create a custom policy with the following settings:**

- Policy name: Maximum session time of 20 minutes
- Conditions: NAS-Port-Type matches Async (Modem); Windows-Groups matches DialUpUsers
- Permission: Grant remote access permission
- Profile settings, **Dial-in Constraints** tab: Select the **Minutes client can be connected** check box, and then type **20**.

For more information, see Add a remote access policy.

**Delete the default policies.**
For more information, see Delete a remote access policy.

# Wireless access example

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Wireless access example**
In this example, the network administrator is managing authorization by using groups. All user accounts have the **Remote Access Permission (Dial-in or VPN)** option set to **Control access through Remote Access Policy**.

The network administrator requires that all IEEE 802.11 wireless clients (members of the WirelessClients group) use certificate-based authentication through the EAP-TLS authentication protocol and 128-bit encryption. Wireless clients that do not have a user certificate installed are placed on a specific virtual local area network (VLAN) from which they can obtain a user certificate. This unauthenticated connection lasts for 10 minutes.

In this case, two policies are needed:

1. A policy that requires wireless connections to use EAP-TLS.

2. A policy that accepts unauthenticated wireless connections and configures the wireless access point for a VLAN with an ID of 3. VLAN 3 contains a certificate server from which the wireless client can obtain a user certificate.

After remote access permission is set for all user accounts, the administrator completes the following steps:

1. Use the New Remote Access Policy Wizard to create a common wireless policy with the following settings:

   - Policy name: Wireless access

   - Access Method: Wireless access

   - User or Group: Select **Group**, and then specify the WirelessClients group (example).

   - Authentication methods: Select **Smart Card or other Certificate**.

   - Policy Encryption Level: Check the **Strongest encryption (MPPE 128-bit)** check box, and then clear all other check boxes.

2. Use the New Remote Access Policy Wizard to create a custom wireless policy with the following settings:

   - Policy name: First-time wireless access

   - Conditions: NAS-Port-Type matches Wireless-Other or Wireless-IEEE 802.11; Windows-Groups matches WirelessUsers; Authentication-Type matches Unauthenticated

   - Permission: Grant remote access permission

   - Profile settings, **Dial-in Constraints** tab: Select the **Minutes client can be connected** check box, and then type **10**.

   - Profile settings, **Advanced** tab: Add the **Tunnel-Type** attribute with the value of **Virtual LANs (VLAN)**; Add the **Tunnel-Pvt-Group-ID** attribute with the value of **3**.

3. Delete the default policies.

   For more information, see Delete a remote access policy.

**Notes**

- For this example, a public key infrastructure (PKI) that has allocated the required computer certificate to the IAS server is being used. Additionally, the wireless access point is configured to use both an IAS server as its RADIUS server and EAP. For more information about wireless access deployment, see Checklist: Configuring the IAS server and wireless access points for wireless access.

- You can configure wireless connection policy so that wireless clients periodically reauthenticate. This ensures that the client Wired Equivalent Privacy (WEP) encryption keys are changed often enough to provide adequate security for the wireless connection. To configure reauthentication, set the session timeout in your remote access policy or connection request policy for wireless connections (using the Session-Timeout attribute) to the required interval (for example, 10 minutes). Additionally, configure the Termination-Action attribute with the **Attribute value** set to **RADIUS-Request**. If the Termination-Action attribute is not set to **RADIUS-Request**, wireless access points might end the connection during reauthentication. For more information, see your hardware documentation.

# Wireless access with secure password authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Wireless access with secure password authentication**
In this example, the network administrator is managing authorization by using groups. All user accounts have the **Remote Access Permission (Dial-in or VPN)** option set to **Control access through Remote Access Policy**.

The network administrator requires that all IEEE 802.11 wireless clients (members of the *WirelessClientsGroupName*) use Protected Extensible Authentication Protocol, or PEAP, for secure password authentication on the network. PEAP uses Transport Level Security (TLS) to create an end-to-end (EAP client to EAP authenticator) encrypted connection after verifying the identity of the authenticator (typically, an IAS server). The IAS server authenticates itself to the client with a certificate that includes the Server Authentication purpose in Enhanced Key Usage (EKU) extensions.

Because PEAP is used with EAP-MS-CHAPv2 as the authentication type, user authentication is accomplished with password-based credentials that are typed by the user. PEAP with EAP-MS-CHAPv2, also called PEAP-EAP-MS-CHAPv2, eliminates the need to deploy certificates to wireless clients for the purpose of client computer and user authentication.

For more information, see Network access authentication and certificates.

**Note**

- You can also use PEAP with EAP-TLS (also known as PEAP-EAP-TLS), which provides strong security. PEAP-EAP-TLS uses a public key infrastructure with certificates, which are used for server authentication, and either smart cards or certificates for client computer and user authentication. When you use PEAP-EAP-TLS, client certificate information is encrypted, providing improved security over EAP-TLS without PEAP.

After remote access permission is set for all user accounts, the administrator completes the following steps:

1. Use the New Remote Access Policy Wizard to create a common wireless policy with the following settings:

   - Policy name: Wireless access
   - Access Method: Wireless access
   - User or Group: Select **Group**, and then specify the WirelessClients group (example).
   - Authentication methods: Select **Protected Extensible Authentication Protocol (PEAP)**.
   - Policy Encryption Level: Check the **Strongest encryption (MPPE 128-bit)** check box, and then clear all other check boxes.

2. Delete the default policies.

   For more information, see Delete a remote access policy.

When you select PEAP as the authentication method, the default authentication type is EAP-MS-CHAPv2. The following defaults are used:

- **Number of authentication retries:** 0
- **Allow client to change password** (not selected)

To change these settings, complete the steps in Configure PEAP and EAP methods.

**Notes**

- Although the deployment of certificates for user and client computer authentication is more difficult than using PEAP with EAP-MS-CHAPv2, certificates are more secure and PEAP with EAP-TLS with smart cards or certificates is the recommended authentication method for wireless clients.

- You can configure wireless connection policy so that wireless clients periodically reauthenticate. This ensures that the client Wired Equivalent Privacy (WEP) encryption keys are changed often enough to provide adequate security for the wireless connection. To configure reauthentication, set the session timeout in your remote access policy or connection request policy for wireless connections (using the Session-Timeout attribute) to the required interval (for example, 10 minutes). Additionally, configure the Termination-Action attribute with the **Attribute value** set to **RADIUS-Request**. If the Termination-Action attribute is not set to **RADIUS-Request**, wireless access points might end the connection during reauthentication. For more information, see your hardware documentation.

# Ethernet switch access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Ethernet switch access example**

In this example, the network administrator is managing authorization by using groups. All computer accounts have the **Remote Access Permission (Dial-in or VPN)** option set to **Control access through Remote Access Policy**.

The network administrator wants all Ethernet switch clients (members of the SwitchClients group) to use password-based authentication through the Extensible Authentication Protocol (EAP) and the Message Digest 5 (MD5) Challenge EAP type. After remote access permission is set for all computer accounts, the administrator completes the following steps:

1. Use the New Remote Access Policy Wizard to create a common dial-up policy with the following settings:

   - Policy name: Ethernet access for switch clients
   - Access Method: Ethernet
   - User or Group: Select **Group**, and then specify the SwitchClients group (example).
   - Authentication methods: Select the **MD5-Challenge** EAP type.

     For more information, see Add a remote access policy.

2. Delete the default policies.

   For more information, see Delete a remote access policy.

**Note**

- This example assumes that the Ethernet switch has been configured to use both EAP and an IAS server as its RADIUS server. For more information about Ethernet switch deployment, see Ethernet switch access with IAS

# Force VPN clients to use strongest encryption

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Force VPN clients to use strongest encryption**
In this example, the network administrator is managing authorization by using groups. All user accounts have the **Remote Access Permission (Dial-in or VPN)** option set to **Control access through Remote Access Policy**.

The network administrator wants all virtual private network (VPN) clients (members of the group VPNClients) to use strong encryption. For PPTP connections, 128-bit Microsoft Point-to-Point Encryption (MPPE) must be used. For L2TP over IPSec connections, Triple DES (3DES)must be used. After remote access permission is set for all user accounts, the administrator completes the following steps:

1. Use the New Remote Access Policy Wizard to create a common VPN policy with the following settings:

   - Policy name: VPN access with strongest encryption
   - Access Method: VPN access
   - User or Group: Select **Group**, and then specify the VPNClients group (example).
   - Authentication methods: Select **Microsoft Encrypted Authentication version 2 (MS-CHAP v2)** and **Microsoft Encrypted Authentication**.
   - Policy Encryption Level: Select the **Strongest encryption (IPSec triple DES or MPPE 128-bit)** check box, and then clear all other check boxes.

     For more information, see Add a remote access policy.

2. Delete the default policies.

   For more information, see Delete a remote access policy.

# Apply packet filters for business partner extranet

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Apply packet filters for business partner extranet**
In this example, the network administrator is managing authorization by using groups. All user accounts have the **Remote Access Permission (Dial-in or VPN)** option set to **Control access through Remote Access Policy**.

The network administrator wants to restrict access for all business partner virtual private network (VPN) connections to the resources of an extranet--a specific network segment that contains Web and file servers. In this example, the extranet is the subnet of 192.168.47.0/24. All business partner user accounts are members of the Partners group.

After remote access permission is set for all user accounts, the administrator completes the following steps.

**Use the New Remote Access Policy Wizard to create a custom policy with the following settings:**

- Policy name: Business partner connections to extranet
- Conditions: Windows-Groups matches Partners
- Permission: Grant remote access permission
- Profile settings, **Dial-in Constraints** tab: Select **Allow access only through these media** and the **Virtual (VPN)** media type.
- Profile settings, **IP** tab, Input packet filter:
    - Deny all traffic except those listed below
    - Destination network, IP address: 192.168.47.0
    - Destination network, Subnet mask: 255.255.255.0
    - Protocol: Any
- Profile settings, **IP** tab, Output packet filter:
    - Deny all traffic except those listed below
    - Source network, IP address: 192.168.47.0
    - Source network, Subnet mask: 255.255.255.0
    - Protocol: Any
- Profile settings, **Authentication** tab: Select both **Microsoft Encrypted Authentication version 2 (MS-CHAP v2)** and **Microsoft Encrypted Authentication**. For both of these authentication types, select **User can change password after it has expired**.
- Clear all other check boxes.
- Profile settings, **Encryption** tab: Select the **Strongest encryption** check box, and then clear all other check boxes

  For more information, see Add a remote access policy.

**Delete the default policies.**

For more information, see Delete a remote access policy.

# Send NAS-specific RADIUS attributes to a RADIUS client

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Send NAS-specific RADIUS attributes to a RADIUS client**
In this example, the network administrator is managing authorization by using groups. All user accounts have the **Remote Access Permission (Dial-in or VPN)** option set to **Control access through Remote Access Policy**.

The network administrator wants to allow dial-up connections for only those user accounts in the DialUpUsers group and send a series of network access server (NAS) attributes that are specific to the Ascend NAS. After remote access permission is set for all user accounts, the administrator completes the following steps:

1. When the NAS is added as a RADIUS client, configure its manufacturer.

   For more information about configuring a RADIUS client for an IAS server, see Add RADIUS clients.

2. Use the New Remote Access Policy Wizard to create a custom policy with the following settings:

   - Policy name: Allow dial-up connections and send attributes to Ascend NAS
   - Conditions: Client-Vendor matches Ascend Communications, Inc.; NAS-Port-Type matches Async (Modem) ; Windows-Groups matches DialUpUsers
   - Permission: Grant remote access permission
   - Profile settings, **Advanced** tab: Add the appropriate Ascend RADIUS attributes with their correct values.

   For more information, see Add a remote access policy.

3. Delete the default policies.

   For more information, see Delete a remote access policy.

# Connection Request Processing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connection request processing**
This section covers:

- Introduction to connection request processing
- Processing a connection request
- Elements of Connection Request Processing
- Connection Request Processing Examples

# Introduction to connection request processing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Introduction to connection request processing**
In Windows 2000, Internet Authentication Service (IAS) can only be used as a RADIUS server. In Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition, IAS can be used as either a RADIUS server or a RADIUS proxy.

When IAS is used as a RADIUS server:

- Access-Request messages are authenticated through Active Directory or a Windows NT server 4.0 domain, or through the Security Account Manager (SAM) in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition. They are authorized with the user or computer account dial-in properties and remote access policies. Additionally, IAS can return an Access-Accept message without authenticating and authorizing the Access-Request message.

- Accounting-Request messages are logged in a local log file based on remote access logging settings.

**Note**

- IAS can be configured for separate use as an authentication RADIUS server or an accounting RADIUS server.

When IAS is used as a RADIUS proxy:

- Access-Request messages are forwarded to another RADIUS server for authentication and authorization.

- Accounting-Request messages are logged in a local log file (based on remote access logging settings) and forwarded to another RADIUS server for accounting.

**Note**

- IAS can be configured for separate use as an authentication RADIUS proxy or an accounting RADIUS proxy.

To determine whether a specific connection attempt request or an accounting message received from a RADIUS client should be processed locally or forwarded to another RADIUS server, the IAS server uses connection request processing. Connection request processing is a combination of:

- Connection request policies

  Connection request policies determine, for any incoming RADIUS request message, whether the message is processed locally or forwarded to another RADIUS server. For more information, see Connection request policies.

- Remote RADIUS server groups

  Remote RADIUS server groups specify multiple RADIUS servers when an incoming RADIUS request message is forwarded. For more information, see Remote RADIUS server groups.

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an

unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Processing a connection request

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Processing a connection request**

When an IAS server receives a valid RADIUS request message from a RADIUS client, it is processed as follows:

1. The first policy in the ordered list of connection request policies is checked. If there are no policies and the RADIUS message is an Access-Request message, an Access-Reject message is immediately sent. If there are no policies and the RADIUS message is an Accounting-Request message, the message is discarded.

2. If all conditions of the policy do not match the RADIUS request message, then go to the next policy. If there are no additional policies and the RADIUS message is an Access-Request message, an Access-Reject message is immediately sent. If there are no additional policies and the RADIUS message is an Accounting-Request message, the message is discarded.

3. If all conditions of the policy match the RADIUS request message, then apply the attribute manipulation rules that are configured in the policy.

4. If the RADIUS message is an Access-Request message, check the authentication settings on the profile of the matching policy.

   - If the authentication setting requires using this server for authentication, use a Windows NT 4.0 domain or the Active Directory directory service, or the local Security Account Manager (SAM) on Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition; for authentication. Use the matching remote access policy and user or computer account dial-in properties for authorization. For more information, see Accepting a connection attempt.

   - If the authentication setting requires forwarding the Access-Request message to a remote RADIUS server group, forward the Access-Request message to a member of the remote RADIUS server on the basis of priority and weight settings.

   - If the authentication setting requires accepting the connection attempt without performing authentication or authorization, an Access-Accept message is immediately sent.

5. If the RADIUS message is an Accounting-Request message, check the accounting settings on the profile of the matching policy.

   - If the accounting settings specify that accounting information is to be sent to a member of a remote RADIUS server group, forward the accounting message to the appropriate RADIUS server in the group on the basis of priority and weight settings.

   - Based on the settings for remote access logging, record the information in the local accounting log file.

The following illustration shows the logic of connection request policies.

For examples of how different connection requests are processed, see Connection Request Processing Examples.

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Elements of Connection Request Processing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Elements of connection request processing**

- Remote RADIUS server groups

# Connection request policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connection request policies**

Connection request policies are sets of conditions and profile settings that give network administrators flexibility in configuring how incoming authentication and accounting request messages are handled by the IAS server. With connection request policies, you can create a series of policies so that some RADIUS request messages sent from RADIUS clients are processed locally (IAS is being used as a RADIUS server) and other types of messages are forwarded to another RADIUS server (IAS is being used as a RADIUS proxy). This capability allows IAS to be deployed in many new RADIUS scenarios.

With connection request policies, you can use IAS as a RADIUS server or as a RADIUS proxy, based on the time of day and day of the week, by the realm name in the request, by the type of connection being requested, by the IP address of the RADIUS client, and so on.

It is important to remember that with connection request policies, a RADIUS request message is processed only if the settings of the incoming RADIUS request message match at least one of the connection request policies. For example, if the settings of an incoming RADIUS Access-Request message do not match at least one of the connection request policies, an Access-Reject message is sent.

For more information about how incoming RADIUS request messages from RADIUS clients are processed, see Processing a connection request.

To create a connection request policy, see Configure Connection Request Policies.

A connection request policy is a named rule that consists of the following elements:

- Conditions
- Profile

Connection request policies, like remote access policies, operate on the following principle:

- Based on the RADIUS request message matching all of the conditions of a connection request policy, the profile settings of the policy are applied to determine the processing of the message.

**Conditions**

Connection request policy conditions are one or more RADIUS attributes that are compared to the attributes of the incoming RADIUS request message. If there are multiple conditions, then all of the conditions must match the attributes of the incoming RADIUS message in order for the RADIUS request message to match the policy.

The following table shows the condition attributes that you can set for a connection request policy.

| Attribute name | Description |
|---|---|
| Called Station ID | The phone number of the network access server (NAS). This attribute is a character string. You can use pattern matching syntax to specify area codes. For more information, see Pattern matching syntax. |
| Calling Station ID | The phone number used by the caller (the access client). This attribute is a character string. You can use pattern matching syntax to specify area codes. For more information, see Pattern matching syntax. |
| Client Friendly Name | The name of the RADIUS client computer that is requesting authentication. This attribute is a character string. You can use pattern matching syntax to specify client names. For more information, see Pattern matching syntax. |
| Client IP Address | The IP address of the network access server (the RADIUS client). This attribute is a character string. You can use pattern matching syntax to specify IP networks. For more information, see Pattern matching syntax. |

| | |
|---|---|
| Client Vendor | The vendor of the network access server (NAS) that is requesting authentication. A computer running the Routing and Remote Access service is the Microsoft NAS manufacturer. You can use this attribute to configure separate policies for different NAS manufacturers. This attribute is a character string. You can use pattern matching syntax. For more information, see Pattern matching syntax. |
| Day and Time Restrictions | The day of the week and the time of day of the connection attempt. The day and time is relative to the day and time of the IAS server. |
| Framed Protocol | The type of framing for incoming packets. Examples are PPP, SLIP, Frame Relay, and X.25. |
| NAS Identifier | The name of the network access server (NAS). This attribute is a character string. You can use pattern matching syntax to specify NAS identifiers. For more information, see Pattern matching syntax. |
| NAS IP Address | The IP address of the network access server (the RADIUS client). This attribute is a character string. You can use pattern matching syntax to specify IP networks. For more information, see Pattern matching syntax. |
| NAS Port Type | The type of media used by the access client. Examples are analog phone lines (known as async), ISDN, tunnels or virtual private networks (known as virtual), IEEE 802.11 wireless, and Ethernet switches. |
| Remote RADIUS to Windows User Mapping | Specifies that Windows authorization occurs for users authenticated by a remote RADIUS server. For example, visitors to your network from partner organizations can be authenticated by their organization's RADIUS server, and can use a Windows user account at your organization to access a guest local area network (LAN) on your network. For more information, see Mapping network authentication and authorization |
| Service Type | The type of service being requested. Examples include framed (for example, PPP connections) and login (for example, Telnet connections). For more information about RADIUS service types, see RFC 2865, "Remote Authentication Dial-in User Service (RADIUS)." |
| Tunnel Type | The type of tunnel that is being created by the requesting client. Tunnel types include the Point-to-Point Tunneling Protocol (PPTP) and the Layer Two Tunneling Protocol (L2TP), used by Windows XP; Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; and Windows 2000 remote access clients and demand-dial routers. |
| User Name | The user name that is used by the access client in the RADIUS message. This attribute is a character string that typically contains a realm name and a user account name. For more information about realm names, see Realm names. You can use pattern matching syntax to specify user names. For more information, see Pattern matching syntax. |

**Profile**

A connection request policy profile is a set of properties that are applied to an incoming RADIUS message. A connection request policy profile consists of the following groups of properties:

- Authentication
- Accounting
- Attribute manipulation
- Advanced

**Authentication**

You can set the following authentication options that are used for RADIUS Access-Request messages:

- Authenticate requests on this server.

  Use a Windows NT 4.0 domain or the Active Directory directory service, or the local Security Account Manager (SAM) on Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition; for both authentication and the matching remote access policy and user account dial-in properties for

authorization. In this case, the IAS server is being used as a RADIUS server.

- Forward requests to another RADIUS server in a remote RADIUS server group.

  Forward the Access-Request message to another RADIUS server in a specified remote RADIUS server group. If the IAS server receives a valid Access-Accept message that corresponds to the Access-Request message, the connection attempt is considered authenticated and authorized. In this case, the IAS server is being used as a RADIUS proxy.

- Accept the connection attempt without performing authentication or authorization.

  Do not check authentication of the user credentials and authorization of the connection attempt. An Access-Accept message is immediately sent to the RADIUS client. This setting is used for some types of compulsory tunneling where the access client is tunneled before the user's credentials are authenticated. For more information, see IAS and tunnels.

  This authentication option cannot be used when the access client's authentication protocol is MS-CHAP v2 or EAP-TLS, both of which provide mutual authentication. In mutual authentication, the access client proves that it is a valid access client to the authenticating server (the IAS server), and the authenticating server proves that it is a valid authenticating server to the access client. When this authentication option is used, the Access-Accept message is returned. However, the authenticating server does not provide validation to the access client and mutual authentication fails.

For information about configuring authentication settings on a connection request profile, see Configure authentication.

**Accounting**
You can set the following accounting options that are used for RADIUS Accounting-Request messages:

- Forward accounting information in a specific remote RADIUS server group.

  Pass the accounting request to another RADIUS server in a specified remote RADIUS server group. In this case, the IAS server is acting as a RADIUS proxy.

### Note

- IAS always records the accounting information for Accounting-Request messages in local log files on the basis of remote access logging settings. For more information, see Select requests to be logged.

For information about setting accounting settings on a connection request profile, see Configure accounting.

**Attribute manipulation**
You can configure a set of find and replace rules that manipulate the text strings of one of the following attributes:

- User Name
- Called Station ID
- Calling Station ID

Find and replace rule processing occurs for one of the above attributes before the RADIUS message is subject to authentication and accounting settings.

Configuring attribute manipulation for the User Name attribute is equivalent to configuring realm replacement rules for IAS in Windows 2000.

If you are using the MS-CHAP v2 authentication protocol, you cannot manipulate the User Name attribute if the connection request policy is used to forward the RADIUS message. The only exception occurs when a backslash (\) character is used and the manipulation only affects the information to the left of it. A backslash character is typically used to indicate a domain name (the information to the left of the backslash character) and a user account name within the domain (the information to the right of the backslash character). In this case, only attribute manipulation rules that modify or replace the domain name are allowed.

For information about configuring attribute manipulation settings on a connection request profile, see Configure attribute

manipulation. For information about the syntax of find and replace rules, see Pattern matching syntax.

### Notes

- Find and replace rules apply only to a single attribute. You cannot configure find and replace rules for each attribute.
- You cannot add to the list of attributes available for manipulation.

#### Advanced

You can set advanced properties to specify the series of RADIUS attributes that are:

- Added to the RADIUS response message when the IAS server is being used as a RADIUS authentication or accounting server.

  When there are attributes specified on both a remote access policy and the connection request policy, the attributes that are sent in the RADIUS response message are the combination of the two sets of attributes.

- Added to the RADIUS message when the IAS server is being used as a RADIUS authentication or accounting proxy. If the attribute already exists in the message that is forwarded, it is replaced with the value of the attribute specified in the connection request policy.

For information about setting advanced options on a profile, see Configure advanced attributes.

#### The default connection request policy

A default connection request policy named **Use Windows authentication for all users** is created when you install IAS. This policy has the following configuration:

- The **Day-and-Time-Restrictions** condition is set to all times and all days.
- Authentication is set to authenticate requests on this server.
- Accounting is not set to forward accounting information to a remote RADIUS server group.
- Attribute manipulation rules are not configured.
- Advanced attributes are not configured.

The default connection request policy uses IAS as a RADIUS server. To configure an IAS server to act as a RADIUS proxy, you must also configure a remote RADIUS server group. You can create a new remote RADIUS server group while you are creating a new connection request policy with the New Connection Request Policy Wizard. You can either delete the default connection request policy or verify that the default connection request policy is the last policy processed. For an example of a connection request policy that uses IAS as a RADIUS proxy, see Remote RADIUS server.

### Note

- If IAS and the Routing and Remote Access service are installed on the same computer, and the Routing and Remote Access service is configured for Windows authentication and accounting, it is possible for Routing and Remote Access service authentication and accounting requests to be forwarded to a RADIUS server. This can occur when Routing and Remote Access service authentication and accounting requests match a connection request policy that is configured to forward them to a remote RADIUS server group.

# Remote RADIUS server groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote RADIUS server groups**

A remote RADIUS server group is a named group that contains one or more RADIUS servers. When IAS is being used as a RADIUS proxy for RADIUS request messages, a remote RADIUS server group must be specified. This group is used to facilitate the common configuration of both a primary and at least one backup RADIUS server. You can specify various settings to either determine the order in which the servers are used or distribute the RADIUS messages across all servers in the group.

Each server in the group has the following settings:

- Name or address

  Each group member must have a unique name within the group. The name can be an IP address or a name that can be resolved to its IP address. For more information, see Configure the name of a group member.

- Authentication and accounting

  When IAS is used as a RADIUS proxy, it is acting as a RADIUS client to another RADIUS server. Therefore, each group member must be configured to send RADIUS messages to the correct User Datagram Protocol (UDP) port that is used by the RADIUS server for RADIUS traffic. Additionally, each group member must be configured for the correct shared secret. The default authentication port is 1812. The default accounting port is 1813. For more information, see Configure the authentication and accounting settings of a group member.

- Load balancing

  A priority setting is used to indicate which member of the group is the primary server (the priority is set to 1). For group members that have the same priority, a weight setting is used to calculate how often RADIUS messages are sent to each of them. You can use additional settings to configure the way in which the IAS server detects when a group member first becomes unavailable and when it becomes available after it has been determined to be unavailable. For more information, see Configure the load balancing properties of a group member.

After a remote RADIUS server group is configured, it can be specified in the authentication and accounting settings of a connection request policy. Because of this, you can configure a remote RADIUS server group first. Next, you can configure the connection request policy to use the newly configured remote RADIUS server group. Alternately, you can use the New Connection Request Policy Wizard to create a new remote RADIUS server group while you are creating the connection request policy.

For information about creating a remote RADIUS server group, see Add a remote RADIUS server group.

**Note**

- Remote RADIUS server groups are separate from Windows groups.

# Connection Request Processing Examples

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connection request processing examples**
This section covers:

- Remote RADIUS server
- Disabling caller-set callback
- Compulsory tunnels

# Remote RADIUS server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote RADIUS server**

To provide RADIUS authentication, authorization, and accounting for an outsourced dial-up and Internet vendor, an IAS server computer that is used as a RADIUS proxy is placed in the organization's perimeter network. To forward RADIUS request messages, where the User-Name attribute contains the realm name example.microsoft.com, to a remote RADIUS server group that corresponds to primary and backup IAS servers inside an organization intranet, the following connection request policy is configured:

1. Use the New Remote RADIUS Server Group Wizard to create a new remote RADIUS server group named **Intranet IAS servers**. Configure the group with primary and backup servers that correspond to the two IAS server computers in the organization intranet.

   For more information, see Add a remote RADIUS server group.

2. Use the New Connection Request Policy Wizard to create a new connection request policy named **Forward to intranet IAS servers**. Configure the policy to forward RADIUS requests, configure the realm name of example.microsoft.com (but do not remove the realm name before authentication), and select the remote RADIUS server group named **Intranet IAS servers**.

   For more information, see Add a connection request policy.

Based on this connection request policy, all RADIUS request messages that contain the realm name example.microsoft.com in the User-Name attribute are forwarded to an IAS server in the organization intranet.

- Delete the default policy named **Use Windows authentication for all users**.

For more information, see Delete a connection request policy.

# Disabling caller-set callback

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Disabling caller-set callback**

In this example, a network administrator wants to disable the use of callback when callback settings are determined by the dial-up access client (also known as caller-set callback). If caller-set callback is not being used, do not disable or modify the use of callback.

To implement this connection request policy example, complete the following steps:

1. Use the New Connection Request Policy Wizard to create a new common connection request policy named **Forward to intranet IAS servers**. Configure the policy to forward RADIUS requests, configure the realm name of example.microsoft.com, and select the remote RADIUS server group named **Intranet IAS servers**. Do not remove the realm name before authentication.

   For more information, see Add a connection request policy.

2. Use the New Remote RADIUS Server Wizard to create a new remote RADIUS server group named **Intranet IAS servers**. Configure the group with primary and backup servers that correspond to the two IAS server computers in the organization intranet.

   For more information, see Add a remote RADIUS server group.

3. Create a new custom connection request policy with the following settings:

   - Policy name: Forward to intranet IAS servers but remove caller-set callback
   - Conditions: User-Name matches *example.microsoft.com*; Service-Type matches Callback Login
   - Profile settings, **Authentication** tab: Select **Forward requests to the following remote RADIUS server group for authentication**, and then select the **Intranet IAS servers** group.
   - Profile settings, **Accounting** tab: Select **Record accounting information on the servers in the following remote RADIUS server group**, and then select the **Intranet IAS servers** group.
   - Profile settings, **Attribute** tab: Select the **User-Name** attribute and add a find and replace rule that finds **example.microsoft.com** and replaces it with nothing.
   - Profile settings, **Advanced** tab: Add the **Service-Type** attribute with the value **Framed**.

   For more information, see Add a connection request policy.

4. Delete the default policy named **Use Windows authentication for all users**.

   For more information, see Delete a connection request policy.

Based on this connection request policy, all RADIUS request messages that contain the realm name example.microsoft.com in the User-Name attribute are forwarded to an IAS server in the organization intranet. When the Access-Accept message is sent to the IAS server computer in the perimeter network, the Callback-ID and Callback-Number RADIUS attributes in the message are set to blank values--effectively disabling callback.

# Compulsory tunnels

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Compulsory tunnels**
In this example, a network administrator wants to enable the use of compulsory tunnels for organization employees when they dial an outsourced Internet vendor.

To provide RADIUS authentication, authorization, and accounting for the outsourced dial-up and Internet vendor, an IAS server computer, used as a RADIUS proxy, is placed on the organization's perimeter network. A connection request policy is configured on the IAS server computer to forward RADIUS request messages, where the User-Name attribute contains the realm name example.microsoft.com, to a remote RADIUS server group that corresponds to primary and backup IAS servers inside an organization intranet. The policy is also configured to add the set of attributes required in creating a compulsory tunnel to a VPN server with the Layer Two Tunneling Protocol (L2TP). The VPN server has the IP address of 131.107.9.41 and uses the example tunnel password of og*37y#cW@95?4xT.

To implement this connection request policy example, complete the following steps:

1. Use the New Remote RADIUS Server Wizard to create a new remote RADIUS server group named **Intranet IAS servers**. Configure the group with primary and backup servers that correspond to the two IAS server computers in the organization intranet.

   For more information, see Add a remote RADIUS server group.

2. Use the New Connection Request Policy Wizard to create a new connection request policy named **Forward to intranet IAS servers**. Configure the policy to forward RADIUS requests and the realm name of example.microsoft.com, and then select the remote RADIUS server group named **Intranet IAS servers**. Do not remove the realm name before authentication.

   For more information, see Add a connection request policy.

3. Configure the advanced properties for the profile of the connection request policy named **Forward to intranet IAS servers** with the following:

   - Add the **Framed-Protocol** attribute with the value set to **PPP**.
   - Add the **Service-Type** attribute with the value set to **Outbound-User**.
   - Add the **Tunnel-Medium-Type** attribute with the value set to **IP**.
   - Add the **Tunnel-Password** attribute with the value set to **og*37y#cW@95?4xT**.
   - Add the **Tunnel-Server-Endpt** attribute with the value set to **131.107.9.41**.
   - Add the **Tunnel-Type** attribute with the value set to **Layer Two Tunneling Protocol (L2TP)**.

     For more information, see Configure advanced attributes.

4. Delete the default policy named **Use Windows authentication for all users**.

   For more information, see Delete a connection request policy.

Based on this connection request policy, all RADIUS request messages that contain the realm name example.microsoft.com in the User-Name attribute are forwarded to an IAS server in the organization intranet. When the Access-Accept message is sent back to the IAS server computer in the perimeter network, the set of attributes that are used to create a compulsory tunnel are

added to the message before they are returned to the outsourced vendor's Front End Processor (FEP).

For more information about compulsory tunneling, see IAS and tunnels.

# Remote Access Logging

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote access logging**

This section contains information about remote access logging in IAS. There are three types of logging:

1. Event logging for IAS

   Event logging is the recording of IAS events in the system event log. It is used primarily for auditing and troubleshooting connection attempts.

2. Logging user authentication and accounting requests

   Recording user authentication and accounting requests in log files is used primarily for connection analysis and billing purposes, and is also useful as a security investigation tool, providing you with a method of tracking down the activity of a malicious user after an attack.

3. SQL Server database logging

   Recording user authentication and accounting requests in a SQL Server XML-compliant database enables multiple IAS servers to share one data source, and provides the advantages of using a relational database.

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Event logging for IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Event logging for IAS**

IAS errors are automatically recorded in the Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition system event logs. IAS authentication events are recorded in the system event log on the basis of event logging settings. You can individually enable the logging of:

- Rejected or discarded authentication events

  These events are useful for understanding why a particular request was rejected or ignored. Requests can be rejected or ignored for many reasons, including the following:

  - The RADIUS message is not formatted according to RFCs 2865 or 2866.
  - The RADIUS client is unknown.
  - The RADIUS client has multiple IP addresses and sent the request on an address other than the one defined in IAS.
  - The shared secret is invalid.
  - The message authenticator (also known as a digital signature) sent by the client is invalid.
  - IAS was unable to locate the user name's domain.
  - IAS was unable to connect to the user name's domain.
  - IAS was unable to access the user account in the domain.

  If the request was rejected, the information in the event text includes the user name, access server identifiers, the authentication type, the name of the first matching remote access policy, the reason for the rejection, and other information.

  The logging of rejected or discarded authentication events is enabled by default.

  Secure channel (Schannel) is a security support provider (SSP) that supports a set of Internet security protocols, such as Secure Sockets Layer (SSL) and Transport Level Security (TLS). These protocols provide identity authentication and secure, private communication through encryption.

  Logging of client certificate validation failures is a secure channel event, and is not enabled on the IAS server by default. You can enable additional secure channel events by changing the following registry key value from **1** (**REG_DWORD** type, data **0x00000001**) to **3** (**REG_DWORD** type, data **0x00000003**):

  **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\SecurityProviders\SCHANNEL\EventLogging**

  **Caution**

  - Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

  For more information, see The Registry.

- Successful authentication requests

If the request was accepted, the information in the event text includes the user name, access server identifiers, the authentication type, and the name of the first matching remote access policy.

The logging of successful authentication events is enabled by default.

For information about configuring event logging options for IAS, see Configure event logging for IAS.

For information about how to view event logs in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition; see Event Viewer.

For more information about troubleshooting IAS, see IAS Troubleshooting.

# Logging user authentication and accounting requests

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Logging user authentication and accounting requests**
You can use IAS to create log files based on the authentication and accounting requests received from access servers, and collect this information in a central location. By setting up and using log files to track authentication information, such as each connection accept and connection reject, you can simplify administration of your service. You can set up and use logs to track accounting information (such as logon and logoff records) to maintain records for billing purposes.

When you set up logging, you can specify:

- Which requests are logged.
- The log-file format.
- How often new logs are started.
- Automatic deletion of the oldest log file when the disk is full.
- Where log files are recorded.
- What the log file records contain.

You can use the IAS console to specify which requests are logged. For more information, see Select requests to be logged.

You can use the IAS console to specify the log-file format, how often new logs are started, and where log files are recorded. For more information, see Configure log file properties.

**Which requests are logged**
You can select the following types of requests to log:

- Accounting requests, including the following:
    - Accounting-on requests, which are sent by the access server to indicate that it is online and ready to accept connections.
    - Accounting-off requests, which are sent by the access server to indicate that it is going offline.
    - Accounting-start requests are sent by the access server (after the user is accepted by the IAS server) to indicate the start of a user session.
    - Accounting-stop requests are sent by the access server to indicate the end of a user session.
- Authentication requests, including the following:
    - Authentication requests are sent by the access server on behalf of the connecting user. These entries in the log contain only incoming attributes.
    - Authentication accepts and rejects, which are sent by IAS to the access server, indicating whether the user should be accepted or rejected. These entries contain only outgoing attributes.
- Periodic status, which is used to obtain interim accounting requests sent by some access servers during sessions.

  Accounting-interim requests, which are sent periodically by the access server during a user session. This type of request can be used when the Acct-Interim-Interval RADIUS attribute is configured to support periodic requests in the remote

access profile on the IAS server.

### Notes

- All types of request logging are disabled by default.
- Initially, it is recommended that you enable the logging of accounting and authentication requests. You can refine your logging methods after you determine which data best matches your needs.
- You can also log accounting, authentication, and periodic status to a SQL Server database. For more information, see SQL Server database logging.

#### The log-file format

You can configure your IAS servers to log data with either the IAS format or the database-import log format.

- If you select the IAS format, attributes are logged in the form of attribute-value pairs. This format has the following characteristics:
    - The sequence of the attributes is dependent on the access server that is sending a request.
    - The logged attributes include RADIUS standard, IAS-specific, and vendor-specific.
    - All attributes that contain unprintable characters or any delimiters are printed in hexadecimal format (for example, 0x026).
- If you select the database-import log format, attributes are logged in a format that supports importing the log into databases. This format has the following characteristics:
    - The attributes of all records are recorded in the same sequence (predefined by IAS), regardless of which access server sent the request.
    - If the attribute is not present in the request or reply (for example, if an attribute is not received from the access server), then the field in the log is empty.
    - The specific set of attributes that are logged is in a sequence that is predefined in IAS. Although the attributes included in this set are limited in number, they are those that are generally most useful in request tracking and analysis.

### Notes

- IAS format is enabled by default.
- Switching log file formats does not cause a new log to be created. If you change log file formats, the file that is active at the time of the change will contain a mixture of the two formats (that is, records at the start of the log have the previous format and records at the end of the log have the new format).

#### How often new logs are started

When you configure your servers, you can specify whether new logs are started daily, weekly, monthly, or after the log reaches a specific size. You can also specify that a single log is maintained continually (regardless of file size), but this is not recommended. The file naming convention for logs is determined by the amount of time that each log is used, which you specify by setting the change frequency. If the log file change frequency is **Daily**, the log file name format is **in***yymmdd* (where *y* is year, *m* is month, and *d* is day).**log**. If the log file change frequency is **Weekly**, the log file name format is **in***yymmww*.**log** (where *w* is week). If the log file change frequency is **Monthly**, the log file name format is **in***yymm*.**log**. Following are some example log file names:

| Log file name | Change frequency | File creation date |
|---|---|---|
| in020528.log | Daily | May 28, 2002 |
| in020304.log | Weekly | The fourth week of March, 2002 |
| in0304.log | Monthly | April, 2003 |

**Notes**

- By default, the new log file change frequency is set to **Monthly**.
- When the log file change frequency is **Never (unlimited file size)**, the IAS log file is named **iaslog.log**.
- When the log file change frequency is **When log file reaches this size**, the file name is **iaslog***n***.log**, where *n* represents the maximum size of the file.

**Automatic deletion of the oldest log file when the disk is full**

You can specify whether IAS deletes the oldest log file when the disk is full. IAS determines which file is oldest by checking the file name rather than the time stamp. The currently configured log file change frequency (where new files are created at either a specified time or when the current file reaches a specified size) determines which log file IAS deletes.

IAS only deletes the oldest file from the same change frequency--it does not delete a file with a different file name format. For example, if the currently configured log file change frequency is set to **Monthly** (which has a log file name format of **in***yymm***.log**), IAS will not delete a log file named in021231.log even if it is the oldest log file, because the log file name and name format indicate that it was created with the change frequency set to **Daily**. The only time that IAS might delete a file from another change frequency occurs when the two change frequency settings are **Daily** and **Weekly**, and the file name can be interpreted both as one of the first four days of the month and as one of the four weeks of the month, as demonstrated in the following examples:

| The file name | Is interpreted as both |
|---|---|
| in020501.log | A **Daily** file created on May 1, 2002 or a **Weekly** file created in the first week of May, 2002. |
| in020502.log | A **Daily** file created on May 2, 2002 or a **Weekly** file created in the second week of May, 2002. |
| in020503.log | A **Daily** file created on May 3, 2002 or a **Weekly** file created in the third week of May, 2002. |
| in020504.log | A **Daily** file created on May 4, 2002 or a **Weekly** file created in the fourth week of May, 2002. |

**Notes**

- If the oldest log file is the log file that is currently in use, the log file is not deleted.
- Because changing the log file change frequency might result in the overwriting of existing logs, you should copy logs to a separate file before making the change.
- For more information about how to effectively configure and use log files, see IAS Best Practices and Configure log file properties.

**Where log files are recorded**

By default, log files are located in the *systemroot*\System32\LogFiles folder. You can specify a different location.

The log file directory can be created by using system environment variables (instead of user variables) such as, %systemdrive%, %systemroot%, and %windir%. For example, the following path, using the environment variable %windir%, locates the log file at the system directory in the subfolder \System32\Logs (that is, %windir%\System32\Logs\).

For information about how to set up the authentication and accounting logging service on an IAS server, see Configure Logging for User Authentication and Accounting.

For information about how to import a log file into a database, see Importing IAS log files into a database.

**Log capture for other processes**
To send log data directly to another process, you can configure IAS to write to a named pipe, instead of a file. To use named pipes, set the log file folder to **\\.\pipe** or *****ComputerName***\pipe**. The named pipe server program should create a named pipe called **\\.\pipe\iaslog.log** to accept the data.

**What the log file records contain**
Attributes are recorded in UTF-8 encoding in a comma-delimited format. The format of the records in a log file depends on the file format.

In IAS-formatted log files, each record starts with a fixed-format header, which consists of the access server IP address, user name, record date, record time, service name, and computer name, followed by attribute-value pairs.

For more information about the attributes and other data logged in the IAS format, see IAS-Formatted Log Files.

In database-import log files, each record contains attribute values in a consistent sequence, including the computer name, service name, record date, and record time. An access server might not use all of the attributes specified in the database-import log format, but the comma-delimited location for each of these pre-defined attributes is maintained, even for attributes that have no value specified in a record.

For more information about the attributes and other data logged in the database-import log format, see Database-Import Log Files.

### Note

- This documentation contains logging information that is specific to IAS. The types of data that your access server sends might vary, depending upon the manufacturer. For information about the specific data that your access server sends and how to configure accounting packets, see your access server documentation.

# SQL Server database logging

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SQL server database logging**

You can use SQL server database logging to log user authentication and accounting requests, which are received from one or more network access servers, to a centralized data source. Log data is passed from IAS to a stored procedure in a database that supports both structured query language (SQL) and extensible markup language (XML), such as one created with Microsoft SQL Server 2000. A stored procedure is a custom program, created by a SQL server database programmer, that runs within the SQL server database environment.

Logging to a relational database instead of a standard text file (that is, either IAS format or database-compatible format) has the advantage that relationships between data tables enable the flexible creation of dynamic data views by using queries and reports.

**Which requests are logged**

By default, no data is logged. When you configure logging, all required attributes, accounting, and authentication data that is normally logged in either IAS or database-compatible format is logged to the SQL server database. You can log the following information in a SQL server database:

- Accounting requests, including the following:
    - Accounting-on requests, which are sent by the access server to indicate that it is online and ready to accept connections.
    - Accounting-off requests, which are sent by the access server to indicate that it is going offline.
    - Accounting-start requests, which are sent by the access server (after the user is accepted by the IAS server) to indicate the start of a user session.
    - Accounting-stop requests, which are sent by the access server to indicate the end of a user session.
- Authentication requests, including the following:
    - Authentication requests, which are sent by the access server on behalf of the connecting user. These entries in the log contain only incoming attributes.
    - Authentication accepts and rejects, which are sent by IAS to the access server, indicating whether the user should be accepted or rejected. These entries contain only outgoing attributes.
- Periodic status, which is used to obtain interim accounting requests sent by some access servers during sessions.

Accounting-interim requests, which are sent periodically by the access server during a user session, can also be logged to a SQL server database. This type of request can be used when the Acct-Interim-Interval RADIUS attribute is configured to support periodic requests in the remote access profile on the IAS server.

**Attributes that are recorded by SQL server**

Unlike database-import log files, which use a fixed sequence of attributes, the sequence of the attributes in a SQL server log file depends upon the sequence used by the access server. For more information about the sequence of these records, see the documentation for the access server. The table in Interpreting IAS-formatted log files lists, in numerical order, RADIUS attributes that can be found in a SQL server database and configured for IAS logging. This table does not cover vendor-specific attributes (VSAs). For information about VSAs, see Interpreting IAS IDs for vendor-specific attributes. For more information about VSAs that are supported by your access server, see your access server documentation.

**Attributes that are not recorded by SQL server**

Although most of the attributes that are sent by an access server and supported in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition are logged when you specify the use

of SQL server logging, some attributes are not logged because they contain sensitive information (for example, passwords) that should not be included. The table in Interpreting IAS-formatted log files lists some of the attributes that are not logged.

You can use the IAS console to specify which requests are logged. For more information, see Select requests to be logged.

You can use the IAS console to specify additional SQL server logging properties. For more information, see Configure log file properties.

**Notes**

- All types of request logging are disabled by default.
- Initially, it is recommended that you enable the logging of accounting and authentication requests. You can refine your logging methods after you determine your required data.
- You can also log accounting, authentication, and periodic status in IAS or database-compatible format. For more information, see Logging user authentication and accounting requests.

**How IAS and SQL server logging works**

When IAS is configured to log to a SQL server database, the following occurs:

1. The IAS server receives or produces the data that it is configured to log to a SQL server database. For example, a network access server configured as a RADIUS client to the IAS server sends the IAS server incoming attributes for an authentication request by a user or computer.
2. The IAS server packages the data as an XML document.
3. The IAS server initiates a connection with the server running SQL server. If the IAS server is unable to establish a connection with SQL server, the IAS server stops processing authentication requests and users cannot log on to the network.

   IAS connects to SQL server using password-based credentials that you can configure on the **Connection** tab in the **Data Link Properties** dialog box.

   If you select **Use Windows NT integrated security**, the IAS server attempts to authenticate the connection with the local computer account. If you select **Use a specific name and password**, you must specify the user name and password for a valid user account that you have already configured on your SQL server.

   For more information about configuring SQL server data link properties, see Configure log file properties.
4. If a connection with the computer running SQL server is successful, the IAS server signals SQL server to run a stored procedure named **report_event**. IAS then sends the accounting data (an XML document) to the computer running SQL server. The stored procedure that is called by IAS must be named **report_event**, or logging will fail.

   The **report_event** stored procedure uses only one parameter. This parameter is a Unicode string of type **ntext**. The Unicode string contains an XML document which in turn contains the accounting data to be logged.
5. The **report_event** stored procedure in the SQL server database processes the XML document and stores the processed data in SQL server database tables.
6. SQL server notifies the IAS server that the transaction is successful.
7. The IAS server is free to process additional data, repeating this process as required.

**How IAS creates an XML document from accounting and authentication data**

If you select the SQL server log format, attribute-value pairs are converted to XML format.

When IAS creates an XML document from attributes, accounting and authentication data, the XML document includes the attribute ID or name, the attribute value, and the data type of the attribute value. With SQL server logging, there are five date

types for attribute values: Non-negative integers, strings (text), hexadecimal numbers, IPv4 addresses, and date and time. The following example XML document, which is created by IAS, includes the attribute name (User-Name), the attribute value (DOMAIN\username), and the data type of (1), indicating a value data type of string:

```
<Event>
    <User-Name data_type="1">DOMAIN\username</User-Name>
</Event>
```

The next example XML document includes the attribute name (NAS-IP-Address), the attribute value (192.168.0.1), and the data type (3), indicating a value data type of IP address:

```
<Event>
    <NAS-IP-Address data_type="3">192.168.0.1</NAS-IP-Address>
</Event>
```

The next example XML document includes the attribute name (Provider-Type), the attribute value (1), and the data type of (0), indicating a value data type of non-negative integers:

```
<Event>
    <Provider-Type data_type="0">1</Provider-Type>
</Event>
```

The last example XML document, which is created by IAS, includes the three previous examples combined into one typical XML document:

```
<Event>
    <User-Name data_type="1">DOMAIN\username</User-Name>
    <NAS-IP-Address data_type="3">192.168.0.1</NAS-IP-Address>
    <Provider-Type data_type="0">1</Provider-Type>
</Event>
```

**Configuring SQL server database logging**

To log information to a SQL server database, you must configure the SQL server data link in **Remote Access Logging** in the IAS console. For more information, see Configure log file properties.

To provide centralized logging, failover, and redundancy with SQL server logging, you can place two SQL server databases on different subnets. Use the SQL server Create Publication Wizard to set up database replication between the two servers.

For larger IAS deployments, you should use more than two computers running SQL server and you should not configure all IAS servers to log to the same one. When you have a primary and backup IAS server configuration, the primary IAS server should log to a computer running SQL server that is other than the one to which the backup IAS server logs. With this configuration, if the primary computer running SQL server fails, preventing the primary IAS server from servicing clients, the backup IAS server, which is configured to log to a different computer running SQL server, can service clients until the primary server is back on line.

If the computer running SQL server runs out of disk space and can no longer perform IAS logging, IAS discards all accounting and authentication requests, preventing client authentication through the IAS server. Make sure you maintain adequate hard disk space on your computer running SQL server.

The performance of the SQL server database (throughput and latency) affects the response time of the IAS server. During an authentication attempt, IAS does not respond to the RADIUS client (network access server) until after SQL server notifies the IAS server that the last data write operation is successful. Because of this, you should ensure that the computer running SQL server is designed to handle the IAS logging load and is able to respond with minimum delay.

In addition, some RADIUS clients might retry authentication attempts if a response is not received from the IAS server within a specific time period (for example, one second). This could add to the load on the computers running IAS and SQL server during periods of slow response due to network conditions. You should configure the network access servers with an appropriate retry interval to prevent overloading the computers running IAS and SQL server with retry attempts.

For more information about SQL server configuration and best practices, see the SQL server 2000 documentation.

**Requirements**

Logging to a SQL server database requires the use of one or more servers running Windows Server 2003 and IAS and an SQLXML-compliant database, such as Microsoft SQL server 2000. Because this feature requires SQLXML, Microsoft Data Engine (MSDE) cannot be used instead of SQL server.

# Deploying IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying IAS**
This section covers:

- Deploying IAS as a RADIUS Server
- Deploying IAS as a RADIUS Proxy
- Setting up IAS in a Test Lab

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Deploying IAS as a RADIUS Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying IAS as a RADIUS server**
This section covers:

- Planning for IAS as a RADIUS Server
- IAS as a RADIUS server

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Planning for IAS as a RADIUS Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Planning for IAS as a RADIUS server**
This section covers:

- IAS as a RADIUS server design considerations
- IAS as a RADIUS server security considerations
- Computer certificates for certificate-based authentication

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. In addition, you can configure RADIUS clients by specifying an IP address range.

# IAS as a RADIUS server design considerations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS as a RADIUS server design considerations**

Consider the following design issues when deploying IAS as a RADIUS server:

- The common uses of IAS as a RADIUS server

  For more information about common ways to use IAS as a RADIUS server, see IAS as a RADIUS server.

- IAS server domain membership

  You must decide in which domain the IAS server computer is a member. For multiple domain environments, an IAS server can authenticate credentials for user accounts in the domain of which it is a member and all domains that trust this domain. To read the dial-in properties for user accounts, however, you must add the computer account of the IAS server to the RAS and IAS servers group for each domain. For more information, see Enable the IAS server to read user accounts in Active Directory. Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition also provide authentication across forests. For more information, see Accessing resources across forests.

- RADIUS ports

  You can configure the IAS server to receive RADIUS messages that are sent to UDP ports other than the default ports of 1812 and 1645 (for RADIUS authentication) and ports 1813 and 1646 (for RADIUS accounting). For more information, see Configure IAS port information.

- RADIUS clients

  A RADIUS client can be an access server (for example, a dial-up or VPN server, a wireless access point, or an Ethernet switch) or a RADIUS proxy. IAS supports all access servers and RADIUS proxies that comply with RFC 2865, "Remote Authentication Dial-in User Service (RADIUS)."

  Configure each access server or RADIUS proxy that sends RADIUS request messages to the IAS server as a RADIUS client on the IAS server. For each RADIUS client, you can configure a friendly name, an IP address or DNS name, the client vendor, the shared secret, and whether to use the RADIUS Message Authenticator attribute. For more information, see Configure RADIUS Clients.

  You can specify IP addresses or DNS names for RADIUS clients. In most cases, it is better to specify RADIUS clients with IP addresses. When you use IP addresses, IAS is not required to resolve host names at startup and will start much more quickly as the result. This is especially beneficial if your network contains a large number of RADIUS clients. You can use DNS names to specify RADIUS clients when you require something other than administrative flexibility (for example, the ability to map multiple RADIUS client IP addresses to a single DNS name).

  IAS in Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition allows you to specify a RADIUS client by using an address range. The address range for RADIUS clients is expressed in the network prefix length notation *w.x.y.z/p*, where *w.x.y.z* is the dotted decimal notation of the address prefix and *p* is the prefix length (the number of high order bits that define the network prefix). This is also known as Classless Inter-Domain Routing (CIDR) notation. An example is 192.168.21.0/24. To convert from subnet mask notation to network prefix length notation, *p* is the number of high order bits in the subnet mask that are set to 1.

