- It is highly recommended that you use 802.1X authentication whenever you connect to an 802.11 wireless network. 802.1X is an IEEE standard that enhances security and deployment by providing support for centralized user identification, authentication, dynamic key management, and accounting. For more information, see Related Topics.

- For enhanced security, in Windows XP Service Pack 1 and in the Windows Server 2003 family, 802.1X authentication is available only for access point (infrastructure) networks that require the use of a network key (WEP). WEP provides data confidentiality by encrypting the data that is sent between wireless clients and wireless access points. For additional information about security for wireless networks, see Related Topics.

- If you attempt to connect to a computer-to-computer network or an access point network that does not require the use of a network key, the settings in the **Authentication** tab are not available, and you cannot configure 802.1X authentication for the connection.

**Notes**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- tok:wirelessicon

- When an error is detected that might limit or prevent a connection to a wireless network, the wireless warning icon is displayed in the notification area.

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

- To define 802.1X authentication, you must select an existing wireless network connection, or you must add a new wireless network connection. For information about how to add a new wireless network connection, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Connect to an available wireless network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to an available wireless network**

1. Right-click the wireless network connection icon in the notification area, and then click **View Available Wireless Networks**. For more information, see Notes.

2. Click on the wireless network that you want to connect to, and then click **Connect**.

3. To configure additional wireless network settings, or if you are having difficulty making a connection to the wireless network that you selected, under **Related Tasks**, click **Change the order of preferred networks**, and then configure the settings in the **Wireless Networks** tab. For more information, see Notes.

## Important

- It is highly recommended that you use 802.1X authentication whenever you connect to an 802.11 wireless network. 802.1X is an IEEE standard that enhances security and deployment by providing support for centralized user identification, authentication, dynamic key management, and accounting. For more information, see Related Topics.

- For enhanced security, in Windows XP Service Pack 1 and in the Windows Server 2003 family, 802.1X authentication is available only for access point (infrastructure) networks that require the use of a network key (WEP). WEP provides data confidentiality by encrypting the data that is sent between wireless clients and wireless access points. For additional information about security for wireless networks, see Related Topics.

- If you attempt to connect to a computer-to-computer network or an access point network that does not require the use of a network key, the settings in the **Authentication** tab are not available, and you cannot configure 802.1X authentication for the connection.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- tok:wirelessicon

- When an error is detected that might limit or prevent a connection to a wireless network, the wireless warning icon is displayed in the notification area.

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

- On the **Wireless Networks** tab, you can view and modify additional wireless configuration settings. However, this tab appears only if you are using a wireless network adapter that supports the Wireless Configuration service. For more information, see Related Topics.

- You must type a network key in hexadecimal or ASCII format. If you use hexadecimal format, specify a key that is 10 or 26 characters in length. If you use ASCII format, specify a key that is 5 or 13 characters in length.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use Resultant Set of Policy (RSoP) to View Wireless Network Policy Assignments

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use Resultant Set of Policy (RSoP) to view wireless network policy assignments**

- Use RSoP to view wireless network policy assignments for a computer
- Use RSoP to view wireless network policy assignments for members of a Group Policy container

# Use RSoP to view wireless network policy assignments for a computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use RSoP to view wireless network policy assignments for a computer**

1. Open Resultant Set of Policy.

   An RSoP query runs in logging mode. For more information, see Related Topics.

2. In the console tree, click **Wireless Network (IEEE 802.11) Policies**.

   **Where?**

   - Computer Configuration/Windows Settings/Security Settings/Wireless Network (IEEE 802.11) Policies

   The list of all wireless network policies is displayed in the details pane.

3. To view detailed policy settings for the wireless network policy that is being applied, in the details pane, right-click the policy with the highest precedence, and then click **Properties**.

## Notes

- To open RSoP, click **Start**, click **Run**, type **rsop.msc**, and then click **OK**.
- To run an RSoP query in logging mode, see Related Topics.
- The RSoP console displays detailed wireless network policy settings for only the policy that is being applied. The detailed policy settings include the list of preferred wireless networks that clients can connect to and, for each preferred wireless network, the wireless network key settings, whether 802.1X authentication is enabled, and, if so, the authentication settings.
- The details pane in RSoP provides two ways to indicate which wireless network policy is being applied:
  - The lower the number in the **Precedence** column, the higher the precedence of the wireless network policy. The wireless network policy with a precedence number of 1 is the policy that is being applied.
  - In the **Name** column, the folder icon that precedes the name of the wireless network policy that is being applied contains a green dot.
- To hide or display columns in the RSoP console, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Run RSoP

# Use RSoP to view wireless network policy assignments for members of a Group Policy container

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use RSoP to view wireless network policy assignments for members of a Group Policy container**

1. On a domain controller, open Resultant Set of Policy (RSoP) as a Microsoft Management Console (MMC). For more information, see Related Topics.

2. On the **Action** menu, click **Generate RSoP Data**.

3. On the **Welcome to the Resultant Set of Policy Wizard** page, click **Next**.

4. On the **Mode Selection** page, click **Planning mode**, and then follow the instructions in the wizard to run a planning mode query. For more information, see Related Topics.

5. In the console tree, click **Wireless Network (IEEE 802.11) Policies**.

   **Where?**

   - Computer Configuration/Windows Settings/Security Settings/Wireless Network (IEEE 802.11) Policies

   The list of all wireless network policies is displayed in the details pane.

6. To view detailed policy settings for the wireless network policy that is being applied, in the details pane, right-click the policy with the highest precedence, and then click **Properties**.

**Notes**

- The RSoP console only displays detailed wireless network policy settings for only the policy that is being applied. The detailed policy settings include the list of preferred wireless networks that clients can connect to, and for each preferred wireless network, the wireless network key settings, whether 802.1X authentication is enabled, and if so, the authentication settings.

- The details pane in RSoP provides two ways to indicate which wireless network policy is being applied:

  - The lower the number in the **Precedence** column, the higher the precedence of the wireless network policy. The wireless network policy with a precedence number of 1 is the policy that is being applied.

  - In the **Name** column, the folder icon that precedes the name of the wireless network policy that is being applied contains a green dot.

- You can run an RSoP planning mode query only on a domain controller (when you run a planning mode query, you must specify the name of the domain controller). However, you can specify any wireless network client as the target for the query, provided you have the appropriate permissions to do so.

- To hide or display columns in the RSoP console, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Monitor Wireless Network Activity

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitor wireless network activity**

- Add the Wireless Monitor snap-in
- Enable or disable Wireless Client Information logging
- Delete Wireless Client Information logs
- View details about wireless network access points
- View details about wireless network clients

# Add the Wireless Monitor snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add the Wireless Monitor snap-in**

1. Click **Start**, click **Run**, type **MMC**, and then click **OK**.
2. Click **File**, click **Add/Remove Snap-in**, and then click **Add**.
3. In the **Add Standalone Snap-in** dialog box, click **Wireless Monitor**, and then click **Add**.
4. Click **Close**, and then click **OK**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To save the console settings, on the **File** menu, click **Save**.
- To open a saved console file, open MMC. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable or disable Wireless Client Information logging

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable Wireless Client Information logging**

1. Create a console containing Wireless Monitor. Or, open a saved console file containing Wireless Monitor.
2. Double-click **Wireless Client Information**.

   **Where?**

   - Wireless Monitor/*ServerName*/Wireless Client Information

3. Right-click **Wireless Client Information**, and then do one of the following:

- To disable logging for wireless network clients, click **Disable Logging**.
- To enable logging for wireless network clients, click **Enable Logging**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- For information about adding the Wireless Monitor snap-in, see Related Topics.
- For information about the items displayed in Wireless Monitor, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete Wireless Client Information logs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete Wireless Client Information logs**

1. Create a console containing Wireless Monitor. Or, open a saved console file containing Wireless Monitor.
2. Double-click **Wireless Client Information**.

   **Where?**

   - Wireless Monitor/*ServerName*/Wireless Client Information

3. Right-click **Wireless Client Information**, and then click **Delete Logs**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- For information about adding the Wireless Monitor snap-in, see Related Topics.
- For information about the items displayed in Wireless Monitor, see Related Topics.

# Manage Infrared Communication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage infrared communication**

- Set up the Computer for Infrared Communication
- Configure Infrared Communication
- Use Infrared for Dial-up or Direct Network Connections
- Send Files over an Infrared Link
- Print to an infrared printer
- Transfer images from a digital camera to your computer

# Set up the Computer for Infrared Communication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up the computer for infrared communication**

- Verify infrared support on a computer
- Add a new infrared device to a serial port
- View infrared device properties
- Establish an infrared link

# Verify infrared support on a computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To verify infrared support on a computer**

1. Verify that your computer has an infrared transceiver (the transceiver will appear as a small, dark red window).

   If your computer does not have an infrared transceiver, see your manufacturer's documentation to verify whether IrDA functionality is supported.

2. Open Device Manager.

3. Double-click **Infrared Devices**.

   If you have an infrared transceiver, but **Infrared Devices** does not appear in Device Manager, you do not have an infrared device installed.

   If no infrared devices are listed, do one or both of the following:

   - Enter BIOS setup to verify whether the infrared device is enabled in BIOS, in IrDA, or Fast IrDA (FIR) mode. For information about how to enter BIOS setup, see your computer manufacturer's documentation. If the infrared device is disabled in BIOS, you might be able to use your computer's BIOS setup to enable it.

     **Caution** Using a BIOS setup utility incorrectly can cause your computer to operate incorrectly. Microsoft cannot guarantee that problems resulting from the incorrect use of the BIOS setup can be solved. Use this utility at your own risk. Before you make any changes, make a note of the original settings so that you can reinstate them if necessary.

   - See your computer manufacturer's documentation to determine whether the BIOS needs to be updated.

4. Verify that at least one infrared device is listed and that it is enabled.

   If infrared devices are listed but they are not enabled, verify that the infrared devices are installed correctly on your computer. For more information see Related Topics.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

- Infrared transceivers are now installed in nearly all new portable computers. If your computer does not have an infrared transceiver, but it supports IrDA, and IrDA is enabled in BIOS, you can install an external infrared transceiver.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

**Concepts**

Add a new infrared device to a serial port

Enable a device

# Add a new infrared device to a serial port

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a new infrared device to a serial port**

1. Connect the infrared device to a serial port on your computer, and note the serial port number (typically COM1 or COM2).
2. In Control Panel, open Add Hardware.
3. In **Welcome to the Add Hardware Wizard**, click **Next**.
4. In **Is the hardware connected?**, click **Yes, I have already connected the hardware**, and then click **Next**.
5. In **Installed hardware**, click **Add a new hardware device**, and then click **Next**.
6. In **The wizard can help you install other hardware**, click **Install the hardware that I manually select from a list**, and then click **Next**.
7. In **Common hardware types**, click **Infrared devices**, and then click **Next**.
8. In **Select Infrared Device**, do one of the following:
   - If you do not have an installation disk for the infrared device, under **Manufacturer**, click the manufacturer, under **Infrared Device**, click the infrared device, and then click **Next**.
   - If you have an installation disk for a compatible driver, click **Have Disk**, insert the disk, click **Next**, and then follow any additional instructions to install the device.
9. In **The wizard is ready to install your hardware**, click **Next**.
10. In **Infrared Device Installation**, select the serial port to which your infrared device is attached, and then click **Next**.

**Important**

- For enhanced security, performance, and stability, it is recommended that you use only signed device drivers. For more information, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.
- This procedure applies only if an infrared device was not installed automatically when you turned on your computer. Typically, USB, PCMCIA, and other Plug and Play compliant infrared devices are automatically detected and installed. These devices do not need additional configuration to be installed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View infrared device properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view infrared device properties**

1. Open Wireless Link in Control Panel.
2. On the **Hardware** tab, click the infrared device for which you want to view properties, and then click **Properties**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.
- The Wireless Link icon appears in Control Panel only if an infrared device is already installed on your computer.
- If a device that is connected to your computer is not listed, you need to add it. For more information, see Related Topics.
- The infrared device **Properties** dialog box shows the device status, driver files, and power management settings for an infrared device.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Establish an infrared link

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To establish an infrared link**

1. Verify that the devices that you want to communicate over an infrared link have infrared functionality enabled and work correctly.

   For information about verifying infrared functionality on your computer, see Related Topics. For information about verifying infrared functionality on other devices, see the device manufacturer's documentation.

   Align your devices so that the infrared transceivers are within 1 meter (approximately 40 inches) of each other, and the transceivers are pointing at each other.

2. When the devices are correctly aligned, the icon appears on the taskbar.

### Important

- To enhance security, align infrared devices so that the infrared transceivers are between 0.1 meter (approximately 4 inches) and 0.5 meter (approximately 20 inches) apart whenever you establish an infrared link between two devices. Although there can be up to 1 meter (approximately 40 inches) between infrared transceivers without a loss in data transfer capability, if you place the transceivers closer to each other, you minimize the risk of interference from an attacker. To further enhance security, ensure that all infrared devices and data sources are trustworthy, and, if you are transferring infrared data with another person, conduct the transfer in a private location whenever possible. For more information about infrared security considerations, see Related Topics.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

- The infrared transceiver is the small, dark red window on your portable computer, printer, digital camera, adapter, or other device.