- Third-party access points

  To determine whether a third-party access point is interoperable with IAS as a RADIUS server, refer to the third-party access point documentation for its use of RADIUS attributes and vendor-specific attributes.

To test basic interoperability for PPP connections, configure the access point and the access client to use Password Authentication Protocol (PAP). Use additional PPP authentication protocols until you have tested the ones that you are using for network access.

- Connection request policy configuration

  The default connection request policy named **Use Windows authentication for all users** is configured for IAS when it is used as a RADIUS server. For more information about the settings of the default connection request policy, see Connection request policies. Additional connection request policies can be used to define more specific conditions, manipulate attributes, and specify advanced attributes. Use the New Connection Request Policy Wizard to create either common or custom connection request policies. For more information about connection request policies and how to configure them when IAS is being used as a RADIUS server, see Introduction to connection request processing.

- Realm replacement

  To correctly replace or convert realm names within the user name of a connection request, you must configure attribute manipulation rules for the User-Name attribute on the appropriate connection request policy. For more information, see Connection request policies and Configure attribute manipulation.

- Remote access policy configuration

  Remote access policies can be used to define specific conditions, set dial-in constraints, set allowed authentication protocols and encryption strength, and specify advanced attributes. Use the New Remote Access Policy Wizard to create either common or custom policies. For more information, see Introduction to remote access policies.

- Remote access policies and authorization by user or group

  In small organizations, you can manage authorization by setting the remote access permission on each user account. For a large organization, set the remote access permission on each user account to be controlled through remote access policy. Next, configure remote access policies to grant access by using group membership. For more information, see Introduction to remote access policies.

- The use of additional RADIUS attributes and vendor-specific attributes

  If you plan to return additional RADIUS attributes or vendor-specific attributes (VSAs) with the responses to RADIUS requests, you must add the RADIUS attributes or VSAs to the appropriate remote access policy. For more information, see Vendor-specific attribute overview and Configure Attributes for a Profile.

- The use of logging

  You can enable event logging for authentication events to assist with troubleshooting and debugging connection attempts. For more information, see Event logging for IAS. For information about logging user authentication and accounting requests for analysis and connection billing, see Logging user authentication and accounting requests.

- Interim accounting

  To use interim accounting, first verify that your access server supports sending interim accounting messages. Next, add the Acct-Interim-Interval RADIUS attribute from the **Advanced** tab on the profile settings of the appropriate remote access policy. Configure the Acct-Interim-Interval attribute with the interval (in minutes) to send periodic interim accounting messages. For more information, see Add RADIUS attributes to a remote access policy. Next, enable logging of periodic status. For more information, see Select requests to be logged.

  The Routing and Remote Access service supports sending interim accounting messages and is enabled from the properties of a RADIUS server when configuring the RADIUS accounting provider. For more information, see Use RADIUS accounting.

- Performance and capacity planning

For information about tuning performance and using IAS in large organizations, see IAS Best Practices.

- Multiple IAS servers

  To provide fault tolerance for RADIUS-based authentication and accounting, you should always use at least two IAS servers. One IAS server is used as the primary RADIUS server and the other is used as a backup. Access servers are configured for both IAS servers. They switch to using the backup IAS server when the primary IAS server becomes unavailable. For information about how to synchronize the configuration of multiple IAS servers, see Managing multiple IAS servers.

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# IAS as a RADIUS server security considerations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS as a RADIUS server security considerations**

Consider the following security issues when deploying IAS as a RADIUS server:

- Shared secrets

  Configure strong shared secrets and change them frequently to prevent dictionary attacks. Strong shared secrets are a long (more than 22 characters) sequence of random letters, numbers, and punctuation. For more information, see Shared secrets.

- Message Authenticator attribute

  To ensure that an incoming RADIUS Access-Request message, for connection requests that use the PAP, CHAP, MS-CHAP, and MS-CHAP v2 authentication protocols, was sent from a RADIUS client configured with the correct shared secret, you can use the RADIUS Message Authenticator attribute (also known as a digital signature or the signature attribute). You must enable the use of the Message Authenticator attribute on both the IAS server (as part of the configuration of the RADIUS client in Internet Authentication Service) and the RADIUS client (the access server or RADIUS proxy). Ensure that the RADIUS client supports the Message Authenticator attribute before enabling it. The Message Authenticator attribute is always used with EAP without having to enable it on the IAS server and access server. For more information, see Edit RADIUS client configuration.

  For information about enabling the RADIUS Message Authenticator attribute for your access server, see the appropriate access server documentation. For the Routing and Remote Access service, the use of the RADIUS Message Authenticator attribute is enabled from the properties of a RADIUS server when you configure the RADIUS authentication provider. For more information, see Use RADIUS authentication.

- Firewall configuration

  If your IAS server is on a perimeter network (also known as a demilitarized zone or DMZ), configure your Internet firewall (between your perimeter network and the Internet) to allow RADIUS messages to pass between your IAS server and RADIUS clients on the Internet. You might need to configure an additional firewall that is placed between your perimeter network and your intranet, to allow traffic to flow between the IAS server on the perimeter network and domain controllers on the intranet. For more information, see IAS and firewalls.

- Authentication protocols

  IAS supports several different authentication protocols. The order of authentication protocols, from the most secure to the least secure, is: PEAP-EAP-TLS (for wireless clients and authenticated switch clients only), EAP-TLS, PEAP-EAP-MS-CHAPv2 (for wireless clients and authenticated switch clients only), MS-CHAP v2, MS-CHAP, EAP-MD5, CHAP, and PAP. Microsoft recommends using only the strongest authentication protocols required for your configuration. For password-based authentication protocols, strong password policies must be enforced to protect from dictionary attacks. The use of PAP is not recommended unless it is required. For more information, see Authentication methods.

- Remote access account lockout

  To provide protection for online dictionary attacks launched against access servers by using known user names, you can enable remote access account lockout. Remote access account lockout disables remote access for user accounts after a configured number of failed connection attempts has been reached. For more information, see Remote access account lockout.

  Remote access account lockout can also be used to prevent a malicious user from intentionally locking out a domain account by attempting multiple dial-up or VPN connections with the wrong password. You can set the number of failed attempts for remote access account lockout to a number that is lower than the logon retries for domain account lockout.

By doing this, remote access account lockout occurs before domain account lockout, which prevents the domain account from being intentionally locked out.

- Certificate-based authentication

  When you use the EAP-TLS authentication protocol, you must install a computer certificate on the IAS server. For client and user authentication, you can either install a certificate on the client computer or use smart cards. Before certificate enrollment occurs, the certificate must be designed with the correct requirements and purposes. For more information, see Network access authentication and certificates and Computer certificates for certificate-based authentication.

- Authentication of wireless clients using Protected Extensible Authentication Protocol (PEAP)

  You can use PEAP with EAP-TLS (also known as PEAP-EAP-TLS) to deploy a certificates with PEAP. PEAP with EAP-MS-CHAPv2 (also known as PEAP-EAP-MS-CHAPv2) provides secure password authentication. PEAP-EAP-TLS uses a public key infrastructure (PKI) with certificates for server authentication and either smart cards or certificates for client and user authentication. When you use PEAP-EAP-TLS, client certificate information is encrypted.

  Although using PEAP-EAP-TLS with smart cards for certificate deployment is the most secure authentication method, the complexity and cost of deploying certificates to wireless and authenticated switch clients might not be practical for your organization. PEAP-EAP-MS-CHAPv2 balances security with deployment cost and complexity. Unlike MS-CHAPv2, PEAP-EAP-MS-CHAPv2 is a mutual authentication method that uses Transport Level Security (TLS) to create an end-to-end encrypted connection between client and authenticator. The client authenticates the server by using the server's certificate and the server authenticates the client with password-based credentials. For an example of a remote access policy using PEAP, see Wireless access with secure password authentication.

- Registration of the IAS server in Active Directory

  Before the IAS server can access Active Directory domains to authenticate user credentials and user access account properties, the IAS server must be registered in those domains. For more information, see Enable the IAS server to read user accounts in Active Directory.

- Using IPSec filters to lock down IAS servers

  You can configure IPSec filters on a granular level to allow specific traffic in and out of network interfaces on RADIUS servers. These filters can be applied to organizational units and stored in Active Directory, or they can be created and applied to individual servers. For more information, see Securing RADIUS traffic with IPSec.

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Computer certificates for certificate-based authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Computer certificates for certificate-based authentication**
Before using Extensible Authentication Protocol-Transport Level Security (EAP-TLS), you must install a computer certificate (also known as a machine certificate) on the Internet Authentication Service (IAS) server computer. The installed computer certificate must be issued from a certification authority (CA) that can follow a certificate chain to a root CA that is trusted by the access clients. Additionally, in order for the IAS server to validate the user or computer certificate of the access client, the IAS server must install the certificate of the root CA that issued the user or computer certificate to the access clients.

For more information, see Network access authentication and certificates.

To install a computer certificate, a CA must be available to issue certificates. After the CA is configured, you can install a computer certificate on the IAS server:

- By configuring the automatic allocation of computer certificates to computers in an Active Directory domain.
- By using Certificate Manager to obtain a computer certificate.
- By using Microsoft Internet Explorer and Web-based enrollment.

To configure a CA and install the computer certificate, complete the following steps:

1. Install the Certificate Services component as an enterprise root CA. For more information, see Install an enterprise root certification authority. This step is only required if you do not already have an enterprise root CA.

   If necessary, configure the computer that is the CA to be a domain controller.

2. To install the computer certificates through auto-enrollment, configure Group Policy on the Active Directory domain for automatic allocation of computer certificates. For more information, see Configure automatic certificate allocation from an enterprise CA.

   To create a computer certificate for the IAS server that is a member of the domain for which auto-enrollment is configured (and other computers that are members of the domain), restart the computer or type **gpupdate /target:computer** from a Command Prompt.

3. To manually enroll computer certificates, use Certificate Manager to install both the CA root certificate of the access client and the computer certificate for the IAS server. For more information, see Manage certificates for a computer and Request a certificate.

4. To manually enroll computer certificates with Internet Explorer, see Submit an advanced certificate request via the Web.

**Notes**

- While Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition allow you to install multiple computer certificates, only a single certificate can be selected for all remote access policies that specify authentication through EAP-TLS.
- An IAS server does not use a new certificate revocation list (CRL), which is published by the certification authority (CA), until the old CRL has expired. If a certificate has expired and the IAS server is checking against an old but unexpired CRL, the IAS server will allow clients with revoked certificates to connect to the network. To prevent this from happening, you can publish CRLs with short expiration times (one hour or longer).
- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address,

but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Configuring IAS as a RADIUS Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS as a RADIUS server**
This section covers:

- Wireless access
- Dial-up and VPN remote access
- Extranet access
- Internet access
- Outsourced VPN remote access
- Outsourced wireless access
- Ethernet switch access with IAS

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Wireless access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Wireless access**

This topic describes how IAS can be used to support authentication, authorization, and accounting for wireless connections to an organization. This topic describes a typical configuration for an organization that uses:

- Two IAS servers.

  Two IAS servers (one primary and one secondary) are used to provide fault tolerance for RADIUS-based authentication. If only one RADIUS server is configured and it becomes unavailable, wireless access clients cannot connect. By using two IAS servers and configuring all wireless access points (RADIUS clients) for both the primary and secondary IAS servers, the RADIUS clients can detect when the primary RADIUS server is unavailable and automatically fail over to the secondary IAS server.

- Active Directory domains.

  Active Directory domains contain the user accounts, passwords, and dial-in properties that each IAS server requires to authenticate user credentials and evaluate both authorization and connection constraints. To both optimize IAS authentication and authorization response times and minimize network traffic, IAS is installed on domain controllers.

- A certificate infrastructure.

  The Extensible Authentication Protocol-Transport Level Security (EAP-TLS) authentication protocol is used with locally installed user certificates to authenticate wireless clients.

- Wireless remote access policies.

  Remote access policies are configured for wireless connections so that authenticated wireless users obtain unrestricted access to the organization intranet and guest wireless users obtain restricted access to a virtual LAN (VLAN) that contains a certificate server.

- Multiple wireless access points.

  Multiple third-party wireless access points provide wireless access in different buildings of an organization.

- A certificate server on a separate VLAN for new wireless clients

  To accommodate new wireless clients, a certificate server is placed on a separate virtual local area network (VLAN). The certificate server is used by a new wireless client to obtain a user certificate for subsequent wireless access. After 10 minutes of receiving a guest connection, the wireless client is disconnected. When the wireless client computer reconnects, it authenticates by using the newly installed user certificate and obtains authenticated wireless access to the network.

The following illustration shows a wireless configuration.

When you configure IAS so that wireless clients can access the certificate server on the VLAN, it is important to note that the term guest refers to user identity and the term unauthenticated refers to user credentials. The following rules illustrate the differences between the Guest account and remote access policy unauthenticated access:

**User identity rules**

| Condition | IAS action |
|---|---|
| If the wireless client has a UserID | IAS maps to the corresponding Windows account. |
| If the wireless client does not have a UserID or uses a null UserID | IAS attempts to default to the Guest account (in the domain in which the IAS server is a member). |

**Credential rules**

| Condition | IAS action |
|---|---|
| If the wireless client provides credentials | The authentication method in use specifies whether to accept the connection attempt. EAP-MD5 guest authentication is standard user authentication with a UserID and password (which can be null). However, secure channel (Schannel) does not support authentication to a Windows account that is based on a NULL certificate. |
| If the wireless client does not provide credentials | IAS checks the remote access policy to determine whether unauthenticated access is allowed. EAP-TLS supports one-way authorization, such as unauthenticated access where the wireless client does not send credentials. However, EAP-MD5 does not support one-way authorization. |

**Notes**

- This topic only describes how to configure IAS. It does not describe the configuration of Active Directory domains, the certificate infrastructure, or the wireless access points. For more information about how to deploy these components, see the appropriate Help topics.

- This topic describes the bootstrapping of wireless clients by using a VLAN that contains a certificate server. You can also bootstrap wireless clients by using an unauthenticated Ethernet connection or a certificate that has been extracted to a floppy disk.

To configure IAS for this example, complete the following steps:

- Configure Active Directory for user accounts and groups.

- Configure the primary IAS server on a domain controller.

- Configure the secondary IAS server on a different domain controller.

- Configure RADIUS accounting and authentication on wireless access points.

**Configuring user accounts and groups**

To configure user accounts and groups, do the following:

1. Ensure that all users that are making wireless connections have a corresponding user account.

2. Manage your wireless access by user by setting the remote access permission on user accounts to **Allow access** or **Deny access**. To manage your wireless access by group, set the remote access permission on user accounts to **Control access through Remote Access Policy**. For more information, see Configure remote access permission for a user.

3. Organize your wireless access users into the appropriate universal and nested groups in order to take advantage of group-based remote access policies. For example, create a universal group named WirelessUsers that contains global groups of wireless user accounts. For more information, see Group scope.

4. Configure the Guest account to allow guest access for new wireless clients. For more information, see Guest authentication. Enable reversibly encrypted password storage on the Guest account. For more information, see User and computer accounts.

5. Create a group named Guests, and add the Guest account as a member. For more information, see Create a new group.

6. Configure the domain in which the IAS server computers will be members for auto-enrollment of computer certificates. For more information, see Configure automatic certificate allocation from an enterprise CA.

**Configuring the primary IAS server on a domain controller**

To configure the primary IAS server on a domain controller, do the following:

1. On the domain controller, install IAS as an optional networking component. For more information, see Install IAS.

2. Configure the IAS server computer (the domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the IAS server authenticates connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the IAS server computer is a member. Next, configure the IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

   If the IAS server authenticates connection attempts for user accounts in other domains, and those domains do not have a two-way trust with the domain in which the IAS server computer is a member, see Authentication across forests.

4. Enable file logging for accounting and authentication events. For more information, see Configure log file properties.

5. If needed, configure additional UDP ports for authentication and accounting messages that are sent by RADIUS clients. For more information, see Configure IAS port information. By default, IAS uses UDP ports 1812 and 1645 for authentication and ports 1813 and 1646 for accounting.

6. Add the wireless access points as RADIUS clients of the IAS server. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets. Enable the use of the Message Authenticator attribute only when it is supported by the wireless access point.

7. Use the New Remote Access Policy Wizard to create a common wireless policy with the following settings:

   - Policy name: Wireless access
   - Access Method: Wireless access
   - User or Group: Select **Group**, and then specify the WirelessUsers group (example).
   - Authentication methods: Select **Smart Card or other Certificate**. If you have multiple computer certificates, click **Configure**, and then select the appropriate computer certificate.

- Policy Encryption Level: Select the **Strongest encryption** check box, and then clear all other check boxes.

8. Use the New Remote Access Policy Wizard to create a custom wireless policy with the following settings:

    - Policy name: New wireless access
    - Conditions:
    - NAS-Port-Type matches Wireless-Other or Wireless-IEEE 802.11
    - Windows-Groups matches Guests
    - Permission: Grant remote access permission
    - Profile settings, **Dial-in Constraints** tab:
    - Select the **Minutes client can be connected** check box, and then type **10**.
    - Profile settings, **Advanced** tab:
    - Add the **Tunnel-Type** attribute with the value of **Virtual LANs (VLAN)**.
    - Add the **Tunnel-Pvt-Group-ID** attribute with the value of the VLAN ID of the VLAN that contains the certificate server for new wireless clients.

For additional examples of remote access policies, see Remote Access Policies Examples.

1. Delete the default remote access policies. For more information, see Delete a remote access policy.

**Configuring the secondary IAS server on a different domain controller**

To configure the secondary IAS server on a different domain controller, do the following:

1. On the other domain controller, install IAS as an optional networking component. For more information, see Install IAS.

2. Configure the secondary IAS server computer (the other domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the secondary IAS server authenticates connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the secondary IAS server computer is a member. Next, configure the secondary IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

   If the secondary IAS server authenticates connection attempts for user accounts in other domains, and those domains do not have a two-way trust with the domain in which the secondary IAS server computer is a member, see Authentication across forests.

4. Copy the configuration of the primary IAS server to the secondary IAS server. For more information, see Copy the IAS configuration to another server.

**Configuring RADIUS authentication and accounting on wireless access points**

Configure your third-party wireless access point as a RADIUS client with two RADIUS servers (the primary and secondary IAS servers). For more information, see the documentation for the wireless access point.

# Dial-up and VPN remote access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Dial-up and VPN remote access**

This topic describes how IAS is used to support authentication, authorization, and accounting for dial-up and virtual private network (VPN) connections to an organization. This topic describes a typical configuration for an organization that uses:

- Two IAS servers.

  Two IAS servers (one primary and one secondary) are used to provide fault tolerance for RADIUS-based authentication. If only one RADIUS server is configured and it becomes unavailable, dial-up and VPN access clients cannot connect. By using two IAS servers and configuring all dial-up and VPN servers (RADIUS clients) for both the primary and secondary IAS servers, RADIUS clients can detect when the primary RADIUS server is unavailable and automatically fail over to the secondary IAS server.

- Active Directory domains.

  Active Directory domains contain the user accounts, passwords, and dial-up properties that each IAS server requires to authenticate user credentials and evaluate both authorization and connection constraints. To optimize IAS authentication and authorization response times and minimize network traffic, IAS is installed on domain controllers.

- A smart card certificate infrastructure.

  The Extensible Authentication Protocol-Transport Level Security (EAP-TLS) authentication protocol is used with smart cards to authenticate employee connections and provide the highest level of security for authentication.

- Custom remote access policies.

  Remote access policies are configured to specify, based on group membership, the different requirements for various types of connections and users.

- Multiple dial-up and VPN servers.

  Dial-up and VPN servers consist of computers running different versions of Windows and the Routing and Remote Access service, and third-party network access server (NAS) devices.

The following illustration shows the common dial-up and VPN remote access configuration.

**Note**

- This topic only describes how to configure IAS. It does not describe the configuration of Active Directory, the smart card certificate infrastructure, or the dial-up and VPN servers. For more information about how to deploy these components, see the appropriate Help topics.

To configure IAS for this example, complete the following steps:

- Configure Active Directory for user accounts and groups.
- Configure the primary IAS server on a domain controller.
- Configure the secondary IAS server on a different domain controller.
- Configure RADIUS accounting and authentication on dial-up and VPN servers.

**Configuring user accounts and groups**

To configure user accounts and groups, do the following:

1. Ensure that all users that are making remote access connections have a corresponding user account. This includes employees, contractors, vendors, and business partners.
2. Set the remote access permission on user accounts to **Allow access** or **Deny access** to manage network access by user. Or, to manage network access by group, set the remote access permission on user accounts to **Control access through Remote Access Policy**. For more information, see Configure remote access permission for a user.
3. Organize remote access users into the appropriate universal and nested groups in order to take advantage of group-based remote access policies. For more information, see Group scope.
4. If you are using the Challenge-Handshake Authentication Protocol (CHAP), enable support for reversibly encrypted passwords in the appropriate domains. For more information, see Enable reversibly encrypted passwords in a domain.
5. If you are using certificate-based authentication, configure the domain in which IAS server computers will be members for the auto-enrollment of computer certificates. For more information, see Configure automatic certificate allocation from an enterprise CA.

**Configuring the primary IAS server on a domain controller**

To configure the primary IAS server on a domain controller, do the following:

1. On the domain controller, install IAS as an optional networking component. For more information, see Install IAS.
2. Configure the IAS server computer (the domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.
3. If the IAS server authenticates connection attempts for user accounts in other domains, verify that these domains have a two-way trust with the domain in which the IAS server computer is a member. Next, configure the IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

   If the IAS server authenticates connection attempts for user accounts in other domains, and those domains do not have a two-way trust with the domain in which the IAS server computer is a member, see Authentication across forests.
4. Enable file logging for accounting and authentication events. For more information, see Configure log file properties.
5. If needed, configure additional UDP ports for authentication and accounting messages that are sent by RADIUS clients. For more information, see Configure IAS port information. By default, IAS uses UDP ports 1812 and 1645 for authentication and ports 1813 and 1646 for accounting.
6. Add the dial-up and VPN servers as RADIUS clients of the IAS server. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets. Enable the use of the Message Authenticator attribute, but only when it is also supported by the RADIUS client.
7. Create remote access policies that reflect your remote access usage scenarios.

For example, to configure a remote access policy to permit members of the Contractors group dial-up connections from 8:00 AM to 5:00 PM, Monday through Friday, create a new custom remote access policy with the following settings:

- Policy name: Contractor connections
- Conditions: Windows-Groups matches Contractors
- Permission: Grant remote access permission
- Profile settings, **Dial-in constraints** tab: **Allow access only on these days and at these times** is set to 8:00 AM to 5:00 PM, Monday through Friday; **llow access only through these media** is set to Async (Modem).

All other settings are at their default values.

8. As another example, to configure a remote access policy that requires VPN connections for members of the Employees group to use smart card authentication and 128-bit encryption, use the New Remote Access Policy Wizard to create a common VPN policy with the following settings:

   - Policy name: VPN connections
   - Access Method: VPN access
   - User or Group: Select **Group**, and then specify the Employees group (example).
   - Authentication methods: Select **Smart Card or other Certificate**, and then clear all other check boxes.
   - Policy Encryption Level: Select the **Strongest encryption** check box, and then clear all other check boxes.

     For additional examples of remote access policies, see Remote Access Policies Examples.

     If you have created new remote access policies, either delete the default remote access policy named **Allow access if dial-up permission is enabled**, or move it so that it is the last policy to be evaluated. For more information, see Delete a remote access policy and Change the policy evaluation order.

**Configuring the secondary IAS server on a different domain controller**

To configure the secondary IAS server on a different domain controller, do the following:

1. On the other domain controller, install IAS as an optional networking component. For more information, see Install IAS.

2. Configure the secondary IAS server computer (the other domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the secondary IAS server authenticates connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the secondary IAS server computer is a member. Next, configure the secondary IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

   If the secondary IAS server authenticates connection attempts for user accounts in other domains, and those domains do not have a two-way trust with the domain in which the secondary IAS server computer is a member, see Authentication across forests.

   For additional examples of remote access policies, see Remote Access Policies Examples.

If you have created new remote access policies, either delete the default remote access policy named **Allow access if dial-up permission is enabled**, or move it so that it is the last policy to be evaluated. For more information, see Delete a remote access policy and Change the policy evaluation order.

4. Copy the configuration of the primary IAS server to the secondary IAS server. For more information, see Copy the IAS configuration to another server.

**Configuring RADIUS authentication and accounting on dial-up and VPN servers**

To configure each dial-up or VPN server to use the primary and secondary IAS servers for authentication, authorization, and accounting of remote access connections, do the following:

1. If the dial-up or VPN server is a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; or Windows 2000 and the Routing and Remote Access service; configure the primary and secondary IAS servers as RADIUS servers for both RADIUS authentication and accounting. For more information, see Use RADIUS authentication and Use RADIUS accounting.

2. If the dial-up or VPN server is a computer running Windows NT Server 4.0 and the Routing and Remote Access Service (RRAS), see the Windows NT Server 4.0 online Help for information about how to configure the primary and secondary IAS servers as RADIUS servers for RADIUS authentication.

3. If the dial-up or VPN server is a third-party network access server (NAS), see the documentation for the NAS to determine how to configure it as a RADIUS client with two RADIUS servers (the primary and secondary IAS servers).

# Extranet access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Extranet access**

This topic describes how IAS and the Routing and Remote Access service are used to support an extranet. An extranet is an extension of an organization intranet that is used to facilitate communication with business partners. It provides business partners with limited access to resources on an organization's intranet through a virtual private network (VPN) connection over the Internet. This enhances the speed and efficiency of the business relationship. The organization has multiple business partners, each of which need access to only a specific subnet or set of addresses within the organization's network. Network access control is defined at the IP level using IP packet filters for specific connection categories. The filters that are applied to VPN connections can be specified by using remote access policies.

This topic describes a typical configuration for an organization extranet that uses:

- Two IAS servers.

  Two IAS servers (one primary and one secondary) are used to provide fault tolerance for RADIUS-based authentication. If only one RADIUS server is configured and it becomes unavailable, VPN users cannot connect. By using two IAS servers and configuring all VPN servers (RADIUS clients) for both the primary and secondary IAS servers, the RADIUS clients can detect when the primary RADIUS server is unavailable and automatically fail over to the secondary IAS server.

- Active Directory domains.

  Active Directory domains contain the user accounts, passwords, and dial-in properties that each IAS server requires to authenticate user credentials and evaluate both authorization and connection constraints. To optimize IAS authentication and authorization response times and minimize network traffic, IAS is installed on domain controllers.

- Custom remote access policies.

  Remote access policies are configured to specify, based on group membership, how different business partners can access different extranet resources.

- VPN servers.

  VPN servers consist of computers running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; and Windows 2000 and the Routing and Remote Access service.

The following illustration shows the configuration for VPN-based remote access to the extranet by business partners.

**Note**

- This topic only describes how to configure IAS. It does not describe the configuration of Active Directory, the VPN servers, or the resources on the extranet. For more information about how to deploy these components, see the appropriate Help topics.

To configure IAS for this example, complete the following steps:

- Configure Active Directory for user accounts, groups, and certificate auto-enrollment.
- Configure the primary IAS server on a domain controller.
- Configure the secondary IAS server on a different domain controller.
- Configure RADIUS authentication and accounting on VPN servers.

**Configuring user accounts, groups, and certificate auto-enrollment**
To configure user accounts, groups, and certificate auto-enrollment, do the following:

1. Ensure that all business partners that are making remote access connections have a corresponding user account. Configure the user principal names (UPNs) for business partner accounts by using the organization name of the business partner. For example, for a user account named Someone for the business partner Microsoft, configure the UPN as someone@example.microsoft.com.
2. Manage your business partner's extranet access by user by setting the remote access permission on user accounts to **Allow access** or **Deny access**. To manage your business partner's extranet by group, set the remote access permission on user accounts to **Control access through Remote Access Policy**. For more information, see Configure remote access permission for a user.
3. Organize your business partner user accounts into the appropriate universal and nested global groups in order to take advantage of group-based remote access policies. Create global groups for each business partner and then add the appropriate user accounts. Next, create universal groups for business partner categories that contain the global groups as members. For example, for the business partner Microsoft, create a global group named Microsoft and add all Microsoft user accounts to the group. Then, because Microsoft is a supplier business partner, create a universal group named Suppliers and add the Microsoft global group as a member. For more information, see Group scope.

**Configuring the primary IAS server on a domain controller**
To configure the primary IAS server on a domain controller, do the following:

**On the domain controller, install IAS as an optional networking component.**
For more information, see Install IAS.

**Configure the IAS server computer (the domain controller) to read the properties of user accounts in the domain.**
For more information, see Enable the IAS server to read user accounts in Active Directory.

If the IAS server is authenticating connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the IAS server computer is a member. Next, configure the IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

**Enable file logging of accounting, authentication, and periodic status events.**
For more information, see Configure log file properties.

**Add the VPN servers as RADIUS clients of the IAS server.**
For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.

**Create remote access policies that reflect your required business partner extranet usage.**
For example, to create a remote access policy that restricts all VPN remote access traffic for members of the Suppliers group to the subnet of 192.168.47.0/24, use the New Remote Access Policy Wizard to create a new custom remote access policy with the following settings:

- Policy name: Supplier business partner connections
- Conditions: Windows-Groups matches Suppliers
- Permission: Grant remote access permission

- Profile settings, **Dial-in Constraints** tab: **Allow access only through these media** and the **Virtual (VPN)** media type are selected.
- Profile settings, **IP** tab, Input packet filter:
    - Deny all traffic except those listed below
    - Destination network, IP address: 192.168.47.0
    - Destination network, Subnet mask: 255.255.255.0
    - Protocol: Any
- Profile settings, **IP** tab, Output packet filter:
    - Deny all traffic except those listed below
    - Source network, IP address: 192.168.47.0
    - Source network, Subnet mask: 255.255.255.0
    - Protocol: Any
- Profile settings, **Authentication** tab: Select the **Microsoft Encrypted Authentication version 2 (MS-CHAP v2)** check box, and then clear all other check boxes.
- Profile settings, **Encryption** tab: Select the **Strongest** check box, and then clear all other check boxes.

For more information, see Add a remote access policy.

As another example, to create a remote access policy that restricts all VPN remote access traffic for members of the business partners Investors group to the IP address of 10.59.192.17, create a new remote access policy with the following settings:

- Policy name: Investor business partner connections
- Conditions: Windows-Groups matches Investors
- Permission: Grant remote access permission
- Profile settings, **Dial-in Constraints** tab: **Allow access only through these media** and the **Virtual (VPN)** media type are selected.
- Profile settings, **IP** tab, Input packet filter:
    - Deny all traffic except those listed below
    - Destination network, IP address: 10.59.192.17
    - Destination network, Subnet mask: 255.255.255.255
    - Protocol: Any
- Profile settings, **IP** tab, Output packet filter:
    - Deny all traffic except those listed below

    - Source network, IP address: 10.59.192.17
    - Source network, Subnet mask: 255.255.255.255
    - Protocol: Any

- Profile settings, **Authentication** tab: Select the **Microsoft Encrypted Authentication version 2 (MS-CHAP v2)** check box, and then clear all other check boxes.
- Profile settings, **Encryption** tab: Select the **Strongest** check box, and then clear all other check boxes.

For more information, see Add a remote access policy.

For additional examples of remote access policies, see Remote Access Policies Examples.

Delete the default remote access policies, or move them so that they are the last policies to be evaluated. For more information, see Delete a remote access policy and Change the policy evaluation order.

**Ensure that a computer certificate that can be validated by computers using smart cards is installed on the IAS server computer.**
For more information, see Computer certificates for certificate-based authentication.

**Configuring the secondary IAS server on a different domain controller**
To configure the secondary IAS server on a different domain controller, do the following:

**On the other domain controller, install IAS as an optional networking component.**
For more information, see Install IAS.

**Configure the secondary IAS server computer (the other domain controller) to read the properties of user accounts in the domain.**
For more information, see Enable the IAS server to read user accounts in Active Directory.

If the secondary IAS server authenticates connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the secondary IAS server computer is a member. Next, configure the secondary IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

**Ensure that a computer certificate that can be validated by computers using smart cards is installed on the IAS server computer.**
For more information, see Computer certificates for certificate-based authentication.

**Copy the configuration of the primary IAS server to the secondary IAS server.**
For more information, see Copy the IAS configuration to another server.

**Configuring RADIUS authentication and accounting on the VPN servers**
To configure each VPN server to use the primary and secondary IAS servers for authentication, authorization, and accounting of remote access connections, do the following:

1. If the VPN server is a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; or Windows 2000 and the Routing and Remote Access service, configure the primary and secondary IAS servers as RADIUS servers for both RADIUS authentication and accounting. For more information, see Use RADIUS authentication and Use RADIUS accounting.

2. If the VPN server is a computer running Windows NT server 4.0 and the Routing and Remote Access Service (RRAS), see the Windows NT server 4.0 online Help for information about how to configure the primary and secondary IAS servers as RADIUS servers for RADIUS authentication.

# Internet access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet access**

This topic describes how IAS is used to authenticate and authorize Internet connections for the customers of an Internet service provider (ISP). In this example, the ISP has a single data center that supports a large number of customers. Dial-up servers are distributed with multiple Points of Presence (POPs). The ISP offers two service plans: A basic plan for users with dial-up modems and a premium plan that provides support for ISDN connections. Connection authorization is provided to customers based on the subscription plan.

For each basic plan customer, a Connection Manager service profile is used to enable access to the Internet through the ISP's POPs. For each premium plan user, the same Connection Manager service profile is used to enable ISDN access. The service profile contains both dial-up and ISDN POPs. Connection Manager makes the appropriate POPs available based on the type of connection device that the user selects.

This topic describes a configuration for an ISP that uses:

- Two IAS servers.

  Two IAS servers (one primary and one secondary) are used to provide fault tolerance for RADIUS-based authentication. If only one RADIUS server is configured and it becomes unavailable, ISP customers cannot connect to the Internet. By using two IAS servers and configuring all dial-up servers (RADIUS clients) for both the primary and secondary IAS servers, RADIUS clients detect when the primary RADIUS server is unavailable and automatically fail over to the secondary IAS server.

- Active Directory domains.

  Active Directory domains contain the user accounts, passwords, and dial-in properties that each IAS server requires to authenticate user credentials and evaluate both authorization and connection constraints. To optimize IAS authentication and authorization response times and minimize network traffic, IAS is installed on domain controllers.

- Custom remote access policies.

  Remote access policies are configured to specify, based on group membership, the different types of connection constraints for the two service plans (basic and premium).

- Multiple dial-up servers.

  Dial-up servers consist of third-party network access server (NAS) devices, and computers running different versions of Windows and the Routing and Remote Access service. The dial-up servers are geographically distributed at various POPs so that ISP customers can access the Internet with a local call.

The following illustration shows the configuration of an ISP providing Internet access.

**Note**

- This topic only describes how to configure IAS. It does not describe the configuration of Active Directory, the dial-up servers, or the Connection Manager profile. For more information about how to deploy these components, see the

appropriate Help topics.

To configure IAS to support Internet access for an ISP, complete the following steps:

- Configure Active Directory for user accounts and groups.
- Configure the primary IAS server on a domain controller.
- Configure the secondary IAS server on a different domain controller.
- Configure RADIUS accounting and authentication on dial-up servers.

**Configuring user accounts and groups**

To configure user accounts and groups, do the following:

1. Ensure that all customers that are making Internet connections have a corresponding user account. The user principal names that are created should contain the @ (at) sign, followed by the ISP name (for example, *UserName***@***ISPName*).
2. If you want to manage access by group, ensure that all user accounts are configured with the **Control access through Remote Access Policy** remote access permission. For more information, see Configure remote access permission for a user.
3. Create two universal groups: one for basic plan users (named BasicPlanUsers) and one for premium plan users (named PremiumPlanUsers). Because of the large number of potential users, create global groups and make user accounts members of global groups. Next, add the global groups as members of the universal groups. For more information, see Group scope.
4. If some customers are using the Challenge-Handshake Authentication Protocol (CHAP), you must enable support for reversibly encrypted passwords in the appropriate domains. For more information, see Enable reversibly encrypted passwords in a domain.

**Configuring the primary IAS server on a domain controller**

To configure the primary IAS server on a domain controller, do the following:

1. On the domain controller, install IAS as an optional networking component. For more information, see Install IAS.
2. Configure the IAS server computer (the domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.
3. If the IAS server authenticates connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the IAS server computer is a member. Next, configure the IAS server computer to read the properties of user accounts in other domains. For more information, seeEnable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.
4. Enable file logging for accounting and authentication events. For more information, see Configure log file properties.
5. If needed, configure additional UDP ports for authentication and accounting messages that are sent by RADIUS clients. For more information, see Configure IAS port information. By default, IAS uses UDP ports 1812 and 1645 for authentication and ports 1813 and 1646 for accounting.
6. Add the dial-up servers as RADIUS clients of the IAS server. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets. Enable the use of the Message Authenticator attribute only when it is supported by the RADIUS client.
7. Create remote access policies for both basic and premium plan customers.

Create two remote access policies. One policy is used to authorize basic plan connections (by using the BasicPlanUsers group). The other policy is used to authorize premium plan connections (by using the PremiumPlanUsers group).

8. Authorize connections for basic plan users by using the New Remote Access Policy Wizard to create a common VPN policy with the following settings:

   - Policy name: Basic plan connections
   - Conditions: Windows-Groups matches BasicPlanUsers
   - Permission: Grant remote access permission
   - Profile settings, **Dial-in Constraints** tab: **Allow access only through these media** and the **Async (Modem)** media type are selected.
   - Profile settings, **Authentication** tab: The **Microsoft Encrypted Authentication version 2 (MS-CHAP v2)**, **Microsoft Encrypted Authentication (MS-CHAP)**, and **Encrypted Authentication (CHAP)** protocols are selected.

     For more information, see Add a remote access policy.

9. Authorize connections for premium plan users by creating a new remote access policy with the following settings:

   - Policy name: Premium plan connections
   - Conditions: Windows-Groups matches PremiumPlanUsers
   - Permission: Grant remote access permission
   - Profile settings, **Dial-in Constraints** tab: **Allow access only through these media** is selected, and then the **ISDN Async V.110**, **ISDN Async V.120**, and **ISDN Async** media type are selected.
   - Profile settings, **Authentication** tab: The **Microsoft Encrypted Authentication version 2 (MS-CHAP v2)**, **Microsoft Encrypted Authentication (MS-CHAP)**, and **Encrypted Authentication (CHAP)** protocols are selected.

10. Because all of the ISP customers are using either the basic or premium plan, delete the default remote access policies so that no other types of connections are authorized. For more information, see Delete a remote access policy.

    For additional examples of remote access policies, see Remote Access Policies Examples.

**Configuring the secondary IAS server on a different domain controller**

To configure the secondary IAS server on a different domain controller, do the following:

1. On the other domain controller, install IAS as an optional networking component. For more information, see Install IAS.

2. Configure the secondary IAS server computer (the other domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the secondary IAS server is authenticating connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the secondary IAS server computer is a member. Next, configure the secondary IAS server computer to read the properties of user accounts in other domains. For more information, seeEnable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

4. Copy the configuration of the primary IAS server to the secondary IAS server. For more information, see Copy the IAS configuration to another server.

**Configuring RADIUS accounting and authentication on dial-up servers**

To configure each dial-up server to use the primary and secondary IAS servers for authentication, authorization, and accounting of remote access connections, do the following:

1. If the dial-up server is a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; or Windows 2000 and the Routing and Remote Access service, configure the primary and secondary IAS servers as RADIUS servers for both RADIUS authentication and accounting. For more information, see Use RADIUS authentication and Use RADIUS accounting

2. If the dial-up server is a computer running Windows NT server 4.0 and the Routing and Remote Access Service (RRAS), see the Windows NT server 4.0 online Help for information about how to configure the primary and secondary IAS servers as RADIUS servers for RADIUS authentication.

3. If the dial-up server is a third-party network access server (NAS), see the documentation for the NAS to determine how to configure it as a RADIUS client with two RADIUS servers (the primary and secondary IAS servers).

# Outsourced VPN remote access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Outsourced VPN remote access**

This topic describes how IAS is used by both an outsourced service provider and an organization to outsource VPN-based remote access. The outsourced service provider offers worldwide Points of Presence (POPs), which organization employees can call. After the call is made, the employee's computer makes a Point-to-Point Tunneling Protocol (PPTP) VPN connection to one of the organization's VPN servers.

The organization in this example configuration has a large central location with remote users. Each user requires secure access to the organization network. The organization has determined that it is more cost-effective to provide VPN remote access through outsourcing than to implement and maintain its own dial-up remote access infrastructure.

The encryption and authentication requirements for the Internet connection are less stringent than those required for the VPN connection. For example, the Internet connection uses CHAP without encryption, while the VPN connection uses smart cards and Extensible Authentication Protocol-Transport Level Security (EAP-TLS) with 128-bit encryption.

This topic describes a configuration for an organization that uses:

- Two IAS servers.

  Two IAS servers (one primary and one secondary) are used to provide fault tolerance for RADIUS-based authentication, authorization, and accounting. If only one RADIUS server is configured and it becomes unavailable, dial-up and VPN users cannot connect. By using two IAS servers, the IAS proxies in the ISP network can detect when the primary RADIUS server becomes unavailable and automatically fail over to the secondary IAS server. The IAS servers are placed in the perimeter network.

- Active Directory domains.

  Active Directory domains contain the user accounts, passwords, and dial-in properties that each IAS server requires to authenticate user credentials and evaluate both authorization and connection constraints.

- Smart card certificate infrastructure.

  The Extensible Authentication Protocol-Transport Level Security (EAP-TLS) authentication protocol is used with smart cards to authenticate VPN remote access users and provide the highest level of security for VPN authentication.

- Custom remote access policies.

  Remote access policies are configured to specify, based on group membership, the different types of connection constraints for users.

- Connection Manager.

  Connection Manager is used to create a profile with all of the phone numbers of the ISP's POPs. This automates both the dialing of the ISP and the creation of the VPN connection. Remote access users select the location from which they are dialing, and then select either a local or other appropriate ISP phone number (POP) from the phone book in the Connection Manager service profile. Remote access users connect to the ISP's dial-up access server through the Challenge Handshake Password Authentication (CHAP). The realm name portion of the user name is used by the ISP's proxies to forward authentication requests to an IAS proxy in the organization’s perimeter network. After the ISP connection is made, the Connection Manager profile automatically initiates a VPN connection to one of the organization's VPN servers.

- VPN servers.

  VPN servers consist of computers running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; and Windows 2000 and the Routing and Remote Access service.

This topic also describes a configuration for an ISP that uses:

- Two IAS proxies in the ISP's network.

  The ISP uses RADIUS proxies on its network to forward RADIUS request messages between the ISP dial-up servers and the RADIUS servers of multiple customers. Two IAS proxies are used to provide fault tolerance for RADIUS authentication.

- Dial-up access servers.

  Dial-up servers consist of computers running:

  - Windows Server 2003, Standard Edition
  - Windows Server 2003, Enterprise Edition
  - Windows Server 2003, Datacenter Edition
  - Windows 2000 and the Routing and Remote Access service
  - Third-party network access server (NAS) devices

The following illustration shows the outsourced VPN configuration.

**Note**

- This topic only describes how to configure IAS. It does not describe the configuration of Active Directory domains, the smart card certificate infrastructure, Connection Manager, or the VPN servers. For more information about how to deploy these components, see the appropriate Help topics.

To configure IAS for this example, complete the following steps:

- Configure Active Directory for user accounts and groups.
- Configure the primary IAS server in the perimeter network.
- Configure the secondary IAS server in the perimeter network.
- Configure RADIUS authentication and accounting on VPN servers.
- Configure the Internet firewall to support RADIUS traffic.
- Configure the primary IAS proxy at the service provider.
- Configure the secondary IAS proxy at the service provider.

- Configure RADIUS accounting and authentication on the dial-up access servers at the service provider.

**Configuring user accounts and groups**

To configure user accounts and groups, do the following:

1. Ensure that all users who are making remote access connections have a corresponding user account.

2. If you want to manage access by group, ensure that all user accounts are configured with the **Control access through Remote Access Policy** remote access permission. For more information, see Configure remote access permission for a user.

3. Create two universal groups: one for employees (named Employees) and one for contractors (named Contractors). Because of the large number of potential users, create global groups and add the user accounts as members to the appropriate group. Next, add the global groups as members to the universal groups. For more information, see Group scope.

4. Because the ISP requires the use of Challenge-Handshake Authentication Protocol (CHAP) authentication for the dial-up connection, you must enable support for reversibly encrypted passwords for the appropriate domains. For more information, see Enable reversibly encrypted passwords in a domain.

**Configuring the primary IAS server in the perimeter network**

To configure the primary IAS server in the perimeter network, do the following:

1. On a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition in the perimeter network; install IAS as an optional networking component. For more information, see Install IAS. The computer on which IAS is installed is not required to be dedicated to forwarding RADIUS messages. You can install IAS on a Web server, file server, or DNS server.

2. Configure the IAS server computer to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the IAS server is authenticating connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the IAS server computer is a member. Next, configure the IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

   If the IAS server is authenticating connection attempts for user accounts in other domains, and those domains do not have a two-way trust with the domain in which the IAS server computer is a member, see Authentication across forests.

4. Enable file logging for accounting and authentication events. For more information, see Configure log file properties.

5. If needed, configure additional UDP ports for RADIUS messages that are sent by the ISP's RADIUS proxies. For more information, see Configure IAS port information. By default, IAS uses UDP ports 1812 and 1645 for authentication and ports 1813 and 1646 for accounting.

6. Add the service provider's RADIUS proxies as RADIUS clients of the IAS server. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.

7. Create remote access policies that allow VPN remote access for employees and deny it for contractors.

   Use the New Remote Access Policy Wizard to create a common remote access policy that both allows VPN remote access for members of the Employees group and requires the use of EAP-TLS and 128-bit encryption with the following settings:

- Policy name: VPN connections for employees
- Access Method: VPN access
- User or Group: Select **Group**, and then specify the Employees group (example).
- Authentication methods: Select the **Extensible Authentication Protocol** check box, ensure that the **Smart Card or other Certificate** EAP type is selected, and then clear all other check boxes.
- Policy Encryption Level: Select the **Strongest encryption** check box, and then clear all other check boxes.

  Create a custom remote access policy that denies VPN remote access for members of the Contractors group with the following settings:

- Policy name: **Deny VPN connections for contractors**
- Conditions:
- Windows-Groups matches Contractors
- NAS-port-type matches Virtual (VPN)
- Permission: Deny remote access permission

  For additional examples of remote access policies, see Remote Access Policies Examples.

8. Delete the default remote access policies. For more information, see Delete a remote access policy.

**Configuring the secondary IAS server in the perimeter network**

To configure the secondary IAS server on another computer in the perimeter network, do the following:

1. On another computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows server 2003, Datacenter Edition in the perimeter network; install IAS as an optional networking component. For more information, see Install IAS.

2. Configure the secondary IAS server computer (the other domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the secondary IAS server is authenticating connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the secondary IAS server computer is a member. Next, configure the secondary IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

   If the secondary IAS server is authenticating connection attempts for user accounts in other domains, and those domains do not have a two-way trust with the domain in which the secondary IAS server computer is a member, see Authentication across forests.

4. Copy the configuration from the primary IAS proxy to the secondary IAS proxy in the perimeter network. For more information, see Copy the IAS configuration to another server.

**Configuring RADIUS authentication and accounting on the VPN servers**

To configure each VPN server to use the primary and secondary IAS servers for authentication, authorization, and accounting of remote access connections, do the following:

1. If the VPN server is a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise

Edition; Windows Server 2003, Datacenter Edition; or Windows 2000 and the Routing and Remote Access service, configure the primary and secondary IAS servers in the perimeter network as RADIUS servers for both RADIUS authentication and accounting. For more information, see Use RADIUS authentication and Use RADIUS accounting.

2. If the VPN server is a computer running Windows NT Server 4.0 and the Routing and Remote Access Service (RRAS), see the Windows NT Server 4.0 online Help for information about how to configure the primary and secondary IAS servers as RADIUS servers for RADIUS authentication.

3. If the VPN server is a third-party network access server (NAS), see the documentation for the NAS to determine how to configure it as a RADIUS client with two RADIUS servers (the primary and secondary IAS servers).

**Configuring the Internet firewall to support RADIUS traffic**

1. Configure the Internet firewall to allow RADIUS traffic between the IAS servers in the perimeter network and the IAS proxies in the ISP's network.

   For more information, see IAS and firewalls

**Configuring the primary IAS proxy at the service provider**

1. On a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition in the ISP's network; install IAS as an optional networking component. For more information, see Install IAS. The computer on which IAS is installed is not required to be dedicated to forwarding RADIUS messages. You can install IAS on a Web server, file server, or DNS server.

2. If needed, configure additional UDP ports for authentication and accounting messages that are sent by the ISP's dial-up access servers. For more information, see Configure IAS port information. By default, IAS uses UDP ports 1812 and 1645 for authentication and 1813 and 1646 for accounting.

3. Add the ISP's dial-up access servers as RADIUS clients of the IAS proxy. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.

4. Create a connection request policy that forwards RADIUS request messages on the basis of the ISP customer’s realm name.

   Use the New Connection Request Policy Wizard to create a connection request policy with the condition that the user name matches the realm name for the customer's organization and forwards RADIUS request messages to a remote RADIUS server for authentication. In the New Connection Request Policy Wizard, use the New Remote RADIUS Server Group Wizard to create a remote RADIUS server group with members that include the two IAS servers in the customer's perimeter network.

   For more information, see Add a connection request policy.

5. Delete the default connection request policy named **Use Windows authentication for all users**. For more information, see Delete a connection request policy.

**Configuring the secondary IAS proxy at the service provider**

To configure the secondary IAS proxy on another computer in the perimeter network, do the following:

1. On another computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition in the ISP's network; install IAS as an optional networking component. For more information, see Install IAS.

2. Copy the configuration of the primary IAS proxy to the secondary IAS proxy in the ISP's network. For more information, see Copy the IAS configuration to another server.

**Configuring RADIUS accounting and authentication on the dial-up access servers at the service provider**

To configure each dial-up or VPN server to use the primary and secondary IAS servers for authentication, authorization, and accounting of remote access connections, do the following:

1. If the dial-up or VPN server is a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; or Windows 2000 and the Routing and Remote Access service, configure the primary and secondary IAS proxies in the ISP's network as RADIUS servers for both RADIUS authentication and accounting. For more information, see Use RADIUS authentication and Use RADIUS accounting.

2. If the dial-up or VPN server is a computer running Windows NT Server 4.0 and the Routing and Remote Access Service (RRAS), see the Windows NT Server 4.0 online Help for information about how to configure the primary and secondary IAS proxies in the ISP's network as RADIUS servers for RADIUS authentication.

3. If the dial-up or VPN server is a third-party network access server (NAS), see the documentation for the NAS to determine how to configure it as a RADIUS client with two RADIUS servers (the primary and secondary IAS proxies) in the ISP's network.

# Outsourced wireless access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Outsourced wireless access**

This topic describes how IAS is used by both an outsourced wireless provider and an organization to outsource wireless Internet access. The wireless service provider offers remote wireless access points in locations such as airports. Employees of an organization can use these points to access the Internet. The wireless service provider forwards the access request of a client to an IAS server in the organization. The IAS server provides authentication and authorization. The wireless service provider determines the employee's organization from the realm name portion of the employee's user name during the authentication process. This enables the service provider to bill the organization for the employee's use of the wireless connection.

This topic describes a configuration for an organization that uses:

- Two IAS servers.

  Two IAS servers (one primary and one secondary) are used to provide fault tolerance for RADIUS-based authentication, authorization, and accounting. If only one RADIUS server is configured and it becomes unavailable, outsourced wireless clients cannot connect. By using two IAS servers, the IAS proxies in the wireless service provider's network can detect when the primary RADIUS server is unavailable and automatically fail over to the secondary IAS server. The IAS servers are placed in the perimeter network.

- Active Directory domains.

  Active Directory domains contain the user accounts, passwords, and dial-in properties that each IAS server requires to authenticate user credentials and evaluate both authorization and connection constraints.

- A certificate infrastructure.

  The Extensible Authentication Protocol-Transport Level Security (EAP-TLS) authentication protocol is used to authenticate wireless clients with locally installed user certificates.

- A wireless remote access policy.

  A common remote access policy is configured so that authenticated wireless users can access the Internet.

This topic also describes a configuration for a wireless service provider that uses:

- Two IAS proxies in the wireless service provider's network.

  The wireless service provider uses RADIUS proxies in its network to forward RADIUS request messages between the wireless access points and the RADIUS servers. Two IAS proxies are used to provide fault tolerance for RADIUS authentication.

- Multiple wireless access points.

  Third-party wireless access points provide wireless access in different airports.

The following illustration shows the outsourced wireless configuration.

**Note**

- This topic only describes how to configure IAS. It does not describe the configuration of Active Directory domains, the certificate infrastructure, or the wireless access points. For more information about how to deploy these components, see the appropriate Help topics.

To configure IAS for this example, complete the following steps:

- Configure Active Directory for user accounts and groups.
- Configure the primary IAS server in the perimeter network.
- Configure the secondary IAS server in the perimeter network.
- Configure the Internet firewall to support RADIUS traffic.
- Configure the primary IAS proxy at the service provider.
- Configure the secondary IAS proxy at the service provider.
- Configure RADIUS accounting and authentication on the wireless access points at the service provider.

**Configuring user accounts and groups**

To configure user accounts and groups, do the following:

1. Ensure that all users that are making remote access connections have a corresponding user account.
2. If you want to manage access by group, ensure that all user accounts are configured with the **Control access through Remote Access Policy** remote access permission. For more information, see Configure remote access permission for a user.
3. Organize your wireless access users into the appropriate universal and nested groups in order to take advantage of group-based remote access policies. For example, create a universal group named WirelessUsers that contains global groups of wireless user accounts. For more information, see Group scope.