- You can choose whether to hide or display the Wireless Link taskbar icon when two infrared devices are aligned. By default, the Wireless Link taskbar icon is displayed. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Infrared Communication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure infrared communication**

- Enable or prevent receipt of files sent over an infrared link
- Change the default location for receipt of files sent over an infrared link
- Hide or display the Wireless Link taskbar icon
- Enable or disable notification of files received over an infrared link
- Enable or disable sound notification when an infrared device is nearby
- Change settings to transfer images from a digital camera

# Enable or prevent receipt of files sent over an infrared link

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or prevent receipt of files sent over an infrared link**

1. Open Wireless Link in Control Panel.
2. On the **Infrared** tab, do one of the following:
   - To enable your computer to receive files from others, select the **Allow others to send files to your computer using infrared communications** check box. This check box is selected by default.
   - To prevent your computer from receiving files from others, clear the **Allow others to send files to your computer using infrared communications** check box.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.
- The Wireless Link icon appears in Control Panel only if an infrared device is already installed on your computer.
- If you clear the **Allow others to send files to your computer using infrared communications** check box, you can still send files to other computers by using Wireless Link.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the default location for receipt of files sent over an infrared link

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the default location for receipt of files sent over an infrared link**

1. Open Wireless Link in Control Panel.
2. On the **Infrared** tab, under **Default location for received files**, click **Browse**.

   By default, files that are sent over an infrared link are copied to the desktop of the recipient computer.
3. Enter a new location, and then click **OK**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.
- The Wireless Link icon appears in Control Panel only if an infrared device is already installed on your computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To hide or display the Wireless Link taskbar icon**

1. Open Wireless Link in Control Panel.
2. On the **Infrared** tab, do one of the following:
   - To hide the **Wireless Link** taskbar icon, clear the **Display an icon on the taskbar indicating infrared activity** check box. This check box is selected by default.
   - To display the **Wireless Link** taskbar icon, select the **Display an icon on the taskbar indicating infrared activity** check box.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.
- The Wireless Link icon appears in Control Panel only if an infrared device is already installed on your computer.

  When another infrared transceiver is in range, this option causes the Infrared status icon to appear on the taskbar. The icon changes to whenever the infrared connection is active. To display the current status of the connection, move the mouse pointer over the icon.

  To open the properties for Wireless Link, right-click the icon, and then click **Properties**.

  To transfer files, right-click the icon, and then click **Transfer Files** to open the **Wireless Link** dialog box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable or disable notification of files received over an infrared link

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable notification of files received over an infrared link**

1. Open Wireless Link in Control Panel.
2. On the **Infrared** tab, do one of the following:
   - If you do not want to be notified when you receive files over an infrared link, clear the **Notify me when receiving files** check box. This check box is selected by default.
   - To be notified when you receive files sent over an infrared link, select the **Notify me when receiving files** check box.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.
- The Wireless Link icon appears in Control Panel only if an infrared device is already installed on your computer.
- If the **Notify me when receiving files** check box is selected, the Wireless Link status dialog box appears when files are being received. The status dialog box indicates that files are being received and shows the name of the computer that is sending the files.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Change the default location for receipt of files sent over an infrared link

# Enable or disable sound notification when an infrared device is nearby

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable sound notification when an infrared device is nearby**

1. Open Wireless Link in Control Panel.
2. On the **Infrared** tab, do one of the following:
   - To enable sound notification when an infrared device is nearby, select the **Play sound when Infrared device is nearby** check box. This check box is selected by default.
   - To disable sound notification when an infrared device is nearby, clear the **Play sound when Infrared device is nearby** check box.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.
- The Wireless Link icon appears in Control Panel only if an infrared device is already installed on your computer.
- If the **Play sound when infrared device is nearby** check box is selected, but you do not hear the notification sound, make sure that your infrared devices are correctly aligned and that an infrared link is established. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change settings to transfer images from a digital camera

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change settings to transfer images from a digital camera**

1. Open Wireless Link in Control Panel.
2. On the **Image Transfer** tab, select the **Use Wireless Link to transfer images from a digital camera to your computer** check box.
3. In **Transfer images to a subfolder of**, specify the default location for images transferred by Wireless Link.
4. To automatically open Windows Explorer to the default location after receiving files, select the **Explore location after receiving pictures** check box.

## Caution

- To enhance security, do not enable infrared image transfer (IrTran-P), that is, do not select the **Use Wireless Link to transfer images from a digital camera to your computer** check box. If you select this check box, all incoming files sent over IrTran-P are automatically accepted. Because incoming files might contain harmful programs, ensure that the files originate from a trustworthy source. Do not open files if you cannot verify the source, do not recognize the file format, or are unsure of the content. Instead, delete the files immediately. For more information about infrared security considerations, see Related Topics.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.
- The Wireless Link icon appears in Control Panel only if an infrared device is already installed on your computer.
- If you are using synchronization software, note that certain software will automatically disable infrared image transfer (IrTran-P). As a result, you will not be able to use Wireless Link to transfer images from a digital camera to your computer. In such cases, you might have to remove the synchronization software before you can use Wireless Link to transfer digital camera images. To determine whether your synchronization software disables infrared image transfer, see your software manufacturer's product documentation.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use Infrared for Dial-up or Direct Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use infrared for dial-up or direct network connections**

- Make a dial-up connection using an infrared-enabled cellular phone
- Establish a direct infrared network connection between computers
- Use an infrared network connection

# Make a dial-up connection using an infrared-enabled cellular phone

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a dial-up connection using an infrared-enabled cellular phone**

1. Make sure that infrared is activated on the cellular phone. To check compatibility, see your cellular phone manufacturer's documentation.

2. Establish an infrared link between the cellular phone and the computer by aligning them so that the infrared transceivers are within 1 meter (approximately 40 inches) of each other, and the transceivers are pointing at each other. For more information, see Related Topics.

3. If you are establishing an infrared link between the cellular phone and the computer for the first time, the Found New Hardware balloon appears when the cellular phone is detected. Do any of the following before proceeding to step 4:

   - If the device driver for the cellular phone already exists on your computer, the driver is installed automatically, and you are notified that the cellular phone is ready to use.

   - If the device driver for the cellular phone does not already exist on your computer, the Found New Hardware Wizard appears. Do one of the following:

     | |
     |---|
     | If you have a setup or installation disk for the driver files, select **Install from a list or specific location (advanced)**, and then follow the instructions in the wizard. |
     | If you do not have a setup or installation disk, select **Install software automatically (recommended)**, and then follow the instructions in the wizard. To complete this task, you need administrative credentials. For more information, see Notes. |

   **Important**

   - If you are installing an unsigned device driver for the cellular phone, a message appears to notify you that the driver is not signed. For enhanced security, performance, and stability, it is recommended that you use only signed device drivers. For more information, see Related Topics.

4. Open Network Connections.

5. Double-click **New Connection Wizard**, and then click **Next**.

6. In **Network Connection Type**, do one of the following:

   - To connect to the Internet, click **Connect to the Internet**.

   - To connect to a business network, click **Connect to the network at my workplace**.

7. Click **Next**, and then do one of the following:

   - If you are connecting to the Internet, in **Internet Connection**, click **Connect using a dial-up modem**, click **Next**, and then follow the instructions in the remaining wizard pages.

- If you are connecting to a business network, in **Network Connection**, click **Dial-up connection**, click **Next**, and then follow the instructions in the remaining wizard pages.

8. To complete the connection, in the **Connect *connection type*** dialog box, type your user name and password, and then click **Dial**.

### Important

- To enhance security, align infrared devices so that the infrared transceivers are between 0.1 meter (approximately 4 inches) and 0.5 meter (approximately 20 inches) apart whenever you establish an infrared link between two devices. Although there can be up to 1 meter (approximately 40 inches) between infrared transceivers without a loss in data transfer capability, if you place the transceivers closer to each other, you minimize the risk of interference from an attacker. To further enhance security, ensure that all infrared devices and data sources are trustworthy, and, if you are transferring infrared data with another person, conduct the transfer in a private location whenever possible. For more information about infrared security considerations, see Related Topics.

### Notes

- To install new driver files on a computer, you must have be a member of the Administrators group on the local computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Establish a direct infrared network connection between computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To establish a direct infrared network connection between computers**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. In **Network Connection Type**, click **Advanced connection**, and then click **Next**.
4. In **Advanced Connection Options**, click **Connect directly to another computer**, and then click **Next.**
5. In **Host or Guest**, specify whether this computer is the host or the guest by doing one of the following:
   - If this computer has information that will be accessed by another computer, click **Host**.
   - If this computer is being used to access information on another computer, click **Guest**.
6. Click **Next**, and then do one of the following:
   - If you specified this computer as a host, in **Devices for this connection**, select **Infrared Port**, click **Next**, and then follow the instructions in the remaining wizard pages.
   - If you specified this computer as a guest, in **Connection Name**, type the name of the computer that you want to access, and then click **Next**. In **Select a device**, select **Infrared Port**, click **Next**, and then follow the instructions in the remaining wizard pages.

     To complete the connection, in the **Connect *connection type*** dialog box, type your user name and password, and then click **Connect**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.
- To examine or change properties for this connection, right-click its icon in Network Connections.
- After you add an infrared device, you may have to restart the computer before you can select **Infrared Port** in step six.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Add a new infrared device to a serial port

# Use an infrared network connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use an infrared network connection**

1. Establish an infrared link by aligning your computers so that the infrared transceivers are within 1 meter (approximately 40 inches) of each other, and the transceivers are pointing at each other. For more information, see Related Topics.
2. Open Network Connections.
3. Double-click the connection that you want to use to access the network.
4. Verify that the connection information is correct, and then click **OK**.
5. On the **File** menu, click **Connect**.

### Important

- To enhance security, align infrared devices so that the infrared transceivers are between 0.1 meter (approximately 4 inches) and 0.5 meter (approximately 20 inches) apart whenever you establish an infrared link between two devices. Although there can be up to 1 meter (approximately 40 inches) between infrared transceivers without a loss in data transfer capability, if you place the transceivers closer to each other, you minimize the risk of interference from an attacker. To further enhance security, ensure that all infrared devices and data sources are trustworthy, and, if you are transferring infrared data with another person, conduct the transfer in a private location whenever possible. For more information about infrared security considerations, see Related Topics.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.
- When you make a network connection over infrared, the infrared link takes the place of a cable. You do not need to use a serial or parallel cable.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Send Files over an Infrared Link

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Send files over an infrared link**

- Send files with the Wireless Link dialog box
- Send files with Send To
- Send files using the command line
- Drag files to an infrared link

# Send files with the Wireless Link dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To send files with the Wireless Link dialog box**

1. Establish an infrared link by aligning your computers so that the infrared transceivers are within 1 meter (approximately 40 inches) of each other, and the transceivers are pointing at each other. For more information, see Related Topics.

2. Click the IrDA status icon on the taskbar.

3. In the **Wireless Link** dialog box, specify the files you want to send, and then click **Send**.

### Important

- To enhance security, align infrared devices so that the infrared transceivers are between 0.1 meter (approximately 4 inches) and 0.5 meter (approximately 20 inches) apart whenever you establish an infrared link between two devices. Although there can be up to 1 meter (approximately 40 inches) between infrared transceivers without a loss in data transfer capability, if you place the transceivers closer to each other, you minimize the risk of interference from an attacker. To further enhance security, ensure that all infrared devices and data sources are trustworthy, and, if you are transferring infrared data with another person, conduct the transfer in a private location whenever possible. For more information about infrared security considerations, see Related Topics.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

  While another infrared transceiver is in range, you can also double-click the Wireless Link icon on the desktop to open the **Wireless Link** dialog box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Send files with Send To

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To send files with Send To**

1. Establish an infrared link by aligning your computers so that the infrared transceivers are within 1 meter (approximately 40 inches) of each other, and the transceivers are pointing at each other. For more information, see Related Topics.

2. On the desktop, in Windows Explorer or in **My Computer**, select the files you want to send.

3. Right-click the selected files, point to **Send To**, and then click **Nearby Computer**.

### Important

- To enhance security, align infrared devices so that the infrared transceivers are between 0.1 meter (approximately 4 inches) and 0.5 meter (approximately 20 inches) apart whenever you establish an infrared link between two devices. Although there can be up to 1 meter (approximately 40 inches) between infrared transceivers without a loss in data transfer capability, if you place the transceivers closer to each other, you minimize the risk of interference from an attacker. To further enhance security, ensure that all infrared devices and data sources are trustworthy, and, if you are transferring infrared data with another person, conduct the transfer in a private location whenever possible. For more information about infrared security considerations, see Related Topics.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

- If **Nearby Computer** does not appear on the **Send To** menu (as described in step 3 of this procedure), make sure that your infrared devices are correctly aligned and that an infrared link is established. The **Nearby Computer** menu command only appears when an infrared link is active.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Send files using the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To send files using the command line**

1. Establish an infrared link by aligning your computers so that the infrared transceivers are within 1 meter (approximately 40 inches) of each other, and the transceivers are pointing at each other. For more information, see Related Topics.

2. Open Command Prompt.

3. At the command prompt, type:

   **irftp**[*Drive:*] [[*Path*] *FileName*] [**/h**]

| Value | Description |
|---|---|
| *Drive:* | Specifies the drive that contains the files that you want to send over an infrared link. |
| [*Path*] *FileName* | Specifies the location and name of the file or set of files that you want to send over an infrared link. |
| **/h** | Specifies hidden mode. When hidden mode is used, the **Wireless Link** dialog box does not display when the files are sent. |

### Important

- To enhance security, align infrared devices so that the infrared transceivers are between 0.1 meter (approximately 4 inches) and 0.5 meter (approximately 20 inches) apart whenever you establish an infrared link between two devices. Although there can be up to 1 meter (approximately 40 inches) between infrared transceivers without a loss in data transfer capability, if you place the transceivers closer to each other, you minimize the risk of interference from an attacker. To further enhance security, ensure that all infrared devices and data sources are trustworthy, and, if you are transferring infrared data with another person, conduct the transfer in a private location whenever possible. For more information about infrared security considerations, see Related Topics.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

- If you do not specify a drive, a path, and a name for the file or set of files that you want to send, the **Wireless Link** dialog box opens, so that you can select the files without using the command line.

- For information about other command-line utilities or manageability, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Drag files to an infrared link

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To drag files to an infrared link**

1. Establish an infrared link by aligning your computers so that the infrared transceivers are within 1 meter (approximately 40 inches) of each other, and the transceivers are pointing at each other. For more information, see Related Topics.

2. In Windows Explorer, in **My Computer**, or on the desktop, select one or more files.

   Drag the selected files onto the desktop icon, which represents the wireless connection.

### Important

- To enhance security, align infrared devices so that the infrared transceivers are between 0.1 meter (approximately 4 inches) and 0.5 meter (approximately 20 inches) apart whenever you establish an infrared link between two devices. Although there can be up to 1 meter (approximately 40 inches) between infrared transceivers without a loss in data transfer capability, if you place the transceivers closer to each other, you minimize the risk of interference from an attacker. To further enhance security, ensure that all infrared devices and data sources are trustworthy, and, if you are transferring infrared data with another person, conduct the transfer in a private location whenever possible. # Print to an infrared printer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To print to an infrared printer**

1. Verify that the infrared printer you want to use is correctly installed.

2. Establish an infrared link between the computer and the printer by aligning them so that the infrared transceivers are within 1 meter (approximately 40 inches) of each other, and the transceivers are pointing at each other. For more information, see Related Topics.

3. Open the document that you want to print, and then proceed with printing.

### Important

- To enhance security, align infrared devices so that the infrared transceivers are between 0.1 meter (approximately 4 inches) and 0.5 meter (approximately 20 inches) apart whenever you establish an infrared link between two devices. Although there can be up to 1 meter (approximately 40 inches) between infrared transceivers without a loss in data transfer capability, if you place the transceivers closer to each other, you minimize the risk of interference from an attacker. To further enhance security, ensure that all infrared devices and data sources are trustworthy, and, if you are transferring infrared data with another person, conduct the transfer in a private location whenever possible. # Transfer images from a digital camera to your computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To transfer images from a digital camera to your computer**

1. Open Wireless Link in Control Panel.
2. On the **Image Transfer** tab, select the **Use Wireless Link to transfer images from a digital camera to your computer** check box.
3. Establish an infrared link by aligning your computers so that the infrared transceivers are within 1 meter (approximately 40 inches) of each other, and the transceivers are pointing at each other. For more information about establishing infrared links, see Related Topics.
4. Refer to the camera manufacturer's instructions to select and transfer images.

**Caution**

- To enhance security, do not enable infrared image transfer (IrTran-P), that is, do not select the **Use Wireless Link to transfer images from a digital camera to your computer** check box. If you select this check box, all incoming files sent over IrTran-P are automatically accepted. Because incoming files might contain harmful programs, ensure that the files originate from a trustworthy source. Do not open files if you cannot verify the source, do not recognize the file format, or are unsure of the content. Instead, delete the files immediately. For more information about infrared security considerations, see Related Topics.

**Important**

- To enhance security, align infrared devices so that the infrared transceivers are between 0.1 meter (approximately 4 inches) and 0.5 meter (approximately 20 inches) apart whenever you establish an infrared link between two devices. Although there can be up to 1 meter (approximately 40 inches) between infrared transceivers without a loss in data transfer capability, if you place the transceivers closer to each other, you minimize the risk of interference from an attacker. To further enhance security, ensure that all infrared devices and data sources are trustworthy, and, if you are transferring infrared data with another person, conduct the transfer in a private location whenever possible. For more information about infrared security considerations, see Related Topics.

**Notes**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.
- The Wireless Link icon appears in Control Panel only if an infrared device is already installed on your computer.
- The Wireless Link icon will automatically create a folder for the transferred images, accept the images, and open the folder when the image transfer is completed.
- Wireless Link cannot initiate the transfer of images. The camera must initiate the transfer of images.
- To use Wireless Link to transfer images, the camera must support infrared image transfer (IrTran-P). If it does not support this protocol, you need to use a program provided by the camera manufacturer or by another party. If you use

another program, make sure you clear the **Use Wireless Link to transfer images from a digital camera to your computer** check box.

- If you are using synchronization software, note that certain software will automatically disable IrTran-P. As a result, you will not be able to use Wireless Link to transfer images from a digital camera to your computer. In such cases, you might have to remove the synchronization software before you can use Wireless Link to transfer digital camera images. To determine whether your synchronization software disables infrared image transfer, see your software manufacturer's product documentation.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Wireless networking overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Wireless networking overview**
Wireless networking technologies range from global voice and data networks, which allow users to establish wireless connections across long distances, to infrared light and radio frequency technologies that are optimized for short-range wireless connections. Devices commonly used for wireless networking include portable computers, desktop computers, hand-held computers, personal digital assistants (PDAs), cellular phones, pen-based computers, and pagers. Wireless technologies serve many practical purposes. For example, mobile users can use their cellular phone to access e-mail. Travelers with portable computers can connect to the Internet through base stations installed in airports, railway stations, and other public locations. At home, users can connect devices on their desktop to synchronize data and transfer files.

**Defining standards**
To lower costs, ensure interoperability, and promote the widespread adoption of wireless technologies, organizations such as the Institute of Electrical and Electronics Engineers (IEEE), Internet Engineering Task Force (IETF), Wireless Ethernet Compatibility Alliance (WECA), and the International Telecommunication Union (ITU) are participating in several major standardization efforts. For example, IEEE working groups are defining how information is transferred from one device to another (whether radio waves or infrared light is used, for example) and how and when a transmission medium should be used for communications. In developing wireless networking standards, organizations such as the IEEE address power management, bandwidth, security, and issues that are unique to wireless networking.

**Wireless network types**
As with wired networks, wireless networks can be classified into different types based on the distances over which data can be transmitted.

**Wireless wide area networks (WWANs)**
WWAN technologies enable users to establish wireless connections over remote public or private networks. These connections can be maintained over large geographical areas, such as cities or countries, through the use of multiple antenna sites or satellite systems maintained by wireless service providers. Current WWAN technologies are known as second-generation (2G) systems. Key 2G systems include Global System for Mobile Communications (GSM), Cellular Digital Packet Data (CDPD), and Code Division Multiple Access (CDMA). Efforts are under way to transition from 2G networks, some of which have limited roaming capabilities and are incompatible with each other, to third-generation (3G) technologies that would follow a global standard and provide worldwide roaming capabilities. The ITU is actively promoting the development of a global standard for 3G.

**Wireless metropolitan area networks (WMANs)**
WMAN technologies enable users to establish wireless connections between multiple locations within a metropolitan area (for example, between multiple office buildings in a city or on a university campus), without the high cost of laying fiber or copper cabling and leasing lines. In addition, WMANs can serve as backups for wired networks, should the primary leased lines for wired networks become unavailable. WMANs use either radio waves or infrared light to transmit data. Broadband wireless access networks, which provide users with high-speed access to the Internet, are in increasing demand. Although different technologies, such as the multichannel multipoint distribution service (MMDS) and the local multipoint distribution services (LMDS), are being used, the IEEE 802.16 working group for broadband wireless access standards is still developing specifications to standardize development of these technologies.

**Wireless local area networks (WLANs)**
WLAN technologies enable users to establish wireless connections within a local area (for example, within a corporate or campus building, or in a public space, such as an airport). WLANs can be used in temporary offices or other spaces where the installation of extensive cabling would be prohibitive, or to supplement an existing LAN so that users can work at different locations within a building at different times. WLANs can operate in two different ways. In infrastructure WLANs, wireless stations (devices with radio network cards or external modems) connect to wireless access points that function as bridges between the stations and the existing network backbone. In peer-to-peer (ad hoc) WLANS, several users within a limited area, such as a conference room, can form a temporary network without using access points, if they do not require access to network resources.

In 1997, IEEE approved the 802.11 standard for WLANs, which specifies a data transfer rate of 1 to 2 megabits per second (Mbps). Under 802.11b, which is emerging as the new dominant standard, data is transferred at a maximum rate of 11 Mbps over a 2.4 gigahertz (GHz) frequency band. Another newer standard is 802.11a, which specifies data transfer at a maximum rate of 54 Mbps over a 5 GHz frequency band.

**Wireless personal area networks (WPANs)**

WPAN technologies enable users to establish ad hoc, wireless communications for devices (such as PDAs, cellular phones, or laptops) that are used within a personal operating space (POS). A POS is the space surrounding a person, up to a distance of 10 meters. Currently, the two key WPAN technologies are Bluetooth and infrared light. Bluetooth is a cable replacement technology that uses radio waves to transmit data to a distance of up to 30 feet. Bluetooth data can be transferred through walls, pockets, and briefcases. Technology development for Bluetooth is driven by the Bluetooth Special Interest Group (SIG), which published the Bluetooth version 1.0 specification in 1999. Alternatively, to connect devices at a very close range (1 meter or less), users can create infrared links.

To standardize the development of WPAN technologies, IEEE has established the 802.15 working group for WPANs. This working group is developing a WPAN standard, based on the Bluetooth version 1.0 specification. Key goals for this draft standard are low complexity, low power consumption, interoperability, and coexistence with 802.11 networks.

# Wireless Link overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Wireless Link overview**
After an infrared device is installed, the Wireless Link icon appears in Control Panel. You can use the Wireless Link icon to configure file transfer and image transfer options and then to send files or transfer images quickly and easily over an infrared link.

When another infrared transceiver comes in range, the Wireless Link icon appears on the desktop and on the taskbar. You can then:

- Send files by specifying a location and one or more files in the **Wireless Link** dialog box. For more information, see Send files with the Wireless Link dialog box.
- Send files by dragging file icons to the Wireless Link icon on the desktop and dropping them there. For more information, see Drag files to an infrared link.
- Transfer images from a digital camera that supports the infrared image transfer (IrTran-P) protocol to your computer. For more information, see Transfer images from a digital camera to your computer.

**Note**

- In the Microsoft® Windows Server 2003 family, only Windows Server 2003, Standard Edition supports infrared networking.

# Understanding 802.1X authentication for wireless networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding 802.1X authentication for wireless networks**
802.1X is an IEEE standard for authenticated network access to wired Ethernet networks and wireless 802.11 networks. IEEE 802.1X enhances security and deployment by providing support for centralized user identification, authentication, dynamic key management, and accounting.

**EAP, EAP-TLS, EAP-MS-CHAP v2, and PEAP authentication**
The support that 802.1X provides for Extensible Authentication Protocol (EAP) types allows you to choose from several different authentication methods for wireless clients and servers.

**EAP**
802.1X uses EAP for message exchange during the authentication process. With EAP, an arbitrary authentication method, such as certificates, smart cards, or credentials, is used. EAP allows for an open-ended conversation between an EAP client (such as a wireless computer) and an EAP server (such as an Internet Authentication Service (IAS) server). The conversation consists of requests for authentication information by the server and responses by the client. In order for authentication to be successful, the client and the server must use the same authentication method.

**EAP-TLS**
EAP-Transport Layer Security (TLS) is an EAP type that is used in certificate-based security environments, and it provides the strongest authentication and key determination method. EAP-TLS provides mutual authentication, negotiation of the encryption method, and encrypted key determination between the client and the authenticating server. If you want to use certificates or smart cards for user and client computer authentication, you must use EAP-TLS or, for enhanced security, Protected EAP (PEAP) with EAP-TLS.

**EAP-MS-CHAP v2**
EAP-Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAP v2) is a mutual authentication method that supports password-based user or computer authentication. During the EAP-MS-CHAP v2 authentication process, both the server and client must prove that they have knowledge of the user's password in order for authentication to succeed. With EAP-MS-CHAP v2, after successful authentication, users can change their passwords, and they are notified when their passwords expire.

### Note

- EAP-MS-CHAP v2 is available only with PEAP.

**PEAP**
PEAP is an authentication method that uses TLS to enhance the security of other EAP authentication protocols. PEAP provides the following benefits: an encryption channel to protect EAP methods running within PEAP, dynamic keying material generated from TLS, fast reconnect (the ability to reconnect to a wireless access point by using cached session keys, which allows for quick roaming between wireless access points), and server authentication that can be used to protect against the deployment of unauthorized wireless access points.

**PEAP authentication process**
The PEAP authentication process consists of two main phases:

1. **Server authentication and the creation of a TLS encryption channel**. The server identifies itself to a client by providing certificate information to the client. After the client verifies the identity of the server, a master secret is generated. The session keys that are derived from the master secret are then used to create a TLS encryption channel that encrypts all subsequent communication between the server and the wireless client.