**Configuring the primary IAS server in the perimeter network**

To configure the primary IAS server in the perimeter network, do the following:

1. On a computer runningWindows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition in the perimeter network; install IAS as an optional networking component. For more information, see Install IAS. The computer on which IAS is installed is not required to be dedicated to forwarding RADIUS messages. You can install IAS on a Web server, file server, or DNS server.
2. Configure the IAS server computer to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the IAS server is authenticating connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the IAS server computer is a member. Next, configure the IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

   If the IAS server is authenticating connection attempts for user accounts in other domains, and those domains do not have a two-way trust with the domain in which the IAS server computer is a member, see Authentication across forests.

4. Enable file logging for accounting and authentication events. For more information, see Configure log file properties.

5. If needed, configure additional UDP ports for RADIUS messages that are sent by the wireless service provider's RADIUS proxies. For more information, see Configure IAS port information. By default, IAS uses UDP ports 1812 and 1645 for authentication and ports 1813 and 1646 for accounting.

6. Add the service provider's RADIUS proxies as RADIUS clients of the IAS server. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.

7. Use the New Remote Access Policy Wizard to create a common wireless policy with the following settings:

   - Policy name: Wireless access
   - Access Method: Wireless access
   - User or Group: Select **Group**, and then specify the WirelessUsers group (example).
   - Authentication methods: Select **Smart Card or other Certificate**. If you have multiple computer certificates, click **Configure**, and then select the appropriate computer certificate.
   - Policy encryption level: Clear the **Basic encryption (MPPE 40-bit)** and **Basic encryption (MPPE 56-bit)** check boxes.

     For additional examples of remote access policies, see Remote Access Policies Examples.

8. Delete the default remote access policies, or ensure that they are the last policies to be evaluated. For more information, see Delete a remote access policy and Change the policy evaluation order.

**Configuring the secondary IAS server in the perimeter network**

To configure the secondary IAS server on another computer in the perimeter network, do the following:

1. On another computer runningWindows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition in the perimeter network; install IAS as an optional networking component. For more information, see Install IAS.

2. Configure the secondary IAS server computer (the other domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the secondary IAS server is authenticating connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the secondary IAS server computer is a member. Next, configure the secondary IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

   If the secondary IAS server is authenticating connection attempts for user accounts in other domains, and those domains do not have a two-way trust with the domain in which the secondary IAS server computer is a member, see

Authentication across forests.

4. Copy the configuration of the primary IAS proxy to the secondary IAS proxy in the perimeter network. For more information, see Copy the IAS configuration to another server.

**Configuring the Internet firewall to support RADIUS traffic**

To configure the Internet firewall to support RADIUS traffic, do the following:

1. Configure the Internet firewall to allow RADIUS traffic between the IAS servers in the perimeter network and the IAS proxies in the wireless service provider's network.

   For more information, see IAS and firewalls.

**Configuring the primary IAS proxy at the service provider**

To configure the primary IAS proxy at the service provider, do the following:

1. On a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition in the wireless service provider's network; install IAS as an optional networking component. For more information, see Install IAS. The computer on which IAS is installed is not required to be dedicated to forwarding RADIUS messages. You can install IAS on a Web server, file server, or DNS server.

2. If needed, configure additional UDP ports for authentication and accounting messages that are sent by the wireless service provider's access points. For more information, see Configure IAS port information. By default, IAS uses UDP ports 1812 and 1645 for authentication and ports 1813 and 1646 for accounting.

3. Add the wireless service provider's access points as RADIUS clients of the IAS proxy. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.

4. Create a connection request policy that forwards RADIUS request messages based on the realm name of the wireless service provider's customer.

   Use the New Connection Request Policy Wizard to create a connection request policy that forwards connection requests to a remote RADIUS server group for authentication and where the user name matches the realm name for the customer's organization. In the New Connection Request Policy Wizard, use the New Remote RADIUS server Group Wizard to create a remote RADIUS server group with members that include the two IAS servers in the customer's perimeter network.

   For more information, see Add a connection request policy.

5. Delete the default connection request policy named **Use Windows authentication for all users**. For more information, see Delete a connection request policy.

**Configuring the secondary IAS proxy at the service provider**

To configure the secondary IAS proxy on another computer in the perimeter network, do the following:

1. On another computer runningWindows Server 2003, Standard Edition; Windows Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition in the wireless service provider network; install IAS as an optional networking component. For more information, see Install IAS.

2. Copy the configuration of the primary IAS proxy to the secondary IAS proxy in the wireless service provider's network. For more information, see Copy the IAS configuration to another server.

**Configuring RADIUS accounting and authentication on the wireless access points at the service provider**

Configure each wireless access point as a RADIUS client with two RADIUS servers (the primary and secondary IAS servers). For more information, see the documentation for the wireless access point.

# Ethernet switch access with IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Ethernet switch access**

This topic describes how IAS can be used to support authentication, authorization, and accounting for authenticated Ethernet switch connections to an organization. In contrast to user-authenticated connections, such as dial-up and VPN connections, Ethernet connections use computer certificates and computer authentication to validate the computer that is connecting to the Ethernet switch. This topic describes a typical configuration for an organization that uses:

- Two IAS servers.

  Two IAS servers (one primary and one secondary) are used to provide fault tolerance for RADIUS-based authentication. If only one RADIUS server is configured and it becomes unavailable, authenticating switch clients cannot connect. By using two IAS servers and configuring all authenticating Ethernet switches (RADIUS clients) for both the primary and secondary IAS servers, the RADIUS clients can detect when the primary RADIUS server is unavailable and automatically fail over to the secondary IAS server.

- Active Directory domains.

  Active Directory domains contain the user accounts, passwords, and dial-in properties that each IAS server requires to authenticate user credentials and evaluate both authorization and connection constraints. To optimize IAS authentication and authorization response times and minimize network traffic, IAS is installed on domain controllers.

- A computer certificate infrastructure.

  The Extensible Authentication Protocol-Transport Level Security (EAP-TLS) authentication protocol is used with computer certificates to authenticate Ethernet connections and provide the highest level of security for authentication.

- Ethernet switch remote access policies.

  Remote access policies are configured for authenticated switch connections so that guest switch users obtain restricted access to a virtual LAN (VLAN) that contains a certificate server and authenticated switch users obtain unrestricted access to the organization intranet.

- Multiple authenticating switches.

  Multiple third-party Ethernet authenticating switches provide access in different buildings of an organization.

- A certificate server on a separate VLAN for new Ethernet switch clients.

  A certificate server is placed on a separate virtual local area network (VLAN) and used by a new switch client to obtain a computer certificate for subsequent switch access. After 10 minutes of receiving a guest connection, the switch client is disconnected. When the switch client computer reconnects, it authenticates by using the newly installed computer certificate and obtains authenticated switch access to the network.

The following illustration shows an Ethernet switch configuration.

**Notes**

- This topic only describes how to configure IAS. It does not describe the configuration of Active Directory domains, the certificate infrastructure, or Ethernet switches. For more information about how to deploy these components, see the appropriate Help topics.

- This topic describes the bootstrapping of new Ethernet clients by using a VLAN that contains a certificate server. You can also bootstrap new Ethernet clients by using an unauthenticated Ethernet connection or a certificate that has been extracted to a floppy disk.

To configure IAS for this example, complete the following steps:

- Configure Active Directory for computer accounts and groups.

- Configure the primary IAS server on a domain controller.

- Configure the secondary IAS server on a different domain controller.

- Configure RADIUS authentication and accounting on Ethernet switches.

**Configuring computer accounts and groups**

To configure computer accounts and groups, do the following:

1. Ensure that all computers that are making authenticating switch connections have a corresponding computer account.

2. If you want to manage switch access by group, set the remote access permission on computer accounts to **Control access through Remote Access Policy**. For more information, see Configure remote access permission for a user.

3. Organize switch access computers into the appropriate universal and nested groups in order to take advantage of group-based remote access policies. For example, create a universal group named SwitchComputers that contains global groups of switch computer accounts. For more information, see Group scope.

4. Configure the domain in which the IAS server computers are members for the auto-enrollment of computer certificates. For more information, see Configure automatic certificate allocation from an enterprise CA.

5. Configure the Guest account to allow guest access for new Ethernet clients. For more information, see Guest authentication. Enable reversibly encrypted password storage on the Guest account. For more information, see User and computer accounts.

6. Create a group named Guests, and add the Guest account as a member. For more information, see Create a new group.

**Configuring the primary IAS server on a domain controller**

To configure the primary IAS server on a domain controller, do the following:

1. On the domain controller, install IAS as an optional networking component. For more information, see Install IAS.

2. Configure the IAS server computer (the domain controller) to read the properties of user and computer accounts in the

domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the IAS server authenticates connection attempts for user and computer accounts in other domains, verify that the other domains have a two-way trust with the domain in which the IAS server computer is a member. Next, configure the IAS server computer to read the properties of user and computer accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

   If the IAS server authenticates connection attempts for user and computer accounts in other domains, and those domains do not have a two-way trust with the domain in which the IAS server computer is a member, see Authentication across forests.

4. Enable file logging for accounting and authentication events. For more information, see Configure log file properties.

5. If needed, configure additional UDP ports for authentication and accounting messages that are sent by RADIUS clients. For more information, see Configure IAS port information. By default, IAS uses UDP ports 1812 and 1645 for authentication and ports 1813 and 1646 for accounting.

6. Add the authenticating Ethernet switches as RADIUS clients of the IAS server. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets. Enable the use of the Message Authenticator attribute only when it is supported by the Ethernet switch.

7. Use the New Remote Access Policy Wizard to create a common Ethernet policy with the following settings:

   - Policy name: Ethernet switch access
   - Access Method: Ethernet
   - User or Group: Select **Group**, and then specify the SwitchComputers group (example).
   - Authentication methods: Select **Smart Card or other Certificate**. If you have multiple computer certificates, click **Configure**, and then select the appropriate computer certificate.

8. If you are using certificate-based authentication, you can use the New Remote Access Policy Wizard to create a custom Ethernet switch policy with the following settings:

   - Policy name: New switch access
   - Conditions: NAS-Port-Type matches Ethernet and Windows-Groups matches Guests
   - Permission: Grant remote access permission
   - Profile settings, **Dial-in Constraints** tab: Select the **Minutes client can be connected** check box, and then type **10**.
   - Profile settings, **Authentication** tab: Select **Extensible Authentication Protocol** and the **MD-5 Challenge** EAP type, and then clear all other check boxes.
   - Profile settings, **Advanced** tab: Add the **Tunnel-Type** attribute with the value of **Virtual LANs (VLAN)**; Add the **Tunnel-Pvt-Group-ID** attribute with the value of the VLAN ID that corresponds to the VLAN that contains the certificate server for new switch clients.

   For additional examples of remote access policies, see Remote Access Policies Examples.

9. Delete the default remote access policies, or ensure that they are the last policies to be evaluated. For more information, see Delete a remote access policy and Change the policy evaluation order.

**Configuring the secondary IAS server on a different domain controller**

To configure the secondary IAS server on a different domain controller, do the following:

1. On the other domain controller, install IAS as an optional networking component. For more information, see Install IAS.

2. Configure the secondary IAS server computer (the other domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the secondary IAS server authenticates connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the secondary IAS server computer is a member. Next, configure the secondary IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

   If the secondary IAS server authenticates connection attempts for user accounts in other domains, and those domains do not have a two-way trust with the domain in which the secondary IAS server computer is a member, see Authentication across forests.

4. Copy the configuration of the primary IAS server to the secondary IAS server. For more information, see Copy the IAS configuration to another server.

**Configuring RADIUS authentication and accounting on Ethernet switches**

To configure your third-party Ethernet switch RADIUS client with two RADIUS servers (the primary and secondary IAS servers), see the Ethernet switch documentation.

# Deploying IAS as a RADIUS Proxy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying IAS as a RADIUS proxy**
This section covers:

- Planning for IAS as a RADIUS Proxy
- IAS as a RADIUS proxy

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Planning for IAS as a RADIUS Proxy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Planning for IAS as a RADIUS proxy**
This section covers:

- IAS as a RADIUS proxy design considerations
- IAS as a RADIUS proxy security considerations

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# IAS as a RADIUS proxy design considerations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS as a RADIUS proxy design considerations**

Consider the following design issues when deploying IAS as a RADIUS proxy:

- The common uses of IAS as a RADIUS proxy

  For more information about common ways to use IAS as a RADIUS proxy, see IAS as a RADIUS proxy.

- Connection request policy configuration

  The default connection request policy named **Use Windows authentication for all users** is configured for IAS when it is used as a RADIUS server. To create a connection request policy to use IAS as a RADIUS proxy, you must first create a remote RADIUS server group. Next, create a connection request policy that forwards authentication requests to a remote RADIUS server group. Finally, either delete the default connection request policy or move the new connection request policy so that it is evaluated first. For more information, see Introduction to connection request processing. For an example of a connection request policy configured when IAS is being used as a RADIUS proxy, see Remote RADIUS server.

- Realm replacement and attribute manipulation

  To convert realm names and configure RADIUS message forwarding based on the realm name, you must configure attribute manipulation for the User-Name attribute on the appropriate connection request policy. For more information, see Connection request policies and Configure attribute manipulation. For an example of a connection request policy that forwards authentication requests based on a specific realm name, see Remote RADIUS server.

  If you are using the MS-CHAP v2 authentication protocol, you cannot manipulate the User Name attribute if the connection request policy is used to forward the RADIUS message. The only exception occurs when a backslash character (\) is used and the manipulation only affects the information to the left of it. A backslash character is typically used to indicate a domain name (the information to the left of it) and a user account name within the domain (the information to the right of it). In this case, only attribute manipulation rules that modify or replace the domain name are allowed.

- The use of additional RADIUS attributes and vendor-specific attributes

  If you plan to return additional RADIUS attributes and vendor-specific attributes (VSAs) with RADIUS requests, you must add the RADIUS attributes and VSAs to the appropriate connection request policy. For more information, see Vendor-specific attribute overview and Configure advanced attributes.

- Remote RADIUS server group configuration

  To forward RADIUS requests, the connection request policy must be configured to use a remote RADIUS server group (a list of one or more RADIUS servers to which RADIUS messages are forwarded). For more information, see Remote RADIUS server groups and Configure Remote RADIUS Server Groups.

- Copy logging information at the IAS proxy

  The IAS proxy can record all RADIUS accounting information in the local log file. This creates a central location for all authentication and accounting information for all of the access servers of the IAS proxy. For more information, see Connection request policies.

- Authentication and accounting ports

  When you configure a server in a remote RADIUS server group, you can configure custom UDP ports to which RADIUS authentication and accounting messages are sent. The default UDP port for authentication requests is 1812. The default

UDP port for accounting requests is 1813. For more information, see Remote RADIUS server groups and Configure the authentication and accounting settings of a group member.

- Load balancing and failure detection

  When you configure multiple servers in a remote RADIUS server group, you can configure settings that determine how the IAS server balances the load of authentication and accounting requests over the RADIUS servers in the group. You can use additional settings to configure IAS to detect and recover from the failure of a remote RADIUS server group member. For more information, see Configure the load balancing properties of a group member.

- Multiple IAS servers

  To provide fault tolerance for RADIUS-based authentication and accounting, you should always use at least two IAS servers. One IAS server is used as the primary RADIUS proxy and the other is used as a backup. Access servers or other RADIUS proxies are configured for both IAS servers. They switch to using the backup IAS proxy when the primary IAS proxy becomes unavailable. For information about how to synchronize the configuration of multiple IAS servers, see Managing multiple IAS servers.

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# IAS as a RADIUS proxy security considerations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS as a RADIUS proxy security considerations**

Consider the following security issues when deploying IAS as a RADIUS proxy:

- Shared secrets

  Configure strong shared secrets to prevent dictionary attacks and change them frequently. Strong shared secrets are a long (more than 22 characters) sequence of random letters, numbers, and punctuation. For more information, see Shared secrets.

- Firewall configuration

  If your IAS proxy is on a perimeter network, configure your Internet firewall (between your perimeter network and the Internet) to allow RADIUS messages to pass between your IAS proxy and RADIUS clients on the Internet. You might need to configure an additional firewall that is placed between your perimeter network and your intranet, to allow RADIUS traffic to flow between the IAS proxy on the perimeter network and an IAS server on the intranet. For more information, see IAS and firewalls.

- Message Authenticator attribute

  You can use the RADIUS Message Authenticator attribute (also known as a digital signature or the signature attribute) to ensure that RADIUS Access-Request messages for connection requests were sent from a RADIUS client configured with the correct shared secret. The Message Authenticator attribute is always used with EAP--without having to enable it on the IAS server and access server. For the PAP, CHAP, MS-CHAP, and MS-CHAP v2 authentication protocols, you must enable the use of the Message Authenticator attribute on both the IAS server (as part of the configuration of the RADIUS client in Internet Authentication Service) and the RADIUS client (the access server or RADIUS proxy). Ensure that the RADIUS client supports the Message Authenticator attribute before enabling it. For more information, see Edit RADIUS client configuration.

  For information about enabling the RADIUS Message Authenticator attribute for your access server, see the appropriate access server documentation. For the Routing and Remote Access service, the use of the RADIUS Message Authenticator attribute is enabled from the properties of a RADIUS server when you configure RADIUS authentication. For more information, see Use RADIUS authentication.

- Using IPSec filters to lock down IAS proxy servers

  You can configure IPSec filters to allow specific network traffic to pass through network interfaces on RADIUS servers. These filters can be applied to organizational units and stored in Active Directory, or they can be created and applied to individual servers. For more information, see Securing RADIUS traffic with IPSec.

- Password Authentication Protocol (PAP)

  The use of Password Authentication Protocol (PAP) is strongly discouraged when using RADIUS proxies. For more information, see IAS and firewalls.

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by

specifying an IP address range.

# Configuring IAS as a RADIUS Proxy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS as a RADIUS proxy**
This section covers:

- Authentication across forests
- Outsourced dial and a proxy in the perimeter network
- Using a different authentication database
- Using IAS proxy for load balancing
- Mapping network authentication and authorization

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Authentication across forests

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authentication across forests**
This topic describes how IAS can be used as both a RADIUS server and proxy to provide authentication between two forests. This configuration can also be used to provide authentication between both untrusted domains and one-way trusted domains.

### Notes

- When using EAP-TLS with certificates as the authentication method, you need to use one or more RADIUS proxy servers that forward authentication requests to the appropriate forest, even when the forests have a two-way, transitive trust relationship.

- When using authentication methods other than EAP-TLS with certificates, IAS supports authentication without a RADIUS proxy across two forests when they consist of only domain controllers running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition; and contain only Windows Server 2003 domains. For more information, see Accessing resources across forests and Domain and forest functionality.

The following configuration is for an organization that uses:

- Active Directory domains.

  Active Directory domains contain the user accounts, passwords, and dial-in properties that each IAS server requires to authenticate user credentials and evaluate both authorization and connection constraints. To optimize IAS authentication and authorization response times and minimize network traffic, IAS is installed on domain controllers.

- Two IAS servers in each forest.

  Two IAS servers (one primary and one secondary) are used to provide fault tolerance for RADIUS-based authentication, authorization, and accounting in each forest. If only one RADIUS server is configured and it becomes unavailable, access clients for that forest cannot connect. By using two IAS servers and configuring the IAS proxies for both primary and secondary IAS servers, the IAS proxies can detect when the primary RADIUS server is unavailable and automatically fail over to the secondary IAS server.

- Remote access policies.

  Remote access policies are configured to specify, based on group membership, the different types of connection constraints for users.

- Two IAS proxies.

  Two IAS proxies are used to provide fault tolerance for RADIUS requests that are sent from access servers.

The following illustration shows the authentication across forests configuration that is using IAS proxies.

**Note**

- This topic only describes how to configure IAS. It does not describe the configuration of Active Directory domains or access servers. For more information about how to deploy these components, see the appropriate Help topics.

To configure IAS for this example, complete the following steps:

- Configure the Active Directory forests for user accounts and groups.
- Configure the primary IAS server on a domain controller in the first forest.
- Configure the secondary IAS server on a different domain controller in the first forest.
- Configure the primary IAS server on a domain controller in the second forest.
- Configure the secondary IAS server on a different domain controller in the second forest.
- Configure the primary IAS proxy.
- Configure the secondary IAS proxy.
- Configure RADIUS authentication and accounting on access servers.

**Configuring forests for user accounts and groups**

To configure forests for user accounts and groups, do the following:

1. Ensure that all users who are making network access connections have a corresponding user account.
2. Manage your network access by group by setting the remote access permission on user accounts to **Control access through Remote Access Policy**. For more information, see Configure remote access permission for a user.
3. Organize your remote access users into the appropriate universal and nested groups in order to take advantage of group-based remote access policies. For more information, see Group scope.
4. If you are using the Challenge-Handshake Authentication Protocol (CHAP), enable support for reversibly encrypted passwords for the appropriate domains. For more information, see Enable reversibly encrypted passwords in a domain.

**Configuring the primary IAS server on a domain controller in the first forest**

To configure the primary IAS server on a domain controller in the first forest, do the following:

1. On the domain controller in the first forest, install IAS as an optional networking component. For more information, see Install IAS.

2. Configure the IAS server computer (the domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the IAS server is authenticating connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the IAS server computer is a member. Next, configure the IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

4. Enable file logging for accounting and authentication events. For more information, see Configure log file properties.

5. Add the IAS proxies as RADIUS clients of the IAS server. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.

6. Create the appropriate remote access policies for access clients in the first forest.

   For examples of remote access policies, see Remote Access Policies Examples.

**Configuring the secondary IAS server on a different domain controller in the first forest**
To configure the secondary IAS server on a different domain controller in the first forest, do the following:

1. On the other domain controller in the first forest, install IAS as an optional networking component. For more information, see Install IAS.

2. Configure the secondary IAS server computer (the other domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the secondary IAS server authenticates connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the secondary IAS server computer is a member. Next, configure the secondary IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

4. Copy the configuration of the primary IAS server to the secondary IAS server. For more information, see Copy the IAS configuration to another server.

**Configuring the primary IAS server on a domain controller in the second forest**
To configure the primary IAS server on a domain controller in the second forest, do the following:

1. On the domain controller in the second forest, install IAS as an optional networking component. For more information, see Install IAS.

2. Configure the IAS server computer (the domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the IAS server authenticates connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the IAS server computer is a member. Next, configure the IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

4. Enable file logging for accounting and authentication events. For more information, see Configure log file properties.

5. Add the IAS proxies as RADIUS clients of the IAS server. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.

6. Create the appropriate remote access policies for access clients in the second forest.

   For examples of remote access policies, see Remote Access Policies Examples.

**Configuring the secondary IAS server on a different domain controller in the second forest**

To configure the secondary IAS server on a different domain controller in the second forest, do the following:

1. On the other domain controller in the second forest, install IAS as an optional networking component. For more information, see Install IAS.

2. Configure the secondary IAS server computer (the other domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the secondary IAS server authenticates connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the secondary IAS server computer is a member. Next, configure the secondary IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

4. Copy the configuration of the primary IAS server to the secondary IAS server. For more information, see Copy the IAS configuration to another server.

**Configuring the primary IAS proxy**

To configure the primary IAS proxy, do the following:

1. On a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition; install IAS as an optional networking component. For more information, see Install IAS. The computer on which IAS is installed is not required to be dedicated to forwarding RADIUS messages. For example, You can install IAS on a Web server, file server, or DNS server.

2. If needed, configure additional UDP ports for RADIUS messages that are sent by the access servers. For more information, see Configure IAS port information. By default, IAS uses UDP ports 1812 and 1645 for authentication and ports 1813 and 1646 for accounting.

3. Add the access servers as RADIUS clients of the IAS proxy. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.

4. Create a connection request policy that forwards RADIUS request messages (that are based on the realm name of accounts in the first forest) to IAS servers in the first forest.

   Use the New Connection Request Policy Wizard to create a connection request policy that forwards connection requests to a remote RADIUS server group and where the realm name matches the realm name of the user accounts in the first forest. Clear the check box that removes the realm name for authentication. In the New Connection Request Policy Wizard, use the New Remote RADIUS server Group Wizard to create a remote RADIUS server group with members that include the two IAS servers in the first forest.

   For more information, see Add a connection request policy.

5. Create a connection request policy that forwards RADIUS request messages (that are based on the realm name of accounts in the second forest) to IAS servers in the second forest.

   Use the New Connection Request Policy Wizard to create a connection request policy that forwards connection requests to a remote RADIUS server group and where the realm name matches the realm name of the user accounts in the second forest. Clear the check box that removes the realm name for authentication. In the New Connection Request Policy Wizard, use the New Remote RADIUS server Group Wizard to create a remote RADIUS server group with members that include the two IAS servers in the second forest.

For more information, see Add a connection request policy.

6. Delete the default connection request policy named **Use Windows authentication for all users**. For more information, see Delete a connection request policy.

**Configuring the secondary IAS proxy**

To configure the secondary IAS proxy on another computer, do the following:

1. On another computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition; install IAS as an optional networking component. For more information, see Install IAS.

2. Copy the configuration of the primary IAS proxy to the secondary IAS proxy. For more information, see Copy the IAS configuration to another server.

**Configuring RADIUS authentication and accounting on the access servers**

To configure each access server to use the primary and secondary IAS proxies for the authentication, authorization, and accounting of network connections, do the following:

1. If the dial-up or VPN server is a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; or Windows 2000 and the Routing and Remote Access service, configure the primary and secondary IAS proxies as RADIUS servers for both RADIUS authentication and accounting. For more information, see Use RADIUS authentication and Use RADIUS accounting.

2. If the dial-up or VPN server is a computer running Windows NT Server 4.0 and the Routing and Remote Access Service (RRAS), see the Windows NT Server 4.0 online Help for information about how to configure the primary and secondary IAS proxies as RADIUS servers for RADIUS authentication.

3. If the dial-up server, VPN server, wireless access point, or authenticating switch is a third-party access server, see the documentation for the access server to determine how to configure it as a RADIUS client with two RADIUS servers (the primary and secondary IAS proxies).

For more information, see Forest trusts, Accessing resources across forests, Upgrading from a Windows NT domain, and Best practices for Active Directory Domains and Trusts.

### Note

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Outsourced dial and a proxy in the perimeter network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Outsourced dial and a proxy in the perimeter network**

This topic describes how IAS can be used as a RADIUS proxy to forward messages between the RADIUS proxies of an outsourced dial service provider and RADIUS servers within an organization intranet. The outsourced service provider offers worldwide Points of Presence (POPs), which the employees of an organization can call. After the call is completed, the employee's computer is connected to the organization's intranet.

This topic describes a configuration for an organization that uses:

- Two IAS servers.

  Two IAS servers (one primary and one secondary) are used to provide fault tolerance for RADIUS-based authentication, authorization, and accounting. If only one RADIUS server is configured and it becomes unavailable, dial-in and VPN users cannot connect. By using two IAS servers and configuring both primary and secondary IAS proxies in the perimeter network for both the primary and secondary IAS servers, the IAS proxies can detect when the primary RADIUS server is unavailable and automatically fail over to the secondary IAS server.

- Active Directory domains.

  Active Directory domains contain the user accounts, passwords, and dial-in properties that each IAS server requires to authenticate user credentials and evaluate both authorization and connection constraints. To optimize IAS authentication and authorization response times and minimize network traffic, IAS is installed on domain controllers.

- Custom remote access policies. Remote access policies are configured to specify, based on group membership, the different types of connection constraints for users.

- Two IAS proxies in the perimeter network.

  To simplify the configuration of the intranet firewall, IAS proxies are used in the perimeter network instead of IAS servers. When IAS servers are used in the perimeter network, you must either configure each IAS server computer with two network adapters (one connected to the perimeter network and one connected to the intranet), or configure the intranet firewall to allow Active Directory traffic between the IAS servers on the perimeter network and all of the domain controllers in the intranet. By replacing the IAS server computers with IAS proxies, the IAS proxy computers do not require two network adapters. Additionally, the intranet firewall is only required to be configured to allow RADIUS traffic between the IAS proxies in the perimeter network and the IAS servers in the intranet.

  Two IAS proxies are used in the perimeter network to provide fault tolerance for RADIUS requests that are sent from the service provider's proxies.

- Connection Manager.

  To automate service provider dialing, Connection Manager is used to create a profile with all of the phone numbers of the service provider POPs. Remote access users select the location from which they are dialing, and then select the appropriate phone number (POP) from the phone book in the Connection Manager service profile for the service provider. The remote access user connects to the service provider's dial-in access server through Challenge Handshake Password Authentication (CHAP). The realm name portion of the user name is used by the service provider's proxies to forward the authentication requests to an IAS proxy in the perimeter network of the organization.

This topic also describes a configuration for a service provider that uses:

- Two IAS proxies in the service provider's network.

  The service provider uses RADIUS proxies in its network to forward RADIUS request messages between the dial-in

servers of the service provider and the RADIUS servers or proxies of multiple customers across the Internet. Two IAS proxies are used to provide fault tolerance for RADIUS authentication.

- Dial-up access servers.

  Dial-up servers consist of computers running:

  - Windows Server 2003, Standard Edition
  - Windows Server 2003, Enterprise Edition
  - Windows Server 2003, Datacenter Edition
  - Windows 2000 and the Routing and Remote Access service
  - Third-party network access server (NAS) devices

The following illustration shows the outsourced dial configuration using IAS proxies in the organization's intranet.

**Note**

- This topic only describes how to configure IAS. It does not describe the configuration of Active Directory domains or Connection Manager. For more information about how to deploy these components, see the appropriate Help topics.

To configure IAS for this example, complete the following steps:

- Configure Active Directory for user accounts and groups.
- Configure the primary IAS server on a domain controller.
- Configure the secondary IAS server on a different domain controller.
- Configure RADIUS authentication and accounting on VPN servers.
- Configure the primary IAS proxy in the perimeter network.
- Configure the secondary IAS proxy in the perimeter network.
- Configure the intranet and Internet firewalls to support RADIUS traffic.

- Configure the primary IAS proxy at the service provider.
- Configure the secondary IAS proxy at the service provider.
- Configure RADIUS accounting and authentication on the dial-up access servers at the service provider.

**Configuring user accounts and groups**

To configure user accounts and groups, do the following:

1. Ensure that all users who are making remote access connections have a corresponding user account.
2. Manage your network access by group by setting the remote access permission user accounts to **Control access through Remote Access Policy**. For more information, see Configure remote access permission for a user.
3. Organize your remote access users into the appropriate universal and nested groups in order to take advantage of group-based remote access policies. For more information, see Group scope.
4. Because the outsourced service provider requires the use of Challenge-Handshake Authentication Protocol (CHAP) authentication for the dial-in connection, you must enable support for reversibly encrypted passwords for the appropriate domains. For more information, see Enable reversibly encrypted passwords in a domain.

**Configuring the primary IAS server on a domain controller**

To configure the primary IAS server on a domain controller, do the following:

1. On the domain controller, install IAS as an optional networking component. For more information, see Install IAS.
2. Configure the IAS server computer (the domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.
3. If the IAS server authenticates connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the IAS server computer is a member. Next, configure the IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

   If the IAS server is authenticating connection attempts for user accounts in other domains, and those domains do not have a two-way trust with the domain in which the IAS server computer is a member, see Authentication across forests.
4. Enable file logging for accounting and authentication events. For more information, see Configure log file properties.
5. Add the IAS proxies in the perimeter network as RADIUS clients of the IAS server. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.
6. Create remote access policies that accurately reflect your remote access usage.

   For example, to configure a custom remote access policy to permit members of the Contractors group to connect from 8:00 AM to 5:00 PM, Monday through Friday, use the New Remote Access Policy Wizard to create a new custom remote access policy with the following settings:

   - Policy name: **Contractor connections**
   - Conditions: Windows-Groups matches Contractors
   - Permission: **Grant remote access permission**
   - Profile settings, **Dial-in Constraints** tab: **Allow access only on these days and at these times** is set to 8:00 AM

to 5:00 PM, Monday through Friday.

To configure a remote access policy that requires members of the Executives group to use EAP-TLS authentication and 128-bit encryption, use the New Remote Access Policy Wizard to create a common remote access policy with the following settings:

- Policy name: High security connections for executives
- Access Method: Dial-up access
- User or Group: Select **Group**, and then specify the Executives group (example).
- Authentication methods: Select **Extensible Authentication Protocol (EAP)** and, in **Type**, select **Smart Card or other Certificate**. If you have multiple computer certificates, click **Configure**, select the appropriate computer certificate, and then clear all other check boxes.
- Policy Encryption Level: Select the **Strongest encryption (MPPE 128-bit)** check box, and then clear all other check boxes.

For additional examples of remote access policies, see Remote Access Policies Examples.

If you have created new remote access policies, either delete the default remote access policies, or ensure that they are the last policies to be evaluated. For more information, see Delete a remote access policy and Change the policy evaluation order.

**Configuring the secondary IAS server on a different domain controller**

To configure the secondary IAS server on a different domain controller, do the following:

1. On the other domain controller, install IAS as an optional networking component. For more information, see Install IAS.
2. Configure the secondary IAS server computer (the other domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.
3. If the secondary IAS server authenticates connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the secondary IAS server computer is a member. Next, configure the secondary IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

   If the secondary IAS server authenticates connection attempts for user accounts in other domains, and those domains do not have a two-way trust with the domain in which the secondary IAS server computer is a member, see Authentication across forests.
4. Copy the configuration of the primary IAS server to the secondary IAS server. For more information, see Copy the IAS configuration to another server.

**Configuring RADIUS authentication and accounting on the VPN servers**

To configure each VPN server to use the primary and secondary IAS servers for authentication, authorization, and accounting of remote access connections, do the following:

1. If the VPN server is a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; or Windows 2000 and the Routing and Remote Access service, configure the primary and secondary IAS servers in the perimeter network as RADIUS servers for both RADIUS authentication and accounting. For more information, see Use RADIUS authentication and Use RADIUS accounting.

2. If the VPN server is a computer running Windows NT server 4.0 and the Routing and Remote Access Service (RRAS), see the Windows NT server 4.0 online Help for instructions about how to configure the primary and secondary IAS servers as RADIUS servers for RADIUS authentication.

3. If the VPN server is a third-party network access server (NAS), see the documentation for the NAS to determine how to configure it as a RADIUS client with two RADIUS servers (the primary and secondary IAS servers).

**Configuring the primary IAS proxy in the perimeter network**

To configure the primary IAS proxy in the perimeter network, do the following:

1. On a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition in the perimeter network; install IAS as an optional networking component. For more information, see Install IAS. The computer on which IAS is installed is not required to be dedicated to forwarding RADIUS messages. You can install IAS on a Web server, file server, or DNS server.

2. If needed, configure additional UDP ports for RADIUS messages that are sent by the service provider's RADIUS proxies. For more information, see Configure IAS port information. By default, IAS uses UDP ports 1812 and 1645 for authentication and ports 1813 and 1646 for accounting.

3. Add the service provider's RADIUS proxies as RADIUS clients of the IAS server. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.

4. Create a connection request policy that forwards RADIUS request messages based on the realm name of your organization.

   Use the New Connection Request Policy Wizard to create a connection request policy that forwards connection requests to a remote RADIUS server group and where the realm name matches the realm name of the user accounts in your organization. Clear the check box that removes the realm name for authentication. In the New Connection Request Policy Wizard, use the New Remote RADIUS server Group Wizard to create a remote RADIUS server group with members that include the two IAS servers within your intranet.

   For more information, see Add a connection request policy.

5. Delete the default connection request policy named **Use Windows authentication for all users**. For more information, see Delete a connection request policy.

**Configuring the secondary IAS proxy in the perimeter network**

To configure the secondary IAS proxy on another computer in the perimeter network, do the following:

1. On another computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition in the perimeter network; install IAS as an optional networking component. For more information, see Install IAS.

2. Copy the configuration of the primary IAS proxy to the secondary IAS proxy in the perimeter network. For more information, see Copy the IAS configuration to another server.

**Configuring the intranet and Internet firewalls to support RADIUS traffic**

To configure the intranet and Internet firewalls to support RADIUS traffic, do the following:

1. Configure the intranet firewall to allow RADIUS traffic between the IAS proxies in the perimeter network and the IAS servers in the intranet.

2. Configure the Internet firewall to allow RADIUS traffic between the IAS proxies in the perimeter network and the IAS proxies in the service provider's network.

   For more information, see IAS and firewalls

**Configuring the primary IAS proxy at the service provider**
To configure the primary IAS proxy at the service provider, do the following:

1. On a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition in the service provider's network; install IAS as an optional networking component. For more information, see Install IAS. The computer on which IAS is installed is not required to be dedicated to forwarding RADIUS messages. You can install IAS on a Web server, file server, or DNS server.

2. If needed, configure additional UDP ports for authentication and accounting messages that are sent by the service provider's dial-up access servers. For more information, see Configure IAS port information. By default, IAS uses UDP ports 1812 and 1645 for authentication and ports 1813 and 1646 for accounting.

3. Add the service provider's dial-up access servers as RADIUS clients of the IAS proxy. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.

4. Create a connection request policy that forwards RADIUS request messages based on the realm name of the service provider's customer.

   Use the New Connection Request Policy Wizard to create a connection request policy that forwards connection requests to a remote RADIUS server group and where the realm name matches the realm name of the customer's organization. Clear the check box that removes the realm name for authentication. In the New Connection Request Policy Wizard, use the New Remote RADIUS server Group Wizard to create a remote RADIUS server group with members that include the two IAS proxies in the customer's perimeter network.

   For more information, see Add a connection request policy.

5. Delete the default connection request policy named **Use Windows authentication for all users**. For more information, see Delete a connection request policy.

**Configuring the secondary IAS proxy at the service provider**
To configure the secondary IAS proxy on another computer in the perimeter network, do the following:

1. On another computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition in the service provider's network; install IAS as an optional networking component. For more information, see Install IAS.

2. Copy the configuration of the primary IAS proxy to the secondary IAS proxy in the service provider's network. For more information, see Copy the IAS configuration to another server.

**Configuring RADIUS accounting and authentication on the dial-up servers at the service provider**
To configure each dial-up server to use the primary and secondary IAS proxies in the service provider's network for the authentication, authorization, and accounting of dial-up connections, do the following:

1. If the dial-up or VPN server is a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; or Windows 2000 and the Routing and Remote Access service, configure the primary and secondary IAS proxies in the service provider's network as RADIUS servers for both RADIUS authentication and accounting. For more information, see Use RADIUS authentication and Use RADIUS accounting.

2. If the dial-up or VPN server is a computer running Windows NT server 4.0 and the Routing and Remote Access Service (RRAS), see the Windows NT server 4.0 online Help for information about how to configure the primary and secondary IAS proxies in the service provider's network as RADIUS servers for RADIUS authentication.

3. If the dial-up or VPN server is a third-party network access server (NAS), see the documentation for the NAS to determine how to configure it as a RADIUS client with two RADIUS servers (the primary and secondary IAS proxies in the

service provider's network).

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Using a different authentication database

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using a different authentication database**
This topic describes how IAS can be used as a RADIUS proxy to forward RADIUS messages between access servers and two different user account databases. An Active Directory forest and another user account database are used as examples.

The following configuration is for an organization that uses:

- Active Directory domains.

  Active Directory domains contain the user accounts, passwords, and dial-in properties that each IAS server requires to authenticate user credentials and evaluate both authorization and connection constraints. To optimize IAS authentication and authorization response times and minimize network traffic, IAS is installed on domain controllers.

- Another user account database.

  There is another user account database that is used to authenticate and authorize connection attempts. Examples of other user account databases are Novell Directory Services (NDS) and Structured Query Language (SQL). Because IAS can only access Windows-based user account databases, a third-party RADIUS server must be used to access another user account database.

- Two IAS servers for each authentication database.

  Two IAS servers (one primary and one secondary) are used to provide fault tolerance for RADIUS-based authentication, authorization, and accounting for each user account database. If only one RADIUS server is configured and it becomes unavailable, access clients for that user account database cannot connect. By using two IAS servers and configuring the IAS proxies for both primary and secondary IAS servers for each account database, the IAS proxies can detect when the primary RADIUS server is unavailable and automatically fail over to the secondary IAS server.

- Remote access policies.

  Remote access policies are configured to specify, based on group membership, the different types of connection constraints for users.

- Two IAS proxies.

  Two IAS proxies are used to provide fault tolerance for RADIUS requests that are sent from access servers.

The following illustration shows the use of IAS proxies to forward RADIUS messages between the access servers and the RADIUS servers that are accessing two different user account databases.

**Note**

- This topic only describes how to configure IAS. It does not describe the configuration of Active Directory domains, access servers, the third-party RADIUS servers, or the other user account database. For more information about how to deploy these components, see the appropriate Help topics.

To configure IAS for this example, complete the following steps:

- Configure the Active Directory forest for user accounts and groups.
- Configure the primary IAS server on a domain controller.
- Configure the secondary IAS server on a different domain controller.
- Configure the primary and secondary RADIUS servers for the other user account database.
- Configure the primary IAS proxy.
- Configure the secondary IAS proxy.
- Configure RADIUS authentication and accounting on the access servers.

**Configuring the forests for user accounts and groups**

To configure the forest for user accounts and groups, do the following:

1. Ensure that all users that are making network access connections have a corresponding user account.
2. Manage your network access by group by setting the remote access permission on user accounts to **Control access through Remote Access Policy**. For more information, see Configure remote access permission for a user.
3. Organize your remote access users into the appropriate universal and nested groups in order to take advantage of group-based remote access policies. For more information, see Group scope.
4. If you are using the Challenge-Handshake Authentication Protocol (CHAP), enable support for reversibly encrypted passwords for the appropriate domains. For more information, see Enable reversibly encrypted passwords in a domain.

**Configuring the primary IAS server on a domain controller**

To configure the primary IAS server on a domain controller, do the following:

1. On the domain controller, install IAS as an optional networking component. For more information, see Install IAS.
2. Configure the IAS server computer (the domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.
3. If the IAS server authenticates connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the IAS server computer is a member. Next, configure the IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

   If the IAS server authenticates connection attempts for user accounts in other domains, and those domains do not have a two-way trust with the domain in which the IAS server computer is a member, see Authentication across forests.
4. Enable file logging for accounting and authentication events. For more information, see Configure log file properties.
5. Add the IAS proxies as RADIUS clients of the IAS server. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.

6. Create the appropriate remote access policies for access clients.

   For examples of remote access policies, see Remote Access Policies Examples.

**Configuring the secondary IAS server on a different domain controller**

To configure the secondary IAS server on a different domain controller, do the following:

1. On the other domain controller, install IAS as an optional networking component. For more information, see Install IAS.

2. Configure the secondary IAS server computer (the other domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

3. If the secondary IAS server authenticates connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the secondary IAS server computer is a member. Next, configure the secondary IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.

   If the secondary IAS server authenticates connection attempts for user accounts in other domains, and those domains do not have a two-way trust with the domain in which the IAS server computer is a member, see Authentication across forests.

4. Copy the configuration of the primary IAS server to the secondary IAS server. For more information, see Copy the IAS configuration to another server.

**Configuring the primary and secondary RADIUS servers for the other user account database**

To configure the primary and secondary RADIUS servers to access the additional user account database and to add the two IAS proxies as RADIUS clients, see the documentation for the RADIUS servers.

**Configuring the primary IAS proxy**

To configure the primary IAS proxy, do the following:

1. On a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition; install IAS as an optional networking component. For more information, see Install IAS. The computer on which IAS is installed is not required to be dedicated to forwarding RADIUS messages. For example, you can install IAS on a Web server, file server, or DNS server.

2. If needed, configure additional UDP ports for RADIUS messages that are sent by the access servers. For more information, see Configure IAS port information. By default, IAS uses UDP ports 1812 and 1645 for authentication and ports 1813 and 1646 for accounting.

3. Add the access servers as RADIUS clients of the IAS server. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.

4. Create a connection request policy that forwards RADIUS request messages to the IAS servers where the realm name matches the user accounts in the forest.

   Use the New Connection Request Policy Wizard to create a connection request policy that forwards connection requests to a remote RADIUS server group and where the realm name matches the realm name for the user accounts in the forest. Clear the check box that removes the realm name for authentication. In the New Connection Request Policy Wizard, use the New Remote RADIUS server Group Wizard to create a remote RADIUS server group with members that include the two IAS servers.

   For more information, see Add a connection request policy.

5. Create a connection request policy that forwards RADIUS request messages based on the realm name of accounts in the additional user account database to the RADIUS servers.

Use the New Connection Request Policy Wizard to create a connection request policy that forwards connection requests to a remote RADIUS server and where the realm name matches the realm name for the user accounts in the additional user account database. Clear the check box that removes the realm name for authentication. In the New Connection Request Policy Wizard, use the New Remote RADIUS server Group Wizard to create a remote RADIUS server group with members that include the two RADIUS servers.

For more information, see Add a connection request policy.

6. Delete the default connection request policy named **Use Windows authentication for all users**. For more information, see Delete a connection request policy.

**Configuring the secondary IAS proxy**

To configure the secondary IAS proxy on another computer, do the following:

1. On another computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition; install IAS as an optional networking component. For more information, see Install IAS.

2. Copy the configuration of the primary IAS proxy to the secondary IAS proxy. For more information, see Copy the IAS configuration to another server.

**Configuring RADIUS authentication and accounting on the access servers**

To configure each access server to use the primary and secondary IAS proxies for the authentication, authorization, and accounting of network connections, do the following:

1. If the dial-up or VPN server is a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; or Windows 2000 and the Routing and Remote Access service, configure the primary and secondary IAS proxies as RADIUS servers for both RADIUS authentication and accounting. For more information, see Use RADIUS authentication and Use RADIUS accounting.

2. If the dial-up or VPN server is a computer running Windows NT server 4.0 and the Routing and Remote Access Service (RRAS), see the Windows NT server 4.0 online Help for information about how to configure the primary and secondary IAS proxies as RADIUS servers for RADIUS authentication.

3. If the dial-up server, VPN server, wireless access point, or authenticating switch is a third-party access server, see the documentation for the access server to determine how to configure it as a RADIUS client with two RADIUS servers (the primary and secondary IAS proxies).

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Using IAS proxy for load balancing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using IAS proxy for load balancing**

This topic describes how IAS proxies, placed between access servers and IAS servers, can be used to balance the load of a large volume of authentication traffic. Without IAS proxies, each access server balances its RADIUS requests across multiple RADIUS servers and detects unavailable RADIUS servers. By using IAS proxy, consistent load balancing is used to spread the load of authentication, authorization, and accounting traffic across all the IAS servers in the organization. Additionally, there is a consistent scheme for failure detection and RADIUS server failover.

The following configuration is for an organization that uses:

- Active Directory domains.

  Active Directory domains contain the user accounts, passwords, and dial-in properties that each IAS server requires to authenticate user credentials and evaluate both authorization and connection constraints. To optimize IAS authentication and authorization response times and minimize network traffic, IAS is installed on domain controllers.

- Multiple IAS servers.

  To balance the load of RADIUS authentication, authorization, and accounting across multiple domain controllers, IAS is installed as a RADIUS server on them.

- Remote access policies.

  Remote access policies are configured to specify, based on group membership, the different types of connection constraints for users.

- Two IAS proxies.

  Two IAS proxies are used to provide fault tolerance for RADIUS requests that are sent from access servers.

The following illustration shows IAS proxies used to balance the load of RADIUS traffic across multiple IAS servers.

**Note**

- This topic only describes how to configure IAS. It does not describe the configuration of Active Directory domains or access servers. For more information about how to deploy these components, see the appropriate Help topics.

To configure IAS for this example, complete the following steps:

- Configure the Active Directory forests for user accounts and groups.

- Configure the IAS server on domain controllers.
- Configure the primary IAS proxy.
- Configure the secondary IAS proxy.
- Configure RADIUS authentication and accounting on access servers.

**Configuring forests for user accounts and groups**

To configure Active Directory for user accounts and groups, do the following:

1. Ensure that all users that are making network access connections have a corresponding user account.
2. Manage your network access by group by setting the remote access permission on user accounts to **Control access through Remote Access Policy**. For more information, see Configure remote access permission for a user.
3. Organize your remote access users into the appropriate universal and nested groups in order to take advantage of group-based remote access policies. For more information, see Group scope.
4. If you are using the Challenge-Handshake Authentication Protocol (CHAP), enable support for reversibly encrypted passwords for the appropriate domains. For more information, see Enable reversibly encrypted passwords in a domain.

**Configuring the IAS server on domain controllers**

To configure IAS as a RADIUS server on each domain controller, do the following:

1. On the domain controller, install IAS as an optional networking component. For more information, see Install IAS.
2. Configure the IAS server computer (the domain controller) to read the properties of user accounts in the domain. For more information, see Enable the IAS server to read user accounts in Active Directory.
3. If the IAS server authenticates connection attempts for user accounts in other domains, verify that the other domains have a two-way trust with the domain in which the IAS server computer is a member. Next, configure the IAS server computer to read the properties of user accounts in other domains. For more information, see Enable the IAS server to read user accounts in Active Directory. For more information about trust relationships, see Trust direction.
4. Enable file logging for accounting and authentication events. For more information, see Configure log file properties.
5. Add the IAS proxies as RADIUS clients of the IAS server. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.
6. Create the appropriate remote access policies for access clients.

   For examples of remote access policies, see Remote Access Policies Examples.

**Configuring the primary IAS proxy**

To configure the primary IAS proxy, do the following:

1. On a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition; install IAS as an optional networking component. For more information, see Install IAS. The computer on which IAS is installed is not required to be dedicated to forwarding RADIUS messages. For example, You can install IAS on a Web server, file server, or DNS server.
2. If needed, configure additional UDP ports for RADIUS messages that are sent by the access servers. For more information, see Configure IAS port information. By default, IAS uses UDP ports 1812 and 1645 for authentication and ports 1813 and 1646 for accounting.

3. Add the access servers as RADIUS clients of the IAS server. For more information, see Add RADIUS clients. Verify that you are configuring the correct name or IP address and shared secrets. For more information, see Shared secrets.

4. Use the New Remote RADIUS server Group Wizard to create a custom remote RADIUS server group. Add each IAS server as a member of the remote RADIUS server group and configure each group member with the priority of 1 and a weight of 50.

5. Create a connection request policy that forwards RADIUS request messages to the IAS servers where the realm name matches the accounts in the domain.

   Use the New Connection Request Policy Wizard to create a connection request policy that forwards connection requests to a remote RADIUS server and where the realm name matches the realm name for the user accounts in the forest. Clear the check box that removes the realm name for authentication. Select the previously created remote RADIUS server group as the group to forward connection requests.

   For more information, see Add a connection request policy.

6. Delete the default connection request policy named **Use Windows authentication for all users**. For more information, see Delete a connection request policy.

**Configuring the secondary IAS proxy**

To configure the secondary IAS proxy on another computer, do the following:

1. On another computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition; install IAS as an optional networking component. For more information, see Install IAS.

2. Copy the configuration of the primary IAS proxy to the secondary IAS proxy. For more information, see Copy the IAS configuration to another server.

**Configuring RADIUS authentication and accounting on the access servers**

To configure each access server to use the primary and secondary IAS proxies for the authentication, authorization, and accounting of network connections, do the following:

1. If the dial-up or VPN server is a computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; or Windows 2000 and the Routing and Remote Access service, configure the primary and secondary IAS proxies as RADIUS servers for both RADIUS authentication and accounting. For more information, see Use RADIUS authentication and Use RADIUS accounting.

2. If the dial-up or VPN server is a computer running Windows NT server 4.0 and the Routing and Remote Access Service (RRAS), see the Windows NT server 4.0 online Help for information about how to configure the primary and secondary IAS proxies as RADIUS servers for RADIUS authentication.

3. If the dial-up or VPN server is a third-party access server, see the documentation for the access server to determine how to configure it as a RADIUS client with two RADIUS servers (the primary and secondary IAS proxies).

### Note

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Mapping network authentication and authorization

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Mapping network authentication and authorization**

You can use IAS proxy to split network access authorization and authentication between two user account databases. You can authenticate visitors (such as partner organization employees) with their password-based credentials stored in an external partner organization user database, while performing authorization with your local Active Directory user account database. To split authentication and authorization, you must create a local user account for each visitor. The visitor account user name must map to an account in the partner organization user database with the same user name. When the visitor logs on to your network, the external user database provides authentication, while the local user database and remote access policies are used to process authorization.

The forwarding of authentication requests to the partner organization RADIUS server is necessary only when visitor authentication is performed with password-based credentials. Visitors can also be authenticated by mapping certificates to local user accounts. If a partner organization uses certificate-based authentication, you can authenticate visitors by trusting the partner organization certification authority (CA) and mapping visitor certificates to local user accounts. Because the visitor is authenticated locally with a certificate, it is not necessary to forward authentication requests to the remote RADIUS server at the partner organization.

For more information about certificate mapping, see Mapping certificates to user accounts, Map a certificate to a user account, and Map an account from a trusted non-Windows kerberos realm to a user account.

**Mapping with password-based authentication**

When partner organizations use password-based authentication, you must configure local user accounts for visitors and configure the IAS proxy server to forward authentication requests to a remote RADIUS server group that contains the partner company RADIUS server.

**Configuring visitor user accounts**

If you are using password-based authentication, you must create a user account for each visitor. The visitor user account must be created so that the user name in the local database and the user name in the partner organization user database match exactly. To allow visitors access to your organization network while authenticating them at their partner organization, perform the following actions to configure visitor accounts:

- **Add the** user principal name suffix **to the domain.**

  For more information, see Add user principal name suffixes.

- **Create an** organizational unit **that will contain the user accounts for visitors.**

  For more information, see Create a new organizational unit.

- **Create user accounts in the organizational unit for visitors.**

  When you create the user account, the user logon name must exactly match the visitor's user logon name as configured in the user account database at the partner organization. For example, if the user's user logon name at Microsoft Corporation is user@microsoft.com, designate "user" as the **User logon name** while creating the new user account with **Active Directory Users and Computers**. Also, select the correct UPN suffix from the drop-down list of suffixes. For example, if in step one you added the UPN suffix "microsoft.com", select "@microsoft.com" from the list. For more information, see Create a new user account

- **Configure user account properties**

  Make sure that the user account is configured in a way that will allow the visitor network access, but will also contain any necessary security restrictions. For example, in user account properties, on the **Dial-in** tab, you can set **Remote Access Permission (Dial-in or VPN)** to **Allow access**.

**Configuring the IAS proxy server**

To allow visitors access to your organization network, you need to perform the following actions on your IAS proxy server:

- **Configure the partner organization RADIUS server as a member of a Remote RADIUS server group.**

  Run the New Remote RADIUS Server Group Wizard, create and name a custom group, and then add the partner organization RADIUS server (or servers) to the group. While adding each server, configure the shared secret (obtained from the partner organization) on the **Authentication/Accounting** tab of the **Add RADIUS server** dialog box.

  For more information, see Add a remote RADIUS server group and Configure the Members of a Remote RADIUS Server Group.

- **Configure a connection request policy for visitor access.**

  To determine whether a specific connection attempt request or an accounting message received from a RADIUS client should be processed locally or forwarded to another RADIUS server, the IAS server uses connection request processing. When you allow visitor access with external authentication, you must configure a minimum of two connection request policies on your IAS proxy server. One policy allows your organization employees access, while denying access to other network access attempts. Another policy allows visitor access. When you configure your policy evaluation order, place the policy or policies for your organization users last, with the visitor policy processed first. For more information, see Change the policy evaluation order.

  To configure a connection request policy, run the New Connection Request Policy Wizard, create and name a custom policy, and then add **Policy Conditions**. You can configure as many conditions as you want, but you must include the **User-Name** attribute. Use wildcard and other characters described in Pattern matching syntax to configure a value that must be matched by the user principal name (UPN) suffix your visitors will use when logging on. For example, if you want to authenticate all visitors from Microsoft Corporation with this connection request policy, you can type "^.@microsoft\.com$" in **User-Name**. In **Request Processing Method**, click **Edit Profile**, and then click the **Advanced** tab. Click **Add**, and then add the attribute **Remote-RADIUS-to-Windows-User-Mapping**, with the attribute value set to **True**. This attribute tells the IAS proxy server to authenticate users (whose properties match other policy conditions) against the RADIUS servers configured in the Remote RADIUS Server Group. On the **Attribute** tab, you can configure replacement text for the **User-Name** attribute, as well as configure any other attributes that you require. On the **Authentication** tab, click **Forward requests to the following remote RADIUS server group for authentication**, and then choose the Remote RADIUS server group that can authenticate your visitors.

  For more information, see Add a connection request policy, Realm names, Configure Connection Request Processing, and Connection Request Processing.

- **Configure a remote access policy for visitor access.**

  Because you can create remote access policies that are based on different types of connections and group membership, you can create a remote access policy used specifically to process network access attempts by visitors. At minimum, you need two remote access policies: one for your employees and a different one for visitors. For more information, see Introduction to remote access policies and Remote Access Policies Examples.

- **Ensure that network access servers are configured as RADIUS clients to this IAS proxy.**

  When visitors log on to your network, they do so through network access servers, such as wireless access points. These access points must be configured as RADIUS clients to your IAS proxy server.

  For more information, see Configure RADIUS Clients.

After the IAS proxy is configured to forward authentication requests and user accounts for visitors are created in Active Directory, the password-based authentication request is forwarded to the partner organization RADIUS server when the visitor logs onto your organization network. If the user is authenticated, authorization is performed against your organization Active Directory user database. Active Directory returns user attributes (values configured for the user account, such as **Allow access** on the **Dial-in** tab of user properties), and IAS performs policy evaluation against these local user account attributes.

**Important**

- By configuring a local user account with the UPN of an account in the remote partner organization user account database, you map one account to the other. If the partner organization changes the user name of an account you have mapped, you must change the user name in your user account database, too.

**Mapping with certificate-based authentication**

Certificate-based authentication is more secure than password-based authentication. In addition, when you map certificates to user accounts instead of using password-based authentication methods, an authentication request is not forwarded to the partner organization RADIUS server and user account database. For these reasons, certificate mapping enhances security and can significantly reduce logon time for users.

A certificate is mapped to a user account in one of two ways: a single certificate is mapped to a single user account (one-to-one mapping) or multiple certificates are mapped to one user account (many-to-one mapping).

**One-to-one mapping**

For one-to-one mapping of certificates to visitor user accounts, you must perform the following steps:

- **Create a user account for each visitor according to the steps in "Configuring visitor user accounts."**

  Because the user account itself is not mapped to the user account at the partner organization, the user account names do not have to exactly match the user account names in the partner organization user accounts database. Configuring the local account with the same user name, however, can make it easier to configure realm manipulation rules.

- **Map the certificate to a user account.**

  For more information, see Mapping certificates to user accounts and Map a certificate to a user account

- **Perform cross-certification or authorize the partner organization CA as a qualified subordinate certification authority using a computer running** Windows Server 2003, Enterprise Edition **and Certificate Services.**

  Performing cross-certification or authorizing the partner organization CA as a qualified subordinate CA is recommended for domains with a Windows Server 2003 domain functional level and clients running Windows XP. If your domains are Windows 2000 native, it is recommended that you use a certificate trust list (CTL) instead.

  For more information, see Domain and forest functionality, Qualified subordination, Qualified subordination overview, and Perform qualified subordination.

- **Configure your IAS server or IAS proxy server**

  Because authentication requests are not forwarded to external RADIUS servers when authentication is performed with certificates, you are not required to use IAS as a proxy server.

  - Configure a connection request policy for visitor access with the New Connection Request Policy Wizard.

    For more information, see Add a connection request policy, Pattern matching syntax, Realm names, Configure Connection Request Processing, and Connection Request Processing.

  - Create a realm manipulation rule to map the partner organization realm name, which is contained in the user's certificate, to the user's local user account.

    For example, if user@tailspintoys.com is mapped to user@microsoft.com, the realm manipulation rule must replace "@tailspintoys.com" with "@microsoft.com" using pattern-matching syntax.

    For more information, see Realm names and Pattern matching syntax.

  - Configure a remote access policy for visitor access. For more information, see Introduction to remote access policies and Remote Access Policies Examples.

  - Ensure that network access servers are configured as RADIUS clients to this IAS server.

When visitors log on to your network, they do so through network access servers, such as wireless access points. These access points must be configured as RADIUS clients to your IAS proxy server or IAS server. For more information, see Configure RADIUS Clients.

**Many-to-one mapping**

Many-to-one certificate mapping allows you to map many certificates to one user account. After you have trusted the enterprise root CA of a partner organization, you can map all certificates issued by the partner organization CA to one account that you create in your local domain. This solution provides ease of management for many users, and eliminates the need to create an individual user account for every visitor to your organization.

For many-to-one mapping of certificates, you must perform the following steps:

- **Perform cross-certification or authorize the partner organization CA as a qualified subordinate certification authority using a computer running** Windows Server 2003, Enterprise Edition **and Certificate Services.**

  Performing cross-certification or authorizing the partner organization CA as a qualified subordinate CA is recommended for domains with a Windows Server 2003 domain functional level and clients running Windows XP. If your domains are Windows 2000 native, it is recommended that you use a certificate trust list (CTL) instead.

  For more information, see Domain and forest functionality, Qualified subordination, Qualified subordination overview, and Perform qualified subordination.

- **Create one user account and map the partner organization certificate to the account.**

  For more information, see Mapping certificates to user accounts and Map a certificate to a user account.

- **Configure your IAS server or IAS proxy server**

  Because authentication requests are not forwarded to external RADIUS servers when authentication is performed with certificates, you are not required to use IAS as a proxy server.

  - Configure a connection request policy for visitor access with the New Connection Request Policy Wizard.

    For more information, see Add a connection request policy, Pattern matching syntax, Realm names, Configure Connection Request Processing, and Connection Request Processing.

  - Create a realm manipulation rule to map the partner organization realm name, which is contained in the user's certificate, to the user's local user account.

    For example, if user@tailspintoys.com is mapped to user@microsoft.com, the realm manipulation rule must replace "@tailspintoys.com" with "@microsoft.com" using pattern-matching syntax.

    For more information, see Realm names and Pattern matching syntax.

  - Configure a remote access policy for visitor access. For more information, see Introduction to remote access policies and Remote Access Policies Examples.

  - Ensure that network access servers are configured as RADIUS clients to this IAS server.

    When visitors log on to your network, they do so through network access servers, such as wireless access points. These access points must be configured as RADIUS clients to your IAS proxy server or IAS server. For more information, see Configure RADIUS Clients.

For more information about designing your IAS proxy server deployment, see IAS as a RADIUS proxy design considerations.

**Notes**

- After you run the New Remote RADIUS Server Group Wizard, the New Connection Request Policy Wizard is opened by

default. If you do not want the New Connection Request Policy Wizard to open, click **Start the New Connection Request Policy Wizard when this wizard closes** in the New Remote RADIUS Server Group Wizard.

- For strong security between your IAS proxy server and your partner organization RADIUS servers, you can use Internet Protocol security (IPSec). For more information, see Securing RADIUS traffic with IPSec. For additional security recommendations and concerns, see IAS as a RADIUS proxy security considerations and Security information for IAS.

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Setting up IAS in a Test Lab

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting up IAS in a test lab**

This section describes how you can use five computers to create a test lab to configure and test the Internet Authentication Service (IAS) features in Windows Server 2003, Standard Edition. These instructions are designed to walk you through a set of tasks that expose you to IAS and its associated functionality. Beyond the set of tasks, you can use these instructions to create a functioning IAS configuration and experiment with IAS features and functionality before deploying these technologies on your production network.

This section covers:

- Setting up the IAS test lab infrastructure
- IAS test lab tasks

**Notes**

- The following instructions are for configuring a test lab using a minimum number of computers. Individual computers are needed to separate the services provided on the network and to clearly show the desired functionality. This configuration is neither designed to reflect best practices nor is it designed to reflect a desired or recommended configuration for a production network. The configuration, including IP addresses and all other configuration parameters, is designed only to work on a separate test lab network.
- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Setting up the IAS test lab infrastructure

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting up the infrastructure**

The infrastructure for the IAS test lab network consists of five computers performing the following services:

- A computer running Windows Server 2003, Standard Edition that is used as both a domain controller and a Domain Name System (DNS) server. This computer is named DC1.
- A computer running Windows Server 2003, Standard Edition that is used as a Remote Authentication Dial-in User Service (RADIUS) server. This computer is named IAS1.
- A computer running Windows Server 2003, Standard Edition that is used as a RADIUS proxy. This computer is named IAS2.
- A computer running Windows Server 2003, Standard Edition that is used as a VPN server. This computer is named VPN1.
- A computer running Windows XP Professional that is used as a VPN client. This computer is named CLIENT1.

The following illustration shows the configuration of the IAS test lab.

There are separate network segments representing a corporate intranet and the Internet. All computers on the corporate intranet are connected to a common hub or Layer 2 switch. All computers on the Internet are connected to a separate common hub or Layer 2 switch. Private addresses are used throughout the test lab configuration. The private network ID 172.16.0.0/24 is used for the intranet, and the private network ID 10.0.0.0/24 is used for the simulated Internet.

Each computer is manually configured with the appropriate IP address, subnet mask, and DNS server. There are no Dynamic Host Configuration protocol (DHCP) or Windows Internet Name Service (WINS) servers present.

The following sections describe how each of the computers in the test lab are configured. To reconstruct this test lab, please configure the computers in the order presented.

**Note**

- The following instructions are for configuring a test lab using a minimum number of computers. Individual computers are needed to separate the services provided on the network and to clearly show the desired functionality. This configuration is neither designed to reflect best practices nor is it designed to reflect a desired or recommended configuration for a production network. The configuration, including IP addresses and all other configuration parameters, is designed only to work on a separate test lab network.

**DC1**

DC1 is a computer running Windows Server 2003, Standard Edition. It is providing the following services:

- A domain controller for the testlab.microsoft.com domain.
- A DNS server for the testlab.microsoft.com DNS domain.
- A certification authority for the testlab.microsoft.com domain.

**Note**

- The domain name testlab.microsoft.com is used here for example purposes only. You can use any domain name in your test lab configuration.

To configure DC1 to perform these services, perform the following steps:

1. Install Windows Server 2003, Standard Edition as a standalone server.
2. After restarting, log on using the local Administrator account.
3. Configure the TCP/IP protocol with the IP address of 172.16.0.1 and the subnet mask of 255.255.255.0. For more information, see Configure TCP/IP for static addressing.
4. At the command prompt, run **dcpromo** for a new domain named testlab.microsoft.com in a new forest. Install the DNS service when prompted.
5. After restarting, log on using the Administrator account to the testlab.microsoft.com domain.
6. Install Certificate Services as an enterprise root certification authority. For more information, see Install an enterprise root certification authority.
7. Configure the testlab.microsoft.com domain for automatic enrollment of computer certificates. For more information, see Configure automatic certificate allocation from an enterprise CA.

**IAS1**

IAS1 is a computer running Windows Server 2003, Standard Edition. It is providing RADIUS authentication, authorization, and accounting for VPN1, the VPN server computer.

To configure IAS1 as a RADIUS server, perform the following steps:

1. On DC1, add a computer account for IAS1. For more information, see Create a new computer account.
2. Install Windows Server 2003, Standard Edition as a standalone server.
3. After restarting, log on using the local Administrator account.
4. Configure the TCP/IP protocol with the IP address of 172.16.0.2, the subnet mask of 255.255.255.0, and the DNS server IP address of 172.16.0.1. For more information, see Configure TCP/IP for static addressing and Configure TCP/IP to use DNS.
5. Join IAS1 to the testlab.microsoft.com domain. For more information, see Join a domain.
6. After restarting, log on using the Administrator account to the testlab.microsoft.com domain.
7. Install the Internet Authentication Service. For more information, see Install IAS.
8. Configure the IAS server to access user account properties in the testlab.microsoft.com domain. For more information, see Enable the IAS server to read user accounts in Active Directory.

9. Install Network Monitor. For more information, see Install Network Monitor.

**IAS2**

IAS2 is a computer running Windows Server 2003, Standard Edition. IAS2 is a RADIUS proxy for VPN1, the VPN server computer.

To configure IAS2 as a RADIUS proxy, perform the following steps:

1. Install Windows Server 2003, Standard Edition as a standalone server.

2. After restarting, log on using the local Administrator account.

3. Configure the TCP/IP protocol with the IP address of 172.16.0.3, the subnet mask of 255.255.255.0, and the DNS server IP address of 172.16.0.1. For more information, see Configure TCP/IP for static addressing and Configure TCP/IP to use DNS.

4. Install the Internet Authentication Service. For more information, see Install IAS.

**VPN1**

VPN1 is a computer running Windows Server 2003, Standard Edition. It is providing VPN server services for VPN clients. To configure VPN1 as a VPN server, perform the following steps:

1. From DC1, add a computer account for the VPN1 computer. For more information, see Create a new computer account.

2. Install Windows Server 2003, Standard Edition as a standalone server.

3. After restarting, log on using the local Administrator account.

4. For the intranet local area connection, configure the TCP/IP protocol with the IP address of 172.16.0.4, the subnet mask of 255.255.255.0, and the DNS server IP address of 172.16.0.1. For more information, see Configure TCP/IP for static addressing and Configure TCP/IP to use DNS.

5. For the Internet local area connection, configure the TCP/IP protocol with the IP address of 10.0.0.2 and the subnet mask of 255.255.255.0. For more information, see Configure TCP/IP for static addressing.

6. Join the VPN1 computer to the testlab.microsoft.com domain. For more information, see Join a domain.

7. After restarting, log on using the Administrator account in the testlab.microsoft.com domain.

8. Configure and enable the Routing and Remote Access service. For more information, see Enable the Routing and Remote Access service. In the Routing and Remote Access server Setup Wizard, select **Virtual private network (VPN) server** from the **Common Configurations** dialog box. When prompted for IP address assignment, select **From a specified range of addresses**, and then configure the range 172.16.0.248 through 172.16.0.255. Do not configure RADIUS authentication.

**CLIENT1**

CLIENT1 is a computer running Windows XP Professional. It is used as a VPN client to gain remote access to intranet resources across the simulated Internet. To configure CLIENT1 as a VPN client, perform the following steps:

1. On DC1, add a computer account for CLIENT1. For more information, see Create a new computer account.

2. Connect CLIENT1 to the intranet network segment.

3. On CLIENT1, install Windows XP Professional as a workgroup computer.

4. After restarting, log on using the local Administrator account.

5. Type **gpupdate /target:computer** at a command prompt to ensure that a computer certificate is installed on CLIENT1.

6. Configure the TCP/IP protocol with the IP address of 172.16.0.5, the subnet mask of 255.255.255.0, and the DNS server IP address of 172.16.0.1. For more information, see Configure TCP/IP for static addressing and Configure TCP/IP to use DNS.

7. Join CLIENT1 to the testlab.microsoft.com domain. For more information, see Join a domain.

8. After restarting, log on using the Administrator account in the testlab.microsoft.com domain.

9. Configure the TCP/IP protocol with the IP address of 10.0.0.1 and the subnet mask of 255.255.255.0. Do not configure a DNS server IP address. For more information, see Configure TCP/IP for static addressing and Configure TCP/IP to use DNS.

10. Shut down CLIENT1, disconnect it from the intranet network segment, and then connect it to the simulated Internet network segment.

11. Restart CLIENT1.

12. After restarting, log on using the local Administrator account.

# IAS test lab tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS test lab tasks**

The following tasks are designed to take you through the common elements of setting up RADIUS server and proxy support with Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition:

- PPTP and L2TP remote access VPN connections
- IAS as a RADIUS server for the VPN server
- Remote access policies for different types of VPN connections
- IAS as a RADIUS proxy for the VPN server

### Note

- The following instructions are for configuring a test lab using a minimum number of computers. Individual computers are needed to separate the services provided on the network and to clearly show the desired functionality. This configuration is neither designed to reflect best practices nor is it designed to reflect a desired or recommended configuration for a production network. The configuration, including IP addresses and all other configuration parameters, is designed only to work on a separate test lab network.

**PPTP and L2TP remote access VPN connections**

To create a PPTP-based remote access VPN connection between CLIENT1 and VPN1, do the following:

**1. Create a user account**

1. On DC1, use Active Directory Users and Computers to create a user account named **PPTPUser** with a password. For more information, see Create a new user account.
2. Set the remote access permission on the **Dial-in** tab to **Allow access**. For more information, see Configure remote access permission for a user.

**2. Create the PPTP connection**

1. On CLIENT1, use the Make New Connection Wizard to create a new virtual private network connection named **PPTP**, with the IP address of 10.0.0.2. For more information, see Make a virtual private network (VPN) connection.
2. On CLIENT1, right-click the new **PPTP** connection, and then click **Properties**.
3. Click the **Networking** tab, and then in **Type of VPN**, click **PPTP VPN**.
4. Click **OK** to save changes to the PPTP connection.

**3. Make the PPTP connection**

1. On CLIENT1, double-click the **PPTP** connection.
2. In the **PPTP** dialog box, type **PPTPUser@testlab.microsoft.com** as the user name, type the password, and then select the **Save this user name and password to use when** check box.
3. Click **Connect**.

**4. Disconnect the PPTP connection**

- On CLIENT1, right-click the **PPTP** connection, and then click **Disconnect**.

To create an L2TP/IPSec remote access VPN connection between CLIENT1 and VPN1, do the following:

**1. Create a user account**

1. On DC1, use Active Directory Users and Computers to create a user account named **L2TPUser** with a password. For more information, see Create a new user account.

2. Set the remote access permission on the **Dial-in** tab to **Allow access**. For more information, see Configure remote access permission for a user.

**2. Create the L2TP connection**

1. On CLIENT1, use the Make New Connection Wizard to create a new L2TP/IPSec connection named **L2TP**, with the IP address of **10.0.0.2**. For more information, see Make a virtual private network (VPN) connection.

2. Right-click the new **L2TP** connection, and then click **Properties**.

3. Click the **Networking** tab, and then in **Type of VPN**, click **L2TP IPSec VPN**.

4. Click **OK** to save changes to the **L2TP** connection.

**3. Make the L2TP connection**

1. On CLIENT1, double-click the **L2TP** connection.

2. In the **L2TP** dialog box, type **L2TPUser@testlab.microsoft.com** as the user name, type the password, and then select the **Save this user name and password to use when** check box.

3. Click **Connect**.

**IAS as a RADIUS server for the VPN server**

To configure IAS1 as the RADIUS authentication and accounting server for the VPN server, do the following:

**1. Add VPN1 as a RADIUS client to IAS1**

- On IAS1, add VPN1 as a RADIUS client with the client address of **172.16.0.4**, the client vendor of **Microsoft**, and a shared secret. For more information, see Add RADIUS clients.

**2. Configure IAS1 to log authentication events**

- On IAS1, configure remote access logging of authentication events. For more information, see Select requests to be logged.

**3. Configure VPN1 for RADIUS and IAS1 as the RADIUS server**

- Configure VPN1 to use RADIUS authentication. Configure IAS1 as the RADIUS server with the IP address of 172.16.0.1 and the shared secret. For more information, see Use RADIUS authentication.

- Configure VPN1 to use RADIUS accounting. Configure IAS1 as the RADIUS server with the IP address of 172.16.0.1 and the shared secret. For more information, see Use RADIUS accounting.

**4. Make a PPTP connection**

1. On CLIENT1, use the **PPTP** connection to create a PPTP-based VPN connection with VPN1. For more information, see Connect to a remote network.

2. At a Command Prompt, use the ping command to ping DC1 at its IP address of 172.16.0.1.

3. Use the ping command to ping IAS1 at its IP address of 172.16.0.2.

4. Disconnect the **PPTP** connection. For more information, see Disconnect from a remote network.

**5. Make an L2TP connection**

1. On CLIENT1, use the **L2TP** connection to create an L2TP/IPSec VPN connection with VPN1.

2. Use the ping command to ping DC1 at its IP address of 172.16.0.1.

3. Use the ping command to ping IAS1 at its IP address of 172.16.0.2.

4. Disconnect the **L2TP** connection.

**6. Check the system event log for RADIUS events**

- On IAS1, use Event Viewer to view IAS events in the system event log for the PPTP and L2TP connections that were recently created using CLIENT1.

**7. Check RADIUS authentication and accounting logs**

- On IAS1, use Windows Explorer to open the systemroot\System32\Logfiles\Iaslog.log file. View the authentication and accounting entries for the connections that were recently created using CLIENT1. For more information about the IAS log file format, see Interpreting IAS-formatted log files.

**8. Capture RADIUS traffic with Network Monitor**

1. On IAS1, run Network Monitor from the Administrative Tools folder.

2. Use Network Monitor to capture network traffic. For more information, see Capture network frames.

3. On CLIENT1, make a VPN connection with VPN1 with the **PPTP** connection.

4. On CLIENT1, disconnect the **PPTP** connection.

5. On IAS1, stop Network Monitor and view the captured frames with the protocol of **RADIUS**. For more information, see Expand and collapse frame details.

**Remote access policies for different types of VPN connections**
To create remote access policies for different types of VPN connections, do the following:

**1. Create different remote access policies for different types of connections**

1. On IAS1, use the New Remote Access Policy Wizard to create a new custom remote access policy with the following settings:

- Policy name: PPTP connections

- Conditions: NAS-Port-Type matches Virtual (VPN) and Tunnel-Type matches Point-to-Point Tunneling Protocol (PPTP)

- Permission: Grant remote access permission
- Profile settings, IP tab, Input packet filter
    - Deny all traffic except those listed below
    - Destination network, IP address: 172.16.0.1
    - Destination network, Subnet mask: 255.255.255.255
    - Protocol: Any
- Profile settings, IP tab, Output packet filter:
    - Deny all traffic except those listed below
    - Source network, IP address: 172.16.0.1
    - Destination network, Subnet mask: 255.255.255.255
    - Protocol: Any

For more information, see Add a remote access policy.

1. Use the New Remote Access Policy Wizard to create a new custom remote access policy with the following settings:

- Policy name: L2TP connections
- Conditions: NAS-Port-Type matches Virtual (VPN) and Tunnel-Type matches Layer Two Tunneling Protocol (L2TP)
- Permission: Grant remote access permission
- Profile settings, IP tab, Input packet filter:
    - Deny all traffic except those listed below
    - Destination network, IP address: 172.16.0.2
    - Destination network, Subnet mask: 255.255.255.255
    - Protocol: Any
- Profile settings, IP tab, Output packet filter:
    - Deny all traffic except those listed below
    - Source network, IP address: 172.16.0.2
    - Destination network, Subnet mask: 255.255.255.255
    - Protocol: Any

**2. Make a PPTP connection and test connectivity**

1. On CLIENT1, make a VPN connection with VPN1 using the **PPTP** connection.

2. Use the ping command to ping DC1 at its IP address of 172.16.0.1.

3. Use the ping command to ping IAS1 at its IP address of 172.16.0.2.

   This command fails because packet filtering for all connections that match the **PPTP connections** policy allows only traffic sent to and from the IP address of 172.16.0.1.

4. Disconnect the **PPTP** connection.

**3. Make an L2TP connection and test connectivity**

1. On CLIENT1, make a VPN connection with VPN1 using the **L2TP** connection.

2. Use the ping command to ping IAS1 at its IP address of 172.16.0.2.

3. Use the ping command to ping DC1 at its IP address of 172.16.0.1.

   This command fails because packet filtering for all connections that match the **L2TP connections** policy allows only traffic sent to and from the IP address of 172.16.0.2.

4. Disconnect the **L2TP** connection.

**4. Check the system event log for RADIUS events**

- On IAS1, use Event Viewer to view the IAS events in the system event log for the connections that were recently created. Note that the authentication event message text contains the name of the remote access policy that accepted the connection.

**IAS as a RADIUS proxy for the VPN server**

To configure IAS2 as the RADIUS proxy for the VPN server, do the following:

**1. Reconfigure VPN1 with IAS2 as its RADIUS server**

1. On VPN1, remove IAS1 as the RADIUS server for the RADIUS authentication provider. Next, configure IAS2 as the RADIUS server for the RADIUS authentication provider with the IP address of 172.16.0.3 and the shared secret. For more information, see Use RADIUS authentication.

2. On VPN1, remove IAS1 as the RADIUS server for the RADIUS accounting provider. Next, configure IAS2 as the RADIUS server for the RADIUS accounting provider with the IP address of 172.16.0.3 and the shared secret. For more information, see Use RADIUS accounting.

**2. Reconfigure IAS1 with IAS2 as a RADIUS client**

1. On IAS1, remove VPN1 as a RADIUS client. For more information, see Delete a RADIUS client.

2. On IAS1, add IAS2 as a RADIUS client with the client address of 172.16.0.4, the client vendor of Microsoft, and a shared secret. For more information, see Add RADIUS clients.

**3. Configure IAS2 as a RADIUS proxy between VPN1 and IAS1**

1. On IAS2, add VPN1 as a RADIUS client with the client address of **172.16.0.4**, the client vendor of **Microsoft**, and a shared secret. For more information, see Add RADIUS clients.

2. On IAS2, create a remote RADIUS server group that contains IAS1. For more information, see Add a remote RADIUS server group. In the New Remote RADIUS server Group Wizard, configure the following:

- Group name: Testlab
- Primary server: 172.16.0.2
- Shared secret: SharedSecret
  Do not configure a backup server.

3. Create a new connection request policy. For more information, see Add a connection request policy. In the New Connection Request Policy Wizard, configure the following:

   - Policy name: Proxy
   - Select the option to **Forward connection requests to a remote RADIUS server for authentication**
   - Realm name: testlab.microsoft.com
   - Clear the **Before authentication, remove the realm name from the user name: check box**.
   - server group: Testlab

**Note**

- IAS1 and IAS2 must use the same shared secret. Additionally, IAS2 and VPN1 must use the same shared secret. The shared secret that is used between IAS1 and IAS2 can be different than the shared secret that is used between IAS2 and VPN1.

#### 4. Make a PPTP connection

1. On CLIENT1, make a VPN connection with VPN1 using the PPTP connection.
2. Use ping to ping DC1 at its IP address of 172.16.0.1.
3. Use ping to ping IAS1 at its IP address of 172.16.0.2.

   This command fails because packet filtering for all connections that match the PPTP connections policy allows only traffic sent to and from the IP address of 172.16.0.1.
4. Disconnect the PPTP connection.

In this configuration, the authentication and accounting messages that are sent by the VPN server are being forwarded from IAS2 to IAS1.

# IAS Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

This section provides information about:

- Troubleshooting tools to use with IAS
- Pattern matching syntax
- IAS Resources: Windows Deployment and Resource Kits
- Database-Import Log Files
- IAS-Formatted Log Files

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Troubleshooting tools to use with IAS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting tools to use with IAS**
To help you gather information to troubleshoot problems with IAS, the following troubleshooting tools are available:

- IAS event logging and Event Viewer
- Network Monitor
- System Monitor counters
- SNMP Service

**IAS event logging and Event Viewer**
Use Event Viewer to obtain information about hardware and software problems and to monitor all security events--including informational, warning, and error events.

To troubleshoot IAS authentication attempts in the system event log, enable event logging for IAS. Viewing the authentication attempts in this log is useful in troubleshooting remote access policies. When you have multiple remote access policies configured, you can use the system event log to determine the name of the remote access policy that either accepted or rejected the connection attempt. Enabling IAS event logging and reading the text of IAS authentication events in the system event log is the most useful tool for troubleshooting failed IAS authentications. For more information, see Event logging for IAS.

**Network Monitor**
You can use Network Monitor, available in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition; or a commercial packet analyzer (also known as a network sniffer), to capture and view RADIUS authentication and accounting messages that are sent to and from the IAS server. Network Monitor includes a RADIUS parser, which you can use to view the attributes of a RADIUS message and troubleshoot connection issues.

For more information, see Network Monitor.

**System Monitor counters**
You can use Performance console overview to monitor the resource use of specific components and program processes. With System Monitor, you can use charts and reports to determine how efficiently your server uses IAS and both identify and troubleshoot potential problems.

You can use System Monitor to monitor the following IAS-related performance objects:

- IAS Accounting Client
- IAS Accounting server
- IAS Authentication Client
- IAS Authentication server

**SNMP Service**
You can use SNMP to monitor status information for your IAS server. IAS supports the RADIUS Authentication server MIB (as specified in RFC 2619) and the RADIUS Accounting server MIB (as specified in RFC 2621).

# Pattern matching syntax

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Pattern matching syntax**

Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition support regular expressions for pattern matching, which is widely used in UNIX environments. You can use this syntax to specify the conditions of remote access policy attributes and RADIUS realms, as specified in the following table.

| Character | Description | Example |
|---|---|---|
| \ | Marks the next character as a character to match. | /n/ matches the character "n". The sequence /\n/ matches a line feed or newline character. |
| ^ | Matches the beginning of the input or line. | |
| $ | Matches the end of the input or line. | |
| * | Matches the preceding character zero or more times. | /zo*/ matches either "z" or "zoo." |
| + | Matches the preceding character one or more times. | /zo+/ matches "zoo" but not "z." |
| ? | Matches the preceding character zero or one times. | /a?ve?/ matches the "ve" in "never." |
| . | Matches any single character except a newline character. | |
| **(** *pattern* **)** | Matches *pattern* and remembers the match. To match ( ) (parentheses), use "\(" or "\)". | |
| *x* **\|** *y* | Matches either *x* or *y*. | /z\|food?/ matches "zoo" or "food." |
| **{** *n* **}** | Matches exactly *n* times (*n* is a nonnegative integer). | /o{2}/ does not match the "o" in "Bob," but matches the first two instances of the letter o in "foooood." |
| **{** *n* **,}** | Matches at least *n* times (*n* is a nonnegative integer). | /o{2,}/ does not match the "o" in "Bob" but matches all of the instances of the letter o in "foooood." /o{1,}/ is equivalent to /o+/. |
| **{** *n* **,** *m* **}** | Matches at least *n* and at most *m* times (*m* and *n* are nonnegative integers). | /o{1,3}/ matches the first three instances of the letter o in "fooooood." |
| **[** *xyz* **]** | Matches any one of the enclosed characters (a character set). | /[abc]/ matches the "a" in "plain." |
| **[^** *xyz* **]** | Matches any characters that are not enclosed (a negative character set). | /[^abc]/ matches the "p" in "plain." |
| **\b** | Matches a word boundary (for example, a space). | /ea*r\b/ matches the "er" in "never early." |
| **\B** | Matches a nonword boundary. | /ea*r\B/ matches the "ear" in "never early." |
| **\d** | Matches a digit character (equivalent to [0-9]). | |
| **\D** | Matches a nondigit character (equivalent to [^0-9]). | |
| **\f** | Matches a form feed character. | |
| **\n** | Matches a line feed character. | |

| | | |
|---|---|---|
| **\r** | Matches a carriage return character. | |
| **\s** | Matches any white space character including space, tab, and form feed (equivalent to [ \f\n\r\t\v]). | |
| **\S** | Matches any non-white space character (equivalent to [^ \f\n\r\t\v]). | |
| **\t** | Matches a tab character. | |
| **\v** | Matches a vertical tab character. | |
| **\w** | Matches any word character, including underscore (equivalent to [A-Za-z0-9_]). | |
| **\W** | Matches any nonword character, excluding underscore (equivalent to [^A-Za-z0-9_]). | |
| **** *num* | Refers to remembered matches (?*num*, where *num* is a positive integer). For example, \1 replaces what is stored in the first remembered match. This option can be used only in the **Replace** text box when configuring attribute manipulation. | |
| **/** *n* **/** | Allows the insertion of ASCII codes into regular expressions (?*n*, where *n* is an octal, hexadecimal, or decimal escape value). | |

**Examples for remote access policy attributes**

The following examples describe the use of the pattern matching syntax to specify remote access policy attributes:

- To specify all phone numbers within the 899 area code, the syntax is:

  899.*

- To specify a range of all IP addresses that begin with 192.168.1, the syntax is:

  192\.168\.1\..+

**Examples for manipulation of the realm name in the User-Name attribute**

The following examples describe the use of the pattern matching syntax to manipulate realm names for the User-Name attribute, which is located on the **Attribute** tab in the properties of a connection request policy. For more information, see Configure attribute manipulation.

- To remove the realm portion of the User-Name attribute

  In the outsourced dial scenario, the Internet service provider (ISP) might require a realm name to route the authentication request. However, the IAS server might not recognize the realm name portion of the user name. Therefore, the realm name must be removed before it is forwarded to the IAS server.

  - **Find:** @microsoft\.com
  - **Replace:**

- To replace *user@example.microsoft.com* with *example.microsoft.com\user*

  - **Find:** (.*)@(.*)
  - **Replace:** $2\$1

- To replace *domain\user* with *specific_domain\user*

  - **Find:** (.*)\\(.*)

- **Replace:** *specific_domain*\$2

- To replace *user* with *user@specific_domain*

  - **Find:** $

  - **Replace:** *@specific_domain*

**Example for RADIUS message forwarding by a proxy server**
You can create routing rules that forward RADIUS messages with a specific realm name to a specific set of RADIUS servers when IAS is used as a RADIUS proxy. Following is a recommended syntax for routing requests based on realm name.

| NetBIOS name | Pattern |
|---|---|
| WCOAST | ^wcoast\\ |

In the following example, wcoast.microsoft.com is a unique user principal name (UPN) suffix for the DNS or Active Directory domain wcoast.microsoft.com. Using the supplied pattern, the IAS proxy can route messages based on domain NetBIOS name or UPN suffix.

| NetBIOS name | UPN suffix | Pattern |
|---|---|---|
| WCOAST | wcoast.microsoft.com | ^wcoast\\\|@wcoast\.microsoft\.com$ |

**Ping user-name**
Some RADIUS proxy servers and network access servers periodically send authentication and accounting requests (known as ping requests) to verify that the IAS server is present on the network. These ping requests include fictional user names. When IAS processes these requests, the event and accounting logs become filled with access reject records, making it more difficult to keep track of valid records.

When you configure a registry entry for **ping user-name**, IAS matches the registry entry value against the user name value in ping requests by other servers. A **ping user-name** registry entry specifies the fictional user name (or a user name pattern, with variables, that matches the fictional user name) sent by RADIUS proxy servers and network access servers. When IAS receives ping requests that match the **ping user-name** registry entry value, IAS rejects the authentication requests without processing the request. IAS does not record transactions involving the fictional user name in any log files, which makes the event log easier to interpret.

### Note

- **Ping user-name** is not installed by default. You must add **ping user-name** to the registry. You can add an entry to the registry using Registry Editor. For more information, see Registry Editor.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**Adding ping user-name to the registry**
**Ping user-name** can be added to the following registry key as a string value by a member of the local Administrators group:

**HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\IAS\Parameters**

| Name | Type | Data |
|---|---|---|
| ping user-name | REG_SZ | *User name* |

### Note

- To indicate more than one user name for a **ping user-name** value, enter a name pattern, such as a Domain Name

System (DNS) name including wildcard characters, in **Data**.

- Interpreting database-import log files

# Importing IAS log files into a database

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Importing IAS log files into a database**

When you select **Database compatible file format** for IAS accounting and authentication logs, the information is recorded in a comma-delimited format. The consistent structure of this format makes it possible to use a database program, such as Microsoft Access, to import a log into a table, which presents data in a way that is easily viewed and interpreted. And, after importing a log, you can filter and analyze the data in a way that is useful for your accounting and auditing processes.

**Importing IAS log files into a table with Microsoft Access 2002 or Microsoft Access 97**

The table that you create with Access is formatted according to the type of data that is contained in each field. Although this example shows you how to create a new table, you can also import a log into an existing table.

Before creating the table, add the two lines in the next paragraph to the beginning of the log file created by IAS. The first line contains the attribute names of each field in the log and Access uses them to create the field names in its table. Using attribute names in the table makes it easier to interpret the log entries. The second line is used by Access to set up the appropriate data type for each column in its table. After you import the log file, you should delete these entries from the Access table.

```

- To create the table using Microsoft Access 2002
- To create the table using Microsoft Access 97

**To create the table using Microsoft Access 2002**

1. Rename log files and give them a file name extension of **.txt**.
2. In Access 2002, click **Blank Database**.
3. In **File New Database**, specify a *FileName*, and then click **Create**.
4. Click **File**, click **Get External Data**, and then click **Import**.
5. In **Import**, in **Files of type**, select **Text Files**, locate the IAS log file, select it, and then click **Import**.
6. In the Import Text Wizard, click **Advanced**.
7. In **Import Specification**:
   - In **File Format**, select **Delimited**.
   - In **Field Delimiter**, select the **,** (comma).

- In the **Text Qualifier**, select **"** (quotation mark).
- In the **Dates, Times, and Numbers**, select **Four Digit Years** and **Leading Zeros in Dates**, and then type the appropriate **Date Order** (such as **MDY**), **Date Delimiter** (such as **/** or forward slash), **Time Delimiter** (such as **:** or colon), and **Decimal Symbol** (such as **.** or period).

8. In the **Import Text Wizard** dialog box, click **Next**, select **First Row Contains Field Names**, and then click **Next**.
9. Select **In a New Table**, and then click **Next**.
10. Leave the defaults in **Field Options**, and then click **Next**.
11. Select **Let Access add primary key**, and then click **Next**.
12. In **Import to Table**, type the name of the new table, click **Finish**, and then click **OK**.
13. In the *FileName***:Database** dialog box, select the name of your database, and then click **Open** to view your table.

**To create the table using Microsoft Access 97**

1. Rename log files and give them a file name extension of **.txt**.
2. In Access 97, click **File**, and then click **New Database**.
3. In **New**, click **Blank Database**, and then click **OK**.
4. In **File New Database**, specify a *FileName*, and then click **Create**.
5. In the *FileName***:Database** dialog box, click **New**.
6. In **New Table**, select **Import Table**, and then click **OK**.
7. In **Import**, in **Files of type**, select **Text Files**, locate the IAS log file, select it, and then click **Import**.
8. In the Import Text Wizard, select **Advanced**.
9. In **Advanced**:

    - In **File Format**, select **Delimited**.
    - In **Field Delimiter**, select the **,** (comma).
    - In the **Text Qualifier**, select **"** (quotation mark).
    - In **File Origin**, select **Windows (ANSI)**.
    - In the **Dates, Times, and Numbers**, select **Four Digit Years** and **Leading Zeros in Dates**, and then type the appropriate **Date Order** (such as **MDY**), **Date Delimiter** (such as **/** or forward slash), **Time Delimiter** (such as **:** or colon), and **Decimal Symbol** (such as **.** or period).

10. In **Import Text Wizard**, click **Next**, select **First Row Contains Field Names**, and then click **Next**.
11. Select **In a New Table**, and then click **Next**.

12. Leave the defaults in **Field Options**, and then click **Next**

13. Select **Let Access add primary key**, and then click **Next**.

14. In **Import to Table**, type the name of the new table, click **Finish**, and then click **OK**.

15. In the *FileName***:Database** dialog box, select the name of your database, and then click **Open** to view your table.

# Interpreting database-import log files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Interpreting database-import log files**

Unlike IAS-formatted log files, database-import log files present the data in a standard sequence and use a structure that is identical, regardless of the network access server (NAS) that sends the data. This consistent sequence and structure helps simplify accounting and authentication records. Data can be easily exported to a database.

### Note

- Although IAS supports both IAS-formatted and database-import log files, the database-import log format should be used in most instances because it supports the use of ODBC-compliant tools.

**Entries recorded in database-import log files**

The following are example entries (Access-Request and Access-Accept) from a database-import log file.

```
"CLIENTCOMP","IAS",06/17/1999,13:04:33,1,"client",,,,,,,,,9,"10.10.10.10","iasclient",,,,,,,1,,0,,,,,,,,
```

| | | | |
|---|---|---|---|
| | Called-Station-ID | Text | The phone number dialed by the user. |
| | Calling-Station-ID | Text | The phone number from which the call originated. |
| | Callback-Number | Text | The callback phone number. |
| | Framed-IP-Address | Text | The framed address to be configured for the user. |
| | NAS-Identifier | Text | The text that identifies the NAS originating the request. |
| | NAS-IP-Address | Text | The IP address of the NAS originating the request. |
| | NAS-Port | Number | The physical port number of the NAS originating the request. |
| 9 | Client-Vendor | Number | The manufacturer of the NAS (this is an IAS-internal attribute). |
| "10.10.10.10" | Client-IP-Address | Text | The IP address of the RADIUS client (this is an IAS-internal attribute). |
| "iasclient" | Client-Friendly-Name | Text | The friendly name for the RADIUS client (this is an IAS-internal attribute). |
| | Event-Timestamp | Time | The date and time that this event occurred on the NAS. |
| | Port-Limit | Number | The maximum number of ports that the NAS provides to the user. |
| | NAS-Port-Type | Number | The type of physical port that is used by the NAS originating the request. |
| | Connect-Info | Text | Information that is used by the NAS to specify the type of connection made. Typical information includes connection speed and data encoding protocols. |
| | Framed-Protocol | Number | The protocol to be used. |
| | Service-Type | Number | The type of service that the user has requested. |
| 1 | Authentication-Type | Number | The authentication scheme, which is used to verify the user and can be:<br>• 1 = PAP<br>• 2 = CHAP<br>• 3 = MS-CHAP<br>• 4 = MS-CHAP v2<br>• 5 = EAP<br>• 7 = None<br>• 8 =Custom<br><br>This is an IAS-internal attribute. |
| | NP-Policy-Name | Text | The friendly name of the remote access policy that either granted or denied access. This attribute is logged in Access-Accept and Access-Reject messages. If a user is rejected because none of the remote access policies matched, then this attribute is blank. |
| 0 | Reason-Code | Number | The reason for rejecting a user, which can be:<br>• 0 = IAS_SUCCESS<br>• 1 = IAS_INTERNAL_ERROR<br>• 2 = IAS_ACCESS_DENIED<br>• 3 = IAS_MALFORMED_REQUEST |

| | | | |
|---|---|---|---|
| | | | • 4 = IAS_GLOBAL_CATALOG_UNAVAILABLE<br>• 5 = IAS_DOMAIN_UNAVAILABLE<br>• 6 = IAS_SERVER_UNAVAILABLE<br>• 7 = IAS_NO_SUCH_DOMAIN<br>• 8 = IAS_NO_SUCH_USER<br>• 16 = IAS_AUTH_FAILURE<br>• 17 = IAS_CHANGE_PASSWORD_FAILURE<br>• 18 = IAS_UNSUPPORTED_AUTH_TYPE<br>• 32 = IAS_LOCAL_USERS_ONLY<br>• 33 = IAS_PASSWORD_MUST_CHANGE<br>• 34 = IAS_ACCOUNT_DISABLED<br>• 35 = IAS_ACCOUNT_EXPIRED<br>• 36 = IAS_ACCOUNT_LOCKED_OUT<br>• 37 = IAS_INVALID_LOGON_HOURS<br>• 38 = IAS_ACCOUNT_RESTRICTION<br>• 48 = IAS_NO_POLICY_MATCH<br>• 64 = IAS_DIALIN_LOCKED_OUT<br>• 65 = IAS_DIALIN_DISABLED<br>• 66 = IAS_INVALID_AUTH_TYPE<br>• 67 = IAS_INVALID_CALLING_STATION<br>• 68 = IAS_INVALID_DIALIN_HOURS<br>• 69 = IAS_INVALID_CALLED_STATION<br>• 70 = IAS_INVALID_PORT_TYPE<br>• 71 = IAS_INVALID_RESTRICTION<br>• 80 = IAS_NO_RECORD<br>• 96 = IAS_SESSION_TIMEOUT<br>• 97 = IAS_UNEXPECTED_REQUEST<br><br>This is an IAS-internal attribute. |
| | Class | Text | The attribute that is sent to client in an Access-Accept packet. |
| | Session-Timeout | Number | The length of time (in seconds) before the session is terminated. |
| | Idle-Timeout | Number | The length of idle time (in seconds) before the session is terminated. |

| | | | |
|---|---|---|---|
| | Termination-Action | Number | The action that the NAS should take when service is completed. |
| | EAP-Friendly-Name | Text | The friendly name that is used with Extensible Authentication Protocol (EAP). |
| | Acct-Status-Type | Number | The number that specifies whether an accounting packet starts or stops a bridging, routing, or Terminal Server session. |
| | Acct-Delay-Time | Number | The length of time (in seconds) for which the NAS has been sending the same accounting packet. |
| | Acct-Input-Octets | Number | The number of octets received during the session. |
| | Acct-Output-Octets | Number | The number of octets sent during the session. |
| | Acct-Session-Id | Text | The unique numeric string that identifies the server session. |
| | Acct-Authentic | Number | The number that specifies which server authenticated an incoming call. |
| | Acct-Session-Time | Number | The length of time (in seconds) for which the session has been active. |
| | Acct-Input-Packets | Number | The number of packets received during the session. |
| | Acct-Output-Packets | Number | The number of packets sent during the session. |
| | Acct-Terminate-Cause | Number | The reason that a connection was terminated. |
| | Acct-Multi-Ssn-ID | Text | The unique numeric string that identifies the multilink session. |
| | Acct-Link-Count | Number | The number of links in a multilink session. |
| | Acct-Interim-Interval | Number | The length of interval (in seconds) between each interim update that the NAS sends. |
| | Tunnel-Type | Number | The tunneling protocol to be used. |
| | Tunnel-Medium-Type | Number | The medium to use when creating a tunnel for protocols. For example, L2TP packets can be sent over multiple link layers. |
| | Tunnel-Client-Endpt | Text | The IP address of the tunnel client. |
| | Tunnel-Server-Endpt | Text | The IP address of the tunnel server. |
| | Acct-Tunnel-Connection | Text | An identifier assigned to the tunnel. |
| | Tunnel-Pvt-Group-ID | Text | The group ID for a specific tunneled session. |
| | Tunnel-Assignment-ID | Text | The tunnel to which a session is assigned. |
| | Tunnel-Preference | Number | The preference of the tunnel type, as indicated with the Tunnel-Type attribute when multiple tunnel types are supported by the access server. |
| | MS-Acct-Auth-Type | Number | A Routing and Remote Access service attribute. For more information, see RFC 2548. |
| | MS-Acct-EAP-Type | Number | A Routing and Remote Access service attribute. For more information, see RFC 2548. |
| | MS-RAS-Version | Text | A Routing and Remote Access service attribute. For more information, see RFC 2548. |

| | | | |
|---|---|---|---|
| | MS-RAS-Vendor | Number | A Routing and Remote Access service attribute. For more information, see RFC 2548. |
| | MS-CHAP-Error | Text | A Routing and Remote Access service attribute. For more information, see RFC 2548. |
| | MS-CHAP-Domain | Text | A Routing and Remote Access service attribute. For more information, see RFC 2548. |
| | MS-MPPE-Encryption-Types | Number | A Routing and Remote Access service attribute. For more information, see RFC 2548. |
| | MS-MPPE-Encryption-Policy | Number | A Routing and Remote Access service attribute. For more information, see RFC 2548. |

# IAS-Formatted Log Files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IAS-formatted log files**

This section provides information about using IAS-formatted log files:

- Interpreting IAS-formatted log files
- Interpreting IAS IDs for vendor-specific attributes

# Interpreting IAS-formatted log files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Interpreting IAS-formatted log files**

In the Windows NT 4 version of IAS, log files are formatted by using a method in which attributes are logged as attribute-value pairs. This formatting is supported in IAS in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; and Windows 2000. The logs that use this format are referred to as IAS-formatted log files. However, in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; and Windows 2000, this format supports the inclusion of additional information in the log file:

- In addition to accounting messages (Accounting-On, Accounting-Off, Accounting-Start, Accounting-Stop, and Accounting-Interim), the IAS server also logs authentication messages (Access-Request, Access-Accept, and Access-Reject).
- All string attributes that contain either unprintable characters or delimiters are printed in hexadecimal format (for example, 0x026).
- If IAS receives an attribute (RADIUS-standard or vendor-specific) that is not defined in the IAS dictionary, it is logged as a string.

### Notes

- Unless you have migration, compatibility, or other issues that require you to use the IAS format, you should use the database-import log format. Although a database-import log file contains a smaller subset of attributes, it contains the attributes required to support most tracking and accounting activities.
- To help read and interpret the log files in IAS format, the Iasparse tool is included in the IAS Resources: Windows Deployment and Resource Kits. This tool can be used to parse log files and provide output in a readable format.

**Entries recorded in IAS-formatted log files**

The following is an example entry (Access-Request) from an IAS-formatted log file.