2. **EAP conversation and user and client computer authentication**. A complete EAP conversation between the client and the server is encapsulated within the TLS encryption channel. With PEAP, you can use any one of several EAP authentication methods, such as passwords, smart cards, and certificates, to authenticate the user and client computer.

The session keys that are generated during the PEAP authentication process provide keying material for the Wired Equivalent Privacy (WEP) encryption keys that encrypt the data that is sent between wireless clients and wireless access points.

You can use PEAP with any of the following authentication methods for wireless authentication:

- EAP-TLS, which uses certificates for server authentication and either certificates or smart cards for user and client computer authentication.
- EAP-MS-CHAP v2, which uses certificates for server authentication and credentials for user authentication.
- Non-Microsoft EAP authentication methods.

### Notes

- PEAP is not supported for use with EAP-MD5.
- PEAP is available as an authentication method for 802.11 wireless clients, but it is not supported for virtual private network (VPN) clients or other remote access clients. Therefore, you can configure PEAP as the authentication method for a remote access policy only when you are using Internet Authentication Service (IAS).

**PEAP support for fast reconnect**

When clients connect to an 802.11 wireless network, the authenticated session has a set expiration interval that the network administrator determines to limit the duration of authenticated sessions. To avoid the notices that require authenticated clients to provide their credentials to reauthenticate and resume a session, you can enable the fast reconnect option.

PEAP supports fast reconnect, which allows roaming users to maintain continuous wireless network connectivity when traveling between different wireless access points on the same network, as long as each wireless access point is configured as a client of the same IAS (RADIUS) server. In addition, fast reconnect must be enabled on both the wireless client and the RADIUS server.

After the initial PEAP authentication succeeds, users are not prompted to supply their credentials (if PEAP with EAP-MS-CHAP v2 is used for authentication) or their personal identification number (PIN) (if PEAP with smart cards is used for authentication) each time they travel to a new wireless access point. Instead, when PEAP fast reconnect is enabled, after the initial PEAP authentication succeeds, the client and the server cache TLS session keys. When users associate with a new wireless access point, the client and the server use the cached keys to reauthenticate each other until the cache has expired. Because the keys are cached, the RADIUS server can quickly determine that the client connection is a reconnect. This reduces the delay in time between an authentication request by a client and the response by the RADIUS server. It also resource requirements for the client and the server.

If the original RADIUS server is not used, full authentication must occur, and the user is again prompted for credentials or a PIN. This can occur in the following situations:

- The user associates with a new wireless access point that is configured as a client of a new RADIUS server.
- The user associates with the same wireless access point, but the wireless access point forwards the authentication request to a new RADIUS server.

In both situations, after the initial authentication with the new RADIUS server succeeds, the client caches the new TLS session keys. Clients can cache TLS session keys for multiple RADIUS servers.

For more information, see EAP, MS-CHAP version 2, and PEAP.

For more information about configuring the session time-out for wireless remote access policies, see Introduction to remote access policies, Configure Remote Access Policies, and Elements of a remote access policy.

**Security and deployment considerations**

When choosing an authentication method, balance the level of security that you require with the effort that you want to devote to deployment. For the highest level of security, choose PEAP with certificates (EAP-TLS). For the greatest ease of deployment, choose PEAP with passwords (EAP-MS-CHAP v2).

Although both PEAP with EAP-TLS and EAP-TLS alone provide strong security through the use of certificates for server authentication and either certificates or smart cards for client computer and user authentication, when PEAP with EAP-TLS is used, client certificate information is encrypted. PEAP with EAP-MS-CHAP v2 requires the least effort to deploy because client authentication is password-based, so certificates or smart cards do not need to be installed on clients. Because PEAP creates an

end-to-end encrypted channel before EAP-MS-CHAP v2 authentication occurs, the authentication exchange reduces the risk of offline dictionary attacks.

For information about certificate requirements for 802.1X authentication methods, see Network access authentication and certificates. For information about deploying smart cards, see Checklist: Deploying smart cards for logging on to Windows.

**Important**

- When you deploy both PEAP and EAP unprotected by PEAP, do not use the same EAP authentication type with and without PEAP. For example, if you deploy PEAP with EAP-TLS (PEAP-EAP-TLS), do not also deploy EAP-TLS without PEAP. Deploying authentication methods with the same type--one with and the other without the protection of PEAP--creates a security vulnerability.

- Certificate Templates provide a new version 2 certificate template, named Workstation Authentication. This certificate template, which can be configured for auto-enrollment, is available for enterprise certification authorities (CAs) on computers running Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; or the 64-bit versions of the Windows Server 2003 family. Certificates based on this template allow client computers to authenticate their identity to servers. You should use this certificate template if you are both using certificate-based authentication for wireless clients running Windows XP and providing an enterprise CA on a computer running Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; or the 64-bit versions of Windows Server 2003 family. If you use the Computer certificate template in this case, client authentication will fail. For more information, see Certificate Templates and Manage Certificate Templates for an Enterprise Certification Authority.

**How 802.1X works on 802.11 wireless networks**

802.1X implements port-based network access control. Port-based network access control uses the physical characteristics of a switched local area network (LAN) infrastructure to authenticate computing devices that are attached to a LAN port and to prevent access to that port when the authentication process fails.

During a port-based network access control interaction, a LAN port adopts one of two roles: authenticator or supplicant. In the role of authenticator, a LAN port enforces authentication before it allows user access to the services that can be accessed through that port. In the role of supplicant, a LAN port requests access to the services that can be accessed through the authenticator's port. An authentication server, which can either be a separate entity or co-located with the authenticator, checks the supplicant's credentials on behalf of the authenticator. The authentication server then responds to the authenticator, indicating whether the supplicant is authorized to access the authenticator's services.

The authenticator’s port-based network access control defines two logical data paths to the LAN through one physical LAN port. The first data path, the uncontrolled port, allows data exchange between the authenticator and a computing device on the LAN, regardless of the authentication state of that device. This is the path that EAPOL (EAP over LAN) messages will take. The second data path, the controlled port, allows data exchange between an authenticated LAN user and the authenticator. This is the path that all other network traffic will take, after the computing device is authenticated.

**802.1X and IAS**

To support authentication, authorization, and accounting for wireless network connections, you can use 802.1X with IAS. IAS is the Microsoft implementation of a Remote Authentication Dial-in User Service (RADIUS) server and proxy server. When RADIUS is implemented, a wireless access point prevents data traffic from being forwarded to a wired network or to another wireless client without a valid authentication key. The process of obtaining a valid authentication key is as follows:

1. When a wireless client comes within range of a wireless access point, the wireless access point challenges the client.

2. The wireless client sends its identity to the wireless access point, which forwards this information to a RADIUS server.

3. The RADIUS server requests the credentials of the wireless client to verify the identity of the client. As part of this request, the RADIUS server specifies the type of credentials that are required.

4. The wireless client sends its credentials to the RADIUS server.

5. The RADIUS server verifies the credentials of the wireless client. If the credentials are valid, the RADIUS server sends an encrypted authentication key to the wireless access point.

6. The wireless access point uses this authentication key to securely transmit per-station unicast session and multicast authentication keys to the wireless client.

For information about configuring IAS for wireless access authentication, see Checklist: Configuring the IAS server and wireless access points for wireless access and Wireless access.

For information about how to configure 802.1X settings for clients, see Define 802.1X authentication for wireless networks on a client computer.

For general information about security for wireless networks, see Security information for wireless networks.

# Understanding wireless provisioning services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding wireless provisioning services**

Wireless Provisioning Services (WPS) are enhancements to wireless networking in Windows XP and the Windows Server 2003 family. WPS enables wireless networks to provide a consistent sign-up and configuration experience while providing more secure access to network resources.

When you connect to a wireless network that supports WPS, you are prompted to download additional files that are used by WPS to enable a more secure, consistent, and automatic setup. These files are generally safe to download, but the information contained within them might not be accurate. You should verify that the Web site from which the files will be downloaded is one that you expected based on your location, or one that you trust to provide you with the information.

If you choose to download the files, XML files are downloaded from the provider and stored on your computer for as long as you wish to use the wireless network. The files contain no personal information about you or your computer.

If you do not choose to download the files, you cannot connect to the wireless network.

When the files are downloaded, the Wireless Network Registration Wizard requests information from you. Some networks might require payment. Other networks might simply require acknowledgement of a usage policy. Follow the instructions in the Wireless Network Registration Wizard to provide the appropriate information to the network provider.

After you have signed up with a wireless network that supports WPS, the files stored on your computer can be updated automatically. If you choose this option, the wireless provisioning services in your computer will connect to the wireless network provider and update the information stored on your computer. This occurs on a schedule determined by the wireless network provider (typically once a week or once a month). This update process will only occur while you are already connected to the Internet and will not interfere with your use of your Internet connection. If you choose not to update the files automatically, the files for a specific network will be updated the next time you connect to that wireless network. (This is required to ensure that your computer has the right information for that network.)

For more information about connecting to wireless networks, see Connect to an available wireless network.

For conceptual information about configuring wireless client computer settings, see Configuring wireless network settings on client computers.

# Understanding Infrared Networking

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding infrared networking**
This section covers:

- Infrared communication
- Infrared implementation
- Links between infrared devices

**Note**

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

# Infrared communication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Infrared communication**
Infrared communication uses infrared light to transfer data. Infrared light is also used almost universally by TV and VCR remote controls. In computers, infrared communication offers an alternative to cables and floppy disks. Infrared communication provides a point-to-point, low-cost way to connect computers with each other or with devices and appliances. Many cellular phones are equipped with infrared ports that allow them to be connected to a computer for dial-up networking connections.

**Note**

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

# Infrared implementation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Infrared implementation**
Infrared data transfer is implemented according to the Infrared Data Association (IrDA) standards and protocols. These standards are designed to allow low-cost components and low power requirements, and to enable connections by simply pointing infrared devices at each other. Infrared transceivers are now installed in nearly all new portable computers. For a computer that does not have a built-in infrared transceiver, you can install an external infrared transceiver.

IrDA is a half-duplex, short-range data transfer technology. The IrDA protocols specify the procedures that support link initialization, device address discovery, connection startup and data rate negotiation, information exchange, disconnection, link shutdown, and device address conflict resolution.

**Infrared device support**
Infrared functionality is provided through the Wireless Link file transfer feature, infrared printing (IrLPT), infrared image transfer (IrTran-P), and infrared networking (IrNET and IrComm) capabilities. Additionally, the IrDA Winsock API supports programs created by other software and equipment manufacturers. These manufacturers sell programs that use the Winsock API (or proprietary interfaces) to provide infrared connections to printers, modems, digital pagers, personal digital assistants, electronic cameras, organizers, cellular phones, and hand-held computers.

### Important

- For enhanced security, performance, and stability, it is recommended that you use only signed device drivers. For more information, see Signed Drivers.

**Infrared transmission speeds**
Many laptops, notebook computers, and hand-held devices now include infrared transceiver ports that provide infrared asynchronous serial transmission with maximum data transfer speeds of either 115.2 kilobytes per second (Kbps) or 4 megabits per second (Mbps), and sometimes 16 Mbps.

**Serial IrDA 115.2 Kbps support (SIR)**
The Serial IrDA (SIR) implementation of IrDA provides a maximum data transfer speed of 115.2 Kbps. The primary benefit of this implementation is that existing serial hardware can be used without additional cost.

**Fast IrDA 4.0 Mbps support (FIR) and Very Fast IrDA 16.0 Mbps support (VFIR)**
The Fast IrDA (FIR) implementation of IrDA provides a maximum data transfer speed (of 4 Mbps) that easily adjusts to slower devices. Very Fast IrDA (VFIR), which provides 16 Mbps half-duplex data transmission, is also supported. FIR and VFIR devices can communicate with SIR devices.

**IrComm and IrNET support**
With IrComm, you can use your computer and infrared-equipped cellular phone to connect to your Internet service provider or to send fax transmissions without additional equipment. With IrNET, you can establish a point-to-point connection between your computer and another computer or another infrared-equipped device. You can also establish a connection between your computer and a network access point.

**IrLPT printer support**
If your computer came with an internal infrared device, or if you install an infrared transceiver, an infrared port appears as a local port in the **Add Printer** dialog box. When you associate a printer with this port and then print to that printer, the IrLPT protocol is used to transmit the data.

**IrTran-P image transfer support**
The IrTran-P image transfer protocol is used in digital cameras and other digital image capture devices. You can use this feature to receive digital images from a camera or other device that supports IrTran-P to your computer through an IrDA connection. The IrTran-P service is implemented as a listen-only service; it never initiates the IrTran-P connection.

### Important

- To enhance security, do not enable IrTran-P. When you enable IrTran-P, all incoming files sent over IrTran-P are automatically accepted. Because incoming files might contain harmful programs, ensure that the files originate from a

trustworthy source. Do not open files if you cannot verify the source, do not recognize the file format, or are unsure of the content. Instead, delete the files immediately. For more information about infrared security considerations, see Security information for infrared communication.

**Note**

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

# Links between infrared devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Links between infrared devices**
Infrared data-link transmission occurs between two infrared devices. All transmissions over the link go from the primary (commanding) device to the secondary (receiving) device. The primary role is determined dynamically when a link is established and continues until the connection is closed. Any station that is capable can assume the primary role. When two computers are in range, either one can assume the primary role, so a user can initiate a data transfer on either computer. Some devices may only be capable of assuming the secondary role.

**How an infrared connection is made**
A device creates a link by automatically detecting the other or by a user request. The commanding station sends a connection request at 9,600 bits per second (bps) to the other device (including information such as an address, data rate, and other capabilities). The responding device assumes the secondary role and returns information that contains its address and capabilities. The primary and secondary stations then change the data rate and link parameters to the common set defined by the initial information transfer. Finally, the primary station sends data to the secondary station confirming the connection. The devices are then connected and begin data transfer under control of the primary device.

**Multiple infrared connections**
The Winsock API supports multiple simultaneous connections over a single IrDA link. This feature allows several different programs to use a single infrared device simultaneously. For example, you might place a portable computer within range of a desktop computer to simultaneously send and receive mail, update your calendar and contacts, and print deferred documents. Each activity can be controlled by a separate program on the laptop computer that locates and connects to its corresponding program on the desktop computer.

**Multiple infrared devices**
A single infrared device cannot link simultaneously with more than one other infrared device. However, you can install multiple infrared devices on a computer to provide simultaneous links to multiple infrared devices. For example, using separate infrared devices, a desktop computer can simultaneously print to an infrared port, communicate with a portable computer, and dial a network connection.

For additional information, see Installing infrared devices.

### Important

- For enhanced security, performance, and stability, it is recommended that you use only signed device drivers. For more information, see Signed Drivers.

- To enhance security, align infrared devices so that the infrared transceivers are between 0.1 meter (approximately 4 inches) and 0.5 meter (approximately 20 inches) apart whenever you establish an infrared link between two devices. Although there can be up to 1 meter (approximately 40 inches) between infrared transceivers without a loss in data transfer capability, if you place the transceivers closer to each other, you minimize the risk of interference from an attacker. To further enhance security, ensure that all infrared devices and data sources are trustworthy, and, if you are transferring infrared data with another person, conduct the transfer in a private location whenever possible. For more information about infrared security considerations, see Security information for infrared communication.

### Note

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

# Using Wireless Networking

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using wireless networking**
This section covers:

- Security information for wireless networks
- Creating, modifying, and assigning Active Directory-based wireless network policies
- Using Resultant Set of Policy to view wireless network policy assignments
- Configuring wireless network settings on client computers
- Logging and viewing wireless network activity
- Using Infrared Communication

# Security information for wireless networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security information for wireless networks**
Wireless networking technologies provide convenience and mobility, but they also introduce security risks on your network. For example, unless authentication and authorization mechanisms are implemented, anyone who has a compatible wireless network adapter can access the network. Without encryption, wireless data is sent in plaintext, so anyone within sufficient distance of a wireless access point can detect and receive all data sent to and from a wireless access point.

The following security mechanisms enhance security over wireless networks:

- Windows Firewall
- 802.11 identity verification and authentication
- 802.11 Wired Equivalent Privacy (WEP) encryption
- Wi-Fi Protected Access (WPA)
- 802.1X authentication
- IAS support for 802.1X authentication

**Windows Firewall**
Windows Firewall runs on each of your clients and servers. It provides protection from network attacks that pass through your perimeter network or originate inside your organization, such as Trojan horse attacks, port-scanning attacks, and worms. Like many firewall technologies, Windows Firewall is a stateful firewall. It drops all incoming traffic unless it has been sent in response to a request from the computer or has been specified as allowed. With the exception of some Internet Control Message Protocol (ICMP) messages, Windows Firewall allows all outgoing traffic.

Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

In Windows Server 2003 with Service Pack 1 (SP1), Windows Firewall is disabled by default for all connections, including LAN (wired and wireless), dial-up, and virtual private network (VPN) connections. Windows Firewall is also disabled by default for new connections.

If your wireless computers do not already have a firewall installed and running, it is recommended that you turn on Windows Firewall. Right-click the wireless icon in the notification area, click **Change Windows Firewall settings**, and then select **On**.

For information about Windows Firewall, see Help: Turn Windows Firewall on or off for a specific connection, Help: Add a program to the Windows Firewall exceptions list, Help: Add a port to the Windows Firewall exceptions list, and Windows Firewall and Message Queuing.

**802.11 identity verification and authentication**
For identity verification and authentication, IEEE 802.11 defines the open system and shared key authentication subtypes:

- Open system authentication does not actually provide authentication; it performs only identity verification through the exchange of messages between the initiator (wireless client) and the receiver (wireless access point).
- Shared key authentication does provide authentication by verifying that the initiator has knowledge of a shared secret. Under the 802.11 standard, it is assumed that the shared secret is sent to the wireless access point over a secure channel that is independent of 802.11.

For information about how to specify the authentication subtype that you want to use, see Define preferred wireless networks in Group Policy or Define a wireless network connection on a client computer.

**Important**

- To enhance security and connectivity, do not use shared key authentication. Shared key authentication is less secure than open system authentication because it requires the exchange of a secret key that is shared by all wireless access points and clients and therefore is more vulnerable to known-text attacks. In addition, if you use shared key authentication for a wireless network that has multiple wireless access points, you will lose network connectivity when you travel from one wireless access point to a new wireless access point. In this case, you will lose connectivity because your network key will no longer match the shared key used by all wireless access points. To determine whether a wireless network you are connecting to has multiple wireless access points, use Wireless Monitor. For information about how to use Wireless Monitor to view details about wireless access points, see View details about wireless network access points.

**802.11 WEP encryption**
For encryption, 802.11 defines the WEP algorithm. WEP provides data confidentiality by encrypting the data that is sent between wireless clients and wireless access points.

To encrypt the data that is sent over wireless networks, WEP uses the RC4 stream cipher with either a standard 40-bit encryption key or, in some implementations, a 104-bit encryption key. A stream cipher is a method of encrypting text (to produce ciphertext) in which a cryptographic key and algorithm are applied to each binary digit in a data stream, one bit at a time. The RC4 stream cipher, designed by RSA Data Security, Inc can accept keys of arbitrary length. Data integrity is provided through an integrity check value (ICV) in the encrypted portion of the wireless frame.

**WPA**
WPA is a new wireless network security technology developed by the Wi-Fi Alliance. Wi-Fi Protected Access strengthens existing cryptographic weaknesses of WEP, and introduces a method to generate and distribute encryption keys automatically. The solution also introduces an integrity check on the data so an attacker cannot modify packets of information being communicated. To improve enterprise-level user authentication, Wi-Fi Protected Access authenticates every user on the network while keeping those users from joining rogue networks. WPA presents a practical answer to dealing with the weaknesses of WEP, based on available technologies and offering forward compatibility with 802.11i and backward compatibility with existing 802.11 solutions.

**802.1X authentication**
802.1X is an IEEE standard for authenticated network access to wired Ethernet networks and wireless 802.11 networks. IEEE 802.1X provides support for centralized user identification, authentication, dynamic key management, and accounting. The 802.1X standard enhances security by allowing a computer and a network to authenticate each other, generating a per-user/per-session key to encrypt data over wireless connections and providing the ability to dynamically change keys.

### Important

- For enhanced security in Windows XP Service Pack 1 and the Windows Server 2003 family, 802.1X authentication is available only for access point (infrastructure) networks that require the use of a network key (WEP).

- It is highly recommended that you use 802.1X authentication whenever you connect to an 802.11 wireless network. If you connect to an 802.11 wireless network, and you do not enable 802.1X, the data that you send is more vulnerable to attacks, such as offline traffic analysis, bit flipping, and malicious packet injection.

**EAP authentication methods**
802.1X uses Extensible Authentication Protocol (EAP) for message exchange during the authentication process. With EAP, an arbitrary authentication method, such as passwords, smart cards, or certificates, is used to authenticate the wireless connection. The support that 802.1X provides for EAP types allows you to use any of the following authentication methods:

- EAP-Transport Level Security (EAP-TLS), which uses certificates for server authentication and either smart cards or certificates for user and client computer authentication.

- Protected EAP with EAP-Microsoft Challenge Handshake Authentication Protocol version 2 (PEAP with EAP-MS-CHAPv2), which uses certificates for server authentication and credentials (user name and password) for user authentication.

- PEAP with EAP-TLS, which uses certificates for server authentication and either smart cards or certificates for user and client computer authentication.

For more information, see EAP, MS-CHAP version 2, Understanding 802.1X authentication for wireless networks, and PEAP.

**Security and ease of deployment**

When choosing an authentication method, balance the level of security that you require with the effort that you want to devote to deployment. For the highest level of security, choose PEAP with certificates (EAP-TLS). PEAP uses TLS to enhance the security of other EAP authentication protocols. With PEAP, TLS is used to create an end-to-end encrypted channel between an EAP client (such as a wireless computing device) and an EAP server (such as an Internet Authentication Service (IAS) server). Although both PEAP with EAP-TLS and EAP-TLS alone provide strong security through the use of certificates for server authentication and either certificates or smart cards for client computer and user authentication, when PEAP with EAP-TLS is used, client certificate information is encrypted.

For the greatest ease of deployment, choose PEAP with passwords (EAP-MS-CHAP v2). PEAP with EAP-MS-CHAP v2 requires the least effort to deploy, because client authentication is password-based, so certificates or smart cards do not need to be installed on clients. Because PEAP creates an end-to-end encrypted channel before EAP-MS-CHAP v2 authentication occurs, the authentication exchange reduces the risk of offline dictionary attacks.

The session keys that are generated during the PEAP authentication process provide keying material for the WEP encryption keys that encrypt the data that is sent between wireless clients and wireless access points. In addition, PEAP supports fast reconnect. PEAP fast reconnect allows roaming users to maintain continuous wireless network connectivity when traveling between different wireless access points on the same network, as long as each wireless access point is configured as a client of the same IAS (RADIUS) server.

For information about certificate requirements for 802.1X authentication methods, see Network access authentication and certificates. For information about deploying smart cards, see Checklist: Deploying smart cards for logging on to Windows.

**Important**

- When you deploy both PEAP and EAP unprotected by PEAP, do not use the same EAP authentication type with and without PEAP. For example, if you deploy PEAP with EAP-TLS (PEAP-EAP-TLS), do not also deploy EAP-TLS without PEAP. Deploying authentication methods with the same type--one with and the other without the protection of PEAP--creates a security vulnerability.

**IAS support for 802.1X authentication**

To enhance the security and deployment of wireless networks, you can use 802.1X with IAS, the Microsoft implementation of a Remote Authentication Dial-in User Service (RADIUS) server and proxy server. When RADIUS is implemented, wireless access points that are configured as RADIUS clients use the RADIUS protocol to send connection requests and accounting messages to a central RADIUS server. The RADIUS server accesses a user account database and set of rules for granting authorization, processes the wireless access point's connection request, and then either accepts or rejects the connection request.

For more information about 802.1X authentication, see Understanding 802.1X authentication for wireless networks. For information about wireless network client configuration, see Configuring wireless network settings on client computers. For information about configuring IAS for wireless access authentication, see Checklist: Configuring the IAS server and wireless access points for wireless access and Wireless access.

# Creating, modifying, and assigning Active Directory-based wireless network policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating, modifying, and assigning Active Directory-based wireless network policies**
Wireless network settings can be configured locally, by users on client computers, or centrally. To enhance the deployment and administration of wireless networks, you can use Group Policy to create, modify, and assign wireless network policies centrally, for Active Directory clients. When you use Group Policy to define wireless network policies, you can specify whether clients can use Windows to configure wireless network connection settings, whether to enable 802.1X authentication for wireless network connections, and the preferred wireless networks that clients can connect to.

When you assign an Active Directory-based wireless network policy, the policy is stored in Active Directory and it is cached in the registry on the local computer. If a computer is temporarily disconnected from a Windows 2000 or a Windows Server 2003 domain, the Active Directory policy that is cached in the local registry is applied instead, if such a policy has been cached.

A Group Policy object defines access, configuration, and usage settings for accounts and resources. Wireless network policies can be assigned to the Group Policy object of a site, domain, or organizational unit. When the wireless network policy is applied to one of the Group Policy objects for the Active Directory object, the wireless network policy is propagated to any computer accounts that are affected by that Group Policy object. For more information, see Group Policy overview.

When assigning a wireless network policy in Active Directory, consider the following:

- Only a single wireless network policy can be assigned at a specific level in Active Directory.
- A wireless network policy that is assigned for the domain takes precedence over local wireless network settings on a client computer, when a client computer is a member of the domain.
- A wireless network policy that is assigned to an organizational unit in Active Directory takes precedence over a domain-level policy for members of that organizational unit.
- An organizational unit inherits the policy of its parent organizational unit unless either policy inheritance is explicitly blocked or policy is explicitly assigned.
- The highest possible level of the Active Directory hierarchy should be used to assign policies to reduce the amount of configuration and administration required.

For information about how to define Active Directory-based wireless network policies, see Define Active Directory-based Wireless Network Policies.

**Note**

- The integration of IPSec policies with Active Directory described here does not apply to computers running Windows XP Home Edition. You cannot administer Active Directory-based IPSec policy from a computer running Windows XP Home Edition because these computers cannot join Active Directory domains.