```
10.10.10.10,client,06/04/1999,14:42:19,IAS,CLIENTCOMP,6,2,7,1,5,9,61,5,64,1,65,1,31,1
```

The format of this record, which is the same for all records in your log file, includes a header, followed by the attribute-value pairs for all attributes that are contained in the packet.

The first six record fields make up the header and include:

| Value shown in example | Attribute | ID | Data type | Represents |
|---|---|---|---|---|
| 10.10.10.10 | NAS-IP-Address | IAS Header | Text | The IP address of the NAS that is sending the request. |
| client | User-Name | IAS Header | Text | The user name that is requesting access. |
| 06/04/1999 | Record-Date | IAS Header | Time | The date that the log is written. |
| 14:42:19 | Record-Time | IAS Header | Time | The time that the log is written. |

| | | | | |
|---|---|---|---|---|
| IAS | Service-Name | IAS Header | Text | The name of the service that is running on the RADIUS server. |
| CLIENTCOMP | Computer-Name | IAS Header | Text | The name of the RADIUS server. |

Beyond the header, RADIUS attributes and values are listed in pairs in the following format:

*<AttributeNumber1>,<ValueForAttributeNumber1>,<AttributeNumber2>,<ValueForAttributeNumber2>,*

For example, the two fields after the header contain a 6 and a 2, which can be interpreted as follows:

- The number 6 represents the RADIUS ID for the Service-Type.
- The number 2 represents the attribute value for the Service-Type. The RADIUS protocol specifies the following values for the Service-Type attribute:
    - 1 = Login
    - 2 = Framed
    - 3 = Callback Login
    - 4 = Callback Framed
    - 5 = Outbound
    - 6 = Administrative
    - 7 = NAS Prompt
    - 8 = Authenticate Only
    - 9 = Callback NAS Prompt

The value of this attribute is 2 (Framed).

This attribute-value pair is interpreted as Service-Type = Framed, which indicates to the IAS server to provide a framed protocol for the user–for example, Point-to-Point Protocol (PPP) or SLIP.

The following table describes the RADIUS attributes, listed in numerical order, which can be found in an IAS-formatted log file record. Unlike database-import log files, which use a fixed sequence of attributes, the sequence of the attributes in IAS-formatted log files depends upon the sequence used by the access server. For additional information about the sequence of these records, see the documentation for the access server.

**Notes**

- This table does not cover vendor-specific attributes (VSAs). For information about interpreting VSAs, see Interpreting IAS IDs for vendor-specific attributes. For more information about VSAs that are supported by your access server, see your access server documentation.
- The entries in the **ID** column, which begin with "IAS," are IAS-specific attributes. They are not found in the RADIUS protocol.

| **Attribute** | **ID** | **Data type** | **Represents** |
|---|---|---|---|
| User-Name | 1 | Text | The user identity, as specified by the user. |

| | | | |
|---|---|---|---|
| NAS-IP-Address | 4 | Text | The IP address of the NAS originating the request. |
| NAS-Port | 5 | Number | The physical port number of the NAS originating the request. |
| Service-Type | 6 | Number | The type of service that the user has requested. |
| Framed-Protocol | 7 | Number | The protocol to be used. |
| Framed-IP-Address | 8 | Text | The framed address to be configured for the user. |
| Framed-IP-Netmask | 9 | Text | The IP netmask to be configured for the user. |
| Framed-Routing | 10 | Number | The Routing method to be used by the user. |
| Filter-ID | 11 | Text | The name of the filter list for the user requesting authentication. |
| Framed-MTU | 12 | Number | The maximum transmission unit to be configured for the user. |
| Framed-Compression | 13 | Number | The compression protocol to be used. |
| Login-IP-Host | 14 | Number | The IP address of the host to which the user should be connected. |
| Login-Service | 15 | Number | The service that connects the user to the login host. |
| Login-TCP-Port | 16 | Number | The TCP port to which the user should be connected. |
| Reply-Message | 18 | Text | The message displayed to the user when an authentication request is accepted. |
| Callback-Number | 19 | Text | The callback phone number. |
| Callback-ID | 20 | Text | The name of a location to be called by the access server when performing callback. |
| Framed-Route | 22 | Text | The routing information that is configured on the access client. |
| Framed-IPX-Network | 23 | Number | The IPX network number to be configured on the NAS for the user. |

| | | | |
|---|---|---|---|
| Class | 25 | Text | The attribute sent to the client in an Access-Accept packet, which is useful for correlating Accounting-Request packets with authentication sessions. The format is:<br>• **Type** Contains the value 25 (1 octet).<br>• **Length** Contains a value of 20 or greater (1 octet).<br>• **Checksum** Contains an Adler-32 checksum that is computed over the remainder of the Class attribute (4 octets).<br>• **Vendor-ID** Contains the ID of the access server vendor (4 octets). The high-order octet is 0 and the low-order 3 octets are the SMI Network Management Private Enterprise Code of the vendor in network byte order, as defined in RFC 1007 "Vendor SMI Network Management Private Enterprise Codes".<br>• **Version** Contains the value of 1 (2 octets).<br>• **server-Address** Contains the IP address of the RADIUS server that issued the Access-Challenge. For multihomed servers, this is the address of the network interface that received the original Access-Request (2 octets).<br>• **Service-Reboot-Time** Specifies the time at which the first serial number was returned (8 octets).<br>• **Unique-Serial-Number** Contains a unique number to distinguish an individual connection attempt (8 octets).<br>• **String** Contains information that is used to classify accounting records for additional analysis (0 or more octets). In IAS, the Class attribute from the profile is copied into the String field.<br>The Class attribute is used to match the accounting and authentication records if the Class attribute is sent by the network access server in the accounting request packets. The combination of Serial-Number, Service-Reboot-Time, and server-Address must be a unique identification for each authentication that the server accepts. |
| Vendor-Specific | 26 | Text | The attribute that is used to support proprietary NAS features. |
| Session-Timeout | 27 | Number | The length of time (in seconds) before a session is terminated. |
| Idle-Timeout | 28 | Number | The length of idle time (in seconds) before a session is terminated. |
| Termination-Action | 29 | Number | The action that the NAS should take when service is completed. |
| Called-Station-ID | 30 | Text | The phone number that is dialed by the user. |
| Calling-Station-ID | 31 | Text | The phone number from which the call originated. |
| NAS-Identifier | 32 | Text | The string that identifies the NAS originating the request. |
| Login-LAT-Service | 34 | Text | The host with which the user is to be connected by LAT. |

| | | | |
|---|---|---|---|
| Login-LAT-Node | 35 | Text | The node with which the user is to be connected by LAT. |
| Login-LAT-Group | 36 | Text | The LAT group codes for which the user is authorized. |
| Framed-AppleTalk-Link | 37 | Number | The AppleTalk network number for the serial link to the user (this is used only when the user is a router). |
| Framed-AppleTalk-Network | 38 | Number | The AppleTalk network number that the NAS must query for existence in order to allocate the user's AppleTalk node. |
| Framed-AppleTalk-Zone | 39 | Text | The AppleTalk default zone for the user. |
| Acct-Status-Type | 40 | Number | The number that specifies whether an accounting packet starts or stops a bridging, routing, or Terminal server session. |
| Acct-Delay-Time | 41 | Number | The length of time (in seconds) for which the NAS has been sending the same accounting packet. |
| Acct-Input-Octets | 42 | Number | The number of octets received during the session. |
| Acct-Output-Octets | 43 | Number | The number of octets sent during the session. |
| Acct-Session-ID | 44 | Text | The unique numeric string that identifies the server session. |
| Acct-Authentic | 45 | Number | The number that specifies which server has authenticated an incoming call. |
| Acct-Session-Time | 46 | Number | The length of time (in seconds) for which the session has been active. |
| Acct-Input-Packets | 47 | Number | The number of packets received during the session. |
| Acct-Output-Packets | 48 | Number | The number of packets sent during the session. |
| Acct-Terminate-Cause | 49 | Number | The reason that a connection was terminated. |
| Acct-Multi-SSN-ID | 50 | Text | The unique numeric string that identifies the multilink session. |
| Acct-Link-Count | 51 | Number | The number of links in a multilink session. |
| Event-Timestamp | 55 | Time | The date and time that this event occurred on the NAS. |
| NAS-Port-Type | 61 | Number | The type of physical port that is used by the NAS originating the request. |
| Port-Limit | 62 | Number | The maximum number of ports that the NAS provides to the user. |
| Login-LAT-Port | 63 | Number | The port with which the user is connected by Local Area Transport (LAT). |
| Tunnel-Type | 64 | Number | The tunneling protocols to be used. |

| | | | |
|---|---|---|---|
| Tunnel-Medium-Type | 65 | Number | The transport medium to use when creating a tunnel for protocols. For example, L2TP packets can be sent over multiple link layers. |
| Tunnel-Client-Endpt | 66 | Text | The IP address of the tunnel client. |
| Tunnel-server-Endpt | 67 | Text | The IP address of the tunnel server. |
| Acct-Tunnel-Connection | 68 | Text | An identifier assigned to the tunnel. |
| Password-Retry | 75 | Number | The number of times a user can try to be authenticated before the NAS terminates the connection. |
| Prompt | 76 | Number | A number that indicates to the NAS whether or not it should (Prompt=1) or should not (Prompt=0) echo the user's response as it is typed. |
| Connect-Info | 77 | Text | Information that is used by the NAS to specify the type of connection made. Typical information includes connection speed and data encoding protocols. |
| Configuration-Token | 78 | Text | The type of user profile to be used (sent from a RADIUS proxy server to a RADIUS proxy client) in an Access-Accept packet. |
| Tunnel-Pvt-Group-ID | 81 | Text | The group ID for a particular tunneled session. |
| Tunnel-Assignment-ID | 82 | Text | The tunnel to which a session is to be assigned. |
| Tunnel-Preference | 83 | Number | A number that indicates the preference of the tunnel type, as indicated with the Tunnel-Type attribute when multiple tunnel types are supported by the access server. |
| Acct-Interim-Interval | 85 | Number | The length of interval (in seconds) between each interim update sent by the NAS. |
| Ascend | 107 to 255 | Text | The vendor-specific attributes for Ascend. For more information, see the Ascend documentation. |
| Client-IP-Address | IAS 4108 | Text | The IP address of the RADIUS client. |
| NAS-Manufacturer | IAS 4116 | Number | The manufacturer of the NAS. |
| MS-CHAP-Error | IAS 4121 | Number | The error data that describes an MS-CHAP transaction. |
| Authentication-Type | IAS 4127 | Number | The authentication scheme that is used to verify the user. |
| Client-Friendly-Name | IAS 4128 | Text | The friendly name for the RADIUS client. |
| SAM-Account-Name | IAS 4129 | Text | The user account name in the Security Accounts Manager (SAM) database. |
| Fully-Qualified-User-Name | IAS 4130 | Text | The user name in canonical format. |
| EAP-Friendly-Name | IAS 4132 | Text | The friendly name that is used with Extensible Authentication Protocol (EAP). |

| | | | |
|---|---|---|---|
| Packet-Type | IAS 4136 | Number | The type of packet, which can be:<br>• 1=Accept-Request<br>• 2=Access-Accept<br>• 3=Access-Reject<br>• 4=Accounting-Request |
| Reason Code | IAS 4142 | Number | The reason for rejecting a user, which can be:<br>• 00 = Success<br>• 01 = Internal error<br>• 02 = Access denied<br>• 03 = Malformed request<br>• 04 = Global catalog unavailable<br>• 05 = Domain unavailable<br>• 06 = server unavailable<br>• 07 = No such domain<br>• 08 = No such user<br>• 16 = Authentication failure<br>• 17 = Password change failure<br>• 18 = Unsupported authentication type<br>• 19 = No reversibly encrypted password is stored for the user account<br>• 32 = Local users only<br>• 33 = Password must be changed<br>• 34 = Account disabled<br>• 35 = Account expired<br>• 36 = Account locked out<br>• 37 = Invalid logon hours<br>• 38 = Account restriction<br>• 48 = Did not match remote access policy<br>• 49 = Did not match connection request policy |

| | | | |
|---|---|---|---|
| | | | • 64 = Dial-in locked out<br>• 65 = Dial-in disabled<br>• 66 = Invalid authentication type<br>• 67 = Invalid calling station<br>• 68 = Invalid dial-in hours<br>• 69 = Invalid called station<br>• 70 = Invalid port type<br>• 71 = Invalid restriction<br>• 80 = No record<br>• 96 = Session timed out<br>• 97 = Unexpected request |
| NP-Policy-Name | IAS 4149 | Text | The friendly name of a remote access policy. |

**Attributes that are not recorded in IAS-formatted log files**

Although most of the attributes that are sent by an access server and supported in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition are logged when you specify the use of IAS-formatted log files, some attributes are not logged because they contain sensitive information (for example, passwords) that should not be included. The following table lists some of the attributes that are not logged.

| **Attribute name** | **ID/Description** |
|---|---|
| User-Password | 2 |
| CHAP-Password | 3 |
| State | 24 |
| Proxy-State | 33 |
| CHAP-Challenge | 60 |
| Tunnel-Password | 69 |
| EAP-Message | 79 |
| Signature | 80 |
| MS-CHAP-Challenge | Microsoft vendor-specific attribute |
| MS-CHAP-Response | Microsoft vendor-specific attribute |
| MS-CHAP-CPW-1 | Microsoft vendor-specific attribute |
| MS-CHAP-CPW-2 | Microsoft vendor-specific attribute |
| MS-CHAP-LM-Enc-PW | Microsoft vendor-specific attribute |
| MS-CHAP-NT-Enc-PW | Microsoft vendor-specific attribute |

| | |
|---|---|
| MS-CHAP-MPPE-Keys | Microsoft vendor-specific attribute |
| MS-MPPE-Send-Key | Microsoft vendor-specific attribute |
| MS-MPPE-Recv-Key | Microsoft vendor-specific attribute |
| MS-Filter | Microsoft vendor-specific attribute |
| MS-CHAP2-Response | Microsoft vendor-specific attribute |
| MS-CHAP2-Success | Microsoft vendor-specific attribute |
| MS-CHAP2-CPW | Microsoft vendor-specific attribute |

# Interpreting IAS IDs for vendor-specific attributes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Interpreting IAS IDs for vendor-specific attributes**
When IAS logs any of the following vendor-specific attributes, it assigns a unique ID to the attribute in order to facilitate interpretation of the log files.

**Note**

- The ID (number) that is assigned by IAS to a vendor-specific attribute might not be the same as the ID that is assigned by the vendor. If you are using the IAS-formatted log file format and want to determine the ID used by the vendor, see your network access server (NAS) documentation. If you are using database-import log files, the ID (number) that is assigned to the attribute does not appear in the log. Use the following table to determine the data type for the attributes listed.

| ID | Attribute name | Vendor | Data type |
|---|---|---|---|
| 107 | Ascend-Calling-Subaddress | Ascend | Text |
| 108 | Ascend-Callback-Delay | Ascend | Number |
| 109 | Ascend-Endpoint-Disc | Ascend | Text |
| 110 | Ascend-Remote-FW | Ascend | Text |
| 111 | Ascend-Multicast-G-Leave-Delay | Ascend | Number |
| 112 | Ascend-CBCP-Enable | Ascend | Number |
| 113 | Ascend-CBCP-Mode | Ascend | Number |
| 114 | Ascend-CBCP-Delay | Ascend | Number |
| 115 | Ascend-CBCP-Trunk-Group | Ascend | Number |
| 116 | Ascend-Appletalk-Route | Ascend | Text |
| 117 | Ascend-Appletalk-Peer-Mode | Ascend | Number |
| 118 | Ascend-Route-Appletalk | Ascend | Number |
| 119 | Ascend-FCP-Parameter | Ascend | Text |
| 120 | Ascend-Modem-Port-No | Ascend | Number |
| 121 | Ascend-Modem-Slot-No | Ascend | Number |
| 122 | Ascend-Modem-Shelf-No | Ascend | Number |
| 123 | Ascend-CallAttempt-Limit | Ascend | Number |
| 124 | Ascend-CallBlock-Duration | Ascend | Number |
| 125 | Ascend-Maximum-Call-Duration | Ascend | Number |
| 126 | Ascend-Route-Preference | Ascend | Number |
| 127 | Ascend-Tunneling-Protocol | Ascend | Number |

# IAS Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
This section covers:

- Troubleshooting IAS as a RADIUS server
- Troubleshooting IAS as a RADIUS proxy

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Troubleshooting IAS as a RADIUS server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting IAS as a RADIUS server**
What problem are you having?

- A connection attempt fails.
- Connection attempts using Protected Extensible Authentication Protocol (PEAP) fail.
- Computers newly joined to the domain cannot enroll certificates.
- Connection attempts using Password Authentication Protocol (PAP) fail.
- Connection attempts using Microsoft Challenge-Handshake Authentication Protocol (MS-CHAP) fail.
- Users with 802.1x authenticated switch client connections with EAP or PEAP are not prompted to input credentials and cannot log on.
- Users who should not have remote access permission can log on
- Users can log on successfully, but their logon attempts do not appear in the log files.
- You have just changed your Active Directory domain from a Windows 2000 mixed domain to a Windows 2000 native domain or a Windows Server 2003 domain, and IAS servers can no longer authenticate valid connection requests.
- Interim accounting messages are not being recorded in the remote access log file
- Third-party network access servers (NASs) drop connections and IAS sends a Microsoft vendor-specific attribute (MS-RAS-MPPE-Encryption-Policy) to the network access server instead of the NAS's vendor ID.
- MS-CHAP v2 or EAP-TLS authentications are being rejected for valid connection attempts.
- You can no longer see the Remote Access Policies node in Routing and Remote Access.
- When you try to open the IAS console, you receive an error message and the console does not open.

**A connection attempt fails.**
**Cause**: IAS has either rejected or discarded the connection attempt for a variety of reasons.

**Solution**: Verify that IAS is configured for the logging of rejected authentication attempts to the event log. Try the connection again, and then check the system event log for an IAS event for the connection attempt. Use the information in the log to determine the reason the connection attempt was either rejected or discarded and the way to fix the problem.

**See also**: Event logging for IAS; Configure event logging for IAS

**Connection attempts using Protected Extensible Authentication Protocol (PEAP) fail.**
**Cause**: The wireless remote access policy on the IAS server is not configured to use PEAP as the authentication method.

**Solution**: Create a wireless remote access policy on the IAS server that is configured with PEAP-EAP-MS-CHAPv2 or PEAP-EAP-TLS.

**See also**: Configure Remote Access Policies; Configure PEAP and EAP methods; Wireless access with secure password authentication

**Cause**: Remote access policy on the IAS server is configured to reject the user or computer.

**Solution**: Make sure that your remote access policy and user account settings are not configured to reject user authentication and authorization attempts. For example, if the user belongs to a group that is restricted in remote access policies to accessing the network between 9 A.M. and 5 P.M., any attempt by the user to log on between 5:01 P.M. and 8:59 A.M. will fail. To resolve the issue, change the day and time restrictions in remote access policies, or move the user to another group with different or no day and time restrictions. In addition, user account settings in Active Directory might prevent the user from accessing the network.

**See also**: Introduction to remote access policies; Elements of a remote access policy; Dial-in properties of a user account

**Cause**: You are using PEAP-EAP-MS-CHAPv2 as the authentication method and the IAS server does not have a certificate to use for server authentication to the client.

**Solution**: If the IAS server is a domain member computer, auto-enroll a certificate that contains the Server Authentication purpose in Enhanced Key Usage extensions and is configured according to minimum server certificate requirements. If the IAS server is not a domain member computer, enroll a certificate that contains the Server Authentication purpose in Enhanced Key Usage extensions (and which is configured according to minimum server certificate requirements) using the CA Web enrollment tool, or install a certificate on the IAS server using a floppy disk.

**See also**: The section "Certificate requirements for EAP" in Network access authentication and certificates.

**Cause**: You are using PEAP-EAP-MS-CHAPv2 as the authentication method and when prompted to make a decision whether or not to trust the server certificate, the user has chosen not to trust the server certificate.

**Solution**: Instruct users to trust the server certificate at next log on.

**Cause**: You are using PEAP-EAP-TLS as the authentication method and the client computer does not have a certificate that contains the Client Authentication purpose in Enhanced Key Usage extensions and is configured according to minimum client certificate requirements.

**Solution**: If the client is a domain member computer, auto-enroll a certificate that contains the Client Authentication purpose in Enhanced Key Usage extensions and is configured according to minimum client certificate requirements. If the client is not a domain member computer, enroll a certificate that contains the Client Authentication purpose in Enhanced Key Usage extensions (and which is configured according to minimum client certificate requirements) using the CA Web enrollment tool, or install a certificate on the IAS server using a floppy disk.

**See also**: The section "Certificate requirements for EAP" in Network access authentication and certificates.

**Cause**: The client computer does not trust the CA that issued the server certificate.

**Solution**: Add your organization's root certification authority certificate to the Trusted Root Certification Authorities folder in the computer certificate store.

**Cause**: You are using PEAP-EAP-TLS as the authentication method and the IAS server does not have a certificate to use for server authentication to the client.

**Solution**: If the IAS server is a domain member computer, auto-enroll a certificate that contains the Server Authentication purpose in Enhanced Key Usage extensions and is configured according to minimum server certificate requirements. If the IAS server is not a domain member computer, enroll a certificate that contains the Server Authentication purpose in Enhanced Key Usage extensions (and which is configured according to minimum server certificate requirements) using the CA Web enrollment tool, or install a certificate on the IAS server using a floppy disk.

**See also**: The section "Certificate requirements for EAP" in Network access authentication and certificates.

**Cause**: Group Policy on domain member computers has not been refreshed after the configuration of certificate auto-enrollment.

**Solution**: Refresh Group Policy on domain member computers. After auto-enrollment is configured and enabled, all domain member computers will receive computer certificates at the next refresh of Group Policy, whether the refresh is triggered manually with the gpupdate command or when the computer next logs on to the domain.

**See also**: Network access authentication and certificates; Configure automatic certificate allocation from an enterprise CA; Use Windows Server 2003 Certificate Services Web Pages; Manage certificates for a computer; and Request a certificate

**Computers newly joined to the domain cannot enroll certificates.**
**Cause**: When a Public Key Infrastructure (PKI) is deployed and autoenrollment is configured for the domain, Active Directory replication latency can temporarily affect the ability of a client or server to obtain a certificate from a certification authority.

**Solution**: Verify that Active Directory has replicated to all domain controllers, and then refresh Group Policy to enroll a certificate on the computer. You can refresh Group Policy by running the gpupdate command or by logging on to the domain.

**See also**: Checklist: Configuring certificate autoenrollment; Authentication methods; Troubleshooting replication

**Connection attempts using Password Authentication Protocol (PAP) fail.**
**Cause**: The password is incorrect.

**Solution**: Try the connection again and verify that the password is correct.

**Cause**: Mismatched shared secrets.

**Solution**: Verify that the same shared secret is configured on the access server and for the RADIUS client in Internet Authentication Service.

**See also**: Edit RADIUS client configuration; Shared secrets

**Connection attempts using Microsoft Challenge-Handshake Authentication Protocol (MS-CHAP) fail.**
**Cause**: The password is incorrect.

**Solution**: Try the connection again and verify that the password is correct.

**Cause**: The access client is using LAN Manager authentication.

**Solution**: By default, MS-CHAP for Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition does not support LAN Manager authentication. If you want to allow the use of LAN Manager authentication with MS-CHAP for older Microsoft operating systems such as Windows NT 3.5x and Windows 95, you must set the following registry value to 1 on the IAS server:
HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\RemoteAccess\Policy\Allow LM Authentication

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**See also**: MS-CHAP; Add a value to a registry key entry

**Users with 802.1x authenticated switch client connections with EAP or PEAP are not prompted to input credentials and cannot log on.**
**Cause**: The icon for the network connection must be displayed in the notification area on the client.

**Solution**: Configure the network connection properties on the client so that the network connection icon is displayed in the notification area when connected.

**See also**: Show a network connection icon in the notification area

**Cause**: The switch is not configured to initiate authentication with an EAP-Request-Identity packet when it detects that a client is active on the port.

**Solution**: Configure the switch to initiate authentication.

**Users who should not have remote access permission can log on.**
**Cause**: A remote access policy might be granting access to these users.

**Solution**: Check the policy list to ensure that you have not included groups in which the user is a member that should be denied access.

**Cause**: The remote access permission on the user account dial-in properties is set to Grant access, which overrides the remote access permission of the remote access policy.

**Solution**: Check the dial-in properties for the user object.

**See also**: Configure remote access permission for a user; Dial-in properties of a user account

**Cause**: Remote access policies might be evaluated in the wrong order.

**Solution**: Authorization is granted or denied by the first policy with conditions that match the connection attempt. Use Move Up to move the policy that denies access to these users, so that it is higher in the list.

**See also**: Configure remote access permission for a user; Dial-in properties of a user account

**Users can log on successfully, but their logon attempts do not appear in the log files.**
**Cause**: IAS is not configured to log successful authentication attempts.

**Solution**: Configure IAS to log successful authentication attempts in the event log.

**See also**: Event logging for IAS; Configure event logging for IAS

**You have just changed your Active Directory domain from a Windows 2000 mixed domain to a Windows 2000 native domain or a Windows Server 2003 domain, and IAS servers can no longer authenticate valid connection requests.**
**Cause**: After you change a domain from a Windows 2000 mixed domain to a Windows 2000 native domain or a Windows Server 2003 domain, every domain controller in the domain must be restarted in order for the change to replicate.

**Solution**: Restart the domain controllers so that the IAS servers can authenticate valid connection requests.

**Interim accounting messages are not being recorded in the remote access log file.**
**Cause**: Remote access logging is not configured to record periodic status.

**Solution**: Configure remote access logging to record periodic status.

**Cause**: You have not added and configured the Acct-Interim-Interval RADIUS accounting attribute on the Advanced tab of the appropriate remote access policy.

**Solution**: Add and configure the Acct-Interim-Interval RADIUS accounting attribute on the Advanced tab of the appropriate remote access policy. The value of the Acct-Interim-Interval attribute is the number of seconds between interim accounting updates.

**Cause**: The access server does not support interim accounting or is not configured to send interim accounting messages.

**Solution**: Verify that the access server supports interim accounting and the Acct-Interim-Interval attribute. If so, consult the access server documentation for instructions about how to enable interim accounting. The Routing and Remote Access service supports sending interim accounting messages and is enabled from the properties of a RADIUS server when configuring the RADIUS accounting provider.

**See also**: Logging user authentication and accounting requests; Add RADIUS attributes to a remote access policy; Use RADIUS accounting

**Third-party network access servers (NASs) drop connections and IAS sends a Microsoft vendor-specific attribute (MS-RAS-MPPE-Encryption-Policy) to the network access server instead of the NAS's vendor ID.**
**Cause**: The encryption policy as configured in remote access policies is not set to the default.

**Solution**: The Microsoft VSA MS-RAS-MPPE-Encryption-Policy is sent to third-party network access servers if the encryption policy as configured in remote access policies is not set to the default. The default encryption policy allows all encryption levels and does not contain any attributes specific to the Routing and Remote Access service, so applying default encryption settings will prevent IAS from sending any Microsoft VSAs to third-party NASs. Take the following steps in the profile of the remote access policy:

- On the Encryption tab, return the encryption policy to the default. Select all encryption levels except No encryption.
- On the Advanced tab, remove all attributes specific to the Routing and Remote Access service from the list of attributes for the remote access policy.
- On the IP tab, remove all IP filters.
- On the Multilink tab, select Server settings determine Multilink usage. Return all other settings to the default (not selected).

**See also**: Configure encryption; Configure vendor-specific attributes for a remote access policy; Vendor-specific attribute overview; Recreate the default remote access policy; Configure IP options

**MS-CHAP v2 or EAP-TLS authentications are being rejected for valid connection attempts.**
**Cause**: The authentication method (in the profile settings of the connection request policy) that matched the connection request is configured for the Accept the connection attempt without performing authentication or authorization setting. MS-CHAP v2 and EAP-TLS are mutual authentication protocols. In mutual authentication, the access client proves that it is a valid

access client to the authenticating server and the authenticating server proves that it is a valid authenticating server to the access client. When this authentication option is used, although the connect request is granted, the authenticating server does not provide validation to the access client. As the result, mutual authentication fails.

**Solution**: Reconfigure connection request policies so that MS-CHAP v2 and EAP-TLS connections are not being accepted without authentication and authorization.

**See also**: Connection request policies

**You can no longer see the Remote Access Policies node in Routing and Remote Access.**
**Cause**: When a Routing and Remote Access server is configured to use RADIUS authentication, the remote access policies on the Routing and Remote Access server are never evaluated for authorization.

**Solution**: This is intended behavior. If the RADIUS server of the server running the Routing and Remote Access service is an IAS server, remote access policies are configured through Internet Authentication Service.

**When you try to open the IAS console, you receive an error message and the console does not open.**
**Cause**: To administer IAS, you must have Administrative credentials.

**Solution**: You can use the Runas command to perform tasks (for example, opening the IAS console), when you are logged on as a member of a group that does not have administrative credentials (such as Users or Power Users). Alternately, you can log on as Administrator to open the console.

**See also**: Run a program with administrative credentials; Create a shortcut using the runas command; Runas

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Troubleshooting IAS as a RADIUS proxy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting IAS as a RADIUS proxy**
What problem are you having?

- No responses to Access-Request messages are sent through the IAS proxy for valid connection attempts.
- MS-CHAP v2 authentications are being rejected for valid connection attempts.
- When you try to open the IAS console, you receive an error message and the console does not open.

**No responses to Access-Request messages are sent through the IAS proxy for valid connection attempts.**
**Cause:** A mismatched shared secret is configured between the IAS proxy and the RADIUS server or proxy to which the RADIUS messages are being forwarded.

**Solution:** Verify that the shared secret that is configured on the IAS proxy for the appropriate remote RADIUS server group member matches the shared secret of the RADIUS client of the RADIUS server or proxy to which the RADIUS messages are being sent.

**See also:** Shared secrets

**MS-CHAP v2 authentications are being rejected for valid connection attempts.**
**Cause:** Attribute manipulation rules on the profile setting for the connection request policy that is forwarding the requests are modifying the User-Name attribute. This causes the validation of the MS-CHAP v2 hash on the authenticating server to fail. The only exception is when a backslash (\) character is used and the manipulation only affects the information to the left of it. A backslash character is typically used to indicate a domain name (the information to the left of the backslash character) and a user account name within the domain (the information to the right of the backslash character). In this case, attribute manipulation rules that only modify or replace the domain name are allowed.

**Solution:** Reconfigure attribute manipulation rules so that they are not modifying the User-Name attribute.

**See also:** Connection request policies

**When you try to open the IAS console, you receive an error message and the console does not open.**
**Cause:** To administer IAS, you must have administrative credentials.

**Solution:** You can use the Runas command to perform tasks (for example, opening the IAS console), when you are logged on as a member of a group that does not have administrative credentials (such as Users or Power Users). Alternately, you can log on as Administrator to open the console.

**See also:** Run a program with administrative credentials, Create a shortcut using the runas command, Runas

**Note**

- You can configure IAS in Windows Server 2003, Standard Edition, with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. You can define a RADIUS client using a fully qualified domain name or an IP address, but you cannot define groups of RADIUS clients by specifying an IP address range. If the fully qualified domain name of a RADIUS client resolves to multiple IP addresses, the IAS server uses the first IP address returned in the DNS query. With IAS in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, you can configure an unlimited number of RADIUS clients and remote RADIUS server groups. In addition, you can configure RADIUS clients by specifying an IP address range.

# Configuring Communication Links

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring communication links**
This section covers:

- Telnet

# Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network Connections**
Network Connections provides connectivity between your computer and the Internet, a network, or another computer. With Network Connections, you can configure settings to reach local or remote network resources or functions.

Network Connections combines Microsoft® Windows® NT 4.0 Dial-Up Networking with features that were formerly located in the Network Control Panel, such as network protocol and service configuration. Each connection in the Network Connections folder contains a set of features that creates a link between your computer and another computer or network. By using Network Connections, performing a task, such as modifying a network protocol, is as easy as right-clicking a connection and then clicking **Properties**.

- Before using Network Connections, see Checklist: Configuring network connections.
- Before setting up a home or small office network, see Checklist: Setting up a home or small office network.
- To find features that have been moved, see New ways to do Network Connections tasks.
- For tips about using Network Connections, see Network Connections Best Practices.
- For help with specific tasks, see Network Connections How To....
- For general background information, see Network Connections Concepts.
- For problem-solving instructions, see Network Connections Troubleshooting.

# Checklist: Configuring network connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Configuring network connections**

| | Step | Reference |
|---|---|---|
| | Review key concepts. | Network Connections Overview |
| | Connect to a local area network. | Make a local area connection |
| | Connect to a network by using a phone line. | Make a dial-up connection by using a phone line;<br>Connect to a remote network |
| | Connect to an Internet service provider (ISP). | Make an Internet connection;<br>Connect to a remote network |
| | Connect to a private network through the Internet (virtual private network). | Make a virtual private network (VPN) connection;<br>Connect to a remote network |
| | Create a direct connection to another computer. | Make a direct network connection;<br>Connect to a remote network |
| | Let other computers connect to this computer. | Accept incoming network connections |
| | Monitor a connection. | Monitor a connection |

# Checklist: Setting up a home or small office network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Setting up a home or small office network**

| Step | Reference |
|---|---|
| Decide whether to use home and small office networking or Routing and Remote Access for your home or small office network. | Home and small office networking compared to Routing and Remote Access |
| If you decide to use home and small office networking, review home and small office networking concepts. | Home and Small Office Networking; Using Home and Small Office Networking Features |
| Decide how you want to save your Internet connection credentials (you will be prompted to select credential settings when you fist attempt to activate your Internet connection or when you run the New Connection Wizard). | Dial-up credentials |
| Familiarize yourself with the icons that indicate that Internet Connection Firewall (ICF), Windows Firewall, Network Bridge, or Internet Connection Sharing (ICS) have been enabled on a network connection. | Network connection icons |
| Enable ICF or Windows Firewall to protect your home or small office network. | Enable or disable ICF |
| Set up Network Bridge to connect network segments. | Set up Network Bridge |
| Enable ICS to provide a shared Internet connection. | Enable ICS |

**Notes**

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

# New ways to do Network Connections tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

This table lists common tasks for Network Connections. The user interface for performing these tasks is different in this version of Windows from the way it was in Windows NT version 4.0.

**Note**

- There are no significant user interface differences between Windows 2000, Windows XP, and the Windows Server 2003 family for this component.

| If you want to | In Windows NT 4.0 use | In this version of Windows use |
|---|---|---|
| Connect to a dial-up server | **Dial-Up Networking** in My Computer | Network Connections. For more information, see Connect to a remote network. |
| Connect to a network by using a modem or ISDN line | **Dial-Up Networking** in My Computer (click **New**) | Network Connections. For more information, see Make a dial-up connection by using a phone line. |
| Connect to a network by using a virtual private network (VPN) | **Dial-Up Networking** in My Computer (click **New**) | Network Connections. For more information, see Make a virtual private network (VPN) connection. |
| Configure a computer for incoming connections | **Network** in Control Panel | Network Connections. For more information, see Accept incoming network connections. |
| Configure the TCP/IP protocol | **Network** in Control Panel | Network Connections. For more information, see Configure TCP/IP settings. |
| Configure a connection | **Dial-Up Networking** in My Computer (click **More**) | Network Connections. For more information, see Configure a connection to a remote network. |
| Add a client or service | **Network** in Control Panel | Network Connections. For more information, see Add a network component. |
| Add a protocol | **Network** in Control Panel | Network Connections. For more information, see Add a network component. |
| Add optional networking components | **Network** in Control Panel | Network Connections. For more information, see Add optional networking components. |
| Monitor incoming or outgoing connections | **Dial-Up Monitor** in Control Panel | Network Connections. For more information, see Monitor a connection. |

# Network Connections Best Practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

The following list provides best practices for implementing Network Connections:

- **When using multiple network adapters, rename each local area connection.**

  Your operating system detects network adapters and automatically creates a local area connection in the Network Connections folder for each network adapter. If more than one network adapter is installed, you can eliminate possible confusion by immediately renaming each local area connection to reflect the network that it connects to.

  You need to add or enable the network clients, services, and protocols that are required for each connection. When you do so, the client, service, or protocol is added or enabled in all other network and dial-up connections.

- **Verify required connection settings for your network adapter.**

  If your network administrator or Internet service provider (ISP) requires static settings, you may need one or more of the following:

  - A specific IP address.
  - DNS addresses.
  - DNS domain name.
  - Default gateway address.
  - WINS addresses.

  DHCP is enabled by default. This gets your IP address and other configuration information automatically. Automated IP settings are used for all connections, and they eliminate the need to configure settings such as DNS, WINS, and so on.

  For more information about enabling DHCP, see Configure TCP/IP settings.

- **Create dial-up, VPN, or direct connections by using the New Connection wizard.**

  After you create a connection, you can copy the connections, rename them and modify the connection settings. By doing so, you can easily create different connections to accommodate multiple modems, ISPs, dialing profiles, and so on.

  For more information, see Copy a network or dial-up connection.

- **Specify the order in which network providers and protocols are accessed.**

  By changing the order of protocols bound to those providers, you can improve performance. For example, if your LAN connection is enabled to access NetWare and Microsoft Windows networks, which use IPX and TCP/IP, but your primary connection is to a Microsoft Windows network that uses TCP/IP, you can move **Microsoft Windows Network** to the top of the **Network providers** list on the **Provider Order** tab, and move **Internet Protocol (TCP/IP)** to the top of the **File and Printer Sharing for Microsoft Networks** binding on the **Adapters and Bindings** tab.

  The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

  For more information about modifying the order of network providers, see Modify the network provider order. For more information about modifying the order of protocol bindings, see Modify the protocol bindings order.

- **Only install and enable the network protocols that you need.**

  Limiting the number of protocols on your computer enhances its performance and reduces network traffic.

  If your computer encounters a problem with a network or dial-up connection, it attempts to establish connectivity by using every network protocol that is installed and enabled. By only installing and enabling the protocols that your system can use, the operating system does not attempt to connect with protocols it cannot use, and returns status information to you more efficiently.

# Network Connections How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Connect to a remote network
- Disconnect from a remote network
- Add optional networking components
- Make Network and Dial-up Connections
- Configure Network and Dial-up Connections
- Monitor Network Connections
- Set up and Manage Home and Small Office Networking

# Connect to a remote network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to a remote network**

1. Open Network Connections.

2. Double-click the connection you want to connect to the network.

3. If you are prompted, in the **Connect***connection type* dialog box, type your user name, password, and logon domain.

   If **Logon domain** does not appear in this dialog box, and you want to log on to a domain, type your user name and the domain name in one of two ways:

   - Your user principal name prefix (your user name) and your user principal name suffix (your domain name), joined by the "at" sign (@). For example, user@sales.westcoast.microsoft.com.

   - Your domain name and your user name, separated by the backslash (\) character. For example, sales\user.

     Note that the suffix in the first example is a fully-qualified DNS domain name. Your administrator might have created an alternative suffix to simplify the logon process. For example, creating a user principal name suffix of "microsoft" allows the same user to log on by using the much simpler user@microsoft.com. For more information, see your system administrator.

   Instead of having to type your domain name, you can also enable Windows to include your logon domain to the **Connect***connection type* dialog box.

   a. Click **Properties** if the button is enabled.

   b. On the **Options** tab, select the **Include Windows logon domain** check box.

   Once you are connected to the network, you can minimize your connection window and use e-mail, Windows Explorer, and so on.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

- To connect to a remote network you can also right-click the connection that you want to connect to the network and click **Connect**.

- Authentication happens at two levels: logging on to the local computer domain and logging on as a valid user.

- If you are on a local area network, your computer logs on to the local computer domain automatically even before you see the logon prompt. When you type your user credentials at the logon prompt, the computer checks your user credentials, opens a user context, and makes your personal data available to you. You are now logged on at both levels.

- If you are not on a local area network, the attempt to log on to the local computer domain fails silently. In this case, user logon can proceed in two ways.

  - When you log on at the logon prompt, the computer checks your cached credentials from the last time you were actually online with the domain controller. If they match, a user context associated with your name is opened. You

are now logged on to the computer as a valid user but you are not logged on to the network. To access your personal files you can now create a remote access connection by using your remote access credentials or by using your cached credentials if your computer is a member of the domain.

- Select the **Log on using dial-up networking** check box if your computer is a member of the domain. In this case, the computer will attempt to make a remote access connection before processing your credentials. Once connected it uses the user logon credentials as though you were on a local area network.

- The logon domain name you type should name the domain that the server is in. This is not the DNS domain name given by some PPP/SLIP providers.

- If you are using IP connectivity on your local network connection and on your remote connection, you may not be able to see all computers on your local network. This is because after you connect, your remote connection becomes your default path for network routing. Consequently, you see computers on the remote network, and you see other computers on the same LAN segment to which your computer is connected. But you cannot communicate with computers on networks that were previously reached through a router on your local LAN.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disconnect from a remote network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disconnect from a remote network**

1. Open Network Connections.
2. Right-click the connection you want to disconnect, and then click **Disconnect**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you disable a local area connection, it disables the network adapter driver until the connection is reactivated.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add optional networking components

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add optional networking components**

1. Open Network Connections.
2. On the **Advanced** menu, click **Optional Networking Components**.
3. Do one of the following:
   - To install all optional networking components, select the **Management and Monitoring Tools**, **Networking Services**, and **Other Network File and Print Services** check boxes, and then click **Next**.
   - To install specific optional networking components, select its corresponding check box, and then click **Details**.

     In **Subcomponents of***component*, select the check boxes next to the components you want to install, and then click **OK**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Examples of optional networking components include Simple Network Management Protocol (SNMP), Simple TCP/IP Services, and Print Services for UNIX.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make Network and Dial-up Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Make network and dial-up connections**

- Make a virtual private network (VPN) connection
- Make a local area connection
- Manage Network Connections
- Set up ISDN Connections
- Set up Dial-up Connections
- Configure Dial-up Options
- Make Internet Connections
- Make Direct Network Connections
- Set up Incoming Connections

# Make a virtual private network (VPN) connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a virtual private network (VPN) connection**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. Click **Connect to the network at my workplace**, and then click **Next**.
4. Click **Virtual Private Network connection**, and click **Next**.
5. Type a name for this connection in **Company Name**, and click **Next**.
6. If you have already established a dial-up connection, do one of the following:
   - If you need to establish a connection with your ISP or some other network before tunneling to your destination computer or network, click **Automatically dial this initial connection**, click a connection in the list, and then click **Next**.
   - If you do not want to automatically dial an initial connection, click **Do not dial the initial connection**, and then click **Next**.
7. Type the host name or IP address of the VPN server to which you are connecting, and then click **Next**.
8. Do one of the following:
   - If you want this connection to be made available to all users on this computer, click **Anyone's use**, and then click **Next**.
   - If you want to reserve the connection for your own use, click **My use only**, and then click **Next**.
9. If you want to create a shortcut for this connection on your desktop, select the **Add a shortcut to this connection to my desktop** check box.
10. Click **Finish**.

### Notes

- To make the connection available to all users, you must be logged on as Administrator or as a member of the Administrators group.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You can create multiple VPN connections by copying them in the Network Connections folder. You can then rename the connections and modify connection settings. By doing so, you can easily create different connections to accommodate multiple hosts, security options, and so on.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make a local area connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a local area connection**

- Typically, most computers running a member of the Windows Server 2003 family are connected to a local area network. When you start your computer, your network adapter is detected and the local area connection automatically starts. Unlike other types of connections, the local area connection is created automatically, and you do not have to click the local area connection in order to start it.

Once the local area connection is running, you can choose to disable it. To do so, do the following.

1. Open Network Connections.
2. Right-click the **LAN or High Speed Internet** connection that you want to disable.
3. Click **Disable**.

If you need to enable a disabled **LAN or High Speed Internet** connection, do the following.

1. Right-click the connection that you want to enable.
2. Click **Enable**.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- A local area connection is automatically created for each network adapter that is detected.
- If more than one network adapter is installed, you can eliminate possible confusion by immediately renaming each local area connection to reflect the network that it connects to.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage network connections**

- Copy a network or dial-up connection
- Show a network connection icon in the notification area
- Rename a network connection icon
- Repair a LAN or high-speed Internet connection

# Copy a network or dial-up connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To copy a network or dial-up connection**

1. Open Network Connections.
2. Right-click your dial-up, VPN, or direct connection, and then click **Create Copy**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You cannot copy local area and incoming connections.
- You can create multiple dial-up, virtual private network, or direct connections by copying them in the Network Connections folder. You can then rename the connections and modify connection settings. By doing so, you can easily create different connections to accommodate multiple modems, ISPs, dialing profiles, and so on.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Network Connections Best Practices
Network connection icons

# Show a network connection icon in the notification area

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To show a network connection icon in the notification area**

1. Open Network Connections.
2. Right-click the icon for the network connection that you want to display in the notification area, and then click **Properties**.
3. Select the **Show icon in notification area when connected** check box, and then click **OK**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If a network connection icon is displayed in the notification area, you can access basic connection and statistical information by pointing to the icon.
- If the **Show icon in notification area when connected** check box is selected for the shared Internet connection, an icon for the shared Internet connection appears in the notification area each time that connection is enabled. When the shared Internet connection is disabled, the icon disappears from the notification area.
- It is a good practice to select this check box when you are using wireless connections.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Rename a network connection icon

# Rename a network connection icon

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To rename a network connection icon**

1. Open Network Connections.
2. Right-click the icon for the network connection that you want to rename, and click **Rename**.
3. Type a new name for the selected network connection icon.

## Notes

- You must be logged on as a member of the Administrators group to rename a network connection icon. For more information, see Default local groups and Default groups.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You should rename each network connection icon with a name that is easy to remember.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Repair a LAN or high-speed Internet connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To repair a LAN or high-speed Internet connection**

1. Open Network Connections.
2. Before using the **Repair** option, try the following steps:
   - Check the status indicator lights on the DSL or cable modem to verify that the connection to your Internet service provider (ISP) is working.
   - Turn off the DSL or cable modem, and then turn it on again.
   - If your Internet connection is not working after these steps, contact your ISP.
3. If media is connected properly, under **LAN or High-Speed Internet**, right-click the connection that you want to repair, and then click **Repair**.

## Notes

- You must be a member of the Administrators group, the Power Users group, or the Network Configuration Operators group to complete this procedure. For more information, see Default local groups and Default groups.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you have more than one network adapter installed in your computer, it is recommended that you rename your Internet connection to easily identify it. For example, you could call your Internet connection "Internet connection" or use the name of your ISP.
- The **Repair** option is not available for media disconnected connections.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set up ISDN Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up ISDN connections**

- Make a dial-up connection by using an ISDN line
- Install an ISDN adapter
- Configure ISDN settings

# Make a dial-up connection by using an ISDN line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a dial-up connection by using an ISDN line**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. In **Network Connection Type**, do one of the following:
   - Click **Connect to the Internet**. In **Internet Connection**, click **Connect using a dial-up modem**, and then click **Next**.
   - Click **Connect to the network at my workplace**. In **Network Connection**, click **Dial-up connection**, and then click **Next**.
4. Follow the instructions in the New Connection wizard.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- To enable automatic dialing for all users, create a connection, save your user name and password for all users, and then enable Internet Connection Sharing for the new connection.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install an ISDN adapter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install an ISDN adapter**

1. Install an Integrated Services Digital Network (ISDN) adapter and start your computer. If you install more than one ISDN adapter, you must restart your computer after you have installed the ISDN drivers. Otherwise, all available ISDN ports may not show up when you configure your network connection for ISDN.

2. You can use Device Manager to configure your system so that your ISDN adapter knows what type of telephone switch it is connected to. The switch type simply refers to the brand of equipment and software revision level that the telephone company uses to provide you with ISDN service. There are only a few types of switches in the world and usually just one in countries/regions other than the United States.

## Notes

- To use Device Manager, you must be logged on as an administrator or a member of the Administrators group.

- To open Device Manager, click **Start**, right-click **My Computer**, click **Manage**, and then click **Device Manager**.

- If your ISDN adapter is internal to your computer, it appears in **Network adapters**. If the ISDN adapter is external to your computer, it appears in **Modems**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure ISDN settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure ISDN settings**

1. Open Network Connections.
2. Right-click the dial-up connection that uses ISDN, and then click **Properties**.
3. On the **General** tab, in **Connect using**, click the ISDN device, and then click **Configure**.
4. In the **ISDN Configure** dialog box, do one or both of the following:
   - In **Line type**, click the line type you want to use. The line types are listed from highest to lowest quality.
   - If you want to start negotiation with the line type you selected, and then negotiate with a lower-quality line type depending on the line's condition, select the **Negotiate line type** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Depending on the type of ISDN adapter that you are using, when you click **Configure** in step 3, you may be presented with **Modem Configuration** settings.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set up Dial-up Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up dial-up connections**

- Make a dial-up connection by using a phone line
- Configure a modem for a dial-up connection
- Make a dial-up connection by using X.25
- Start Remote Access Auto Connection Manager

# Make a dial-up connection by using a phone line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a dial-up connection by using a phone line**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. In **Network Connection Type**, do one of the following:
   - Click **Connect to the Internet**. In **Internet Connection**, click **Connect using a dial-up modem**, and then click **Next**.
   - Click **Connect to the network at my workplace**. In **Network Connection**, click **Dial-up connection**, and then click **Next**.
4. Follow the instructions in the New Connection wizard.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- To enable automatic dialing for all users, create a connection, save your user name and password for all users, and then enable Internet Connection Sharing for the new connection.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Configure a modem for a dial-up connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure a modem for a dial-up connection**

1. Open Network Connections.
2. Right-click the dial-up connection you want to configure, and then click **Properties**.
3. On the **General** tab, under **Connect using**, click the modem you want to configure, and then click **Configure**.
4. Under **Hardware Features**, select the check box options you want to enable.
5. If you want to enable the modem speaker, select the **Enable modem speaker** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- To ensure compatibility, you need to use the same kind of modem as the one connected to the remote access server, select the same initial speed, and enable the same features. If you do not select the same model, at least select a modem with the same ITU-T standard as the modem on the server.
- Selecting a feature that is not supported by your modem has no effect on its performance.
- Network Connections automatically configures connections according to the devices that are available. For example, you might use a laptop and docking station when you are in the office, with your connection configured to use the docking station modem. When you are on the road, and the docking station modem is not available, the connection is automatically configured to use the laptop's PCMCIA modem. When you return to the office and re-dock your laptop into its docking station, Network Connections detects that the docking station modem is available again, and automatically reconfigures the connection to use the docking station modem.
- Modem changes made as described in this procedure are unique to this connection. To make global changes, you will need to change each modem.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make a dial-up connection by using X.25

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a dial-up connection by using X.25**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. In **Network Connection Type**, click **Connect to the Internet** or **Connect to the network at my workplace**, and then click **Next**.
4. In **Network Connection**, click **Connect using a dial-up modem** or **Dial-up connection**, and then click **Next**.
5. Follow the instructions in the New Connection wizard.
6. When the wizard is finished, right-click the new connection, and then click **Properties**.
7. On the **Options** tab, click **X.25**.
8. In **Network**, click your X.25 network provider.
9. In **X.121 address**, type the X.121 address (the X.25 equivalent of a phone number) for the server you want to call.
10. If required by the X.25 host computer, in **User Data**, type additional connection information.
11. In **Facilities**, type any additional facility options you want to request from your X.25 provider. (For example, some providers support the **/r** option to specify reverse charging.)

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- To enable automatic dialing for all users, create a connection, save your user name and password for all users, and then enable Internet Connection Sharing for the new connection.
- For details on facility options, consult your X.25 documentation or provider.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Start Remote Access Auto Connection Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start Remote Access Auto Connection Manager**

1. Open Computer Management.
2. In the console tree, click **Services**.

   **Where?**

   - Computer Management/Services and Applications/Services

3. In the details pane, right-click **Remote Access Auto Connection Manager**, and then click **Start**.

   Under the **Status** column, **Started** appears.

### Note

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Dial-up Options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure dial-up options**

- Configure client callback options
- Configure autodial
- Enable logging
- Enable multiple device dialing
- Configure phone number modifiers
- Configure redial options
- Assign multiple phone numbers to a connection
- Enable operator-assisted calls or manual dialing

# Configure client callback options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure client callback options**

1. Open Network Connections.
2. On the **Advanced** menu, click **Remote Access Preferences**.
3. On the **Callback** tab, do one of the following:
   - If you do not want to use callback, click **No callback**.
   - If you want to decide whether to use callback at the time you connect, click **Ask me during dialing when the server offers**.
   - If you want to consistently use callback, click **Always call me back at the number(s) below**, and select the modem or device you want to be called back.

     If **Phone number** is blank for the device you have selected, click **Edit**, and then type the number.

     If you want to remove a modem or device from the list of possible callback devices, click the modem or device, and then click **Delete**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Your system administrator can override any callback settings that you configure. Through server settings, the administrator can deny the use of callback, allow you to set callback options, or require callback to a particular number. Contact your system administrator to determine your callback options.
- To use callback, Link Control Protocol (LCP) extensions must be enabled.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

# Configure autodial

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure autodial**

1. Open Network Connections.
2. On the **Advanced** menu, click **Remote Access Preferences**.
3. On the **Autodial** tab, select the check box next to the location where you want to enable autodial, and then click **OK**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Autodial is enabled by default in Windows XP. In support of this feature, the Remote Access Auto Connection Manager is also started by default.
- Autodial maps the resources that are required to initially make a connection, but it does not map resources after the connection is made. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**

# Enable logging

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable logging**

1. Open Network Connections.
2. On the **Advanced** menu, click **Remote Access Preferences**.
3. On the **Diagnostics** tab, do one or more of the following:
   - To enable logging for all remote access connections, select the **Enable logging** check box.
   - To clear logs created during a previous connection, click **Clear Log**.
   - To generate a report, click **Generate Report**.
4. If you clicked **Generate Report** in the previous step, do one of the following:
   - To view the diagnostic report, click **View report**.
   - To save the report to a file, click **Save report to this file**, and specify the location and the name of the file you want to create. Specify the location by typing it or by clicking **Browse** and browsing to the location you want.
   - To send the report to an e-mail address, click **Send report to this e-mail address**, and type the e-mail address to which you want to send the report.
   - To quickly generate a more concise report, select the **Generate summary report** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Creating a diagnostic report in HTML can take several minutes. If you need only configuration and installation information, you can create a summary report.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Logging remote access connections

# Enable multiple device dialing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable multiple device dialing**

1. Open Network Connections.
2. Right-click the connection on which you want to enable the dialing of multiple devices, and then click **Properties**.
3. On the **Options** tab, in **Multiple devices**, do one of the following:
   - If you want to dial only the first available device, click **Dial only first available device**.
   - If you want to use all of your devices, click **Dial all devices**.
   - If you want to dynamically dial and hang up devices as needed, click **Dial devices only as needed**, and then click **Configure**.

     In **Automatic dialing**, click the **Activity at least** percentage and **Duration at least** time you want to set. Another line is dialed when connection activity reaches this level for the amount of time that you specify.

     In **Automatic hangup**, click the **Activity no more than** percentage and **Duration at least** time you want to set. A device is disconnected when connection activity decreases to this level for at least the amount of time that you specify.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you selected **Dial devices only as needed**, the last multilinked device ignores the **Automatic hangup** setting, and a twenty-minute time-out is used for the last device.
- If you use multiple devices to dial a server that requires callback, then only one of your multilinked devices is called back. This is because only one number is stored in a user account. Therefore, only one device connects and all other devices fail to complete the connection, and your connection loses Multilink functionality.

  You can avoid this problem if the multilinked phonebook entry is an ISDN with two channels that have the same phone number.
- Multiple device dialing is available only if multiple adapters are available on the computer.
- If you select **Dial all devices**, dropped links in the multilinked bundle are not automatically reinitialized. You can force links to reinitialize by selecting **Dial devices only as needed**, then **Configure**, and then setting easily achieved **Automatic dialing** conditions which cause another line to be dialed. For example, set **Activity at least** to 1% and **Duration at least** to 3 seconds.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure phone number modifiers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure phone number modifiers**

1. Open Network Connections.
2. Right-click the dial-up connection you want to configure, and then click **Properties**.
3. On the **General** tab, modify the phone number by using one or more characters from the following list.

| Character | Function |
|---|---|
| , (comma) | Pauses briefly (two seconds for most modems) before continuing. |
| P | Switches from touch-tone to pulse/rotary dialing. |
| T | Switches from pulse/rotary to touch-tone dialing. |
| $ | Waits for a calling card prompt tone. |

For example, when you dial in from a hotel room, you may have to add 9 to the number you are calling to get an outside line. Your number may look similar to the following:

9,555-0100

The comma after the 9 gives a pause long enough to get an outside line before continuing to dial the full number.

**Notes**

- To configure phone number modifiers, you must be logged on as a member of the Administrators group.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- By selecting the **Use dialing rules** check box, and then clicking **Dialing Rules**, you can create a **Location** for which specific dialing rules automatically apply. For example, if you frequently connect from home and need to disable call waiting, you can create a location for use from home that automatically dials the code to disable call waiting before the connection call is placed.
- If you see unfamiliar characters being dialed before your number, check to make sure the **Use dialing rules** check box is not selected. If it is selected, a location may be enforcing a dialing rule that you do not need. For example, a location may be selected that always dials 1 to accommodate long distance dialing.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure redial options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure redial options**