# Using Resultant Set of Policy to view wireless network policy assignments

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Resultant Set of Policy to view wireless network policy assignments**

Resultant Set of Policy (RSoP) is an addition to Group Policy that you can use to view wireless network policy assignments for a computer or for members of a Group Policy container. This information can help you troubleshoot policy precedence issues and plan your deployment.

To view wireless network policy assignments in RSoP, you must first open the RSoP MMC console, and then run a query. RSoP provides two types of queries: logging mode queries (for viewing wireless network policy assignments for a computer) and planning mode queries (for viewing wireless network policy assignments for members of a Group Policy container).

**Logging mode queries**

You can run an RSoP logging mode query to view all of the wireless network policies that are assigned to an wireless network client. The query results display the precedence of each wireless network policy assignment, so that you can quickly determine which wireless network policies are assigned but are not being applied and which wireless network policy is being applied. The RSoP console also displays detailed settings (that is, whether 802.1X authentication is enabled, the list of preferred wireless networks that clients can connect to, and wireless network key settings) for the wireless network policy that is being applied.

When you run a logging mode query, RSoP retrieves policy information from the Windows Management Instrumentation (WMI) repository on the target computer, and then displays this information in the RSoP console. In this way, RSoP provides a view of the policy settings that are being applied to a computer at a given time.

For information about how to run RSoP logging mode queries for wireless network policies, see Use RSoP to view wireless network policy assignments for a computer. For general information about RSoP logging mode queries, see RSoP logging mode. For general information about RSoP, see RSoP overview.

**Planning mode queries**

You can run an RSoP planning mode query to view all of the wireless network policies that are assigned to members of a Group Policy container. For example, a planning mode query can be useful if you are planning a company reorganization and you want to move computers from one organizational unit to a new organizational unit. By supplying the appropriate information and then running a planning mode query, you can determine which wireless network policies that are assigned but are not being applied to the new organizational unit and which wireless network policy is being applied. In this way, you can identify which policy would be applied if you were to move the computers to the new organizational unit. As with logging mode queries, when you run a planning mode query, the RSoP console displays detailed policy settings for the wireless network policy that is being applied.

When you run a planning mode query, RSoP retrieves the names of the target user, computer, and domain controller from the WMI repository on the domain controller. WMI then uses the Group Policy Data Access Service (GPDAS) to create the policy settings that would be applied to the target computer, based on the RSoP query settings that you entered. RSoP reads the policy settings from the WMI repository on the domain controller, and then displays this information in the RSoP console user interface.

For information about how to run RSoP planning mode queries for wireless network policies, see Use RSoP to view wireless network policy assignments for members of a Group Policy container. For general information about RSoP planning mode queries, see RSoP planning mode.

**Note**

- You can run an RSoP planning mode query only on a domain controller (when you run a planning mode query, you must explicitly specify the domain controller name). However, you can specify any wireless network client as the target for the query, provided you have the appropriate permissions to do so.

**Assigning and processing wireless network policies in Group Policy**

Wireless network policies can be assigned from and stored in Active Directory, as part of Group Policy, or they can be assigned and stored locally, on a computer. When a computer is joined to an Active Directory domain, the domain-level wireless network policy applies. If a computer is not joined to an Active Directory domain, the local settings apply.

Group Policy settings are contained in Group Policy objects, which are linked with specific Active Directory objects (sites, domains, and organizational units). When a wireless network policy is assigned to a Group Policy object for an Active Directory object (such as an organizational unit), that wireless network policy is propagated to any computer accounts that are affected by the Group Policy object.

Multiple Group Policy objects, each of which can contain an wireless network policy, can be assigned to a computer account. When multiple wireless network policies are assigned, the last policy that is processed is the policy that is applied (that is, the last policy takes the highest precedence and overrides the settings of any wireless network policy assignments that were processed earlier).

Policy precedence is based on the Group Policy inheritance model. The policy used is the policy assigned at the lowest level of the domain hierarchy for the domain container of which the computer is a member. For example, if there are wireless network policies that are configured for both the domain and for an organizational unit within the domain, the computers that are members of the domain use the domain wireless network policies. The computers that are members of the organizational unit within the domain use the organizational unit wireless network policies. If there are multiple organizational units, members of each organizational unit use the wireless network policy assigned to the organizational unit that is closest in level to their container in the Active Directory hierarchy. If no wireless network policies are configured for Active Directory, or if a computer is not connected to an Active Directory domain, the local wireless settings are used.

**Wireless network policy information displayed in the RSoP console**

The RSoP snap-in simplifies the task of determining which wireless network policy is being applied by displaying the following information for each Group Policy object that contains a wireless network policy assignment: the name of the wireless network policy, the name of the Group Policy object that the wireless network policy is assigned to, the wireless network policy precedence (the lower the number, the higher the precedence), and the name of the site, domain, and organizational unit to which the Group Policy object containing the wireless network policy applies (that is, the scope of management for the Group Policy object).

For general information about Group Policy, see Group Policy overview.

# Configuring wireless network settings on client computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring wireless network settings on client computers**

The Wireless Configuration service in Windows XP and the Windows Server 2003 family supports the IEEE 802.11 standard for wireless networks and minimizes the configuration that is required to access wireless networks. This service is enabled by default and allows you to travel to different wireless networks without reconfiguring all of the network connection settings on your computer at each location. As you move from one location to another, the Wireless Configuration service searches and sends notifications when there are wireless networks available. When connecting to a new wireless network, you will need only to configure the settings specific to that network. The Wireless Configuration service updates your wireless network adapter to match those settings and attempts to connect to the wireless network.

The Windows Configuration service allows you to use Windows to configure your wireless network settings. When you use Windows to configure your wireless network settings, you can create a list of preferred wireless networks and you can specify the order in which to attempt connections to these networks.

For more information, see Define Wireless Network Policies on a Client Computer.

**Viewing available 802.11 wireless networks**

In addition to the wireless network notifications that are provided by the Wireless Configuration service, in Windows XP with Service Pack 2 and Windows Server 2003 with Service Pack 1, computers equipped with wireless network adapters have an enhanced interface called **Wireless Network Connection**.

The **Wireless Network Connection** interface was designed with several user benefits in mind. The interface makes it easier to view information about available 802.11 wireless networks, including network type (infrastructure or ad hoc), wireless signal strength, state (connected or disconnected), and whether networks are security enabled. The **Wireless Network Connection** interface also makes it easier to configure and control connections to 802.11 wireless networks. Direct access to 802.11 wireless properties, where both general 802.11 wireless settings and advanced configurations are made, can be accessed through the following interface links: **Related Tasks**, **Change the order of preferred networks**, and **Change advanced settings**.

To control connections to wireless networks, under **Choose a wireless network**, click **Connect** or **Disconnect**. To refresh the list of available wireless networks, use **Network Tasks**.

As an example, while attempting to connect to a wireless network, under **Choose a wireless network**, you might see status that reads **Limited or no connectivity**. Click the **Limited or no connectivity** link for more information, including possible remedies for connectivity problems.

**Wireless icons**

You can access the **Wireless Network Connection** interface by using new wireless icons that are provided in both the notification area and in Network Connections. To open the **Wireless Network Connection** interface, right-click the wireless icon, and then select **View Available Wireless Networks**. For more information, see Define Wireless Network Policies on a Client Computer.

**Notification area wireless icons**

In Windows XP with Service Pack 2 and Windows Server 2003 with Service Pack 1, wireless icons are displayed to indicate the state of the wireless connection:

| Notification area icon | Wireless connection state |
|---|---|
| | Connected |
| | Connecting |
| | Not connected |
| | Warning |

The warning icon is displayed when an IP address error is detected while attempting to connect to a wireless network. In the event of an error, the warning icon will always be displayed in the notification area, provided the device has not been disabled or the **Show icon in notification area when connected** check box on the properties page of the device has not been

cleared.

**Note**

- When the wireless connection is in any of these states, you can right-click the wireless connection icon in the notification area and then select **View Available Wireless Networks**. Wireless adapters that have been disabled by right-clicking the wireless connection icon, and then clicking **Disable**, will not appear in the notification area. Disabled wireless adapters can be enabled only by right-clicking the wireless network connection icon in Network Connections, and then clicking **Enable**.

**Network Connections wireless icons**

There are five views that can be applied to icons in Network Connections: Thumbnails, Tiles, Icons, List, and Details. In each of these views, the various states of wireless connections are represented in a similar way to the wireless icons in the notification area. For example, a wireless icon with a red X indicates there is no connection to a wireless network; a wireless icon with a yellow triangle indicates an error state.

Wireless icons in Network Connections do not indicate connecting or transitioning states. However, if you select the wireless icon and then expand **Details** in the left-hand pane, you have access to the following information:

| **Information type** | **Example or explanation:** |
|---|---|
| Connection status | • Acquiring Network address<br>• Not connected, Firewalled<br>• Connected, Firewalled |
| Assigned IP Address | Displays the IP address that is assigned to the wireless adapter |
| Subnet Mask | Displays the associated subnet mask. |
| Method of IP address and subnet mask assignment | • Assigned by DHCP<br>• Manually Configured |
| Network type | • Access Point<br>• Peer-to-Peer (same as computer to computer) |
| Network | The name of the network. This is also known as the SSID. |
| Signal Strength: | Excellent |

**Selecting a wireless network type**

When you configure new or existing wireless network connections or connect to an available wireless network, you can choose from the following wireless network types:

- **Access point (infrastructure)**

  In access point wireless networks, wireless clients (computing devices with wireless network adapters, such as your portable computer or personal digital assistant) connect to wireless access points. The access points function as bridges between wireless clients and the existing network backbone. As you move from one location to another, and the signal for one wireless access point weakens, or the access point becomes congested with traffic, you can connect to a new access point. For example, if you work in a large corporation, you might connect to several different wireless access points as you move between different floors of a building or different buildings in a campus, while still maintaining uninterrupted access to network resources.

- **Computer-to-computer (ad hoc)**

In computer-to-computer wireless networks, wireless clients connect to each other directly, rather than through wireless access points. For example, if you are in a meeting with co-workers, and you do not need to gain access to network resources, your wireless device can make direct connections to the wireless devices of your co-workers, and you can form a temporary network.

- **Any available network (access point preferred)**

  In access point preferred wireless networks, a connection to an access point wireless network is always attempted first, if there are any available. If an access point network is not available, a connection to a computer-to-computer wireless network is attempted. For example, if you use your laptop at work in an access point wireless network, and then you take your laptop home to use in your computer-to-computer home network, the Windows Configuration service will change your wireless network settings as needed so that you can connect to your home network.

#### Configuring wireless network security settings

802.1X is an IEEE standard for authenticated network access to wired Ethernet networks and wireless 802.11 networks. IEEE 802.1X enhances security and deployment by providing support for centralized user identification, authentication, dynamic key management, and accounting. For enhanced security in Windows XP Service Pack 1 and the Windows Server 2003 family, 802.1X authentication is available only for access point (infrastructure) networks that require the use of a network key (WEP). Wired Equivalent Privacy (WEP) provides data confidentiality by encrypting the data that is sent between wireless clients and wireless access points.

**Important**

- It is highly recommended that you use 802.1X authentication whenever you connect to an 802.11 wireless network. If you connect to an 802.11 wireless network without using 802.1X authentication, the data that you send is more vulnerable to attacks, such as offline traffic analysis, bit flipping, and malicious packet injection. For more information about security considerations for wireless networks, see Security information for wireless networks.

#### Configuring wireless network key settings

When Wired Equivalent Privacy (WEP) is enabled, a network key can be used to encrypt data that is sent over wireless networks. The network key can be provided for you automatically (for example, if 802.1X is being used for dynamic key distribution), or you can specify the key by typing it yourself. If you specify the key yourself, you can also specify the key index (the location where a specific key is stored).

A wireless client can be configured with up to four keys (the key index values are 0, 1, 2, and 3). When a wireless access point or a wireless client transmits an encrypted message using a key that is stored in a specific key index, the transmitted message indicates the key index that was used to encrypt the message body. The receiving wireless access point or wireless client can retrieve the key that is stored at the key index and use it to decode the encrypted message body.

**Important**

- To enhance security and connectivity, do not use shared key authentication. Shared key authentication is less secure than open system authentication because it requires the exchange of a secret key that is shared by all wireless access points and clients and therefore is more vulnerable to known-text attacks. In addition, if you use shared key authentication for a wireless network that has multiple wireless access points, you will lose network connectivity when you travel from one wireless access point to a new wireless access point. In this case, you will lose connectivity because your network key will no longer match the shared key used by all wireless access points. To determine whether a wireless network you are connecting to has multiple wireless access points, use Wireless Monitor. For information about how to use Wireless Monitor to view details about wireless access points, see View details about wireless network access points.

#### Configuring 802.1X authentication settings for wireless network connections

The support that 802.1X provides for Extensible Authentication Protocol (EAP) types allows you to select from several authentication methods for wireless network connections. For more information about choosing an authentication method, see Understanding 802.1X authentication for wireless networks.

# Logging and viewing wireless network activity

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Logging and viewing wireless network activity**

Wireless Monitor allows you to view details about access points and wireless clients. You can use this information to troubleshoot your wireless service. The Wireless Configuration service logs information in Wireless Monitor that allows you to:

- Identify service configuration changes.
- Check the events logged in the Wireless Configuration service log that are generated from outside of your network, such as media event notifications, 802.1X events, and timer expiration events.
- Check how the Wireless Configuration service reacts to external events by following transitions, as they are reflected in the log.