1. Open Network Connections.
2. Right-click the dial-up connection you want to configure, and then click **Properties**.
3. On the **Options** tab, in **Redialing options**, click the arrows to set the number of times the dial-up connection is automatically redialed if the first attempt to connect fails.
4. In **Time between redial attempts**, click the down arrow to set the amount of time to pause between the end of one attempt and the beginning of another.
5. In **Idle time before hanging up**, click the down arrow to set the amount of idle time before a client hangs up a connection.
6. If you want the connection to automatically redial if the line is dropped, select the **Redial if line is dropped** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- The **Time between redial attempts** pause lets the device reset itself before redialing. The default is one minute. If that is not enough time, increase this setting. You can also experiment with shorter times, but if you make the pause too short, the device does not have time to reset itself.
- Keep in mind that the remote access server also has a disconnect timer. If **Idle time before hanging up** is set to a high time-out number, there is no guarantee that the connection will not disconnect before the time passes. This is because the server may choose to disconnect you before the time set here.
- If you are using Internet Explorer, the browser's own settings for dial-up connections may conflict with these redial options.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign multiple phone numbers to a connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign multiple phone numbers to a connection**

1. Open Network Connections.
2. Right-click the dial-up connection to which you want to assign multiple phone numbers, and then click **Properties**.
3. On the **General** tab, click **Alternates**.
4. If you want the connection to attempt a different phone number if the first number in the list is not successful, select the **If number fails, try next number** check box.
5. If you want the connection to move the first successful phone number to the top of the list under **Phone numbers** and use it on the next connection attempt, click **Move successful number to top of list**.
6. To add a new phone number to the list, click **Add**, and in **Phone number**, type the phone number.
7. If you want the connection to use established area code and dialing rules, select the **Use dialing rules** check box.
8. When you are finished adding the new phone number, click **OK**.
9. If you want to change the order of phone numbers under **Phone numbers**, click a phone number, and then click the **Up** button or **Down** button until the phone number is in the correct order.
10. If you want to remove a phone number under **Phone numbers**, click the phone number, and then click **Delete**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you have alternate phone numbers defined for a connection, you can specify a particular phone number at the time you initiate your connection.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable operator-assisted calls or manual dialing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable operator-assisted calls or manual dialing**

1. Open Network Connections.
2. On the **Advanced** menu, click **Operator-Assisted Dialing**.
3. Double-click the connection you want to dial.
4. Pick up the telephone handset, and then dial the number or ask the operator to dial it for you.

   The number assigned to the entry is displayed in the dialog box for easy reference.
5. Immediately after you have finished dialing, click **Dial**.
6. Hang up the handset only after the modem takes control of the line, which is typically signaled with a click followed by silence.

   It is always safe to replace the handset once Network Connections begins verifying your user name and password. The status message will remind you of this.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If operator-assisted dialing is enabled, a check mark appears next to **Operator-Assisted Dialing** on the **Advanced** menu.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make Internet Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Make Internet connections**

- Make an Internet connection
- Make a broadband connection using Point-to-Point Protocol over Ethernet (PPPoE)

# Make an Internet connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make an Internet connection**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. Click **Connect to the Internet**, and then click **Next**.
4. Click **Connect using a dial-up modem**, and click **Next**.
5. If prompted, select the check box for the modem you want to use for this connection, and click **Next**.
6. Type the name of your ISP in **ISP Name**, and click **Next**.
7. Type the phone number of your ISP, including the area code, in **Phone number**, and click **Next**.
8. Make the connection available to any user or only to yourself by selecting **Anyone's use** or **My use only**.
9. In **User name**, type the account name your ISP assigned to you. In **Password** and **Confirm password**, type the password for your account name, and click **Next**.
10. If you want to create a shortcut for this connection on your desktop, select the **Add a shortcut to this connection to my desktop** check box.
11. Click **Finish.**

## Notes

- To make a connection available to any user, you must be logged on as a member of the Administrators group.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- To enable automatic dialing for all users, create a connection, save your user name and password for all users, and then enable Internet Connection Sharing for the new connection.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make a broadband connection using Point-to-Point Protocol over Ethernet (PPPoE)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a broadband connection using Point-to-Point Protocol over Ethernet (PPPoE)**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. Click **Connect to the Internet**, and then click **Next**.
4. To create a high-speed connection that requires you to sign in, click **Connect using a broadband connection that requires a user name and password**, and click **Next**.
5. Type the name of your ISP in **ISP Name**, and click **Next**.
6. Do one of the following:
   - If you want this connection to be made available to all users on your network, click **Anyone's use**, and then click **Next**.
   - If you want to reserve the connection for your own use, click **My use only**, and then click **Next**.
7. In **User name**, type the account name your ISP assigned to you. In **Password** and **Confirm password**, type the password for your account name, and click **Next**.
8. To create a shortcut for this connection on your desktop, select the **Add a shortcut to this connection to my desktop** check box.
9. Click **Finish**.

## Notes

- To make a connection available to any user, you must be logged on as a member of the Administrators group.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make Direct Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Make direct network connections**

- Make a direct network connection
- Make a direct network connection by using a DirectParallel cable

# Make a direct network connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a direct network connection**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. Click **Set up an advanced connection**, and then click **Next**.
4. Click **Connect directly to another computer**, click **Next**, and then follow the instructions in the New Connection Wizard.

## Notes

- To create a direct network connection that acts as a host, you must be logged on as Administrator or be a member of the Administrators group. Guest direct network connections do not require administrator credentials.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you specify your connection as a host when you create it, the connection appears as **Incoming Connections** in the Network Connections folder.
- You can create multiple direct connections by copying them in the Network Connections folder. You can then rename the connections and modify connection settings. By doing so, you can easily create different connections to accommodate multiple ports, host computers, and so on.
- Direct connections can bypass authentication requirements. This is useful for devices such as handheld PCs. You must configure this setting in the host incoming connection. For more information, see Related Topics.
- If you create a direct connection by using a serial (RS-232C) cable, the port that you select in the New Connection Wizard is enabled for connections that use a null modem.
- If you are logged on to your computer as Administrator or a member of the Administrators group when you create a direct connection, you are presented with a list of connection devices to choose from that includes all of the parallel ports for the computer, infrared ports that are installed and enabled, and COM ports. If you need to use a COM port for a direct connection, ask your system administrator to configure one of the COM ports on your computer with a null modem by using Phone and Modem Options in Control Panel.
- Users do not need to use direct connections to allow access to shared resources, such as files and printers, over a local area network. In order to enable shared access to resources on the local computer, you must enable file and print sharing, share the resources, and then set up the appropriate permissions.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make a direct network connection by using a DirectParallel cable

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a direct network connection by using a DirectParallel cable**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. Click **Set up an advanced connection**, and then click **Next**.
4. Click **Connect directly to another computer**, click **Next**, and then do one of the following:
   - If you want your computer to act as the host, click **Host**, and click **Next**. Click **Direct Parallel (LPT1)** in the **Device for this connection**, and click **Next**.
   - If you want your computer to act as the guest, click **Guest**, and click **Next**. Type the name of the other computer in **Computer Name**, and click **Next**.
5. Follow the remaining instructions in the New Connection Wizard.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- For information about contacting Parallel Technologies or their local dealers to order DirectParallel cables, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set up Incoming Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up incoming connections**

- Accept incoming network connections
- Grant incoming connection access rights to your computer
- Configure an incoming connection to use TCP/IP
- Configure callback for incoming connections

# Accept incoming network connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To accept incoming network connections**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. Click **Set up an advanced connection**, and then click **Next**.
4. Click **Accept incoming connections**, click **Next**, and then follow the instructions in the New Connection Wizard.

## Notes

- To create an incoming network connection, you must be a member of the Administrators group.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you make another incoming network connection, and you use the New Connection Wizard again, the existing incoming network connection is reconfigured.
- For large numbers of incoming connections on a server that operates as part of a distributed network or as a domain controller, use Routing and Remote Access to create a remote access server.
- If your incoming connection and Fax Service have problems working together (for example, you cannot receive incoming connection calls on a device enabled for Fax receive), the modem may not support adaptive answer. Check your modem documentation to verify that you need to disable Fax receive for that device to accept incoming connections.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Grant incoming connection access rights to your computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To grant incoming connection access rights to your computer**

1. Open Network Connections.
2. Right-click **Incoming Connections**, and then click **Properties**.
3. On the **General** tab, do one or more of the following:
   - In **Devices**, click the check boxes next to the devices through which incoming connections can connect.
   - If you have more than one device selected, and you want to enable Multilink dialing, select the **Enable multilink** check box.
   - If you want to enable others to make private connections to your computer by tunneling through the Internet or other network, select the **Allow others to make private connections to my computer by tunneling through the Internet or other network** check box.
   - If you want to show icons on the taskbar when incoming connections are connected, select the **Show icon in notification area when connected** check box.
4. On the **Users** tab, do one or more of the following:
   - If you want to allow a user to connect, select the check box next to the user's name.
   - If you want to revoke a user's right to connect, clear the check box next to a user's name.
   - To create a new user and grant them access to connect, click **New**.
   - To remove a user, click **Delete**.
   - To modify a user's name, password, and callback options, click **Properties**.
   - If you want directly connected devices to connect without providing a password, select the **Always allow directly connected devices such as palmtop computers to connect without providing a password** check box.
5. On the **Networking** tab, do one or more of the following:
   - If you want to enable a network component, in **Network components**, select the check box next to the component name.
   - If you want to disable a network component, in **Network components**, clear the check box next to the component name.
   - To add a network component, click **Install**.
   - To remove a network component, click **Uninstall**.

- To configure a network component, click **Properties**.

**Notes**

- To modify an incoming connection, you must be logged on as a member of the Administrators group.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you enable or disable TCP/IP for incoming connections, the settings affect only incoming connections. Other protocols, such as AppleTalk, are enabled or disabled for all connection types.

# Configure an incoming connection to use TCP/IP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure an incoming connection to use TCP/IP**

1. Open Network Connections.
2. Right-click **Incoming Connections**, and then click **Properties**.
3. On the **Networking** tab, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
4. If you want incoming users to be able to access the local area network on which the dial-up computer resides, select the **Allow callers to access my local area network** check box.
5. Do one of the following:

   - If you want to automatically assign TCP/IP addresses, select the **Assign TCP/IP addresses automatically using DHCP** check box.
   - If you want to specify TCP/IP addresses, click **Specify TCP/IP addresses**, and do the following:

     In **From**, type the starting IP address.

     In **To**, type the ending IP address.

     Based on the addresses you type in **From** and **To**, the number of addresses that are allocated is displayed in **Total**. The starting and ending IP addresses that you choose depend on the originating address space and the number of addresses needed. For more information on defining IP addresses for incoming connections, see Related Topics.

6. If you want incoming connections to be able to use a specific TCP/IP address, select the **Allow calling computer to specify its own IP address** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Most TCP/IP networks use subnets in order to effectively manage routed IP addresses. The closest matching subnet is calculated for the range that you specified in **From** and **To**. The range of addresses in the closest matching subnet may exceed the range that you specified. Unless the addresses specified in **From** and **To** are subnet boundaries, the range based on the calculated subnet will be larger than the range that you specified. To avoid this, specify a range that falls on subnet boundaries. For example, if you are using the 10.0.0.0 private network ID for your intranet, a range that falls on subnet boundaries is 10.0.1.168 to 10.0.1.175. Or, if you are using the 192.168.0.0 private network ID for your intranet, a range that falls on subnet boundaries is 192.168.1.0 to 192.168.1.255.
- If you select **Allow callers to access my local area network** or **Allow calling computer to specify its own IP address**, these changes take effect immediately.
- If you select **Assign TCP/IP addresses automatically using DHCP**, but there is no DHCP server available, random addresses from the range 169.254.0.1 to 169.254.255.254 are assigned.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure callback for incoming connections**

1. Open Network Connections.
2. Right-click **Incoming Connections**, and then click **Properties**.
3. On the **Users** tab, click the user for which you want to configure callback, and then click **Properties**.
4. On the **Callback** tab, do one of the following:
   - If you do not want to use callback for incoming connections, click **Do not allow callback**.
   - If you want to give incoming connections the option of setting a specific callback number, click **Allow the caller to set the callback number**.
   - If you want to consistently use the same callback number, click **Always use the following callback number**, and type the number.

**Note**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**Configure network and dial-up connections**

- Configure a connection to a remote network
- Set up Network Components
- Secure Network or Dial-up Connections

# Configure a connection to a remote network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure a connection to a remote network**

1. Open Network Connections.
2. Right-click the dial-up connection that you want to configure, and then click **Properties**.
3. Do one or more of the following:
   - To configure dialing devices, phone numbers, host address, country/region codes, or dialing rules, click the **General** tab.
   - To configure dialing and redialing options, multilink configuration, or X.25 parameters, click the **Options** tab.
   - To configure identity authentication, data encryption, or terminal window and scripting options, click the **Security** tab.
   - To configure the remote access server and protocols used for this connection, click the **Networking** tab.
   - To enable or disable Internet Connection Firewall, Windows Firewall, Internet Connection Sharing, and on-demand dialing, click the **Advanced** tab. For more information, see Related Topics.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.
- Depending on the type of connection you are configuring, different options appear in the properties dialog box.
- For more information about a specific item on a tab, right-click the item, and then click **What's This?**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

- PPP Settings

# Configure TCP/IP settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure TCP/IP settings**

1. Open Network Connections.
2. Right-click the connection you want to configure, and then click **Properties**.
3. Do one of the following:
   - If the connection is a local area connection, on the **General** tab, in **This connection uses the following items**, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
   - If the connection is a dial-up or VPN connection, on the **Networking** tab, in **This connection uses the following items**, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
   - If the connection is an incoming connection, on the **Networking** tab, in **Network components**, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
4. Do one of the following:
   - If you want IP settings to be assigned automatically, click **Obtain an IP address automatically**, and then click **OK**.
   - If you want to specify an IP address or a DNS server address, do the following:

     Click **Use the following IP address**, and in **IP address**, type the IP address.

     Click **Use the following DNS server addresses**, and in **Preferred DNS server** and **Alternate DNS server**, type the addresses of the primary and secondary DNS servers.
5. To configure DNS, WINS, and IP settings, click **Advanced**.
6. In a local area connection, selecting the **Obtain an IP address automatically** option enables the **Alternate Configuration** tab. Use this to enter alternate IP settings if your computer is used on more than one network. To configure DNS, WINS, and IP settings, click **User configured** on the **Alternate Configuration** tab.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You should use automated IP settings (DHCP) whenever possible for all connections because they eliminate the need to configure settings such as IP address, DNS server address, and WINS server address.
- The **Alternate Configuration** settings specify a second set of IP settings that are used when a DHCP server is not available. This is very useful for laptop users who often switch between two different network environments such as DHCP and static IP network environments.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

New ways to do Network Connections tasks

# Add a network component

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a network component**

1. Open Network Connections.
2. Right-click the connection to which you want to add a network component, and then click **Properties**.
3. Do one of the following:
   - If this is a local area connection, click **Install**.
   - If this is a dial-up, VPN, or incoming connection, on the **Networking** tab, click **Install**.
4. In the **Select Network Component Type** dialog box, click either **Client**, **Service**, or **Protocol**, and then click **Add**.
5. Do one of the following:
   - If you do not have an installation disk for the component, click the appropriate client, service, or protocol, and then click **OK**.
   - If you have an installation disk for the component, click the appropriate client, service, or protocol, click **Have Disk**, insert the installation disk into the selected drive, and then click **OK**.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You should only install the network components that you need, for the following reasons:
  - Network performance is enhanced and network traffic is reduced when only the required protocols and clients are installed.
  - If a problem with a network or dial-up connection occurs, your computer attempts to establish connectivity by using every network protocol that is installed and enabled. By only installing and enabling the protocols that your system can use, the operating system does not attempt to connect with protocols it cannot use, and returns status information to you more efficiently.
  - Excessive services can hinder performance on your local computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove a network component

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove a network component**

1. Open Network Connections.
2. Right-click the connection on which you want to remove a network component, and then click **Properties**.
3. Do one of the following:
   - If this is a local area connection, on the **General** tab, in **This connection uses the following items**, click the client, service, or protocol you want to remove, and then click **Uninstall**.
   - If this is a dial-up or VPN connection, on the **Networking** tab, in **This connection uses the following items**, click the client, service, or protocol you want to remove, and then click **Uninstall**.
   - If this is an incoming connection, on the **Networking** tab, in **Network components**, click the client, service, or protocol you want to remove, and then click **Uninstall**.
4. In the **Uninstall***component name* dialog box, click **Yes**.

**Note**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable a network component

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable a network component**

1. Open Network Connections.
2. Right-click a connection, and then click **Properties**.
3. Do one of the following:
   - If this is a local area connection, on the **General** tab, in **This connection uses the following items**, select the check box next to the client, service, or protocol you want to enable.
   - If this is a dial-up or VPN connection, on the **Networking** tab, in **This connection uses the following items**, select the check box next to the client, service, or protocol you want to enable.
   - If this is an incoming connection, on the **Networking** tab, in **Network components**, select the check box next to the client, service, or protocol you want to enable.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You should only enable the network components that you need, for the following reasons:
  - Network performance is enhanced and network traffic is reduced when only the required protocols and clients are enabled.
  - If your computer encounters a problem with a network or dial-up connection, it attempts to establish connectivity by using every network protocol that is installed and enabled. By only enabling the protocols that your system can use, the operating system does not attempt to connect with protocols it cannot use, and returns status information to you more efficiently.
  - Excessive services can hinder performance on your local computer.

# Disable a network component

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable a network component**

1. Open Network Connections.
2. Right-click the connection on which you want to disable a network component, and then click **Properties**.
3. Do one of the following:
   - If this is a local area connection, on the **General** tab, in **This connection uses the following items**, clear the check box next to the client, service, or protocol you want to disable.
   - If this is a dial-up, VPN, or incoming connection, on the **Networking** tab, in **Use these components with this connection**, clear the check box next to the client, service, or protocol you want to disable.

**Note**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modify the protocol bindings order

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To modify the protocol bindings order**

1. Open Network Connections.
2. On the **Advanced** menu, click **Advanced Settings**.
3. In **Connections**, click the connection that you want to modify.
4. Click the protocol that you want to move up or down in the list, and then click the up or down arrow button.

## Notes

- To modify the protocol bindings order, you must be logged on as a member of the Administrators group.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modify the network provider order

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To modify the network provider order**

1. Open Network Connections.
2. Click the connection you want to modify, and on the **Advanced** menu, click **Advanced Settings**.
3. On the **Provider Order** tab, in **Network Providers**, click the provider you want to move up or down in the list, and then click the **Up** or **Down** button.

## Notes

- To modify the network provider order, you must be logged on as a member of the Administrators group.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Network providers are accessed in the order they appear in this list.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Client for Microsoft Networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure Client for Microsoft Networks**

1. Open Network Connections.
2. Right-click a connection, and then click **Properties**.
3. Do one of the following:
   - If this is a local area connection, on the **General** tab, in **This connection uses the following items**, click **Client for Microsoft Networks**, and then click **Properties**.
   - If this is a dial-up, VPN, or incoming connection, on the **Networking** tab, in **Use these components with this connection**, click **Client for Microsoft Networks**, and then click **Properties**.
4. In **Name service provider**, click an RPC name service provider.
5. If you selected **DCE Cell Directory Service**, in **Network address** type the network address of your provider.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Windows Locator is the default name service provider.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure File and Printer Sharing for Microsoft Networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure File and Printer Sharing for Microsoft Networks**

1. Open Network Connections.
2. Right-click a connection, and then click **Properties**.
3. Do one of the following:
   - If this is a local area connection, on the **General** tab, in **This connection uses the following items**, click **File and Printer Sharing for Microsoft Networks**, and then click **Properties**.
   - If the connection is a dial-up or VPN connection, on the **Networking** tab, in **This connection uses the following items**, click **File and Printer Sharing for Microsoft Networks**, and then click **Properties**.
   - If the connection is a incoming connection, on the **Networking** tab, in **Network components**, click **File and Printer Sharing for Microsoft Networks**, and then click **Properties**.
4. Do one of the following:
   - To optimize the server for a small number of clients, click **Minimize memory used**.
   - To optimize the server for a mixed usage of file and printer sharing in addition to other services, such as serving as an interactive workstation, click **Balance**.
   - To dedicate as many resources as possible to file and print server services, click **Maximize data throughput for file sharing**.
   - To optimize server memory for distributed applications that perform their own memory caching, such as Microsoft SQL Server, click **Maximize data throughput for network applications**.
5. To specify that LAN Manager 2.*x* clients on your network can browse for shared resources on this computer, select the **Make browser broadcasts to LAN Manager 2.x clients** check box.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You can only configure File and Printer Sharing for Microsoft Networks on a server.
- To share local folders, you must enable File and Printer Sharing for Microsoft Networks. For more information, see Related Topics.
- The File and Printer Sharing for Microsoft Networks component is the equivalent of the Server service in Windows NT 4.0.
- This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# PPP Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PPP settings**

- Stop requesting LCP extensions in PPP
- Start requesting LCP extensions in PPP
- Turn off IP header compression in PPP
- Disable software compression

# Stop requesting LCP extensions in PPP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To stop requesting LCP extensions in PPP**

1. Disconnect from the remote server.
2. Open Network Connections.
3. Right-click the dial-up connection you want to configure, and then click **Properties**.
4. On the **Networking** tab, click **Settings**.
5. In the **PPP Settings** box, clear the **Enable LCP extensions** check box.

### Note

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Turn off IP header compression in PPP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To turn off IP header compression in PPP**

1. Disconnect from the remote server.
2. Open Network Connections.
3. Right-click the dial-up connection you want to configure, and then click **Properties**.
4. On the **Networking** tab, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
5. Click **Advanced**, and then clear the **Use IP header compression** check box.

## Notes

- To turn off IP header compression, you must be logged on as an administrator or a member of the Administrators group. Some connections do not display the **IP header compression** check box.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disable software compression

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable software compression**

1. Open Network Connections.
2. Right-click the dial-up, VPN, or incoming connection you want to configure, and then click **Properties**.
3. On the **Networking** tab, click **Settings**, and clear the **Enable software compression** check box.

### Note

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Secure Network or Dial-up Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Secure network or dial-up connections**

- Configure identity authentication and data encryption settings
- Enable smart card or other certificate authentication
- Terminal and Scripting Options

For information on security considerations for routing, remote access and VPN, see Security information for routing, Security information for remote access and Security issues for VPN.

# Configure identity authentication and data encryption settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure identity authentication and data encryption settings**

1. Open Network Connections.
2. Right-click the dial-up connection you want to configure, and then click **Properties**.
3. On the **Security** tab, do one of the following:

   - To select preconfigured combinations of identity authentication methods and data encryption requirements, click **Typical (recommended settings)**, and in **Validate my identity as follows**, click a method to use for validation.

     Depending on your **Validate my identity as follows** selection, you can select (enable) or clear (disable) the **Automatically use my Windows logon name and password (and domain if any)** or **Require data encryption (disconnect if none)** check boxes. The following table shows which selections are available.

     If **Require data encryption (disconnect if none)** is not enabled, encryption is optional. To prevent encryption, click **Advanced (custom settings)**, and then click **Settings**. In **Data encryption**, click **No encryption allowed (server will disconnect if it requires encryption)**.

     For dial-up connections:

     | Validate my identity as follows | Automatically use my Windows logon name and password (and domain if any) | Require data encryption (disconnect if none) |
     |---|---|---|
     | Allow unsecured password | Unavailable | Unavailable |
     | Require secured password | Available | Available |
     | Use smart card | Unavailable | Available |

     For VPN connections:

     | Validate my identity as follows | Automatically use my Windows logon name and password (and domain if any) | Require data encryption (disconnect if none) |
     |---|---|---|
     | Require secured password | Available | Available (enabled by default) |
     | Use smart card | Unavailable | Available (enabled by default) |

   - To individually enable, configure, and disable authentication methods and encryption requirements, click **Advanced (custom settings)**, and then click **Settings**.

**Important**

- Modifying **Advanced (custom settings)** requires a knowledge of security protocols.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

- Among the advanced custom settings is the **Allow older MS-CHAP version for Windows 95 servers** check box. You must select this check box to configure a connection to a server running Windows 95.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**

# Enable smart card or other certificate authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable smart card or other certificate authentication**

1. Open Network Connections.
2. Right-click the dial-up, VPN, or incoming connection on which you want to use smart card or other certificate authentication, and then click **Properties**.
3. If you are using typical settings for your smart card, on the **Security** tab, click **Typical (recommended settings)**, and in the **Validate my identity as follows** list, click **Use smart card**, and then click **OK**.
4. If you are individually enabling, configuring, and disabling authentication methods and encryption requirements, on the **Security** tab, click **Advanced (custom settings)**, and click **Settings**. In **Logon security**, click **Use Extensible Authentication Protocol (EAP)**, click **Smart card or other certificate (encryption enabled)**, click **Properties**, and then do the following:
   - If you want to use the certificate that resides on your smart card, click **Use my smart card**.
   - If you want to use the certificate that resides in the certificate store on your computer, click **Use a certificate on this computer**.
   - If you want to verify that the server certificate presented to your computer has not expired, has the correct signature, and has a trusted root certification authority, select the **Validate server certificate** check box.
   - If you only want to connect to servers within a particular domain, select the **Connect only if server name ends with** check box, and then type the name of the domain.
   - To specify that the root certification authority for your server certificate must be in a particular root certification authority, in **Trusted root certification authority**, click the appropriate certification authority.
   - To use a different user name when the user name in the smart card or certificate is not the same as the user name in the domain that you are logging on to, select the **Use a different user name for the connection** check box.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If, for example, you only want to connect to servers that reside in Microsoft.com, you type **Microsoft.com** in **Connect only if server name ends in**.
- If, for example, you are working for a consulting company where you need to log on to the domain of the company to which you are assigned, but your smart card contains a user name specific to your home company, select the **Use a different user name for the connection** check box.
- If you select the **Use a different user name for the connection** check box, your certificate is exported without private keys and submitted to your system administrator to be explicitly mapped to your domain user account. For more information, see Related Topics.
- If you select the **Connect only if server name ends with** check box, and do not type a domain name, at the time you connect you are prompted to use the domain name in the server certificate.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Terminal and Scripting Options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal and scripting options**

- Use the Terminal feature to log on to a remote computer
- Activate a logon script
- Log and view modem commands

# Use the Terminal feature to log on to a remote computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use the Terminal feature to log on to a remote computer**

1. Open Network Connections.
2. Right-click the dial-up connection on which you want to use Terminal, and then click **Properties**.
3. On the **Security** tab, select the **Show terminal window** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- After you connect, the After Dial Terminal window appears and prompts you from the remote computer display. You then use this window to log on to the remote computer. After you have completed all interactions with the remote computer, click **Done**. At this point, authentication on the remote access server begins.
- If the logon sequence does not vary, you can write a script that automatically passes information to the remote computer during the logon sequence, which enables completely automatic connections.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

# Activate a logon script

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To activate a logon script**

1. Open Network Connections.
2. Right-click the dial-up connection on which you want to run a script, and then click **Properties**.
3. On the **Security** tab, select the **Run script** check box.
4. To use an existing script file, click **Browse**.

   Or, to use Switch.inf, click **Edit**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- In addition to Switch.inf, the Windows 95 scripting language is supported for computers running the Windows Server 2003 family that connect to computers running operating systems other than Windows. You may find the Windows 95 scripting language easier to use than Switch.inf. For more information, see Related Topics.
- If you click **Edit** and load Switch.inf into Notepad, immediately resave the file with a different name to preserve the default Switch.inf file.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Log and view modem commands

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To log and view modem commands**

1. Open Phone and Modem Options in Control Panel.
2. On the **Modems** tab, click the modem whose commands you want to log.
3. Click **Properties**, then click the **Diagnostics** tab.
4. In **Logging**, select the **Append to Log** check box if you are working on a computer running Windows XP or **Record a Log** check box if you are working on a computer running a member of the Windows Server 2003 family.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- Click **View Log** to display the log file. This file identifies the modem and displays information about how it is functioning.
- Commands sent to the modem are captured in the file:

  *systemroot*\System32\ModemLog_*Model*.txt.

  The path is usually C:\Windows\System32\. *Model* is the name of the modem as it appears in the list of installed modems on the **Modems** tab of **Phone and Modem Options**.
- In Windows XP, logging is always turned on, and the log is overwritten at the beginning of every session unless you select the **Append to Log** check box. In the Windows Server 2003 family, logging is turned off unless you select the **Record a Log** check box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Monitor Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitor network connections**

- Monitor a connection
- View the status of a local area connection

# Monitor a connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To monitor a connection**

1. Open Network Connections.
2. Do one of the following:
   - To monitor activity for the current session, right-click the connection you want to monitor, and then click **Status**.
   - To automatically enable the status monitor each time the connection is active, right-click the connection, click **Properties**, and then select the **Show icon in taskbar when connected** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If your computer is set up to accept incoming connections, a connection with a user name assigned to it appears in the Network Connections folder as each user connects. You can view the progress of incoming connections by right-clicking a named connection, and then clicking **Status**.
- You can also monitor a connection by clicking **Status** on the **File** menu or by clicking the status icon in the taskbar. You can also right-click the taskbar icon and click **Status**.
- If you want to view the general status (**Disconnected**, **Connected**) of all of your connections, on the **View** menu, click **Details**.
- You also can disconnect an active connection by clicking **Disconnect** in the **Status** dialog box.
- By default, the status monitor is disabled for local area connections, but enabled for all other types of connections.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View the status of a local area connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view the status of a local area connection**

1. Open Network Connections.
2. Do one of the following:
   - To monitor activity for the current session, right-click the local area connection, and then click **Status**.
   - To automatically enable the status monitor each time the connection is active, right-click the local area connection, click **Properties**, and then select the **Show icon in taskbar when connected** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You can view and modify the network components of a local area connection, such as network protocol settings, by clicking **Properties**.
- By default, the status monitor is disabled for local area connections, but enabled for all other types of connections.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set up and Manage Home and Small Office Networking

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up and manage home and small office networking**

- Set up and Manage Internet Connection Firewall (ICF)
- Set up and Manage Network Bridge
- Set up and Manage Internet Connection Sharing (ICS)
- Manage service definitions for ICF or ICS

**Note**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Set up and Manage Internet Connection Firewall (ICF)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up and manage Internet Connection Firewall (ICF)**

- Enable or disable ICF
- Enable or disable Internet Control Message Protocol requests for ICF
- Enable or disable ICF security log options
- View the ICF security log
- Change the file size of the ICF security log
- Change the path and file name of the ICF security log
- Restore the default settings to the ICF security log

# Enable or disable ICF

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable ICF**

1. Open Network Connections.
2. Under **Dial-up** or **LAN or High-Speed Internet**, right-click the connection that you want to protect, and then click **Properties**.
3. On the **Advanced** tab, under **Internet Connection Firewall**, do one of the following:
   - To enable Internet Connection Firewall (ICF), select the **Protect my computer and network by limiting or preventing access to this computer from the Internet** check box.
   - To disable ICF, clear the **Protect my computer and network by limiting or preventing access to this computer from the Internet** check box.

**Caution**

- If you clear the **Protect my computer and network by limiting or preventing access to this computer from the Internet** check box, the firewall on this connection is disabled. When the firewall is disabled, your computer is exposed to possible external attacks through the unprotected connection.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You need to enable ICF only on connections that connect to the Internet. You should not enable ICF on virtual private network (VPN) connections or on network client computers because ICF interferes with network activities such as file and printer sharing.
- If ICF is enabled on two or more connections on a single computer, the ICF settings are global. If you select a setting or change a setting in **Logging Options** or **Services** on any one of the connections on which ICF is enabled, that setting is applied to all of the ICF firewalls on that computer.
- ICF cannot be enabled on the private connections of the Internet Connection Sharing host computer, on Network Bridge, or on the adapters that are included in Network Bridge.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.
- This topic applies only to product features available in the original release of Windows Server 2003.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable or disable Internet Control Message Protocol requests for ICF

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable Internet Control Message Protocol requests for ICF**

1. Open Network Connections.
2. Right-click the connection on which Internet Connection Firewall (ICF) has been enabled, and then click **Properties**.
3. On the **Advanced** tab, click **Settings**.
4. On the **ICMP** tab, do one of the following:
   - To enable Internet Control Message Protocol (ICMP) options, select the check box next to each type of request for information to which you would like your computer to respond.
   - To disable ICMP options, clear any or all of the ICMP check boxes.

### Caution

- All ICMP options are disabled by default. If you enable ICMP options on a computer running ICF, that computer may become visible to the Internet and vulnerable to attacks.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- This topic applies only to product features available in the original release of Windows Server 2003.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable or disable ICF security log options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable ICF security log options**

1. Open Network Connections.
2. Right-click the connection on which Internet Connection Firewall (ICF) has been enabled, and then click **Properties**.
3. On the **Advanced** tab, click **Settings**.
4. On the **Security Logging** tab, under **Logging Options**, select from the following:

   To enable ICF security log options:

   - To enable the logging of all dropped packets that originate from either the home or small office network or the Internet, select the **Log dropped packets** check box.
   - To enable the logging of all successful connections that originate from either the home or small office network or the Internet, select the **Log successful connections** check box.

   Or, to disable ICF security log options:

   - To disable the logging of all dropped packets that originate from either the home or small office network or the Internet, clear the **Log dropped packets** check box.
   - To disable the logging of all successful connections that originate from either the home or small office network or the Internet, clear the **Log successful connections** check box.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Security logging is not enabled by default when ICF is enabled.
- ICF functions whether security logging is enabled or disabled.
- If ICF is enabled on two or more connections on a single computer, the ICF settings are global. If you select a setting or change a setting in **Logging Options** or **Services** on any one of the connections on which ICF is enabled, that setting is applied to all of the ICF firewalls on that computer.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- This topic applies only to product features available in the original release of Windows Server 2003.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View the ICF security log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view the ICF security log**

1. Open Network Connections.
2. Right-click the connection on which Internet Connection Firewall (ICF) has been enabled, and then click **Properties**.
3. On the **Advanced** tab, click **Settings**.
4. On the **Security Logging** tab, under **Log file options**, in **Name**, click **Browse**.
5. Scroll to the ICF security log, right-click the file, and then click **Open**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- The default name for the ICF security log is pfirewall.log, and the default location is in the Windows directory.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- This topic applies only to product features available in the original release of Windows Server 2003.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the file size of the ICF security log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the file size of the ICF security log**

1. Open Network Connections.
2. Right-click the connection on which Internet Connection Firewall (ICF) has been enabled, and then click **Properties**.
3. On the **Advanced** tab, click **Settings**.
4. On the **Security Logging** tab, under **Log file options**, in **Size limit**, use the arrow buttons to adjust the size limit.

### Caution

- If the maximum allowable size for pfirewall.log is exceeded, the information that pfirewall.log contains is saved as pfirewall.log.old, and new information is saved as pfirewall.log. If the maximum allowable size for pfirewall.log is exceeded again, the information that pfirewall.log contains is saved as pfirewall.log.old, and the information that had been in pfirewall.log.old is overwritten. New information is always saved in pfirewall.log.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If ICF is enabled on two or more connections on a single computer, the ICF settings are global. If you select a setting or change a setting in **Logging Options** or **Services** on any one of the connections on which ICF is enabled, that setting is applied to all of the ICF firewalls on that computer.
- The default size limit of the ICF security log is 4,096 kilobytes.
- You must enable ICF before you can adjust the size limit of the ICF security log.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- This topic applies only to product features available in the original release of Windows Server 2003.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the path and file name of the ICF security log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the path and file name of the ICF security log**

1. Open Network Connections.
2. Right-click the connection on which Internet Connection Firewall (ICF) has been enabled, and then click **Properties**.
3. On the **Advanced** tab, click **Settings**.
4. On the **Security Logging** tab, under **Log file options**, click **Browse**, and then do the following:
   - To change the path of the ICF security log, navigate to the location where you want the ICF security log to be saved. (If you do not want to change the path, do not navigate to a new location.)
   - To change the file name of the ICF security log, in **File name**, type a new name, and then click **Open**. (If you do not want to change the default file name, in **File name**, type **pfirewall**, and then click **Open**.)

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- The default name for the ICF security log is pfirewall.log, and the default location is in the Windows directory.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- This topic applies only to product features available in the original release of Windows Server 2003.

**Information about functional differences**

# Restore the default settings to the ICF security log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To restore the default settings to the ICF security log**

1. Open Network Connections.
2. Right-click the connection on which Internet Connection Firewall (ICF) has been enabled, and then click **Properties**.
3. On the **Advanced** tab, click **Settings**.
4. On the **Security Logging** tab, click **Restore Defaults**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- The default size limit of the log is 4,096 kilobytes.
- The default name for the ICF security log is pfirewall.log, and the default location is in the Windows directory.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- This topic applies only to product features available in the original release of Windows Server 2003.

# Set up and Manage Network Bridge

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up and manage Network Bridge**

- Set up Network Bridge
- Add a connection to or remove a connection from Network Bridge
- Enable or disable Network Bridge
- Remove Network Bridge

**Note**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Set up Network Bridge

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set up Network Bridge**

1. Open Network Connections.
2. Under **LAN or High-Speed Internet**, hold down the CTRL key, and then click each of the adapters that you want to include in the bridge.
3. Right-click one of the connections that you have selected, and then click **Bridge Connections**.

**Caution**

- If Internet Connection Firewall (ICF), Windows Firewall, or Internet Connection Sharing (ICS) are not enabled on your network, do not set up Network Bridge between the public Internet connection and the private network connection. Setting up Network Bridge between the public Internet connection and the private network connection creates an unprotected link between your network and the Internet, leaving your network vulnerable to external attacks. When ICF, Windows Firewall, or ICS are enabled, this risk is mitigated.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Connections that run ICF, Windows Firewall, or adapters that provide shared Internet connections cannot be a part of the Network Bridge and do not appear under **LAN or High-Speed Internet**. Similarly, the **Bridge Connections** menu command is available only for adapters that you can add as connections to Network Bridge.
- You must select at least two private network connections in order for **Bridge Connections** to create a bridge.
- You can create only one Network Bridge on a computer, but the bridge can accommodate numerous network connections.
- Network adapters that previously appeared under **LAN or High-Speed Internet**, appear under **Network Bridge** when you add them as connections to the bridge. Network adapters that provide Internet connectivity, such as DSL and cable modems, cannot be bridged and always appear under **LAN or High-Speed Internet**.
- Only Ethernet, IEEE-1394 adapters, or Ethernet-compatible adapters, such as wireless and Home Phoneline Network adapters, can be a part of Network Bridge.
- Network Bridge with a wireless or IEEE-1394 connection supports traffic using Internet Protocol version 4 (IPv4) only.
- You cannot create Network Bridge on a computer running Windows 2000 or earlier versions of Windows.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a connection to or remove a connection from Network Bridge

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a connection to or remove a connection from Network Bridge**

1. Open Network Connections.
2. Under **Network Bridge**, right-click **Network Bridge**, and then click **Properties**.
3. On the **General** tab, under **Adapters**, do one of the following.
   - To add a connection to Network Bridge, select the check box next to each adapter you want to add to the bridge, and then click **OK**.
   - To remove a connection from Network Bridge, clear the check box next to each adapter you want to remove from the bridge, and then click **OK**.

**Caution**

- If Internet Connection Firewall (ICF), Windows Firewall, or Internet Connection Sharing (ICS) are not enabled on your network, do not set up Network Bridge between the public Internet connection and the private network connection. Setting up Network Bridge between the public Internet connection and the private network connection creates an unprotected link between your network and the Internet, leaving your network vulnerable to external attacks. When ICF, Windows Firewall, or ICS are enabled, this risk is mitigated.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you remove network adapters from Network Bridge and less than two adapters remain, Network Bridge does not perform its intended function but continues to use system resources.
- You must set up Network Bridge before you can add connections to it. For more information, see Related Topics.
- Connections that run ICF, Windows Firewall, or adapters that provide shared Internet connections cannot be a part of Network Bridge and do not appear under **Adapters**. Similarly, the **Add to Bridge** menu command is available only for adapters that you can add as connections to Network Bridge.
- Network adapters that previously appeared under **LAN or High-Speed Internet**, appear under **Network Bridge** when you add them as connections to the bridge. Network adapters that provide Internet connectivity, such as DSL and cable modems, cannot be bridged and always appear under **LAN or High-Speed Internet**.
- Only Ethernet, IEEE-1394 adapters, or Ethernet-compatible adapters, such as wireless and Home Phoneline Network adapters, can be a part of Network Bridge.
- Network Bridge with a wireless or IEEE-1394 connection supports traffic using Internet Protocol version 4 (IPv4) only.

- You can also add a connection to or remove a connection from Network Bridge by opening Network Connections, right-clicking the adapter that you want to add, and then clicking **Add to Bridge**.

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable or disable Network Bridge

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable Network Bridge**

1. Open Network Connections.
2. Under **Network Bridge**, right-click **Network Bridge**, and do one of the following:
   - To enable Network Bridge, click **Enable**.
   - To disable Network Bridge, click **Disable**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you remove or disable Network Bridge, computers on your network are unable to communicate with computers that are on different network segments. Some of the computers on your network may lose Internet connectivity.
- You must set up Network Bridge before you can enable or disable it. For more information, see Related Topics.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

# Remove Network Bridge

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove Network Bridge**

1. Open Network Connections.
2. Under **Network Bridge**, right-click **Network Bridge**, and then click **Delete**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you remove or disable Network Bridge, computers on your network are unable to communicate with computers that are on different network segments. Some of the computers on your network may lose Internet connectivity.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

# Set up and Manage Internet Connection Sharing (ICS)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up and manage Internet Connection Sharing (ICS)**

- Enable ICS
- Enable ICS on-demand dialing
- Configure client computers for ICS

**Note**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Enable ICS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable ICS**

1. Open Network Connections.
2. Under **Dial-up** or **LAN or High-Speed Internet**, right-click the connection on which you want to enable (ICS), and then click **Properties**.
3. On the **Advanced** tab, under **Internet Connection Sharing**, select the **Allow other network users to connect through this computer's Internet connection** check box.
4. If present, under **Home networking connection**, in the **Select a private network connection** drop-down box, select the connection that connects directly to your network. For more information, see Notes.

**Important**

- You can enable ICS only when two or more network adapters are installed.
- If your computer has multiple private connections that connect to private LAN segments, you should bridge the private connections before you enable ICS. For information about how to set up Network Bridge, see Related Topics.
- When ICS is enabled, it automatically provides an IP address for the private connection of the ICS host.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- **Home networking connection** and the **Select a private network connection** drop-down box are present only when two or more adapters that can connect to the private network are installed.
- For information about the protocols, services, interfaces, and routes that are automatically configured by ICS when you connect to the Internet in a home or small office network, see Related Topics.
- If you are having difficulty connecting the ICS host to the Internet, you can use **Repair** to obtain refreshed IP address configurations from your Internet service provider (ISP).
- If a computer on your network is unable to communicate with other network computers, you can use **Repair** to force the connection to refresh its IP address configuration from the ICS host.
- Before using **Repair**, ensure that the client computers are plugged into the network and that the ICS host is running, configured, and connected to the network and the Internet.
- For information about how to configure client computers for ICS, see Related Topics.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable ICS on-demand dialing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable ICS on-demand dialing**

1. Open Network Connections.
2. Right-click the dial-up connection on which you want to enable ICS on-demand dialing, and then click **Properties**.
3. On the **Advanced** tab, under **Internet Connection Sharing**, do one of the following:
   - To enable ICS on-demand dialing, select the **Establish a dial-up connection whenever a computer on my network attempts to access the Internet** check box.
   - To disable ICS on-demand dialing, clear the **Establish a dial-up connection whenever a computer on my network attempts to access the Internet** check box.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- In order for ICS on-demand dialing to work correctly, the shared Internet connection must be available for all ICS clients, and the dial-up credentials must be saved for all users. For more information, see Related Topics.
- **Establish a dial-up connection whenever a computer on my network attempts to access the Internet** is selected by default. Unless you clear the check box, clients can activate the shared Internet connection from their computers by starting their Internet browsers or mail programs.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure client computers for ICS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure client computers for ICS**

1. Insert the Windows Server 2003, Standard Edition or Windows Server 2003, Enterprise Edition CD into the CD-ROM drive of your computer running Windows 98, Windows 98 Second Edition, or Windows Millennium Edition.

2. When the Welcome screen appears, click **Perform additional tasks**, and then click **Browse this CD**.

3. Double-click **Support**, and then double-click **Netsetup**.

4. Follow the instructions that appear on your screen.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

- Enable Internet Connection Sharing (ICS) on your ICS host computer before you attempt to configure client computers for your home or small office network. For more information, see Related Topics.

- You can run Netsetup.exe only on computers running Windows 98, Windows 98 Second Edition, or Windows Millennium Edition.

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage service definitions for ICF or ICS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manage service definitions for ICF or ICS**

1. Open Network Connections.
2. Right-click the shared Internet connection or the Internet connection on which Internet Connection Firewall (ICF) or Internet Connection Sharing (ICS) is enabled, and then click **Properties**.
3. On the **Advanced** tab, click **Settings**.
4. On the **Services** tab, do one of the following:
   - If you want to enable a service, under **Services** select the check box next to service that you want to enable, and then enter the required information.
   - If you want to add a service definition, click **Add**, and then enter the required information.
   - If you want to edit a service definition, click the service that you want to edit, click **Edit**, and then change the appropriate information.
   - If you want to delete a service definition, click the service that you want to delete, and then click **Delete**.

**Caution**

- This feature is intended for advanced users. When you add or edit a service definition, you create a port mapping that can expose your network to the Internet. For more information about service definitions, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Before you can add, edit, or delete service definitions, you must enable ICF, ICS, or both.
- You can obtain the correct configuration values for the TCP or UDP port number from the service's documentation or Web site.
- No two service definitions can use the same port numbers simultaneously.
- For service definitions that are preconfigured, you can edit only the field that is labeled **Name or IP address of the computer hosting this service on your network**.
- For service definitions that you have added, you can edit only the fields that are labeled **Name or IP address of the computer hosting this service on your network**, **External Port number for this service**, and **Internal Port number for this service**.
- You can delete only the service definitions that you have added. You cannot delete service definitions that are preconfigured.

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

- This topic applies only to product features available in the original release of Windows Server 2003.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

- Protocols and Access Methods
- Home and Small Office Networking Overview

# About Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**About Network Connections**

Network Connections provides connectivity between your computer and the Internet, a network, or another computer. With Network Connections, you can gain access to network resources and functionality, whether you are physically located at the location of the network or in a remote location. Connections are created, configured, stored, and monitored from within the Network Connections folder. For information about creating connections, see Make Network and Dial-up Connections. For a list of network connection icons, see Network connection icons.

Each connection in the Network Connections folder contains a set of features that you can use to create a link between your computer and another computer or network. Outgoing connections contact a remote access server by using a configured access method (LAN, modem, ISDN line, cable modem, DSL line, X.25 line, and so on) to establish a connection with a remote network. Conversely, an incoming connection enables a computer running Microsoft® Windows® XP or a stand-alone computer running a member of the Windows Server 2003 family to be contacted by other computers. This means your computer can operate as a remote access server. Whether you are connected locally (LAN), remotely (dial-up, VPN, and so on), or both, you can configure any connection so that it can perform any needed network function. For example, you can print to network printers, access network drives and files, browse other networks, or access the Internet.

Because all services and communication methods are configured within the connection, you do not need to use external management tools to configure connection settings. For example, the settings for a dial-up connection include features to be used before, during, and after connecting. These include the modem you use to dial, the type of password encryption you want to use upon connecting, and the network protocols you use after you connect. Connection status, which includes the duration and speed of a connection, is viewed from the connection itself; you do not need to use an external status tool. For information about configuring a connection, see Configure a connection to a remote network.

Logon and domain security, support for security hosts, data encryption, authentication, and callback provide secure network access for network and dial-up connections. For more information about security features, see Security Features of Network Connections.

# Hardware requirements for network and dial-up connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Hardware requirements for network and dial-up connections**
Depending on your configuration, you may need some or all of the following hardware:

- One or more network adapters with a Network Driver Interface Specification (NDIS) driver for LAN connectivity
- One or more compatible modems and an available COM port
- ISDN adapter (if you are using an ISDN line)
- DSL adapter
- X.25 adapter or PAD (if you are using X.25)
- Analog telephone line, ISDN line, X.25 line, or DSL line
- Smart card reader
- Wireless adapter

To verify the compatibility of all hardware, see the compatibility information at Support resources.

For information about configuring a connection, see Configure a connection to a remote network. For a list of network connection icons, see Network connection icons.

# Network connection types

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network connection types**

You can use Network Connections to create several types of connections between computers. The following table shows each type of connection you can create, the communication methods you can use to create each type of connection, and an example of each connection type. For more information, click the appropriate connection type in the table.

| Connection type | Communication method | Example |
|---|---|---|
| Dial-up connections | Modem, ISDN, X.25 | Connect to a private network or the Internet by using remote access |
| Virtual Private Network (VPN) Connections | VPN connections to organization networks over the Internet using PPTP or L2TP | Connect securely to a private network over the Internet |
| Connection Manager Administration Kit | See dial-up or VPN connections | Connect to a private network using a collection of dial-up or VPN settings provided by your network administrator in a self-installing profile |
| Using local area connections | Ethernet, token ring, cable modem, DSL, FDDI, IP over ATM, IrDA, wireless, WAN technologies (T1, Frame Relay), PPPoE | Connect directly to a local area network, to your cable modem, or to your DSL modem through an Ethernet adapter or a similar device |
| Using direct connections | Serial cabling, infrared link, DirectParallel cable | Connect a handheld computer running Microsoft® Windows® CE to a desktop computer so you can synchronize information |
| Incoming connections | See dial-up, VPN, or direct connections | Accept dial-up, VPN, or direct connections from other computers |

For a list of icons that appear in the Network Connections folder, see Network connection icons.

# Dial-up connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Dial-up connections**

A dial-up connection connects you to a network or the Internet by using a device that utilizes the telephone network. This device can be a modem that uses a standard phone line, an ISDN adapter with a high-speed ISDN line, DSL, broadband, a cable modem, or an X.25 network.

If you are a typical user, you may have one or two dial-up connections, perhaps to the Internet and to your corporate network.

You can create multiple dial-up connections by copying them in the Network Connections folder. You can then rename the connections and modify connection settings. By doing so, you can easily create different connections to accommodate multiple modems, dialing profiles, and different destinations.

For more information about creating dial-up connections, see Set up Dial-up Connections.

# Network connection icons

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network connection icons**

The following table displays the different icons that appear in the Network Connections folder.

| Icon | Description | Location |
|---|---|---|
| | The local area connection is active | Network Connections folder |
| | The local area connection is disabled | Network Connections folder |
| | The default remote access connection | Network Connections folder |
| | An incoming connection | Network Connections folder |
| | The media is disconnected | Network Connections folder |
| | The media is disconnected | Taskbar |
| | The driver is disabled | Network Connections folder |
| | The adapter in this connection has an invalid IP address | Network Connections folder |
| | The adapter in this connection has an invalid IP address | Taskbar |
| | A connection on which Internet Connection Sharing (ICS) has been enabled. | Network Connections folder |