For information about how to use Wireless Monitor, see Monitor Wireless Network Activity.

**Wireless Monitor access point information**

The following table describes the items that are displayed when you use Wireless Monitor to view details about **Wireless Access Point Information**.

| Access point statistics | Description |
|---|---|
| Network Name | Displays the names of the networks that are within the reception range of the wireless adapter on your computer. |
| Network Type | Displays the type of network listed in the logged event. Network Types include Access Point and Peer to Peer. |
| MAC Address | Displays the media access control (MAC) address of the networks that are within the reception range of the wireless adapter on your computer. |
| Privacy | Displays whether privacy is enabled or disabled for any network within the reception range of the wireless adapter on your computer. |
| Signal Strength | Displays the strength of the signals that are broadcast from the networks that are within the reception range of the wireless adapter on your computer. IEEE specifies that 802.11 wireless devices receive at a signal strength range between -76 dBmW (decibel milliwatts) and -10 dBmW, with -10 dBmW indicating the strongest signal; some receivers that are more sensitive may be able to accept weaker signals, possibly as weak as -85 dBmW to -90 dBmW. |
| Radio Channel | Displays the radio channels on which the networks that are within the reception range of the wireless adapter on your computer are broadcasting. |
| Access Point Rate | Displays the data rate that the wireless network will support. |
| Network Adapter GUID | Displays a 16-byte value generated by the operating system in order to identify, uniquely, each wireless adapter on your computer. A globally unique identifier (GUID) is used to identify a particular device or component. |

**Wireless Monitor wireless client information**

The following table describes the items that are displayed when you use Wireless Monitor to view details about **Wireless Client Information**.

| Wireless client statistics | Description |
|---|---|
| Source | Identifies the software that generated the event. Events displayed in Wireless Monitor are generated either by the Wireless Configuration service or EAP over LAN (EAPOL). |
| Type | Displays the type of event. The event type is the classification of the event, such as Error, Warning, Information, or Packet. |
| Time | Displays the time at which the event was logged. |
| Local MAC Address | Displays the media access control (MAC) address of the local network adapter. |
| Remote MAC Address | Displays the MAC address of the remote network interface. This is frequently a wireless access point, or, in wireless computer-to-computer networks, this is the MAC address of the network adapter in the remote computer. |
| Network Name | Displays the name of the wireless network for which the event was generated. Under the 802.11 standard for wireless networks, the network name is also known as a service set identifier (SSID). |
| Description | Provides a brief summary of the logged event. (For a list of the events that are logged in the **Description** field and for brief explanations of these events, see the following table. |

**Wireless Client Information events**

The following table describes the events that are logged in the **Description** column of Wireless Monitor for **Wireless Client Information**.

| Description | Explanation |
|---|---|
| Adding interface "x." | Indicates that a new network adapter has been inserted into the computer running the Wireless Configuration service. This does not necessarily mean that the adapter is a wireless adapter. The Wireless Configuration service determines whether this is a wireless adapter and, if so, ceases to control it (the Wireless Configuration service removes the internal context of the adapter from its hashes). The description includes the NDIS adapter as parameter "x." |
| Configuration "x" has a default random WEP key. Authentication is disabled. Assuming invalid configuration. | Indicates that the Wireless Configuration service associated successfully to a network after providing a random Wired Equivalent Privacy (WEP) key. If 802.1X is not taking control over the connection, then this is considered to be an invalid configuration. If 802.1X is disabled, the Wireless Configuration service deletes this configuration. If 802.1X is taking control, the Wireless Configuration service does not delete the configuration, and the Wireless Configuration service retains the configuration as "Successful." The log contains the SSID of the network to which it is associated as parameter "x." |
| Deleting configuration "x" and moving on (If no better match is found, the configuration will be revived). | Indicates that the Wireless Configuration service is failing to detect the presence of an ad hoc network. This means that the adapter might be the only 802.11 wireless device in the ad hoc network, in which case there is no "Media connect" notification and media status shows "Disconnected" after the two seconds allowed to associate. If this happens, the Wireless Configuration service deletes the network but tags the deleted network such that association will be reattempted if all of the other networks fail. If all other attempts to associate with a network fail, then the tagged network is "Revived," and the Wireless Configuration service will mark it "Successful," regardless of the media indications. This is how the system becomes the first node in the ad hoc network. The description includes the SSID of the ad hoc network that failed as parameter "x." |

| | |
|---|---|
| Deleting configuration "x" and moving on. | Indicates that the Wireless Configuration service attempted to associate to an infrastructure network and failed. There are two possible reasons for the failure:<br>• The Wireless Configuration service provided the 802.11 settings, but two seconds elapsed and there was no "Media connect" notification received or, at the end of the two seconds, media status indicated "Disconnected."<br>• The association succeeded, but 802.1X requested that the Wireless Configuration service disassociate from this network explicitly (as a result of an authentication failure). The description includes the SSID of the network that failed as parameter "x." |
| Driver failed scanning, rescheduling another scan in 5sec. | Indicates that the Wireless Configuration service queried the driver, and the driver reported an error. This can happen if the driver cannot serve the request immediately. In such instances, the Wireless Configuration service schedules another attempt in five seconds. This event does not occur regularly (ideally, it does not occur at all). If this event is logged often, it could indicate that the wireless adapter drivers have been corrupted. |
| Failed to associate to any wireless network. | Indicates that the Wireless Configuration service is in a "Failed" state. In most cases, this event is logged every minute, when:<br>• The Wireless Configuration service is disabled.<br>• The wireless adapter is outside of the broadcast range of any preferred networks.<br>• There is no available wireless network.<br>This description indicates that no networks are detected to which the wireless adapter can associate. In the "Failed" state, the Wireless Configuration service provides a random SSID for this purpose. |
| Hard resetting interface. | Indicates that the wireless adapter has been hard-reset. This usually means that any existing association is broken before the Wireless Configuration service reanalyzes the available networks and the user preferences and configures the appropriate 802.11 settings on the adapter. This event is usually logged when you roam from one network to another and is associated with a "Media disconnect" notification from the previous network. This event is also logged once every minute if the Windows Configuration service is looping through a failure state, indicating that the Wireless Configuration service could not associate to any network. This event does not occur in the case of a steady successful, association. |
| Initiating scanning for wireless networks. | Indicates that the Wireless Configuration service is initiating a scanning cycle. Subsequently, the Wireless Configuration service causes the driver to scan for networks, query the list of available networks, and either associate to a more appropriate network or, if it detects there is no change, retain the current successful association (if any). This event is logged once every minute. |
| No configuration change. Still associated to "x." | Indicates that the Wireless Configuration service processed the list of available networks and the list of user preferred networks and determined there is no change that would allow it to break the existing successful association. Subsequently, the Wireless Configuration service will transition into "Association successful" state. This event is logged once every minute in the case of a steady successful association. The description includes the SSID of the associated network as parameter "x." |
| No configurations left in the selection list. | Indicates that the Wireless Configuration service went through all of the selected wireless networks and failed to associate to any of them. This could happen either as a result of an NDIS media status indicating "Disconnected" or as a result of the 802.1X forcing the networks to be deleted because of a failed authentication. This description indicates that the Wireless Configuration service is transitioning into a "Failed" state. This is not necessarily an error; it could mean the service is not configured, that no preferred network is available, or that no wireless networks are available at all. |

| | |
|---|---|
| Plumbing configuration SSID: "x," Network Type: "y." | Indicates that the Wireless Configuration service processed the list of available networks and the list of user preferred networks and determined something has changed such that the adapter needs to be reconfigured. This description indicates that a current, successful association is broken. This event occurs when the computer is disconnected from one network or when a new, preferred network became available. This event does not occur in the case of a successful, steady association. The description includes the new SSID that has been configured on the adapter ("x") and the infrastructure parameter ("y;" where 0 = an ad hoc network, and 1 = an infrastructure network). |
| Processing command Next Configuration. | Indicates that 802.1X directed the Wireless Configuration service to break the association to the current network but retain it for subsequent attempts. This event indicates that 802.1X attempted one type of authentication and failed. 802.1X can try authentication if the wireless adapter reassociates with the network. |
| Processing command Remove Configuration. | Indicates that the Wireless Configuration service is directed by 802.1X to break the existing association with the current network and delete it from its list such that it does not refresh that association again. This event indicates that 802.1X failed all attempts for all types of authentication. |
| Processing command Update data. | Indicates that 802.1X is providing new data to the Wireless Configuration service in order to have it associated with the network to which it is currently associated. |
| Processing user command Refresh. | Indicates that the Wireless Configuration service received a command to refresh. Most commonly, this command is a result of the user clicking the **Refresh** in the user interface. This action interrupts the one minute scanning cycle by instantly initiating scanning. |
| Processing user command Reset. | Indicates that the Wireless Configuration service received a command to reset. Most commonly this command is issued by 802.1X whenever something changes in the configuration. This command breaks any existing association while the Wireless Configuration service provides new 802.11 settings. |
| Received Device Arrival notification for "x." | Indicates that the Wireless Configuration service received a "Device arrival" notification. The description includes the NDIS of the device being added as parameter "x." |
| Received Device Removal notification for "x." | Indicates that the Wireless Configuration service received a "Device removal" notification. The description includes the NDIS of the device being removed as parameter "x." |
| Received Media Connect notification. | Indicates that the Wireless Configuration service received a "Media connect" notification. This event can occur repeatedly while the Wireless Configuration service configures the initial association. This description can also indicate that the adapter is randomly switching from one access point to another, which highlights problems with the wireless adapter driver. |
| Received Media Disconnect notification. | Indicates that the Wireless Configuration service received a "Media disconnect" notification from the driver. This event occurs when the Wireless Configuration service provides the adapter with the SSID of a wireless network has been detected, but the adapter fails to associate with that network. This event also occurs whenever the user roams out of the area covered by the network. |

| | |
|---|---|
| Received Timeout notification. | Indicates that an internal Wireless Configuration service timer elapsed. This event description should occur at the following times:<br>• Three seconds after the Wireless Configuration service initiates a scanning cycle.<br>• Two seconds after the Wireless Configuration service provides any network configuration, if there is no "Media connect" notification in between.<br>• Every minute while in "Failed" or "Association successful" states. |
| Scan completed. | Indicates that the Wireless Configuration service has transitioned into scanning cycle after allowing three seconds for the driver of the wireless adapter to scan for wireless networks. Once in this state, the Wireless Configuration service will query the driver in order to get all 802.11 settings, the most important one being the list of available networks. This event occurs every minute. |
| Skipping configuration "x" for now, attempt authentication later. | Indicates that 802.X directed the Wireless Configuration service to skip the current successful association and move to another association. The network configuration is retained for another attempt at a subsequent loop (802.1X will attempt computer authentication instead of user authentication). The description includes the SSID of the network that is being disassociated as parameter "x." |
| Wireless configuration has been changed via an administrative call. | Indicates that a configuration change has been received through an administrative call. This is either the result of the user changing the wireless configuration or a policy object being applied. |
| Wireless Configuration service failed to start. | Indicates that the service failed to initialize. |
| Wireless Configuration service was started successfully. | Indicates that the service has started successfully. This is an indication that the service:<br>• Initialized all of its global objects successfully.<br>• Initialized the logging database framework successfully.<br>• Initialized 802.1X authentication successfully.<br>• Initialized the policy module successfully.<br>• Registered with the Service Control Manager (SCM) successfully, including registering for device notifications.<br>• Registered with Windows Management Instrumentation (WMI) for NDIS media event notifications successfully.<br>• Registered as an RPC server successfully. |
| Wireless interface successfully associated to "x" [MAC "y"]. | Indicates that the Wireless Configuration service associated to a network successfully and that network is sending a "Success" notification to 802.1X. The description includes the SSID of the network to which it is associated as parameter "x." The MAC address of the remote endpoint is also included as parameter "y." |

# Using Infrared Communication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using infrared communication**
You can transfer data over infrared connections with computers, printers, cameras, and other devices that use IrDA protocols. In addition, you can use an infrared-enabled cellular phone to make a dial-up connection to the Internet or to your corporate network. This section covers:

- Security information for infrared communication
- Installing infrared devices
- Establishing infrared network connections between computers
- Transferring files
- Printing to an infrared printer
- Transferring digital camera images to the computer

**Note**

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

# Security information for infrared communication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security information for infrared communication**

Infrared provides a secure and simple way to transfer and synchronize data. In order for infrared communication to work properly, infrared transceivers must operate on a line-of-sight basis--they must be placed at a 30-degree angle and no farther than 1 meter (approximately 40 inches) apart. Because infrared operates at such a short distance and a narrow angle, it is relatively difficult for an attacker to intercept data that is sent over infrared. However, infrared does not provide data encryption. Because data is sent in plaintext, it is vulnerable to packet sniffing attacks. Therefore, take precautions to ensure that data that is sent over infrared is not intercepted.

To enhance security when using infrared communication, do the following:

- **Do not enable infrared image transfer (IrTran-P).**

  IrTran-P is disabled by default (that is, the option to use Wireless Link to transfer images from a digital camera to your computer is disabled). If you enable this option, all of the incoming files that are sent over IrTran-P are automatically accepted. Because incoming files might contain harmful programs, ensure that the files originate from a trustworthy source. Do not open files if you cannot verify the source, do not recognize the file format, or are unsure of the content. Instead, delete the files immediately.