| | A connection on which Internet Connection Firewall (ICF) has been enabled. | Network Connections folder |
| | A connection on which Network Bridge has been enabled. | Network Connections folder |

**Notes**

- This topic applies only to product features available in the original release of Windows Server 2003.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Protocols and Access Methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Protocols and access methods**
This section covers:

- Network communications
- TCP/IP
- IPX
- AppleTalk
- ISDN access
- Serial (RS-232) cable access
- DirectParallel cable access
- SLIP
- Point-to-Point Protocol (PPP)

**Note**

- The IPX/SPX protocol is not available on the Itanium-based versions of the Windows operating systems.

# Network communications

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network communications**
Network protocols, access methods, and server protocols help create a communications link between your computer and a network.

Whether information is transported from your computer to a server by using a direct serial cable, or across a secure VPN from your Internet service provider (ISP) to the corporate network, different combinations of access methods and protocols are used to send information. These access methods and protocols are listed as follows:

**Network protocols**

- TCP/IP
- IPX
- AppleTalk

**Access methods**

- Using phone lines and modems
- ISDN access
- Serial (RS-232) cable access
- DirectParallel cable access

**Server protocols**

- Point-to-Point Protocol (PPP)
- SLIP
- Layer Two Tunneling Protocol (L2TP)
- Point-to-Point Tunneling Protocol (PPTP)

The IPX/SPX protocol is not available on the Itanium-based versions of the Windows operating systems.

# TCP/IP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TCP/IP**
Transmission Control Protocol/Internet Protocol (TCP/IP) is the most popular protocol, and the basis for the Internet. Its routing capabilities provide maximum flexibility in an enterprise-wide network.

On a TCP/IP network, you must provide IP addresses to clients. Clients may also require a naming service or a method for name resolution. This section explains IP addressing and name resolution for Network Connections on TCP/IP networks. It also describes the FTP and Telnet tools that are provided by the Microsoft® Windows Server 2003 family.

**Assigning IP addresses to remote access connections**
Each remote computer that connects to a remote access server on a Windows TCP/IP network is provided an IP address by the server. This IP address is either automatically provided through the server by DHCP on the target network or selected from the static range that is assigned to the remote access server. For more information see Incoming connections and IP addresses.

If you use a specific IP address, the remote access server must be configured to permit users to request a specific address.

**Name resolution for network and dial-up connections**
In addition to requiring an IP address, network and dial-up connections for a NetBT gateway on a TCP/IP network may require a mechanism to resolve computer names to IP addresses. You can use any one of the following mechanisms for name resolution: DNS, WINS, broadcast name resolution, and the Hosts and Lmhosts files.

Incoming connections clients are assigned the same WINS and DNS servers that are assigned to the incoming connections computer. The TCP/IP settings of a network or dial-up connection can override these automatic assignments.

Incoming connections that do not have a DNS or WINS server rely completely on broadcast name resolution, which occurs by using broadcasts to locate network resources that match a computer name.

**Internet tools**
The Windows Server 2003 family provides File Transfer Protocol (FTP) and Telnet. FTP is a character-based utility that permits you to connect to FTP servers and transfer files. Telnet is a command-line application that lets you log on to remote computers and issue commands as if you were at the keyboard of the remote computer. Multiple variations of FTP, Telnet, and other services based on earlier Internet standards are also available on the Internet or commercially.

For information about configuring a connection, see Configure a connection to a remote network. For information about configuring TCP/IP, see Configure TCP/IP settings.

### Note

- FTP and Telnet tools run on top of TCP/IP networks.

# IPX

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IPX**
Internetwork Packet Exchange (IPX) is the protocol that is used on many Novell NetWare networks. This section explains how to integrate Network Connections into an IPX network.

**Support for NetWare and IPX**
Network Connections supports NetWare and IPX networks by including:

- NWLink IPX/SPX/NetBIOS Compatible Transport Protocol, also known as NWLink, which is the Microsoft® Windows Server 2003 family implementation of the IPX protocol.
- Client Service for NetWare client component, which provides access to NetWare shared file and printer resources.
- Point-to-Point Protocol (PPP) IPX Configuration Protocol (IPXCP), which supports IPX over PPP for dial-up, virtual private network (VPN), and incoming connections. PPP connections use IPXCP, as defined in RFC 1552, "The PPP Internetwork Packet Exchange Control Protocol (IPXCP)," to configure PPP connections for IPX.

For information about configuring a connection, see Configure a connection to a remote network. For information about configuring NWLink IPX/SPX/NetBIOS Compatible Transport Protocol, see Configure NWLink.

**Notes**

- The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.
- IPX routing is not supported in the Windows Server 2003 family.
- IPX cannot be configured for incoming or dial-up connections in the Windows Server 2003 family.

# AppleTalk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AppleTalk**

Networking on an Apple Macintosh computer is implemented through the AppleTalk protocol. Applications and processes can communicate across a single AppleTalk network or an AppleTalk internet, which is a number of interconnected AppleTalk networks. By using AppleTalk, applications and processes can transfer and exchange data and share resources, such as printers and file servers. AppleTalk remote access is supported by the AppleTalk Control Protocol (ATCP).

With ATCP, Macintosh clients can run the AppleTalk network protocol over the Point-to-Point Protocol (PPP). With ATCP support, a remote user can access a Web server over TCP/IP, print a document to an AppleTalk printer, and connect to a Macintosh file server (over TCP/IP or AppleTalk), all with the same dial-up connection over PPP.

For more information, see AppleTalk over PPP.

For information about configuring a connection, see Configure a connection to a remote network.

# ISDN access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ISDN access**

To enhance your network connection speed, you can use an Integrated Services Digital Network (ISDN) line. Whereas standard phone lines typically transmit at up to 56 kilobits per second (Kbps), ISDN lines can transmit at speeds of 64 or 128 Kbps.

An ISDN line must be installed by the phone company at both the server and at the remote site. ISDN also requires that you install an ISDN adapter on the server and your computer. Costs for ISDN equipment and lines may be higher than standard modems and phone lines. However, the speed of communication reduces the duration of the connection, possibly saving toll charges.

An ISDN line comes with two B channels that transmit data at 64 Kbps, and one D channel for signaling that transmits data at 16 Kbps. You can configure each B channel to operate as a port. With some ISDN drivers, you can aggregate the channels. This means you can statically assign a higher bandwidth by configuring both B channels to act as a single port. With this configuration, line speed increases to 128 Kbps. For information about configuring a connection to use ISDN, see Make a dial-up connection by using an ISDN line or Configure ISDN settings.

The Multilink feature performs channel aggregation for ISDN. Multilink combines multiple physical links into a logical bundle. This aggregate link increases the bandwidth of a connection. In addition, you can allocate multiple links dynamically, which means ISDN lines are used only as they are required. This eliminates excess bandwidth, representing a significant efficiency advantage to users. You can configure the conditions under which extra lines are dialed, and underused lines are disconnected, through Network Connections settings. For more information, see Configuring multiple device dialing.

# Serial (RS-232) cable access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Serial (RS-232) cable access**

Suppose you have two networks in the same location that are not physically connected. To use resources on both networks from one computer, you can use RS-232 cables and COM ports to create null modems. You connect an RS-232 cable from a COM port to a COM port on each remote access server. To the servers, the COM ports then appear to be modems. You can use server remote access, a part of the integrated Routing and Remote Access service, to create network access.

For information about creating a direct connection by using serial access, see Make a direct network connection.

# DirectParallel cable access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DirectParallel cable access**

The DirectParallel feature supports computer-to-computer connections by using standard and enhanced (ECP) parallel ports, which use Parallel Technologies' Basic or Fast parallel cables. For information about configuring a direct network connection to use a DirectParallel cable, see Make a direct network connection by using a DirectParallel cable. Direct cable connection cables are available from several sources. You can obtain DirectParallel cables from Parallel Technologies or from their local dealers. For more information, see To contact Parallel Technologies.

# SLIP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SLIP**
Serial Line Internet Protocol (SLIP) is an older remote access standard typically used by UNIX remote access servers. Network Connections supports SLIP for dial-up connections.

When you connect to a SLIP server, a **Windows Terminal** dialog box appears for an interactive logon session with the UNIX SLIP server. The UNIX logon overrides and prevents the remote access logon session from appearing. After a connection is established, remote network access becomes transparent to the user.

The RFCs supported in remote access are:

- RFC 1055, "A Nonstandard for Transmission of IP Datagrams Over Serial Lines: SLIP"
- RFC 1144, "Compressing TCP/IP Headers for Low-Speed Serial Links"

For information about configuring a network or dial-up connection, see Configure a connection to a remote network.

**Notes**

- Microsoft® Windows® XP does not support SLIP for incoming connections.
- You must use the TCP/IP protocol and a serial COM port to connect to a SLIP server.

# Point-to-Point Protocol (PPP)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Point-to-Point Protocol (PPP)**
The Point-to-Point Protocol (PPP) is a set of standard protocols that allow remote access software from different vendors to interoperate. A PPP-enabled connection can dial into remote networks through any industry-standard PPP server. PPP also permits a remote access server to receive calls from, and provide network access to, other vendors' remote access software that complies with the PPP standards.

The PPP standards also permit advanced features that are not available with older standards such as SLIP. PPP supports several authentication methods, as well as data compression and encryption. With most PPP implementations, you can automate the entire logon sequence.

PPP also supports multiple LAN protocols. You can use TCP/IP or IPX as your network protocol.

The IPX/SPX protocol is not available on the Itanium-based versions of the Windows operating systems.

PPP is the basis for the Point-to-Point Tunneling Protocol (PPTP) and Layer Two Tunneling Protocol (L2TP) protocols, which are used in secure virtual private network (VPN) connections.

PPP is the primary standard for most remote access computing.

This section covers:

- PPP operation and protocols
- Point-to-Point Protocol over Ethernet (PPPoE) Protocols

# PPP operation and protocols

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PPP operation and protocols**

Connections made using Point-to-Point Protocol (PPP) must adhere to standards established in PPP RFCs. For information on PPP RFCs, see "Introduction to TCP/IP" at the Microsoft Windows Resource Kits Web site. This topic gives an overview of PPP operations and the protocols used in a PPP connection. For information about how to configure PPP settings, see PPP Settings.

**PPP connection process**

After a physical or logical connection is made to a PPP-based remote access server, the following negotiations establish a PPP connection:

1. Negotiate the use of the link

   PPP uses Link Control Protocol (LCP) to negotiate link parameters such as the maximum PPP frame size, the use of Multilink, and the use of a specific PPP authentication protocol.

2. Authenticate the remote access computer

   The remote access client and the remote access server exchange messages according to the negotiated authentication protocol. If EAP is being used, the client and the server negotiate a specific EAP method, known as an EAP type, and then exchange the messages of that EAP type.

3. Use callback

   If callback for the dial-up connection is configured, the physical connection is terminated, and the remote access server calls the remote access client back.

4. Negotiate the use of network protocols

   This process involves using a series of network control protocols (NCPs) to configure the network protocols the remote access client uses. For example, the NCP for TCP/IP is Internet Protocol Control Protocol (IPCP). If the remote access client is configured to use TCP/IP, IPCP is used to assign an IP address to the client and to configure the client with the IP addresses of DNS and WINS servers.

The resulting connection remains active until the line is disconnected for any of the following reasons:

- The user or the administrator explicitly hangs up the line.
- The line is disconnected due to idle time-out.
- An unrecoverable link error occurs.

**Link Control Protocols**

Link Control Protocol (LCP) establishes and configures PPP framing. PPP framing defines how data is encapsulated before it is transmitted on the wide area network. The PPP standard framing format ensures that remote access software from any vendor can communicate and recognize data packets from any remote access software that adheres to the PPP standards.

PPP and the Microsoft® Windows Server 2003 family use variants of High-level Data Link Control (HDLC) framing for serial or ISDN connections.

**Authentication protocols**

Authentication protocols are negotiated immediately after link quality is determined and before the network layer is negotiated. For more information about available authentication protocols, see Authentication Protocols and Methods.

**Network control protocols**

Network control protocols establish and configure different network protocol settings for TCP/IP, IPX, and AppleTalk. The following table describes network control protocols used with a PPP connection.

The IPX/SPX protocol is not available on the Itanium-based versions of the Windows operating systems.

| Network control protocol | Description |
|---|---|
| Internet Protocol Control Protocol (IPCP) | IPCP is used to configure TCP/IP on the remote access client. Configuration parameters include an IP address and the IP addresses of DNS and WINS servers. |
| Internetwork Packet Exchange Control Protocol (IPXCP) | IPXCP is used to configure IPX on the remote access client. IPXCP is widely implemented by PPP vendors. Configuration parameters include the IPX network and node numbers. |
| AppleTalk Control Protocol (ATCP) | ATCP is used to configure AppleTalk on the remote access client. Configuration parameters include an AppleTalk address. |

**Note**

- The **PPP settings** dialog box includes the option **Negotiate multi-link for single-link connections**. This option enables separation of high and low-priority channels over a single link connection. If your remote access server supports this feature, you might notice improved audio quality. However, because this feature is incompatible with many remote access servers, you should leave it disabled unless instructed otherwise. For more information on PPP settings, see PPP Settings.

# Point-to-Point Protocol over Ethernet (PPPoE) Protocols

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Point-to-Point Protocol over Ethernet (PPPoE) Protocols**
Using Point-to-Point Protocol over Ethernet (PPPoE) and a broadband modem, LAN clients can gain individual authenticated access to high-speed data networks. By combining Ethernet and Point-to-Point Protocol (PPP), PPPoE provides an efficient way to create a separate connection to a remote server for each user. Access, billing, and choice of service are managed on a per-user basis, rather than a per-site basis. Clients can create both dial-up and dial-on-demand connections using PPPoE.

**PPPoE RFCs**
Requests for Comments (RFCs) are an evolving series of technical reports, proposals for protocols, and protocol standards used by the Internet community. PPPoE is defined in RFCs published by the Internet Engineering Task Force (IETF) and other working groups. The following is an example of a PPPoE RFC:

**RFC number** - 2516A

**Title** - Method for Transmitting PPP Over Ethernet (PPPoE)

**Obtaining RFCs**
You can obtain RFCs from the RFC Editor Web site. This Web site is currently maintained by members of the Information Sciences Institute (ISI) who publish a classified listing of all RFCs. RFCs are classified as one of the following: approved Internet standards, proposed Internet standards (circulated in draft form for review), Internet best practices, or For Your Information (FYI) documents.

### Notes

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.
- PPPoE is supported on clients running Microsoft® Windows® XP. All members of the Windows Server 2003 family can connect to and route PPPoE traffic. However, they cannot accept an incoming PPPoE connection.

For more information, see Make a broadband connection using Point-to-Point Protocol over Ethernet (PPPoE).

# Home and Small Office Networking Overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Home and small office networking overview**
With home and small office networking, even if you do not have the resources, time, or experience of a network administrator, you can build a small network in your home or small office. Home and small office networking is a group of features that limits hardware requirements and automates configurations for routing and private IP addressing. This reduces the work that is typically required to connect and configure a network. It also reduces the associated costs.

Home and small office networking provides many of the benefits of traditional networks and offers benefits that are uniquely suited for a home or small office network. With home and small office networking you can:

- Share one Internet connection with all of the computers on your network.
- Provide local private network services, such as name resolution and addressing, automatically.
- Share printers or other hardware devices, such as cameras and scanners, from any computer on your network.
- Share folders and files with other computers on your network.
- Use one computer to secure your entire network and protect your Internet connection.
- Easily establish network connections across two or more types of network media, such as IEEE 1394, Ethernet, wireless, and Home Phoneline Network adapters.

This section covers:

- Home and small office networking features
- Home and small office networking compared to Routing and Remote Access

# Home and small office networking features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Home and small office networking features**
Home and small office networking uses the following features to simplify the implementation and administration of small networks.

**Internet Connection Firewall (ICF) and Windows Firewall**
Home and small office networking offers computers that are directly connected to the Internet the added security of firewall protection. The firewall checks all communications that cross the connection between your network and the Internet and is selective about which responses from the Internet it allows. ICF and Windows Firewall protect only the computer on which they are enabled. However, if ICF or Windows Firewall are enabled on the Internet Connection Sharing (ICS) host computer, ICS clients that use the shared Internet connection for Internet connectivity are protected because they cannot be seen from outside your network. For this reason, you should always enable ICF or Windows Firewall on the ICS host computer. In addition, if there are clients on your network with direct Internet connections, or if you have a stand-alone computer that is connected to the Internet, then it is recommended that you enable ICF or Windows Firewall on those Internet connections as well.

For more information about ICF, see Internet Connection Firewall. For more information about Windows Firewall, see Help: Windows Firewall.

**Network Bridge**
Network Bridge removes the need for routing and bridging hardware in a home or small office network that consists of multiple LAN segments. With Network Bridge, multiple LAN segments become a single IP subnet, even if the LAN segments are of mixed network media types. Network Bridge automates the configuration and management of the address allocation, routing, and name resolution that is typically required in a network that consists of multiple LAN segments.

For more information see Network Bridge.

**Internet Connection Sharing (ICS)**
ICS allows you to provide Internet access for a home or small office network by using one common connection as the Internet gateway. The ICS host is the only computer that is directly attached to the Internet. Multiple ICS clients simultaneously use the common Internet connection and benefit from Internet services as if the clients were directly connected to the Internet service provider (ISP) (for more information, see Dial-up credentials). Security is enhanced when ICS is enabled because only the ICS host computer is visible to the Internet. The addresses of ICS clients are hidden from the Internet rendering ICS clients invisible to the Internet. In addition, ICS simplifies the configuration of small networks by providing local private network services, such as name resolution and addressing.

For more information about ICS, see Connecting to the Internet in a home or small office network.

**Note**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Home and small office networking compared to Routing and Remote Access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Home and small office networking compared to Routing and Remote Access**
Home and small office networking and the Routing and Remote Access service are both included in Microsoft® Windows® XP and the Windows Server 2003 family to provide the following networking capabilities:

- Network address translation (NAT)
- Packet filtering
- Dial-up access
- Virtual private network (VPN) access
- Automated IP addressing for network clients
- Name resolution
- Internet connections

Because home and small office networking features and Routing and Remote Access share common drivers, they cannot coexist, and you need to decide which to implement in order to meet the needs of your networking environment.

**Home and small office networking**
You can use home and small office networking features--Internet Connection Firewall (ICF), Windows Firewall, Network Bridge, and Internet Connection Sharing (ICS)--to simplify the configuration of your home or small office network. These features are intended for networks that consist of two to 10 computers when you want to:

- Protect computers that are connected to the Internet using an easily configured firewall. For more information, see Internet Connection Firewall.
- Connect LAN segments simply, by using the **Bridge Connections** menu command. For more information, see Network Bridge.
- Provide simultaneous Internet access for up to 10 computers using a single dial-up or high-speed Internet connection. For more information, see Connecting to the Internet in a home or small office network.
- Support up to 10 simultaneous dial-up or VPN connections to provide remote computers with access to network resources. For more information, see Incoming connections.

**Routing and Remote Access**
You can use Routing and Remote Access in combination with Internet Security and Acceleration (ISA) server to meet the needs of your small business with high security needs, your medium-sized private business, or your enterprise network that spans multiple subnets and supports up to 1,000 computers running Windows Server 2003, Standard Edition or up to 5,000 computers running Windows Server 2003, Enterprise Edition. Internet connectivity for branch offices is routed through the corporate routing and firewall infrastructure. Use Routing and Remote Access when you want to:

- Provide local and branch office computers with high-security Internet access.
- Connect branch offices with corporate intranets, and share resources as if all computers are connected to the same LAN.

- Protect network interfaces with static packet filters or dynamic packet filters.
- Support up to 1,000 simultaneous dial-up or VPN connections to provide remote computers with access to corporate network resources.

**Comparisons**

The following table summarizes the differences between the way that home and small office networking features (and incoming connections) and Routing and Remote Access (with ISA server) implement basic networking services.

| Service | Description | Home and small office networking features (and incoming connections) | Routing and Remote Access (with ISA server) |
|---|---|---|---|
| **NAT** | Hides internally managed IP addresses from external networks by translating private internal addresses to public external addresses. This reduces IP address registration costs by letting you use unregistered IP addresses internally, with translation to a small number of registered IP addresses externally. It also hides the internal network structure, reducing the risk of attacks against internal systems. | ICS | Routing and Remote Access NAT |
| **Dynamic packet filtering** | Provides protection from unsolicited traffic for the private network. Permits only traffic that is sent in response to an internal request. | ICF, Windows Firewall | Basic Firewall |
| **VPN and dial-up access** | Allows clients on a remote computer to connect to a private network and to access network resources as if the computer was physically attached to the network. | Incoming connections | Routing and Remote Access |
| **Address assignment** | Automates the assignment of client IP addresses on the private network in order to configure clients to allow client-access to network resources. | ICS DHCP allocator | Routing and Remote Access NAT, with a DHCP allocator or a DHCP server |
| **DNS name resolution** | Converts the names of computers and other network devices, such as printers, to IP addresses. | ICS DNS Proxy | NAT, with a DNS proxy or a DNS server |
| **Internet connections** | Provides a high-speed or dial-up connection for the computer that is connected to the Internet to use to publish its services to the private network. | Configured through Network Connections | Configured through Routing and Remote Access |

The following table summarizes which components, features, and connection types are best suited to provide networking services in a given networking scenario.

| Service | Scenario: Small office, non-domain network | Scenario: Small office, domain network | Scenario: Medium office network with NAT traversal | Scenario: Medium office network without NAT traversal | Scenario: Enterprise network | Scenario: Branch office network |
|---|---|---|---|---|---|---|
| **NAT** | ICS | ICS | Routing and Remote Access | Routing and Remote Access | Routing and Remote Access | Routing and Remote Access with ISA (on the corporate network) |

| | | | | | | |
|---|---|---|---|---|---|---|
| **Packet filtering** | ICF, Windows Firewall | ICF, Windows Firewall | Basic Firewall or ISA | Basic Firewall or ISA | ISA | ISA (on the corporate network) |
| **VPN/remote access** | Incoming connections | Incoming connections | Routing and Remote Access | Routing and Remote Access | Routing and Remote Access | Routing and Remote Access with ISA (on the corporate network) |
| **Address assignment** | ICS DHCP allocator | DHCP server | DHCP server | DHCP server | DHCP server | DHCP server |
| **Internet connection** | Dial-up, ISDN, broadband, DSL, or LAN | Dial-up, ISDN, broadband, DSL, or LAN (with ISA) | Any combination of T1 or T3, dial-up, ISDN, broadband, DSL, and LAN | Any combination of dial on demand (DoD) routing, T1 or T3, dial-up, ISDN, broadband, DSL, or LAN | Any combination of dial on demand (DoD) routing, T1 or T3, dial-up, ISDN, broadband, DSL, or LAN | Any combination of dial on demand (DoD) routing, T1 or T3, dial-up, ISDN, broadband, DSL, or LAN |
| **NAT traversal** | Not available | Not available | ISA | Does not apply | ISA | ISA (on the corporate network) |
| **DNS** | DNS proxy | DNS server | DNS server | DNS server | DNS server | DNS server |

**Notes**

- In the case of ICS with a DNS or DHCP server, ICS discovers the DHCP service or DNS service and, if present, disables the DNS proxy, DHCP allocator, or both.
- Because ICS, ICF, and Windows Firewall are not compatible with Routing and Remote Access, you cannot enable ICS or ICF if Routing and Remote Access is configured. Likewise, if ICS or ICF are enabled, they must first be disabled in order to configure Routing and Remote Access.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Understanding Network Connections

Updated: January 21, 2005

- Security Features of Network Connections
- Intermediary Devices

# Security Features of Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security features of Network Connections**

You can configure your dial-up, virtual private network (VPN), broadband, and direct connections to enforce various levels of password authentication and data encryption. Authentication methods range from unencrypted to custom, using Extensible Authentication Protocol (EAP). EAP provides an infrastructure to support a wide range of authentication methods, including smart cards, certificates, one-time passwords, and public keys. You can also specify the type of data encryption, depending on the level of password authentication (MS-CHAP, MS-CHAP v2, or EAP-TLS) that you select. Finally, you can configure callback options to increase dial-up security.

User accounts and domains provide security with encrypted authentication and encrypted data. For more information about security, see Security.

This section covers:

- Callback
- How security works at connection
- Group Policy for Network Connections
- Group Policy settings that prohibit home and small office networking on your domain
- Dial-up credentials
- Data Encryption and Encryption Methods
- Network Authentication

# Callback

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Callback**
The callback feature instructs the remote access server to disconnect after authentication and then to call you back. Callback provides cost advantages to you and security advantages to your network. By immediately hanging up and then dialing you back, callback reduces phone charges. Required callback enhances network security by ensuring that only users from specific locations can access the server. By dropping the call, and then calling back a moment later to the preassigned callback number, most impersonators can be thwarted.

If callback has been required by your administrator, the following steps occur when your call reaches the remote access server:

1. The server determines whether your user name and password are correct.

2. If they are correct, the server disconnects and then returns the call.

If your administrator has configured callback for your connection through the **Remote Access Preferences** menu option, the following steps occur when your call reaches the remote access server:

1. The server determines whether your user name and password are correct.

2. If they are correct, the **Callback** dialog box appears on your computer.

3. You then type the current callback number in the dialog box and wait for the server to disconnect and return the call.

   Optionally, you can press ESC to cancel the callback process and remain connected.

For more information about configuring your callback options, see Configure client callback options.

**Notes**

- Your callback options are determined by your system administrator. The administrator may deny the use of callback, allow user-defined callback, or require callback to a particular number. You can contact your system administrator to determine your callback options.

- If your computer is configured to accept incoming connections, you can enforce callback options on that computer. For more information, see Configure callback for incoming connections.

# How security works at connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How security works at connection**

The following steps describe what happens during a call to a remote access server:

1. The remote access client computer calls a remote access server.

2. Depending on the authentication methods that have been negotiated, one of the following happens:

   - If you are using PAP or SPAP:

     The client sends its user name and password to the server.

     The server checks the account credentials against the user database.

   - If you are using CHAP or MS-CHAP:

     The server sends a challenge to the client.

     The client sends an encrypted response to the server.

     The server checks the response against the user database.

   - If you are using MS-CHAP v2:

     The server sends a challenge to the client.

     The client sends an encrypted response and a challenge to the server.

     The server checks the encrypted response of the client against the user database and sends the client its own encrypted response.

     The client verifies the encrypted response of the server.

   - If you are using certificate-based authentication:

     The server sends its computer certificate to the client.

     If the client is configured for certificate-based authentication, the client validates the server certificate.

     The client sends its user certificate to the server.

     The server verifies that the user certificate is valid and has not been revoked.

3. If the connection attempt is both authenticated (the user credentials are valid, the user account is enabled and not locked out, and the connection is occurring within the allowed logon hours) and authorized (for incoming connections, the user account has remote access permission), the server accepts the remote access connection.

   If callback is enabled, the server calls your computer back and repeats steps 2 through 3.

**Notes**

- For the Routing and Remote Access service, authorization of the connection is determined by the dial-in properties of the

user account and remote access policies. Remote access policies are a set of conditions and connection settings that give network administrators more flexibility in granting remote access permissions and usage. If the settings of the connection do not match at least one of the remote access policies that apply to your connection, the connection attempt is rejected, regardless of the dial-in properties of the user account.

- Network Connections authentication methods control access to your network, not to resources on the network. Once you are connected to a network, resource access control is managed through access control lists (ACLs) in various ways: Local Users and Groups, Active Directory, Group Policy, file and printer sharing, and so on.

- Authentication methods are designed for remote computing environments where the computer that is dialing in does not have access to the network until credentials, such as user name and password, are validated.

- For information about configuring security options for your connections, such as identity authentication protocols and data encryption settings, see Secure Network or Dial-up Connections.

# Group Policy for Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy for Network Connections**
By using the Group Policy snap-in, an administrator can configure the desktop settings of many computers at once. Some Group Policy settings apply specifically to Network Connections, such as user access to connections and the ability to change the properties of connections. These settings can be found in the Administrative Templates of the Group Policy snap-in.

### Where?

- *Group_Policy_object_name*/Computer Configuration (or User Configuration)/Administrative Templates/Network/Network Connections

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- If you do not have write access to a Group Policy object, you cannot see the settings contained in that object.

For an overview of Group Policy, Group Policy objects, and administrative templates, see Group Policy overview. For more information on how to use Group Policy to define policy settings that are applied to computers or users, see Group Policy (pre-GPMC).

# Group Policy settings that prohibit home and small office networking on your domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy settings that prohibit home and small office networking on your domain**

Group Policy settings define the various components of the user's environment that a system administrator can manage. The following Group Policy settings are available to prohibit home and small office networking on your domain:

- **prohibit use of Internet Connection Sharing on your DNS domain network** determines whether computer users with administrator accounts can enable and configure Internet Connection Sharing (ICS) on network connections on your domain.

- **prohibit use of Internet Connection Firewall on your DNS domain network** determines whether computer users with administrator accounts can enable and configure Internet Connection Firewall (ICF) on network connections on your domain.

- **prohibit installation and configuration of Network Bridge on your DNS domain network** determines whether computer users with administrator accounts can enable Network Bridge on your domain.

**Group Policy for ICS**

ICS allows a user with an administrator account to provide Internet access for a home or small office network, using one common connection as the Internet gateway, and to provide local private network services, such as name resolution and addressing. The ICS host is the only computer that is directly connected to the Internet. Multiple ICS clients simultaneously use the common (shared) Internet connection. ICS is available only on computers that have two or more network connections. Users with administrator accounts enable ICS by accessing the **Advanced** tab on network connections. For more information about ICS, see Connecting to the Internet in a home or small office network.

If you do not want users on your domain to be able to enable or configure ICS, apply the **prohibit use of Internet Connection Sharing on your DNS domain network** Group Policy setting. When you apply the **prohibit use of Internet Connection Sharing on your DNS domain network** Group Policy setting, users with administrator accounts cannot enable or configure ICS because the **Advanced** tab on network connections becomes unavailable, and the related wizard options on computers running Windows XP Professional are blocked.

Computer users with user rights are prohibited from configuring ICS, regardless of this Group Policy setting.

**Group Policy for ICF**

ICF allows a user with an administrator account to activate a firewall to protect the public connection of a small network or a single computer that is connected to the Internet. ICF is enabled by default only on dial-up connections. Users with administrator accounts can enable ICF on other types of connections, such as LAN and wireless connections, by accessing the **Advanced** tab on network connections. For more information about ICF, see Internet Connection Firewall.

If you do not want users to be able to enable or configure ICF, apply the **prohibit use of Internet Connection Firewall on your DNS domain network** Group Policy setting. When you apply the **prohibit use of Internet Connection Firewall on your DNS domain network** Group Policy setting, users with administrator accounts cannot enable or configure ICF because the **Advanced** tab becomes unavailable, and the related wizard options on computers running Windows XP Professional are blocked.

Computer users with user rights are prohibited from configuring ICF, regardless of this Group Policy setting.

**Group Policy for Network Bridge**

Network Bridge automates the configuration that is required to route traffic between multi-segment networks comprised of a single type of media or mixed media. With Network Bridge, no configuration is required, and you do not need purchase additional hardware such as routers or bridges. The Network Bridge menu command **Bridge Connections** is available only when two or more network adapters are present. By default, Network Bridge is disabled, but users with administrator accounts can use **Bridge Connections** to enable Network Bridge. For more information about Network Bridge, see Network Bridge.

If you do not want users on your domain to be able to enable or configure Network Bridge, apply the **prohibit installation and configuration of Network Bridge on your DNS domain network** Group Policy setting. When you apply the **prohibit**

**installation and configuration of Network Bridge on your DNS domain network** Group Policy setting, users with administrator accounts cannot enable or configure Network Bridge because the **Bridge Connections** command is removed from the menu on network connection icons, and the related wizard options on computers running Windows XP Professional are blocked.

Computer users with user rights are prohibited from configuring Network Bridge, regardless of this Group Policy setting.

**Important**

The Group Policy settings for ICS and ICF are location-aware. A location-aware Group Policy setting applies only when a computer is connected to the domain that it was connected to when the setting was last refreshed. If a computer, such as a laptop computer, is connected to your domain, but the setting on the computer was last refreshed on another domain, then the Group Policy setting on your network do not apply to that computer.

For example, if ICS is enabled on a computer that is on your network, and then you apply the Group Policy setting for ICS, ICS continues to run as normal until you restart the computer or log off of the network and then log on again. The same is true if the Group Policy setting for ICS is set on your network, and then a computer on which ICS is enabled joins your network. In this case also, ICS continues to run as normal until you restart the new computer or log off of the network and then log on again. This example applies to ICF as well.

The Group Policy setting for Network Bridge works somewhat differently. If Network Bridge is enabled on a computer that is on your network, and then you apply the Group Policy setting for Network Bridge, or if the Group Policy setting for Network Bridge is set on your network, and then a computer on which Network Bridge is enabled joins your network, Network Bridge continues to exist in the Network Connections folder and to use system resources, but the functionality of Network Bridge changes. In these cases, Network Bridge continues to receive and send data over the network connections that are included in the bridge but, for security reasons, no longer forwards traffic from one network connection to another. This change is immediate; it does not require that you restart the computer or log off of the network and then log on again.

For an overview of Group Policy, see Group Policy (pre-GPMC).

**Note**

- This topic applies only to product features available in the original release of Windows Server 2003.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Dial-up credentials

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Dial-up credentials**

Credentials are required to successfully connect to the Internet using dial-up connections. Your credentials are the combination of your ISP account name and password. Your computer user profile identifies your account as either an administrator account or a user account. If you log on using user credentials, you will have two options for how your credentials are saved when you create a dial-up connection. If you log on with administrative credentials, you will have three options for how your credentials are saved when you create a dial-up connection. If you have account profiles with both administrator and user credentials, only the credentials for the account that you have logged on with will apply.

If you log on with user account credentials, you can create only dial-up connections for **My use only**. These connections will be successful only when you are logged on to the computer, and they will not be accessible to any other users. When creating user account dial-up connections, you can either save your credentials as **Me only** (for your use only) or not save your credentials. If you save your credentials as **Me only**, and you are logged on to the computer using the account you used when you created the connection, your credentials will be automatically supplied when using the connection. If you do not save your credentials, a dialog box will be provided for you to enter your credentials each time you are logged on to the computer using the account you used when creating the connection and you attempt to connect to the Internet.

If you log on with administrative credentials, you can create connections for either **Anyone's use** or **My use only**. If you create a connection for **My use only**, the connection options are the same as those created by anyone with a user account. Connections created for **Anyone's use** can be seen by any user who logs on to that computer, but connection success to the Internet is affected by how credentials were saved. When creating a connection for **Anyone's use**, you can save your credentials so that they will be supplied automatically for **Anyone who logs on to this computer** or **Me only**. You can also choose not to save your credentials.

If you save your credentials for **Anyone who logs on to this computer**, your saved credentials will automatically be supplied for any user who has logged on to the computer and attempts to connect to the Internet using that connection or on-demand dialing. If you save your credentials but do not make them available for **Anyone who logs on to this computer**, then your saved credentials will be automatically supplied only if you are logged on to the computer. Other users will see a dialog box that prompts them for your user name and password; they will be unable to connect to the Internet using this connection unless they can provide your credentials. If you do not save your credentials, a dialog box will appear and prompt you or any other user to enter your credentials before the connection to the Internet can be completed.

The following summarizes the experience of a user logging on with user credentials and experience of a user logging on with administrative credentials:

**Logging on with user credentials**

| Connection type created | Credential save options | Local computer access |
|---|---|---|
| • **My use only** | • **Me only**<br>• Not saved | This connection will work only when you are logged on with the account that you used when you created the connection. If you did not save your credentials, you will be prompted to supply them every time you use the connection. You cannot configure Internet Connection Sharing (ICS), Internet Connection Firewall (ICF), or Windows Firewall on this connection. If you want to enable ICS or configure ICF or Windows Firewall, you should log on with administrative credentials before you create the dial-up connection because only administrators can access the **Advanced** tab. If you want to enable ICS, ICF, or Windows Firewall on a dial-up connection that was created with user credentials, the user who created the connection must be promoted to an administrator. |

| ICS client Internet access through My use only ICS connections |
|---|

| |
|---|
| Users of ICS client computers can connect to the Internet through connections on the ICS host computer that are saved for **My use only** if:<br>• The user who created the connection saved credentials and is logged on to the ICS host computer.<br>• The user who created the connection did not save credentials but that user or another user can supply those credentials when prompted by the ICS host computer to do so. |

**Logging on with administrative credentials**

| Connection type created | Credential save options | Local computer access |
|---|---|---|
| • **My use only** | • **Me only**<br>• Not saved | This connection will work only when you are logged on with the account that you used when you created the connection. If you did not save your credentials, you will be prompted to supply them every time you use the connection. You cannot configure Internet Connection Sharing (ICS), Internet Connection Firewall (ICF), or Windows Firewall on this connection. If you want to enable ICS or configure ICF or Windows Firewall, you should log on with administrative credentials before you create the dial-up connection because only administrators can access the **Advanced** tab. If you want to enable ICS, ICF, or Windows Firewall on a dial-up connection that was created with user credentials, the user who created the connection must be promoted to an administrator. |
| • **Anyone's use** | • **Anyone who uses this computer**<br>• **Me only**<br>• Not saved | All users can see the Internet connection. If you saved your credentials for all users, any user who is logged on to the computer can connect to the Internet. If you saved your credentials as **Me only**, the connection is automatically completed only if you log on to the computer as the administrator who saved the credentials when you created the connection. If you did not save your credentials, when you or another user attempts to connect to the Internet, your credentials must be supplied when prompted in order to complete the connection. You can access the **Advanced** tab to enable ICS or configure ICF or Windows Firewall because you logged on as an administrator when you created the dial-up connection. |

| **ICS client Internet access through Anyone's use connections** |
|---|
| Users of ICS client computers can connect to the Internet through connections on the ICS host computer that are saved for **Anyone's use** only if:<br>• The administrator who created the connection saved credentials for use by anyone who uses the computer. (This attempt will succeed whether a user is logged on to the ICS host computer or the ICS client computer.)<br>• The administrator who created the connection saved credentials as **User only** and is now logged on to the ICS host computer with the same credentials.<br>• The administrator who created the connection did not save credentials, but a user can supply those credentials when prompted by the ICS host computer. |

You must enable on-demand dialing in order for programs to automatically initiate dial-up connections to your Internet service provider. For more information, see Enable ICS on-demand dialing.

You must enable ICS in order for computers on your network to share a common Internet connection. For more information, see Connecting to the Internet in a home or small office network.

**Notes**

- As a security measure, you should log on using user credentials rather than administrative credentials.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Data Encryption and Encryption Methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Data encryption and encryption methods**

This section covers:

- Data encryption
- Microsoft Point-to-Point Encryption (MPPE)
- Internet Protocol Security (IPSec) Encryption

# Data encryption

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Data encryption**

You can think of encryption as locking something valuable into a strong box with a key. Sensitive data is encrypted by using an encryption algorithm and a key, which renders it unreadable without the knowledge of the key. Data encryption keys are determined at connect time between the connecting computers. The use of data encryption can be initiated by your computer or by the server you are connecting to.

Network Connections supports two types of encryption:

- Microsoft MPPE, which uses RSA RC4 encryption.
- An implementation of Internet Protocol security (IPSec) that uses Data Encryption Standard (DES) encryption.

Both MPPE and IPSec support multiple levels of encryption, as shown in the following table.

| Encryption type | Level of encryption supported |
|---|---|
| MPPE Standard | 40-bit, 56-bit |
| MPPE Strong | 128-bit |
| IPSec DES | 56-bit |
| IPSec Triple DES | 3DES |

For more information, see the following:

- Microsoft Point-to-Point Encryption (MPPE)
- Internet Protocol Security (IPSec) Encryption

**Notes**

- Server controls are flexible and can be set to deny the use of encryption, require a specific encryption strength, or allow your computer to select an encryption strength. By default, most servers allow encryption and allow clients to select their encryption methods. This works for most computers. A system administrator sets encryption requirements. To determine your options, contact your system administrator.
- To enable MPPE-based data encryption for dial-up or virtual private network (VPN) connections, you must select the MS-CHAP, MS-CHAP v2, or EAP-TLS authentication methods. These authentication methods generate the keys used in the encryption process.
- Virtual Private Networks (VPNs) use encryption depending on the type of server they are connecting to. If the VPN connection is configured to connect to a PPTP server, then MPPE encryption is used. If the VPN is configured to connect to an L2TP server, then IPSec encryption methods are used. If the VPN is configured for an Automatic server type, which is the default selection, then L2TP, and its associated IPSec encryption, will be attempted first, then PPTP, and its associated MPPE encryption.

# Microsoft Point-to-Point Encryption (MPPE)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft Point-to-Point Encryption (MPPE)**
Microsoft Point-to-Point Encryption (MPPE) encrypts data in Point-to-Point Protocol (PPP)-based dial-up connections or Point-to-Point Tunneling Protocol (PPTP) virtual private network (VPN) connections. 128-bit key (strong), 56-bit key, and 40-bit key (standard) MPPE encryption schemes are supported. MPPE provides data security for the PPTP connection that is between the VPN client and the VPN server.

For more information about configuring connections, see Configure a connection to a remote network.

**Note**

- MPPE requires encryption keys as generated by Microsoft Challenge Handshake Authentication Protocol (MS-CHAP), Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAP v2), or Extensible Authentication Protocol-Transport Level Security (EAP-TLS) authentication process.

# Internet Protocol Security (IPSec) Encryption

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet Protocol security (IPSec)**
The long-term direction for secure networking, IPSec is a suite of cryptography-based protection services and security protocols. Because it requires no changes to applications or protocols, you can easily deploy IPSec for existing networks.

IPSec provides computer-level authentication, as well as data encryption, for VPN connections that use the L2TP protocol. IPSec is negotiated between your computer and an L2TP-based VPN server before an L2TP connection is established. This negotiation secures both passwords and data.

L2TP uses standard PPP-based authentication protocols, such as EAP, MS-CHAP, MS-CHAP v2, CHAP, SPAP, and PAP with IPSec.

Encryption is determined by the IPSec Security Association, or SA. A security association is a combination of a destination address, a security protocol, and a unique identification value, called a Security Parameters Index (SPI). The available encryptions include:

- Data Encryption Standard (DES), which uses a 56-bit key.
- Triple DES (3DES), which uses three 56-bit keys and is designed for high-security environments.

For more information about IPSec, see Internet Protocol Security (IPSec).

For more information about configuring connections, see Configure a connection to a remote network.

# Network Authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authentication**
This section covers:

- Authentication process
- Authentication Protocols and Methods

# Intermediary Devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Intermediary devices**
This section covers:

- Using an intermediary device
- Security hosts
- Writing scripts for intermediary devices

# Tunneling Protocols

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Tunneling protocols**
This section covers:

- Point-to-Point Tunneling Protocol (PPTP)
- Layer Two Tunneling Protocol (L2TP)

# Home and Small Office Networking

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Home and small office networking**
This section covers:

- Internet Connection Firewall
- Internet Connection Firewall security log
- Network Bridge
- Service definitions for Internet Connection Firewall and Internet Connection Sharing

**Note**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Using Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Network Connections**

Network Connections is automatically installed. This section covers:

- Monitoring network and dial-up connections
- Making Network Connections
- Using Home and Small Office Networking Features

# Administering Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administering Network Connections**

This section covers:

- Managing network connections from the command line
- Logging remote access connections
- Configuring Network and Dial-up Connections

# Network Connections Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
This section covers:

- Troubleshooting network and dial-up connections
- Error messages in Network Connections (Windows Server 2003)

# Installing and configuring Modems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Modems**
Modem support is provided by the TAPI Unimodem 5 Service Provider. It enables you to install and use almost any modem available today. Modems are used by programs such as HyperTerminal, Network Connections, and Fax, as well as by many products, including software required to gain access to Internet service providers.

- Before you begin using modems with this computer, see Checklist: Installing and configuring modems.
- To find features that have been moved in the Microsoft® Windows Server 2003 family, see New ways to do familiar modem tasks.
- For tips about using modems, see Modem best practices.
- For help with specific tasks, see Modems How To ....
- For general background information, see Modems Concepts.
- For problem-solving instructions, see Modems Troubleshooting.

# Checklist: Installing and configuring modems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Installing and configuring modems**

| Step | Reference |
|---|---|
| Review key concepts. | Modem overview; Understanding Modems; Dialing rules overview |
| Install modem hardware. | Installing a modem |
| Install the modem. | Install a modem; Install an unsupported modem |
| Configure the installed modem. | Configure an installed modem; Change How Modems Initialize and Connect; Change Modem Data and Hardware Settings |
| Set dialing properties for your location. | Dialing rules overview; Change dialing properties for a location |
| Connect using your modem. | Connecting using your modem |

# New ways to do familiar modem tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

The following table lists common tasks for configuring modems. The user interface for performing these tasks is different in this version of Windows from the way it was in Windows NT version 4.0.

| If you want to | In Windows NT 4.0 use | In this version of Windows use |
|---|---|---|
| Install a modem | **Modems** in Control Panel. | Open Phone and Modem Options. For more information, see Install a modem. |
| Configure a modem | **Modems** in Control Panel. | Open Phone and Modem Options. For more information, see Configure an installed modem. |
| Test or troubleshoot a modem | Terminal program, such as **Hyperterminal**. | Open Phone and Modem Options. For more information, see Test a modem. |

# Modem best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

The following list provides best practices for installing and using modems. Review this list before you use modems.

- **Turn on any external modems before you start Windows.**

  If an external Plug and Play modem is not turned on before you start Windows, Windows may not detect it correctly.

  For more information, see Troubleshooting modems.

- **If Windows does not support your modem make and model, check the manufacturer's Web site for the latest installation or** .inf **file.**

  The installation files, particularly for new modems, are often added or updated by manufacturers. If you cannot find your modem listed in Windows, look in the manufacturer's documentation to find if the modem has the same characteristics as another supported modem.

  Some legacy modems are not supported. For a list of supported modems, see Support resources.

  For more information, see Installing a modem.

- **Use the Phone and Modem Options diagnostics utility to test and troubleshoot a modem.**

  To see if the modem is responding to commands, in Control Panel, double-click **Phone and Modem Options**. In **Phone and Modem Options** click the **Modems** tab, right-click the modem that you are interested in, click **Properties**, and then click the **Diagnostics** tab. You can also configure logging and view logs at this location.

  For more information, see Modem diagnostics, Test a modem, Log and view modem commands.

- **Before you connect to another computer or online service provider, check the hardware settings for your modem.**

  The data connection parameters for two modems need to be identical for them to connect successfully. Refer to the documentation provided by your service provider for the correct settings. Typical settings are:

  - 8 data bits
  - None for parity
  - One stop bit

  Bulletin boards and most service providers use these settings. If these do not work, try seven data bits, even parity, and one stop bit. A few online service providers use these settings. Other settings are extremely rare.

  For more information, see Hardware settings.

- **When you install the same make and model of modem on multiple ports, first install it on one port, and then duplicate the installation for the remaining ports.**

  For more information, see Duplicate a modem installation on multiple ports.

- **To change the same setting for modems installed on multiple ports, first change the setting on one modem and then copy the change to the remaining modems.**

For more information, see Copy modem properties to modems on multiple ports.

- **Rarely, you may have to configure the COM port before installing a modem.**

  The COM port is automatically configured for most modems. The following exceptions may occur:

  - If you install an internal modem card that is not compatible with Plug and Play specifications, you may have to configure its built-in COM port by using **Add Hardware** in Control Panel before you can install the modem.

  - If you are using PCMCIA drivers, your computer will detect and configure the PCMCIA modem cards automatically when you first insert them. If the card is not detected, you might need to run **Add Hardware** in Control Panel to configure the card's built-in COM port. You then install the PCMCIA modem by using the **Phone and Modem Options** in Control Panel.

  For more information, see Install a modem, Troubleshooting network and dial-up connections.

- **If you create a direct connection to a computer, Windows CE device, or other device, make sure that the maximum port speed in the connection properties is set as high as supported by the device.**

  The initial maximum port speed for a direct connection created in the **Phone and Modem Options** in Control Panel is 19.2 Kbps. If the device on a connection supports higher data transmission speeds, you can increase the maximum port speed to that supported by the device. To find the correct speed, refer to the manufacturer's documentation provided with the device.

  For more information, see Change the maximum modem port speed, Optimizing data transfer speed.

# Modems How To ...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to ...**

- Install or Remove Modems
- Install and Configure Modems on Multiple Ports
- Test Modems
- Change How Modems Initialize and Connect
- Change Modem Data and Hardware Settings

# Install or Remove Modems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Install or remove modems**

- Install a modem
- Install an unsupported modem
- Configure an installed modem
- Change the COM port for a modem
- Remove a modem

# Install a modem

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install a modem**

1. Open Phone and Modem Options in Control Panel.
2. (Optional) If you are prompted for location information, enter dialing information for your location and click **OK**.
3. On the **Modems** tab, click **Add**.
4. Follow the instructions in the Install New Modem wizard.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- If the Install New Modem wizard doesn't detect your modem or you cannot find it listed, see Related Topics for instructions on installing an unsupported modem.
- If you are installing an external modem, if a cable is not provided, refer to the manufacturer's instructions for cabling requirements. Most common cables will work, but some cables do not have all the pins connected. Do not use the 9-to-25 pin converters that come with most mouse hardware, because some of them do not carry modem signals.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install an unsupported modem

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install an unsupported modem**

1. Open Phone and Modem Options in Control Panel.

   If you are prompted for location information, enter dialing information for your location and click **OK**.

2. On the **Modems** tab, click **Add**.

3. In the Install New Modem wizard, select the **Don't detect my modem; I will select it from a list** check box, and then click **Next**.

4. Do one of the following:

| If | Do this |
|---|---|
| A modem is listed that is a good match for your modem | On the list of modems, click the manufacturer and model that is the best match for your modem, and then click **Next**. |
| Your modem is not listed, and you have an installation disk or .inf file provided by the manufacturer | Click **Have Disk** and specify the location of the disk or .inf file. |

5. Follow the remaining instructions provided by the Install New Modem wizard.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

- If possible, get the latest installation disk or modem .inf file designed for your operating system from the manufacturer. This can usually be downloaded from the manufacturer's Web pages. If the installation files for your operating system are unavailable, you can try using an installation disk or .inf file for Windows 95, Windows 98, Windows NT, Windows 2000, Windows Millennium Edition, or Windows XP. It may work correctly in the Windows Server 2003 family as well.

- If no installation file is available for the modem, the manufacturer's instructions that came with the modem may specify a compatible modem. Otherwise, click **(Standard Modem Types)** in **Manufacturers**, and try choosing the standard modem with the speed matching your modem.

- If a cable is not provided with an external modem, refer to the manufacturer's instructions for cabling requirements. Most but not all off-the-shelf cables will work. Some cables do not have all the pins connected. Do not use the 9-to-25 pin converters that come with most mouse hardware, because some of them do not carry modem signals.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure an installed modem

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure an installed modem**

1. Open Phone and Modem Options in Control Panel.
2. On the **Modems** tab, click the modem you want to configure, and then click **Properties**.
3. Enter the changes you want:

| To | Do this |
|---|---|
| Change the speaker volume, maximum port speed, or wait for a dial tone before dialing. | Click the **Modem** tab. |
| View diagnostic information, including commands supported by your modem, or to view a log of modem activity. | Click the **Diagnostics** tab. |
| Add extra initialization commands. | Click the **Advanced** tab. |
| Change call preferences (manual dialing or disconnecting) or data connection preferences (port speed, data protocol, compression, or flow control). | Click the **Advanced** tab, and then click **Change Default Preferences**. |
| Change hardware settings (data bits, parity, stop bits, or modulation). | Click the **Advanced** tab, click **Change Default Preferences**, and then click the **Advanced** tab. |

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- Not all default configurations in the connection interface are secure. Ensure that you change settings appropriately.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Change the COM port for a modem

# Change the COM port for a modem

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the COM port for a modem**

1. Open Phone and Modem Options in Control Panel.
2. On the **Modems** tab, click the modem you want to configure, and then click **Properties**.
3. On the **Advanced** tab, click **Advanced Port Settings**.

   If this option is not displayed, the modem does not support changing the assigned COM port
4. In **Com Port Number**, click the port number you want to use.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- Do not change this setting unless it is required by your system configuration. The communications port is normally assigned correctly when you install a modem.
- The advanced COM port settings are available only for certain brands of modems. If you do not have one of these modems, to change the assigned COM port, you must reinstall the modem and choose the desired COM port.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install and Configure Modems on Multiple Ports

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Install and configure modems on multiple ports**

- Duplicate a modem installation on multiple ports
- Copy modem properties to modems on multiple ports

# Duplicate a modem installation on multiple ports

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To duplicate a modem installation on multiple ports**

1. Install the modem you want to duplicate on at least one port.

   See Related Topics if you have not done this already.

2. Open Phone and Modem Options in Control Panel.

3. On the **Modems** tab, right-click the modem you want to duplicate to other ports.

4. Click **Duplicate**.

5. Choose to duplicate the modem installation on all ports in the list or only on selected ports.

   - Click **All ports** to duplicate the modem installation on all ports shown on the list.

   - Click **Selected ports** and then select the ports to duplicate the modem installation only on selected ports.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

- Use this procedure to quickly duplicate a modem installation when you are installing the same make and model of modem on more than one port.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Log and view modem commands

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To log and view modem commands**

1. Open Phone and Modem Options in Control Panel.
2. On the **Modems** tab, click the modem whose commands you want to log.
3. Click **Properties**, then click the **Diagnostics** tab.
4. In **Logging**, select the **Append to Log** check box if you are working on a computer running Windows XP or **Record a Log** check box if you are working on a computer running a member of the Windows Server 2003 family.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- Click **View Log** to display the log file. This file identifies the modem and displays information about how it is functioning.
- Commands sent to the modem are captured in the file:

  *systemroot*\System32\ModemLog_*Model*.txt.

  The path is usually C:\Windows\System32\. *Model* is the name of the modem as it appears in the list of installed modems on the **Modems** tab of **Phone and Modem Options**.
- In Windows XP, logging is always turned on, and the log is overwritten at the beginning of every session unless you select the **Append to Log** check box. In the Windows Server 2003 family, logging is turned off unless you select the **Record a Log** check box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change How Modems Initialize and Connect

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Change how modems initialize and connect**

- Specify initialization commands
- Select a country/region
- Wait for dial tone before dialing
- Adjust modem speaker volume
- Specify disconnect times

# Specify initialization commands

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify initialization commands**

1. Open Phone and Modem Options in Control Panel.
2. On the **Modems** tab, click the modem that you want to configure.
3. Click **Properties**, then click the **Advanced** tab.
4. In **Extra initialization commands**, type the commands that should be sent to the modem when it is initialized.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- Type the commands exactly as they should be sent, with no extra spaces or characters. The AT prefix is unnecessary.
- The commands you enter here are sent after the standard initialization commands for the selected modem. This enables you to change the modem behavior or configuration as required by your communication software or to communicate with a service provider. For more information about the commands recognized by your modem, refer to the manufacturer's documentation or Web site.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Select a country/region

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To select a country/region**

1. Open Phone and Modem Options in Control Panel.
2. On the **Modems** tab, click the modem that you want to configure.
3. Click **Properties**, and then click the **Advanced** tab.
4. In **Country/Region Select**, click the country/region from which you are dialing.

## Notes

- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- You might not be able to configure your modem to accommodate the telephone networks of different countries/regions. If you should be able to configure your modem for different countries/regions but **Country/Region Select** does not appear, contact your modem manufacturer for an update.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Wait for dial tone before dialing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To wait for dial tone before dialing**

1. Open Phone and Modem Options in Control Panel.
2. On the **Modems** tab, click the modem that you want to configure, then click **Properties**.
3. On the **Modem** tab, select the **Wait for dial tone before dialing** check box.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- If you clear the **Wait for dial tone before dialing** check box, your modem will dial without waiting for a dial tone. This may be necessary if a phone line does not provide a standard dial tone.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Adjust modem speaker volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To adjust modem speaker volume**

1. Open Phone and Modem Options in Control Panel.
2. On the **Modems** tab, click the modem that you want to configure, then click **Properties**.
3. On the **Modem** tab, under **Speaker volume**, move the slider to the left or right to adjust the volume.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- Some modems do not support this functionality.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify disconnect times

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify disconnect times**

1. Open Phone and Modem Options in Control Panel.
2. On the **Modems** tab, click the modem that you want to configure, then click **Properties**.
3. Click the **Advanced** tab, then click **Change Default Preferences**.
4. On the **General** tab, under **Call preferences**:

| To | Do this |
|---|---|
| Automatically disconnect when a connection is not used for a specified time. | Select the **Disconnect a call if idle for more than** check box, and then type the number of minutes the modem should wait before disconnecting. |
| Change the time allowed to make a new connection. | Type the number of seconds in **Cancel the call if not connected within**. |

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- Note that these are the default settings. If these parameters are specified by a program, the program's settings take precedence.
- If you are using a network connection, the disconnect time is determined by the redialing options for the network connection rather than by the setting in the modem's properties. See Related Topics for the procedure to configure a connection.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

- Designate hardware or software compression

# Change the maximum modem port speed

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the maximum modem port speed**

1. Open Phone and Modem Options in Control Panel.
2. On the **Modems** tab, click the modem that you want to configure, then click **Properties**.
3. On the **Modem** tab, in the **Maximum Port Speed** list, click the speed for the modem.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- This value is usually set correctly when the modem is installed.
- This speed represents the maximum speed programs are allowed to transmit data to the modem and is normally faster than the modem speed. For example, this is usually set to 57,600 bps for a 33.6 Kbps (V.34) modem.
- Changing this setting also sets the current speed for the modem. To set a different value for the current speed, see Related Topics for the procedure to change the data connection preferences.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modem overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Modem overview**

Telephone lines that are used in a conventional phone system are designed to transmit human speech with analog signals. Analog signals vary continuously, like waves, along their length. Computers store and process data in digital format and communicate both internally and with each other in binary digits.

When two computers communicate with each other over a conventional phone line, a modem translates the binary information from the computer at the sending end to an analog signal that can pass over the phone line. At the receiving end, another modem translates the analog signal back to binary information that can be used by the computer. The conversion from binary to analog information is called *modulation* and the conversion back from analog to binary is called *demodulation*. The word *modem*, short for modulator/demodulator, is the name for the device that performs these conversions.

Both standard modems and fax machines perform this conversion. When you communicate over analog telephone lines, you use standard modems. There are also ISDN and cable modems that provide digital communication. They enable computers to transmit digital information directly without the conversion over special lines. The most recent developments with the fastest transmissions are broadband technologies such as cable or DSL (Digital Subscriber Line) that transmit over cable or phone lines as waves similar to radio or television.

The speed at which modems transmit data is called the *throughput*. This is measured in bits per second (bps).

The conversion between digital and analog data is governed by proprietary and international standards, called *modem protocols*. Improving protocols have allowed faster data throughput rates. Besides using the available bandwidth more effectively, protocols have incorporated data compression to speed the throughput and error control for greater reliability. The protocols for modems operating at 56 kilobits per second (Kbps) are now designed to support data that is received from an Internet service provider that is connected to a digital line but that sends data with the standard digital-to-analog conversion.

The Microsoft® Windows Server 2003 family supports many different modems. If you are looking for a new modem that is compatible with Windows, see the compatibility information in Support resources. Microsoft has tested these modems with Network Connections. If you have a modem that is not on this list, it may still work perfectly well with Windows, especially if the manufacturer provides an installation disk or .inf file for Windows. Some modems are compatible with a supported modem and may be installed by choosing the supported information. Check the documentation provided with the modem for details. You may also find installation files or other useful information at the manufacturer's Web site.

# Understanding Modems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding modems**

This section presents concepts related to modem use:

- Data transfer speed
- Data compression
- Flow control
- Hardware settings

# Data transfer speed

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Data transfer speed**

When you initiate a dial-up connection, there are three separate components that determine the speed of the connection:

- The *local interface speed* is the speed of the connection between your computer and your modem, also called the DTE rate.
- The *connection speed* is the speed at which data is transmitted between modems over the communication lines, also called the DCE rate.
- The *remote interface speed* is the speed at which data is transmitted between the receiving modem and computer.

The actual speed at which data is transmitted between computers depends on all three rates. When you buy a modem, the manufacturer normally specifies the maximum connection speed. The maximum port speed that can be set in **Phone and Modem Options** represents the maximum local interface speed that communications programs can use to send data to the modem. The remote interface speed may also limit transmission speeds. For example, an online service provider must support the same 56 Kbps protocol used by your modem for you to receive high speed transmissions with a 56 Kbps modem. (See Attaining fast speeds with a 56 Kbps modem.)

Most high-speed modems today fix their local interface speed at a given value instead of changing it according to the connection speed. The local interface speed is then normally higher than the actual transmission of data over the phone line. For example, a V.34 modem that supports 33.6 Kbps may have its maximum port speed set for 115.2 Kbps.

This difference, called speed buffering, allows a modem to seem faster than the actual connection speed. Using this, a modem can compress the data and send it in fewer bits. Since there are fewer bits, it takes less time to transmit than the uncompressed data. The V.34 modem may then obtain throughput rates of 33.6 Kbps even though the line is carrying fewer actual bits than that.

# Data compression

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Data compression**
Data compression enables information to be transmitted beyond the actual connection speed. Data, particularly text and graphics, usually contain repeated sequences of identical information. Data compression works by replacing many characters of repeated information with a few characters and transmitting only one copy of repeated sequences of data.

Common methods for compressing data include MNP 3, MNP 4, MNP 5, and V.42bis.

The effectiveness of compression varies, depending on the data. Text and graphics may often be compressed considerably. Compression for data that is already compressed may be less efficient because the modem is trying to compress data that is already compressed. V.42bis handles compressed data better than the other protocols.

For any error correction or data compression protocol to work, modems on both ends of the connection must support the protocol. Once two modems are connected, they automatically negotiate to determine the best mutual protocol. For example, if V.42bis fails, the backup is MNP 5, and if it fails, the backup is "no compression."

To achieve maximum rates when transferring data, hardware flow control is required, and the maximum port speed must be set for two to four times the rated speed of the modem. This is usually configured correctly when you install a modem. If you know which type of compression is supported by your modem, you can calculate this value by multiplying the modem speed by the ratio shown above. For example, for a 14.4 kilobit per second (Kbps) modem with V.42bis compression, you would perform the following calculation.

14.4 Kbps x 4 = 57.6 Kbps

This value is the maximum rate that data may be transferred by the modem. The actual throughput depends on the data.

**Software data compression**
Communication software, such as Network Connections, may support data compression. For example, using a 56 Kbps V.90 modem, you can enable software compression, and experience an average throughput of 44 Kbps. Tests show that software compression can result in higher data transfer rates than hardware compression.

If you use software compression, you may want to check the settings. For best results with software compression, you can check your modem's properties for the following:

- Enable modem error correction by setting **Data Protocol** to **Standard EC** or **Forced EC**.
- Disable hardware compression by setting **Compression** to **Disabled**.
- Enable the software compression provided by your communication software.

See Change data connection preferences to change this setting for a modem.

# Flow control

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Flow control**
There are six different links involved in a connection: transmitting computer to transmitting modem, transmitting modem to receiving modem, receiving modem to computer, and the reverse of all three links. They can all have different data transmission rates. When the receiving modem is temporarily unable to accept the data, it needs a way to tell the transmitting modem to slow down or wait for it. Flow control is the method by which a modem controls the rate at which other modems send data to it.

If flow control is improperly configured, it may be impossible to connect to a remote system, the transfer rate may be considerably slowed, or the connection may be disrupted. If you see many errors and retransmittal of data when downloading files, check both the modem and the communication program settings for flow control. Flow control settings for both the communication program and the modem must be the same. Many communication programs set these automatically based on the modem, but some must be configured separately.

**Hardware flow control**
Hardware flow (RTS/CTS) control depends on the modem to control the flow of data. This should be used with all high-speed modems or modems that compress data.

**Software flow control**
Software flow (also called XON/XOFF or CTRL+S/CTRL+Q) control uses data characters to indicate that the data flow should start or stop. This enables a modem to send a control character to signal another modem to stop transmitting while it catches up.

Software flow control is slower and usually less desirable than hardware flow control. Software flow control is used only for transmitting text. It cannot be used for binary file transfer because binary data may contain the special flow control characters.

See Change data connection preferences to set hardware or software flow control for a modem.

# Hardware settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Hardware settings**
The connection preferences for a modem provide hardware settings that determine how data is sent and reassembled by modems. To change hardware settings, see Change hardware settings.

**Data bits**
Data bits are the number of bits in a word. Most systems now use eight bits to represent a single data character (extended ASCII). In rare instances, some older systems still use seven bits.

**Parity**
Parity controls how modems check for errors. Line noise can insert extra bits into data being transmitted over a phone line. In older modulation types, parity checked for these errors. With parity checking, the transmitting modem adds a *parity bit* to the data packet in order to make the number of 1 bits in the packet odd or even. The receiving modem adds up the number of 1 bits that is received and accepts or rejects the packet depending on whether the sum agrees with the parity bit.

Several settings for parity are available:

| Set this | To do this |
|---|---|
| Even | Set the parity bit to 0 or 1 to make the number of 1 bits even. |
| Odd | Set the parity bit to 0 or 1 to make the number of 1 bits odd. |
| None | Send no parity bit. |
| Mark | Set the parity bit always to 1. |
| Space | Set the parity bit always to 0. |

Most modem connections now use more reliable and sophisticated methods of error checking, so this is usually set to None.

**Stop bits**
Stop bits frame data packets in asynchronous communication. These tell the receiving modem that a byte has been sent. Modern asynchronous protocols never require more than one stop bit.

**Modulation**
In the hardware settings, modulation is the protocol that a modem uses to translate digital information to the audio tones transmitted over a standard telephone line. Both computers must be using the same type of modulation to exchange information successfully.

You can switch the modulation type to be compatible with the modem signals for the computer to which you are trying to connect. Most modems fall into the standard category, but if you are having trouble connecting, try switching to a nonstandard modulation type.

# Using Modems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using modems**

This section contains information you can use to install and configure modems:

- Installing a modem
- Setting hardware connections
- Optimizing data transfer speed
- Attaining fast speeds with a 56 Kbps modem
- Modem diagnostics
- Connecting using your modem

# Installing a modem

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Installing a modem**
To install the modem hardware on your computer, refer to the manufacturer's documentation. Generally, the following instructions apply:

- If you have an internal modem with jumpers, set the jumpers for Plug and Play for the Windows Server 2003 family or, if that option is unavailable, for Windows 95, Windows 98, Windows NT, Windows 2000, or Windows Millennium Edition.
- Install an internal modem in an empty slot. Attach an external serial modem to an unused COM port.
- If you have an external modem, ensure that it is attached to the computer, plugged into the power source, and turned on before you turn on the computer and start Windows.
- Ensure that your modem is properly connected to the phone line and to your computer.

Most modems manufactured now are compatible with Plug and Play and installed automatically after they are connected to the computer. However, older modems and external serial modems may not be detected. If your modem is not installed automatically, then use **Phone and Modem Options** in **Control Panel** to install it manually. To install a modem, see Install a modem. To choose the modem type manually, see Install an unsupported modem.

# Setting hardware connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting hardware connections**
A modem has to be connected to the telephone system and to a power source.

**Telephone connections**
Both internal and external modems use a modular phone cord, called an RJ-11 coupler. Usually, a new modem includes the coupler. If you have an older, four-pronged jack, you may also need an adapter to connect to your phone line.

If your office has digital, PBX or multiline phones, you cannot connect a modem directly to the phone system. You need to either install a standard line or install a device that connects your modem to one of these systems. See your computer or telephone supplier for specialized solutions.

**Power connections**
Internal modems are powered directly by the computer. External modems usually come with a power adapter, but are sometimes powered by the computer. Most portable modems for portable computers use batteries, although they often come with an adapter too. Some are powered directly from the computer. Modems use different sizes and styles of adapters, so if you lose the adapter, you need to get a new one from the modem or computer manufacturer. Refer to the manufacturer's documentation for additional information about the power requirements of your computer.

**Cabling Connections**
External serial modems connect to the computer with a serial cable, also called an RS-232 cable. If a cable is not provided with your modem, make sure you get one that fits both your computer's serial port and the modem's port.

# Optimizing data transfer speed

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Optimizing data transfer speed**

The speed settings for a modem are usually set correctly during installation. There are two different speeds set in **Phone and Modem Options**: **Maximum Port Speed** in the general modem properties and **Port Speed** in the default preferences. Both of these specify the speed at which communication programs send data to the modem, not the speed at which data is transferred between your modem and the remote modem.

The **Maximum Port Speed** specifies the maximum speed programs can transmit data to a modem. Most programs set their own speed, so this limits the speed at which they can send data. The **Port Speed** is the current port speed for the modem. These two settings are usually the same, although there are some instances in which one should be changed. Do not change these speeds just to match the rated speed for your modem.

**Measuring your modem speed**

There are several separate components that determine the speed of the connection. When a program or hardware reports transmission speeds, note carefully what is being reported. For example, if a V.34 modem rated at 33.6 kilobits per second (Kbps) reports a connection speed of 38.4 Kbps or higher, it is reporting the port speed that data is transmitted from the computer to the modem rather than the rate that data is transmitted between modems.

For practical purposes, you want to know the *throughput speed*, the speed that your data is transferred between your communications program and the program on another computer. Communications programs usually report the throughput speed and normally provide the speed in either bits per second (bps) or characters per second (cps). For serial communications, speed in bits per second can be divided by 10 to approximate the characters transmitted per second.

Check the throughput speed after you start communicating with the remote computer. The initial throughput speed is not necessarily a good estimate of the transmission speed. Modems often shift speed up or slow down after the initial connection. Modems can fall forward or fall back depending on the quality of the connection and other factors.

**Transmission speeds for direct serial connections**

When you create a direct serial connection to another computer or device, you may need to adjust the maximum port speed for the connection. The initial setting for a direct serial connection is 19.2 Kbps. For a Windows CE device or other device that supports higher data transmission speeds, change the maximum port speed to the correct speed. Refer to the manufacturer's instructions for the transmission speed supported by the device.

For additional information, see Attaining fast speeds with a 56 Kbps modem, Data transfer speed, Improving modem throughput speeds, Change data connection preferences, or Change the maximum modem port speed.

# Attaining fast speeds with a 56 Kbps modem

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Attaining fast speeds with a 56 Kbps modem**

A modem connection must fulfill three requirements to support a 56 kilobits per second (Kbps) (also called V.90) connection.

- The host server must use a digital connection to the network. Your Internet service provider can tell you if they support 56 Kbps service.
- Both ends of the connection must support the same protocol, the V.90 standard or either of its predecessors, K56flex, or 3COM/USR X2. For example, if your Internet service provider has a V.90 device, your modem must support the V.90 protocol.
- There can only be one analog connection between your modem and the host computer. The phone line in most homes is an analog line.

If a connection does not meet these requirements, a modem falls back to the fastest protocol that works for the connection. For example, a 56 Kbps V.90 modem falls back to the 33.6 Kbps V.34 protocol if it cannot make a V.90 connection. Even if your connection fulfills these requirements, other factors may reduce either the transmission speed or the number of times that you successfully obtain the highest speed connection. For example, old lines or lines that are subject to interference may reduce transmission speeds. Maximum throughput speeds of 26 Kbps are not unusual in these cases.

Devices to improve the quality of your telephone service may also hamper 56 Kbps V.90 modem connections. Load coils found on long wire lengths to improve voice quality do not usually prevent V.90 connections, but can reduce the speed. Digital pads, which balance the volume of voice calls, usually do not prevent V.90 connections, but they can reduce the speed. Analog pads prevent V.90 connections, because they convert the digital data to analog to balance the volume and then back to digital. This inserts an additional analog section in the line.

In practice, the 56 Kbps speed supported by the V.90 and other protocols is unattainable. U.S. government regulations to safeguard public phone systems right now limit transmission speeds to 53 Kbps. Phone-line noise and other limitations of phone systems usually keep average transmissions in the 40 to 50 Kbps range.

For more information, see Data transfer speed, Improving modem throughput speeds, and Optimizing data transfer speed.

# Modem diagnostics

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Modem diagnostics**

You can verify that your modem is working properly by using the diagnostics that are available through the **Phone and Modem Options** icon in Control Panel. (For more information on this procedure, see Test a modem.)

When you query a modem, Windows tries the following commands and displays the results.

| Command | Response |
|---|---|
| ATQ0V1E0 | Initializes the query. |
| AT+GMM | Model identification (ITU V.250 recommendation is not supported by all modems). |
| AT+FCLASS=? | Fax classes supported by the modem, if any. |
| AT#CLS=? | Shows whether the modem supports the Rockwell voice command set. |
| ATI*n* | Displays manufacturer's information for *n* = 1 through 7. This provides information such as the port speed, the result of a checksum test, and the model information. Check the manufacturer's documentation for the expected results. |
| AT+GCI? | Displays the current selected country/region. |
| AT+GCI=? | Displays all countries/regions supported by this modem. |

You can also record a log of commands as they are sent to the modem by communication programs or the operating system. For more information, see Log and view modem commands.

# Connecting using your modem

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connecting using your modem**

The following uses of a modem are supported:

| To | See |
|---|---|
| Make a phone connection to another computer. | HyperTerminal |
| Make a direct connection another computer. | Using direct connections |
| Log onto a network or connect to another computer. | About Network Connections |

**Notes**

- You can also install communications programs provided by other manufacturers. They can provide added or different functionality or serve a specific purpose, such as connecting to an online service.
- Because connection settings are not cleared after a call is completed, connection details (including the phone number) can be misused by malicious users.

# Modems Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**

- Troubleshooting modems
- Improving modem throughput speeds
- Information about specific modems

# Troubleshooting modems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting modems**
What problem are you having?

- The modem diagnostics indicate that an external serial modem is not receiving commands.
- The modem cable is good, but the modem still does not receive commands.
- The modem is installed correctly but the diagnostics indicate that it is not responding correctly.
- According to the modem diagnostics, the modem works but you still cannot make a connection.
- You cannot connect or are having problems connecting to another computer or an online service provider.
- Your PCMCIA modem card was not detected automatically when you inserted it.
- An RS-232 serial device is functioning poorly or not at all.
- A connection in Network Connections reports that a port is in use or not configured for remote access.

**The modem diagnostics indicate that an external serial modem is not receiving commands.**
**Cause:** If the modem diagnostics indicate that the modem is not receiving commands, the modem cabling may be faulty.

**Solution:** Try connecting the modem with a new cable.

**The modem cable is good, but the modem still does not receive commands.**
**Cause:** The modem is installed incorrectly.

**Solution:** Check the modem's documentation to make sure that you installed it correctly.

**The modem is installed correctly but the diagnostics indicate that it is not responding correctly.**
**Cause:** The incorrect model and make were specified during installation in Windows or an obsolete installation (.inf) file was used to install the modem.

**Solution:** Check the modem documentation for the correct model and make or a compatible model and make, and reinstall the modem. You can check with the manufacturer to see if there are more recent installation files available for installing the modem.

**According to the modem diagnostics, the modem works but you still cannot make a connection.**
**Cause:** The modem is connected incorrectly to the phone line or there is a problem with the phone line.

**Solution:** Check the connection to the phone line. If the modem is connected correctly, have a telephone professional check your phone line.

**You cannot connect or are having problems connecting to another computer or an online service provider.**
**Cause:** The data connection parameters (see Hardware settings) for the two modems are not the same. Data connection parameters for two modems need to be identical for them to connect successfully.

**Solution:** Check the hardware settings for both computers. Typical settings are eight data bits, None for parity, one stop bit.

If you are connecting to an online service provider, refer to the documentation provided by your service provider for the correct settings. These are typically eight data bits, None for parity, one stop bit. Bulletin boards and most service providers use these settings. If these do not work, try seven data bits, even parity, and one stop bit. A few online service providers use these settings. Other settings are extremely rare.

**Your PCMCIA modem card was not detected automatically when you inserted it.**
**Cause:** The card's built-in COM port is not configured.

**Solution:** Use Add Hardware in Control Panel to configure the card's built-in COM port. You can then install the PCMCIA modem by using the Phone and Modem Options in Control Panel. (See Install a modem.)

**An RS-232 serial device is functioning poorly or not at all.**
**Cause:** Some RS-232 serial devices now support speeds faster than the 115.2 Kbps currently supported by the standard serial ports installed on most computers. (For example, some serial devices support 230 Kbps.)

**Solution:** If the **Port speed** in the connection preferences is faster than 115.2 Kbps, then try reducing the speed to 115.2 Kbps. You can leave the **Maximum Port Speed** in the modem properties at the higher setting. If the serial port on your computer supports speeds faster than 115.2 Kbps, then set the **Port speed** to whichever is slower, the serial port speed or the device speed.

**A connection in Network Connections reports that a port is in use or not configured for remote access.**
**Cause:** There are several possible causes:

- When you started Windows, a Plug and Play modem was not connected or it was turned off, so it was not detected correctly.
- The port is in use by another program, such as Fax.
- The connection may not have been updated to reflect changes in communications equipment, such as new serial ports or modems.

**Solution:** Use one of the following solutions:

- If the modem was disconnected or turned off, reconnect or turn on your modem, and then either restart Windows or use Device Manager to scan for new hardware.
- If the communications port is already in use by another connection, hang up the connection, or modify the connection to use a different port.
- If you have changed your hardware (such as a new serial port or modem), you must reconfigure the connection.

**See also:** Configure a connection to a remote network; Reinstall a Plug and Play device

**Notes**

- To diagnose and correct modem problems with the interactive modem troubleshooter, see List of troubleshooters and click **Modem**. For modem diagnostics, see Test a modem. Refer to the modem manufacturer's documentation or customer service representative for the correct modem commands and responses.
- It is usually a good idea to note changes to modem settings and switches as you make them. This enables you to return the modem to its previous state, if necessary.
- If you have modem problems, you may want to report them to the modem manufacturer or your supplier. In your report, include your modem log, which records information about your attempts to connect to other systems. For information about creating a modem log, see Log and view modem commands.

# Improving modem throughput speeds

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Improving modem throughput speeds**

If you have a 33.6 kilobits per second (Kbps) (V.34 protocol) modem and consistently connect at 26 Kbps or higher, or you have a 56 Kbps (V.90, K56flex, or X2 protocols) modem and consistently receive data from your Internet service provider or online provider at 40,000 bps or higher, there is not much you can do to go faster. Higher speeds are not possible with most phone circuits. The rated speeds are only possible with a near-perfect connection.

If you consistently connect at slower speeds (24 Kbps or less for a 33.6 Kbps modem or less than 40 Kbps for a 56 Kbps modem), you can try the following:

- Check that the correct manufacturer and model are listed for your modem in Phone and Modem Options. If your modem is not listed correctly, try following the steps in Install an unsupported modem to install the correct modem.
- Check if the manufacturer has a new installation disk or .inf file available. Files can often be downloaded from a manufacturer's Web site or bulletin board.
- For a 33.6 Kbps modem, make sure the **Maximum Port Speed** is set at 38,400 bps or higher (57,600 is recommended). For a 56 Kbps modem make sure it is set at 115,200 bps. See Change the maximum modem port speed for instructions.
- Make sure the modem is operating at the correct temperature. Most modems operate better if they do not get too hot or too cold. Do not block air flow by placing things on top, under, or around your modem or computer.
- Try connecting to numbers that you know support a given speed. This lets you know whether the problem is at your end or the other end.
- Make sure a local number is actually a local call. Many online service providers forward local calls to a distant location to provide local calling service. This works well at 14,400 bps, but can degrade the signal and limit higher speeds.
- If your phone line has a surge protector, you can try using your modem without it. Note, however, that doing so eliminates the protection provided to your equipment by the surge protector.
- Have an expert check the telephone wiring between the telephone company connection and your computer. Faulty wiring, soldered connections, long connecting cables, inferior equipment (phones, fax machines, or even other modems) can all degrade the signal. To distinguish between wiring and line problems, check the voice quality, both while the local wiring is connected and on the telephone company line while it is disconnected from the local wiring. Many phone companies now connect their service with a modular plug, which consumers can disconnect to perform this check.

Telephone companies normally do not guarantee data throughput speeds. When you ask your telephone company to fix a noisy line, you may be told you need a data line or *conditioned circuit*. This is usually an expensive solution. Modems can perform well on a good quality voice circuit. Ideally you want your system tested with a sophisticated line tester (a "bit error rate tester" or "data test set") rather than the regular line tester. You can also ask the company to switch you to a different cable pair from the central office. Sometimes, people solve the problem by ordering a different phone number.

For additional information, see Attaining fast speeds with a 56 Kbps modem, Data transfer speed, and Optimizing data transfer speed

# Information about specific modems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Information about specific modems**
This section gives additional information about specific modems that are supported by Network Connections. For a list of supported modems, see Support resources.

**Characteristics of specific modems**
Modems supported by Network Connections do not necessarily work in all modes with other modems on the list of compatible modems.

For example, some V.32bis modems do not work with port speeds of 14,400 bps although they communicate at a modem-to-modem speed of 14,400 bps. If your V.32bis modem does not work at an initial speed of 14,400 bps, you should change the speed to 19,200 bps. For information about changing initial modem speed, see Configure a modem for a dial-up connection for a dial-up connection.

**Internal modems**
Certain internal modems cannot be automatically detected. You must install the modem manually through Control Panel.

**Callback**
Modems supported as server modems may not support callback when used as client modems.

# Wireless Networking

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Wireless networking**
Wireless technology makes it possible for you to use a wide range of devices to access data from anywhere in the world. Wireless networks reduce or eliminate the high cost of laying expensive fiber and cabling and provide backup functionality for wired networks. To ensure that wireless networks and devices are compatible, cost-effective, and secure, organizations and special interest groups are working to develop standards for wireless communications.

The Microsoft® Windows Server 2003 family provides support for infrared communication and for 802.11 wireless networks. In Windows Server 2003, Standard Edition, support is provided for infrared communication. 802.11 wireless networking is supported in all versions of the Windows Server 2003 family.

- For help with specific tasks, see Wireless Networking How To....
- For general background information, see Wireless Networking Concepts.
- For problem-solving instructions, see Windows Server 2003 Wireless Troubleshooting.

**Note**

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition supports infrared networking.

# Wireless Networking How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Access Active Directory-based wireless network policies
- Define Active Directory-based Wireless Network Policies
- Define Wireless Network Policies on a Client Computer
- Use Resultant Set of Policy (RSoP) to View Wireless Network Policy Assignments
- Monitor Wireless Network Activity
- Manage Infrared Communication

# Access Active Directory-based wireless network policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To access Active Directory-based wireless network policies**

1. Open Active Directory Users and Computers.

2. In the console tree, right-click the domain or organizational unit for which you want to set Group Policy.

   **Where?**

   - Active Directory Users and Computers [*DomainControllerName.DomainName*]/*Domain*/*OrganizationalUnit*/*ChildOrganizationalUnit*...

3. Click **Properties**, and then click the **Group Policy** tab.

4. Click **Edit** to open the Group Policy object that you want to edit. Or, click **New** to create a new Group Policy object, and then click **Edit**.

5. In the Group Policy console tree, click **Wireless Network (IEEE 802.11) Policies**.

   **Where?**

   - *PolicyName* [*ComputerName*] Policy/Computer Configuration/Windows Settings/Security Settings/Wireless Network (IEEE 802.11) Policies

## Notes

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have permission to edit Group Policy objects (for information, see Related Topics). As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- In **Wireless Network (IEEE 802.11) Policies**, you can add, edit, or remove wireless network policies, define preferred wireless networks, and define 802.1X authentication. For more information, see Related Topics.

- You can define only one wireless network policy for a domain or an organizational unit. If a wireless network policy already exists, the option to create a new wireless network policy will not be available.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define Active Directory-based Wireless Network Policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Define Active Directory-based wireless network policies**

- Add, edit, or remove Active Directory-based wireless network policies
- Define preferred wireless networks in Group Policy
- Define 802.1X authentication for wireless networks in Group Policy

# Add, edit, or remove Active Directory-based wireless network policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add, edit, or remove Active Directory-based wireless network policies**

1. In **Wireless Network (IEEE 802.11) Policies**, choose whether to add a new policy or edit or remove an existing one:

   - To add a new policy, click **Wireless Network (IEEE 802.11) Policies**. Next, on the **Action** menu, click **Create Wireless Network Policy**. Follow the instructions in the Wireless Network Policy Wizard until the **Properties** dialog box for your new policy appears.
   - To edit an existing policy, right-click the policy that you want to edit, and then click **Properties**.
   - To remove an existing policy, right-click the policy that you want to delete, and then click **Delete**.

2. If you are adding or editing a policy, in **Properties**, click the **General** tab, and then do any of the following:

   - To name the policy or change the existing name of the policy, type a unique name in **Name**.
   - To provide a description of the wireless network policy, such as which groups or domains it affects, type a description in **Description**.
   - To specify how often Active Directory is polled for updates, type a value in **Check for policy changes every***number***minutes**.
   - To specify the type of wireless network that clients can access, click a network type in the **Networks to access** list.
   - To allow clients to use Windows to configure their wireless network settings, select the **Use Windows to configure wireless network settings for clients** check box. This check box is selected by default. For information about this option, see Notes.

     Or, to prevent clients from using Windows to configure their wireless network settings, clear the **Use Windows to configure wireless network settings for clients** check box.
   - To allow clients to automatically connect to available networks that do not appear on the **Preferred Networks** tab, select the **Automatically connect to non-preferred networks** check box.

     Or, to ensure that clients connect only to networks that appear on the **Preferred Networks** tab, clear the **Automatically connect to non-preferred networks** check box.

3. If you are adding or editing a policy, click the **Preferred Networks** tab, and do any of the following:

   - To change the order in which connection attempts to preferred wireless networks are made, click the wireless network that you want to move to a new position on the list, and then click **Move Up** or **Move Down**.
   - To specify a new preferred wireless network, click **Add**, and then configure the settings as needed. For more information, see Related Topics.
   - To change the settings for a preferred wireless network, click the wireless network for which you want to change

settings, click **Edit**, and then change the settings as needed. For more information, see Related Topics.

- To remove a wireless network from the list of preferred networks, under **Networks**, click the wireless network that you want to remove, and then click **Remove**.

### Important

- It is highly recommended that you use 802.1X authentication whenever you connect to an 802.11 wireless network. 802.1X is an IEEE standard that enhances security and deployment by providing support for centralized user identification, authentication, dynamic key management, and accounting. For information about how to define 802.1X authentication settings in Group Policy, see Related Topics.

- For enhanced security, in Windows XP Service Pack 1 and in the Windows Server 2003 family, 802.1X authentication is available only for access point (infrastructure) networks that require the use of a network key (WEP). WEP provides data confidentiality by encrypting the data that is sent between wireless clients and wireless access points. For additional information about security for wireless networks, see Related Topics.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have permission to edit Group Policy objects (for more information, see Related Topics). As a security best practice, consider using Run asto perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open **Wireless Network (IEEE 802.11) Policies**, you must access Active Directory-based wireless network policies. For more information, see Related Topics.

- When you allow clients to use Windows to configure their wireless network settings, they can connect to the wireless networks that you specify, and they are notified when new wireless networks are available. After the client selects a wireless network, the Windows Configuration service automatically configures the wireless network adapter to match the settings of that network, and a network connection attempt is made. For more information, see Related Topics.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define preferred wireless networks in Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To define preferred wireless networks in Group Policy**

1. In **Wireless Network (IEEE 802.11) Policies**, double-click the wireless network policy that you want to configure.
2. On the **Preferred Networks** tab, choose whether to add a new preferred wireless network or edit or remove an existing one:
   - To add a new preferred wireless network, click **Add**.
   - To edit an existing preferred wireless network, click **Edit**.
   - To remove an existing preferred wireless network, click **Remove**.
3. If you are adding or editing a preferred wireless network, in **Properties**, click the **Network Properties** tab, and then do any of the following:
   - To name the preferred wireless network or to change the existing name, type a unique name in Name.
   - To provide a description of the preferred wireless network, such as the type of network, whether a network key is required, and whether IEEE 802.1X authentication is enabled, type a description in **Description**.
   - If a network key is required to connect to the preferred wireless network, do the following:

     To specify that a network key is used for authentication to the wireless network, from the drop-down list in **Network authentication**, select one of the following:

     - **Shared**
     - **WPA**
     - **WPA-PSK**

     If you do not select this check box, open system authentication is used. For more information, see Notes.

| |
|---|
| To specify that a network key is used to encrypt the data that is sent over the network, from the drop-down list in **Data encryption**, select one of the following:<br><br>For Shared, select one of the following:<br><br>• **Disabled**<br><br>• **WEP**<br><br>For WPA, select one of the following:<br><br>• **WEP**<br><br>• **TKIP**<br><br>• **AES**<br><br>For WPA-PSK, select one of the following:<br><br>• **WEP**<br><br>• **TKIP**<br><br>• **AES**<br><br>**Note**<br><br>By default, **Data encryption, WEP** is selected. |
| To specify that a network key is automatically provided for clients (for example, if you are using 802.1X for dynamic key distribution), select the **The key is provided automatically** check box. |

- If the preferred wireless network connection that you are configuring is to a computer-to-computer (ad hoc) network, select the **This is a computer-to-computer (ad hoc) network; wireless access points are not used** check box.

4. To specify that 802.1X authentication is used for the preferred wireless network connection, click the **IEEE 802.1x** tab, and then configure settings as needed. For more information, see Related Topics.

**Important**

- It is highly recommended that you use 802.1X authentication whenever you connect to an 802.11 wireless network. 802.1X is an IEEE standard that enhances security and deployment by providing support for centralized user identification, authentication, dynamic key management, and accounting. For information about how to define 802.1X authentication settings in Group Policy, see Related Topics.

**Important**

- For enhanced security, in Windows XP Service Pack 1 and in the Windows Server 2003 family, 802.1X authentication is available only for access point (infrastructure) networks that require the use of a network key (WEP). WEP provides data confidentiality by encrypting the data that is sent between wireless clients and wireless access points. For additional information about security for wireless networks, see Related Topics.

**Important**

- For enhanced security and connectivity, do not select the **Network authentication (Shared mode)** check box. When this check box is selected, shared key authentication is used, rather than open system authentication. Shared key authentication is less secure than open system authentication because it requires the exchange of a secret key that is

shared by all wireless access points and clients and therefore is more vulnerable to known-text attacks. In addition, if you select this check box for a wireless network that has multiple wireless access points, clients will lose network connectivity when they travel from one wireless access point to a new wireless access point.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have permission to edit Group Policy objects (for more information, see Related Topics). As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open **Wireless Network (IEEE 802.11) Policies**, you must access Active Directory-based wireless network policies. For more information, see Related Topics.

- WPA includes two modes: one using 802.1X and RADIUS authentication, which is simply known as WPA, and another, simpler scheme for SOHO environments using a pre-shared key (known as WPA-PSK). For environments with a RADIUS infrastructure, WPA supports EAP and RADIUS.

- Although WPA support is now mandatory for all Wi-Fi certified hardware, existing network equipment that is not WPA-compliant must be upgraded to support WPA.

- Support for Wireless Policy Group Policy controlled settings is not available in Windows Server operating systems before Windows Server 2003 with Service Pack 1 (SP1). There is no way to script WLAN settings for Windows XP without Windows Server 2003 SP1.

- If the **Network authentication (Shared mode)** check box is not selected (that is, if open system authentication is used), no authentication is provided. Open system authentication only performs identity verification.

### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define 802.1X authentication for wireless networks in Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To define 802.1X authentication for wireless networks in Group Policy**

1. In **Wireless Network (IEEE 802.11) Policies**, double-click the wireless network policy for which you want to configure 802.1X authentication.

2. On the **Preferred Networks** tab, under **Networks**, choose whether to configure 802.1X authentication for an existing wireless network or for a new wireless network:

   - To configure 802.1X authentication for an existing wireless network, click the wireless network for which you want to configure 802.1X authentication, and then click **Edit**.

   - To configure 802.1X authentication for a new wireless network, click **Add**.

3. On the **IEEE 802.1x** tab, do one of the following:

   - To enable IEEE 802.1X authentication for this wireless network, select the **Enable network access control using IEEE 802.1x** check box. This check box is selected by default.

   - To disable IEEE 802.1X authentication for this wireless network, clear the **Enable network access control using IEEE 802.1x** check box.

4. In **EAPOL-Start message**, specify whether to transmit Extensible Authentication Protocol over LAN (EAPOL)-Start message packets and, if so, how to transmit them.

5. In **Parameters (seconds)**, specify EAPOL-Start message packet parameters.

6. In **EAP type**, click the EAP type to be used with this wireless network.

7. If you select **Smart Card or other certificate** in **EAP type**, click **Settings** and, in **Smart Card or other Certificate Properties**, do the following:

   - To allow wireless clients to use the certificate that resides on their smart card for authentication, click **Use my smart card**.

   - To allow wireless clients to use the certificate that resides in the certificate store on their computer for authentication, click **Use a certificate on this computer**, and then specify whether to use simple certificate selection.

   - To verify that the server certificate presented to client computers is still valid, select the **Validate server certificate** check box, click the **Connect to these servers** check box, specify the server or servers to which client computers will automatically connect, and then specify the trusted root certification authorities.

   - To view detailed information about the selected root certification authority, click **View Certificate**.

   - To allow users to specify a different user name when the user name in their smart card or certificate is not the same as the user name in the domain to which they are logging on, select the **Use a different user name for the**

**connection** check box.

8. If you select **Protected EAP (PEAP)** in **EAP type**, click **Settings**, and then do the following:

   To verify that the server certificate presented to client computers is still valid, select the **Validate server certificate** check box, click the **Connect to these servers** check box, specify the server or servers to which client computers will automatically connect, and then specify the trusted root certification authorities.

   In **Select Authentication Method**, click the authentication method that clients are to use within PEAP, and then click **Configure**.

   - If you selected **Secured password (EAP-MSCHAP v2)**, in **EAP MSCHAPv2 Properties**, specify whether to use the user name and password (and domain, if applicable) that users on client computers type in the Windows logon screen for authentication, and then click **OK**.

   - If you selected **Smart Card or other certificate**, in **Smart Card or other Certificate Properties**, configure the settings as needed by following the instructions in step 7, and then click **OK**.

   To enable fast reconnect for wireless clients, select the **Enable Fast Reconnect** check box. For more information about PEAP fast reconnect, see Notes.

9. On the **IEEE 802.1x** tab, do the following:

   To specify that client computers attempt authentication to the network if user information or computer information is not available, select the **Authenticate as guest when user or computer information is unavailable** check box.

   To specify that client computers attempt authentication to the network if a user is not logged on, select the **Authenticate as computer when computer information is available** check box, and in **Computer authentication**, click an option to specify how the computer should attempt authentication. For information about each of the options that you can select for **Computer authentication**, see Notes.

**Important**

- It is highly recommended that you use 802.1X authentication whenever you connect to an 802.11 wireless network. 802.1X is an IEEE standard that enhances security and deployment by providing support for centralized user identification, authentication, dynamic key management, and accounting.

- For enhanced security, in Windows XP Service Pack 1 and in the Windows Server 2003 family, 802.1X authentication is available only for access point (infrastructure) networks that require the use of a network key (WEP). WEP provides data confidentiality by encrypting the data that is sent between wireless clients and wireless access points. For additional information about security for wireless networks, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have permission to edit Group Policy objects (for more information, see Related Topics). As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open **Wireless Network (IEEE 802.11) Policies**, you must access Active Directory-based wireless network policies. For more information, see Related Topics.

- To define 802.1X authentication, you must select an existing preferred wireless network, or you must define a new preferred wireless network. For information about how to define preferred wireless networks, see Related Topics.

- PEAP fast reconnect allows roaming users to maintain continuous wireless network connectivity when traveling between different wireless access points on the same network, as long as each wireless access point is configured as a client of the same IAS (RADIUS) server. In addition, both the wireless client and the RADIUS server must have fast reconnect enabled.

- If you select the **Authenticate as computer when computer information is available** check box, you can select one of the following options:

    - **With user authentication**. When this option is selected, when users are not logged on to the computer, authentication is performed using the computer credentials. After a user logs on to the computer, authentication is maintained using the computer credentials. If a user travels to a new wireless access point, authentication is performed using the user credentials.

    - **With user re-authentication (recommended)**. When this option is selected, when users are not logged on to the computer, authentication is performed using the computer credentials. After a user logs on to the computer, authentication is performed using the user credentials. When a user logs off of the computer, authentication is performed using the computer credentials.

    - **Computer only.** When this option is selected, authentication is always performed using the computer credentials. User authentication is never performed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define Wireless Network Policies on a Client Computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Define wireless network policies on a client computer**

- Use Windows to configure wireless network settings on a client computer
- Add, edit, or remove wireless network connections on a client computer
- Define a wireless network connection on a client computer
- Define 802.1X authentication for wireless networks on a client computer
- Connect to an available wireless network

# Use Windows to configure wireless network settings on a client computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To use Windows to configure wireless network settings on a client computer

1. Right-click the wireless network connection icon in the notification area, and then click **View Available Wireless Networks**. For more information, see Notes.

2. Under **Related Tasks**, click **Change the order of preferred networks**.

3. On the **Wireless Networks** tab, do one of the following:

    - To use Windows to configure wireless network settings on your computer, select the **Use Windows to configure my wireless network settings** check box. This check box is selected by default. For information about this option, see Notes.

    - If you do not want to use Windows to configure wireless network settings on your computer, clear the **Use Windows to configure my wireless network settings** check box.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- tok:wirelessicon

- When an error is detected that might limit or prevent a connection to a wireless network, the wireless warning icon is displayed in the notification area.

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

- When you select the **Use Windows to configure my wireless network settings** check box, you enable the Wireless Configuration service. When the Wireless Configuration service is enabled, you can connect to an existing wireless network, change wireless network connection settings, configure a new wireless network connection, and manage preferred wireless networks. You will be notified when new wireless networks are available. After you select a wireless network, your wireless network adapter will be automatically configured to match the settings of that network, and a network connection attempt will be made.

- The **Wireless Networks** tab appears only if you are using a wireless network adapter that supports the Wireless Configuration service. If you are unsure whether your wireless network adapter supports the Wireless Configuration service, contact the wireless network adapter manufacturer.

- For more information about configuring wireless network settings, including information about the Wireless Configuration service, see Related Topics.

- If you are using non-Microsoft wireless networking software to configure wireless network settings, clear the **Use Windows to configure my wireless network settings** check box.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add, edit, or remove wireless network connections on a client computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add, edit, or remove wireless network connections on a client computer**

1. Right-click the wireless network connection icon in the notification area, and then click **View Available Wireless Networks**. For more information, see Notes.

2. To add, modify, change the preferred order of, or remove wireless networks, under **Related Tasks**, click **Change the order of preferred networks**, and on the **Wireless Networks** tab, do any of the following:

| To | Do this |
|---|---|
| Remove a preferred wireless network | Under **Preferred networks**, click the wireless network that you want to remove from the list, and then click **Remove**. |
| Add a new wireless network | Select the **Use Windows to configure my network settings** check box. Under **Preferred networks**, click **Add**. |
| Automatically connect to available networks that do not appear in the **Preferred networks** list | Under **Preferred networks**, click **Advanced**, and then select the **Automatically connect to non-preferred networks** check box. |
| Modify settings for an existing wireless network | Select the **Use Windows to configure my network settings** check box. Under **Preferred networks**, click the wireless network connection that you want to modify, and then click **Properties**. |
| Change the order in which connection attempts to preferred networks are made | Under **Preferred networks**, click the wireless network that you want to move to a new position in the list, and then click **Move up** or **Move down** until the wireless network is at the desired position. |

3. If you are adding or modifying a wireless network, click the **Association** tab, configure wireless network settings as needed, and then click **OK**. For more information, see Related Topics.

4. To define 802.1X authentication for the wireless network connection, click the **Authentication** tab, configure the settings as needed, and then click **OK**. For more information, see Related Topics.

5. On the **Wireless networks** tab, under **Available networks**, click on **View Wireless Networks**, and then do any of the following:

| To | Do this |
|---|---|
| Update the list of available wireless networks that are within range of your computer | Under **Network Tasks**, click **Refresh network list**. |

| | |
|---|---|
| Connect to a wireless network after configuring network settings on the **Wireless Networks** tab | Under **Choose a wireless network**, click the network to which you want to connect, and then click **Connect**.<br><br>**Important**<br><br>If a network does not broadcast its network name, it does not appear under **Choose a wireless network**. To connect to an access point (infrastructure) network that you know is available but that does not appear under **Available network**, follow the instructions in the previous table for adding a new wireless network. |

**Important**

- It is highly recommended that you use 802.1X authentication whenever you connect to an 802.11 wireless network. 802.1X is an IEEE standard that enhances security and deployment by providing support for centralized user identification, authentication, dynamic key management, and accounting. For more information, see Related Topics.

- For enhanced security, in Windows XP Service Pack 1 and in the Windows Server 2003 family, 802.1X authentication is available only for access point (infrastructure) networks that require the use of a network key (WEP). WEP provides data confidentiality by encrypting the data that is sent between wireless clients and wireless access points. For additional information about security for wireless networks, see Related Topics.

- If you attempt to connect to a computer-to-computer network or an access point network that does not require the use of a network key, the settings in the **Authentication** tab are not available, and you cannot configure 802.1X authentication for the connection.

**Notes**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- tok:wirelessicon

- When an error is detected that might limit or prevent a connection to a wireless network, the wireless warning icon is displayed in the notification area.

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

- The **Wireless Networks** tab appears only if you are using a wireless network adapter that supports the Wireless Configuration service. If you are unsure whether your wireless network adapter supports the Wireless Configuration service, contact the wireless network adapter manufacturer. For more information about automatic wireless network configuration, see Related Topics.

- If you are unable to connect to an existing wireless network, and the name of the network that you want to connect to appears under the **Preferred networks** list, click the network, and then click **Properties**. In **Wireless Network Properties**, review the settings to ensure that they are correct.

- If the **Preferred networks** list includes both access point (infrastructure) and computer-to-computer (ad hoc) networks, you cannot move a computer-to-computer network to a position in the list that is higher than the position of an access point network. To connect to a computer-to-computer (ad hoc) network when both computer-to-computer and access point (infrastructure) networks are within range of your computer, click **Advanced**, and then click **Computer-to-computer (ad hoc) networks only**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define a wireless network connection on a client computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To define a wireless network connection on a client computer**

1. Right-click the wireless network connection icon in the notification area, and then click **View Available Wireless Networks**. For more information, see Notes.

2. Under **Related Tasks**, click **Change the order of preferred networks**, and then on the **Wireless Networks** tab do one of the following:

| To | Do this |
|---|---|
| Add and configure a new wireless network | Click **Add**, and then on the **Association** tab, in **Network name (SSID)**, type a unique name (also known as a service set identifier). |
| Reconfigure the settings for an existing wireless network | Click on the wireless network that you want to reconfigure, and then click **Properties**. |

3. If a network key is required to connect to the wireless network, under **Wireless network key**, do the following:

   - To specify that a network key for Wired Equivalent Privacy (WEP) is used to encrypt the data that is sent over the network, in **Data encryption**, select **WEP**. WEP is selected by default.

   - To specify that a network key is used for authentication to the wireless network, in **Network Authentication**, select **Shared**, **WPA**, or **WPA-PSK**. For more information, consult your network administrator, or see the product documentation for your access point.

   - If the network key is automatically provided for you (for example, if 802.1X is being used for dynamic key distribution), select the **The key is provided for me automatically** check box, and leave **Network key** and **Confirm network key** blank.

   - If the network key is not automatically provided for you, clear the **The key is provided for me automatically** check box, and in **Network key**, type the key, and then type it again in **Confirm network key**. For information about how to specify a network key, see Notes.

   - To specify the location where the network key is stored, in **Key index**, type a number, or click the arrows to select a number.

4. If you are configuring settings to a wireless network that is for a computer-to-computer (ad hoc) network, select the **This is a computer-to-computer (ad hoc) network; wireless access points are not used** check box.

5. To specify that 802.1X authentication is used for the wireless network connection, click the **Authentication** tab, and then configure settings as needed. For more information, see Related Topics.

**Important**

- It is highly recommended that you use 802.1X authentication whenever you connect to an 802.11 wireless network. 802.1X is an IEEE standard that enhances security and deployment by providing support for centralized user identification, authentication, dynamic key management, and accounting. For more information, see Related Topics.

- In Windows XP Service Pack 1 and in the Windows Server 2003 family, 802.1X authentication is available only for access point (infrastructure) networks that require the use of a network key (WEP). WEP provides data confidentiality by

encrypting the data that is sent between wireless clients and wireless access points. For additional information about security for wireless networks, see Related Topics.

- For enhanced security, in Windows XP Service Pack 2 and in the Windows Server 2003 family with Service Pack 1, Wi-Fi Protected Access (WPA) has been included to strengthen WEP. For more information, see Security information for wireless networks.

- If you attempt to connect to a computer-to-computer network or an access point network that does not require the use of a network key, the settings in the **Authentication** tab are not available, and you cannot configure 802.1X authentication for the connection.

- To enhance security and connectivity, do not select the **Network Authentication (Shared mode)** check box. When this check box is selected, shared key authentication is used, rather than open system authentication. Shared key authentication is less secure than open system authentication because it requires the exchange of a secret key that is shared by all wireless access points and clients and therefore is more vulnerable to known-text attacks. In addition, if you select this check box for a wireless network that has multiple wireless access points, you will lose network connectivity when you travel from one wireless access point to a new wireless access point. To determine whether the wireless network you are connecting to has multiple wireless access points, use Wireless Monitor. For information about how to use Wireless Monitor to view details about wireless access points, see Related Topics.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- tok:wirelessicon

- When an error is detected that might limit or prevent a connection to a wireless network, the wireless warning icon is displayed in the notification area.

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

- The **Wireless Networks** tab appears only if you are using a wireless network adapter that supports the Wireless Configuration service. If you are unsure whether your wireless network adapter supports the Wireless Configuration service, contact the wireless network adapter manufacturer. For more information about using Windows to configure wireless network settings on your computer, see Related Topics.

- You must type a network key in hexadecimal or ASCII format. If you use hexadecimal format, specify a key that is 10 or 26 characters in length. If you use ASCII format, specify a key that is 5 or 13 characters in length.

### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define 802.1X authentication for wireless networks on a client computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To define 802.1X authentication for wireless networks on a client computer**

1. Right-click the wireless network connection icon in the notification area, and then click **View Available Wireless Networks**. For more information, see Notes.

2. Under **Related Tasks**, click **Change the order of preferred networks**.

3. On the **Wireless Networks** tab, under **Preferred networks**, click the wireless network connection for which you want to configure 802.1X authentication, and then click **Properties**.

4. On the **Authentication** tab, do one of the following:

   - To enable IEEE 802.1X authentication for this connection, select the **Enable IEEE 802.1x authentication for this network** check box. This check box is selected by default.

   - To disable IEEE 802.1X authentication for this connection, clear the **Enable IEEE 802.1x authentication for this network** check box.

5. In **EAP type**, click the Extensible Authentication Protocol (EAP) type to be used with this connection.

6. If you select **Smart Card or other Certificate** in **EAP type**, click **Properties** and, in **Smart Card or other Certificate Properties**, do the following:

   - To use the certificate that resides on your smart card for authentication, click **Use my smart card**.

   - To use the certificate that resides in the certificate store on your computer for authentication, click **Use a certificate on this computer**, and then specify whether to use simple certificate selection.

   - To verify that the server certificate presented to your computer is still valid, select the **Validate server certificate** check box, specify the server or servers to which your computer will automatically connect, and then specify the trusted root certification authorities.

   - To view detailed information about the selected root certification authority, click **View Certificate**.

   - To use a different user name when the user name in the smart card or certificate is not the same as the user name in the domain to which you are logging on, select the **Use a different user name for the connection** check box.

7. If you select **Protected EAP (PEAP)** in **EAP type**, click **Properties**, and then do the following:

   - To verify that the server certificate presented to your computer is still valid, select the **Validate server certificate** check box, specify the server or servers to which your computer will automatically connect, and then specify the trusted root certification authorities.

   - In **Select Authentication Method**, click the authentication method that you want to use within PEAP, and then click **Configure**.

If you select **Secured password (EAP-MSCHAP v2)**, then, in **EAP MSCHAP v2 Properties**, specify whether to use the user name and password (and domain, if applicable) that you type in the Windows logon screen for authentication, click **OK**, and then click **OK** again.

If you select **Smart Card or other certificate**, then, in **Smart Card or other Certificate Properties**, configure the settings as needed by following the instructions in step 6, click **OK**, and then click **OK** again.

8. On the **Authentication** tab, do the following:

   - To specify that the computer attempt authentication to the network if a user is not logged on, select the **Authenticate as computer when computer information is available** check box. This check box is selected by default.

   - To specify that the computer attempt authentication to the network if user information or computer information is not available, select the **Authenticate as guest when user or computer information is unavailable** check box.

**Important**