  For more information, see Transferring digital camera images to the computer and Infrared implementation.

- **Align infrared devices so that the infrared transceivers are between 0.1 meter (approximately 4 inches) and 0.5 meter (approximately 20 inches) apart whenever you establish an infrared link between two devices.**

  Although there can be up to 1 meter (approximately 40 inches) between infrared transceivers without a loss in data transfer capability, if you place the transceivers closer to each other, you minimize the risk of interference from an outside infrared device. To further enhance security, ensure that all infrared devices and data sources are trustworthy. Finally, if you are transferring infrared data with another person, conduct the transfer in a private location whenever possible.

  For more information, see Links between infrared devices and Establish an infrared link.

- **Use only signed device drivers.**

  For security, performance, and stability, it is recommended that you use only signed device drivers.

  For more information, see Signed Drivers.

**Note**

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

# Installing infrared devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Installing infrared devices**
Most internal infrared devices are installed by Setup or when you start your computer after adding one of these devices. However, when you attach a serial infrared transceiver to a serial (COM) port or to a USB port, you do need to install it as described in this topic. This topic also describes how to install an internal infrared device that is not automatically detected.

**Installing an infrared device connected to a serial port**
If you have a desktop computer or a portable computer without an internal infrared device, you can connect a serial infrared transceiver to a serial (COM) port or a USB port. To do so, attach the infrared transceiver to the port, note which port you are using, and then follow the steps in Add a new infrared device to a serial port.

**Installing an undetected internal infrared device**
If you add an internal infrared device to a computer with Windows XP Home Edition, Windows XP Professional, or Windows Server 2003, Standard Edition already installed, the device is typically detected and installed the next time you start the computer. If this does not occur, you might have to install the device manually. To do so, follow the instructions in Add a new infrared device to a serial port.

**Note**

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

# Establishing infrared network connections between computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Establishing infrared network connections between computers**
An infrared network connection allows you to establish a direct connection between two infrared-enabled devices without using modems, cables, or network hardware. Instead, you align the two devices to establish an infrared link, and then use Network Connections to create an infrared network connection.

**How you can use infrared network connections**
You can use infrared network connections to perform a variety of tasks. For example, you can:

**Access the Internet from a public location**
While at an airport, a hotel, or any other location that provides public Internet access, you can sit at a kiosk and use your laptop, personal digital assistant (PDA), or other infrared-enabled device to connect to the Internet. Kiosks at such locations provide a built-in infrared port, so that you can align your infrared-enabled device with the built-in port and establish an infrared network connection.

When making this type of infrared network connection, you configure the infrared device as the guest. The server that your device connects to is the host.

**Access shared information on another computer**
You can establish an infrared network connection between two computers to access shared resources on one of the computers. For example, if you have a portable computer that you want to use to access files in a shared folder on your desktop computer, you can establish an infrared network connection between the two computers.

When making this type of infrared network connection, you configure the portable computer as the guest and the desktop computer as the host.

**Creating network connections on both computers**
To create an infrared network connection, follow the steps in Establish a direct infrared network connection between computers on both computers. When you create the network connections, specify the computer that has the information you want to access as the host computer, and the computer you are going to use to access the information as the guest computer.

For both computers, specify the infrared port as the device that will be used to make the connection.

**Configuring permissions on the host computer**
If you are connecting two Windows XP Home Edition, Windows XP Professional, or Windows Server 2003, Standard Edition computers, you can access shared folders on the host. However, before you can make the connection, make sure that the user name for the connection is given membership in a group on the host computer. For information on how to add users to your computer, see Create a local user account. The new user must have sufficient permissions to perform any expected tasks. If you are adding a user so that someone else can access your computer, you might want to add the new user to the Guest, User, or Power Users groups.

**Accessing the local computer**
After you set up network connections on both the host and guest computers, follow the steps in Use an infrared network connection. Working on the guest computer, you can then map shared drives on the host computer and use **My Computer** or Windows Explorer to open folders and access files.

## Notes

- If you only want to send files from one infrared-enabled device to another, you do not need to establish an infrared network connection. Instead, you only need to establish an infrared link, as described in Establish an infrared link.
- Infrared network connections use the Point-to-Point protocol (PPP). Typically, this protocol does not require additional configuration.
- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

# Transferring files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Transferring files**
You can use Wireless Link to send selected files or an entire folder to another computer running Windows 98, Windows 2000, Windows XP Home Edition, Windows XP Professional, or Windows Server 2003, Standard Edition.

**Establishing an infrared connection**
To send files, first establish an infrared link with another computer or other infrared device, as described in the procedure Establish an infrared link. When an infrared device is in range, the infrared connection status icon appears on the taskbar, and the Wireless Link item appears on the desktop. These indicate only that an infrared device is in range. A data connection is made when Wireless Link or another program communicates over the link. While a program is connected over a link, the taskbar icon changes to the icon. As long as an infrared transceiver is in range, you can transfer data over the link.

The IrDA Winsock API enables programs to communicate with any device that implements one of the supported protocols, described in Infrared implementation. Simultaneous connections over an infrared link are supported (unless the link is being used for a network connection), so more than one program can use the same link. If you use another program, refer to the documentation provided with it for procedures to transfer data.

**Important**

- To enhance security, align infrared devices so that the infrared transceivers are between 0.1 meter (approximately 4 inches) and 0.5 meter (approximately 20 inches) apart whenever you establish an infrared link between two devices. Although there can be up to 1 meter (approximately 40 inches) between infrared transceivers without a loss in data transfer capability, if you place the transceivers closer to each other, you minimize the risk of interference from an attacker. To further enhance security, ensure that all infrared devices and data sources are trustworthy, and, if you are transferring infrared data with another person, conduct the transfer in a private location whenever possible. For more information about infrared security considerations, see Security information for infrared communication.

**Note**

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

# Printing to an infrared printer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Printing to an infrared printer**

Printing to a printer that is connected by an infrared link is very much the same as printing to any other printer. After you establish an infrared connection between your computer and a printer, the printer is typically installed automatically by Plug and Play. If your computer is not infrared-capable, you can attach an infrared transceiver to your serial (COM) port. For more information, see Add a new infrared device to a serial port.

After you add an infrared printer, the only difference between printing to it and printing to any other printer is that you must first establish an infrared link between the computer and the printer by aligning them so that the infrared transceivers are within 1 meter (approximately 40 inches) of each other, and the transceivers are pointing at each other. For more information, see Establish an infrared link.

**Important**

- For enhanced security, performance, and stability, it is recommended that you use only signed device drivers. For more information, see Signed Drivers.

- To enhance security, align infrared devices so that the infrared transceivers are between 0.1 meter (approximately 4 inches) and 0.5 meter (approximately 20 inches) apart whenever you establish an infrared link between two devices. Although there can be up to 1 meter (approximately 40 inches) between infrared transceivers without a loss in data transfer capability, if you place the transceivers closer to each other, you minimize the risk of interference from an attacker. To further enhance security, ensure that all infrared devices and data sources are trustworthy, and, if you are transferring infrared data with another person, conduct the transfer in a private location whenever possible. For more information about infrared security considerations, see Security information for infrared communication.

**Note**

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

# Transferring digital camera images to the computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Transferring digital camera images to the computer**

The **Image Transfer** tab of the **Wireless Link** dialog box includes a check box in which you can specify whether you want to transfer images from a digital camera to your computer using Wireless Link.

The **Image Transfer** tab also specifies the default location for image files received from a digital camera. This location is used by Wireless Link. Other programs may use other locations or require you to specify a location when you begin the transfer. You can also elect to have Windows Explorer automatically open to this location after images have been transferred.

The transfer is initiated by the digital camera rather than the computer. To transfer images, point the infrared window on your camera at the infrared transceiver on the computer. Then follow the camera manufacturer's instructions to select the picture and send it to the computer. Some cameras can transfer more than one picture at a time. The exact steps to transfer pictures depends on the make and model of the camera, and should be described in the instructions for operating the camera.

To configure Wireless Link to transfer camera images, see Change settings to transfer images from a digital camera. To transfer camera images to your computer using Wireless Link, see Transfer images from a digital camera to your computer.

**Caution**

- To enhance security, do not enable infrared image transfer (IrTran-P), that is, do not select the **Use Wireless Link to transfer images from a digital camera to your computer** check box. If you select this check box, all incoming files sent over IrTran-P are automatically accepted. Because incoming files might contain harmful programs, ensure that the files originate from a trustworthy source. Do not open files if you cannot verify the source, do not recognize the file format, or are unsure of the content. Instead, delete the files immediately. For more information about infrared security considerations, see Security information for infrared communication.

**Important**

- To enhance security, align infrared devices so that the infrared transceivers are between 0.1 meter (approximately 4 inches) and 0.5 meter (approximately 20 inches) apart whenever you establish an infrared link between two devices. Although there can be up to 1 meter (approximately 40 inches) between infrared transceivers without a loss in data transfer capability, if you place the transceivers closer to each other, you minimize the risk of interference from an attacker. To further enhance security, ensure that all infrared devices and data sources are trustworthy, and, if you are transferring infrared data with another person, conduct the transfer in a private location whenever possible. For more information about infrared security considerations, see Security information for infrared communication.

**Notes**

- If you are using synchronization software, note that certain software will automatically disable infrared image transfer (IrTran-P). As a result, you will not be able to use Wireless Link to transfer images from a digital camera to your computer. In such cases, you might have to remove the synchronization software before you can use Wireless Link to transfer digital camera images. To determine whether your synchronization software disables infrared image transfer, see your software manufacturer's product documentation.

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

# Wireless Networking Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**
This page provides sources of additional information about wireless technologies.

**Microsoft product support**
For Microsoft product support, see Microsoft product Support Services at the Microsoft Web site.

**Windows Resource Kits**
The Windows Resource Kits contain extensive technical information about wireless networking protocols and deploying wireless technologies.

- For information about wireless networking protocols, see "Wireless Networking protocols" at the Microsoft Windows Resource Kits Web site.

- For information about deploying wireless technologies, see "Deploying a Wireless LAN" at the Microsoft Windows Resource Kits Web site.

**The Infrared Data Association (IrDA)**
The Infrared Data Association (IrDA) is an international organization that sets standards for infrared data connections. The infrared support provided by Windows XP Home Edition, Windows XP Professional, and Windows Server 2003, Standard Edition is designed to meet these standards.

For more information about IrDA, see the Infrared Data Association Web site.

### Note

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

# Windows Server 2003 Wireless Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic provides basic troubleshooting information for wireless computers connecting to Windows Server 2003 with Service Pack 1 (SP1) domain wireless networks. If you are looking for wireless troubleshooting for a Windows XP home office environment, see the following:

- Troubleshooting Microsoft Windows XP-based Wireless Networks in the Small Office or Home Office at http://go.microsoft.com/fwlink/?LinkID=55033
- How to troubleshoot wireless network connections in Windows XP at http://go.microsoft.com/fwlink/?LinkId=83226
- Troubleshooting IEEE 802.11 Wireless Access with Microsoft Windows at http://go.microsoft.com/fwlink/?LinkId=83227
- Configuring Windows XP IEEE 802.11 Wireless Networks for the Home and Small Business at http://go.microsoft.com/fwlink/?LinkID=30045

**Quick lists for common connectivity problems**

This section provides a series of tables and lists that can help you to quickly identify conditions that can cause connectivity problems. The quick lists are presented in two categories: by symptom and by network type.

Quick lists by symptom

- Symptom: Inability to connect
- Symptom: Intermittent connectivity
- Symptom: Incorrect, missing, or stale visible networks
- Symptom: Wireless client has associated, but there is no valid IP address configuration or no network connectivity
- Symptom: There are no visible wireless networks or the Wireless Networks tab is not present in the Network Connections folder

Quick lists by network type

- General network connectivity problems
- Domain network connectivity problems
- 802.1X-authenticated network connectivity problems

**Quick lists by symptom**

The following series of tables present common symptoms, their causes, and likely solutions.

**Symptom: Inability to connect**

| Possible Causes | Corrective Measures |
|---|---|

| | |
|---|---|
| • Incorrect or incompatible wireless network configuration. For example, shared key authentication is configured on the wireless AP, and the wireless client is attempting open system authentication.<br>• Inadvertent media access control (MAC) address filtering.<br>• The wireless network name is not visible.<br>• The wireless AP and wireless network adapter are not using the same 802.11 standard (for example, you are using an 802.11b network adapter and an 802.11a wireless AP).<br>• | • Verify that the wireless network configurations between the wireless client and wireless AP are compatible.<br>• Double-check the steps you followed during configuration. User error is a common source of incorrect configuration.<br>• |
| • Radio frequency (RF) interference from nearby devices, such as cordless phone and Bluetooth devices.<br>• Wireless client is at the periphery of the RF range of the wireless AP. | • Review the wireless network environment and network topology.<br>• Double-check the steps you followed during configuration. User error is a common source of incorrect configuration. |
| • Improperly functioning or outdated wireless network adapter driver. | • Obtain and install the most recent version of the wireless network adapter driver. |

**Symptom: Intermittent connectivity**

| Possible Causes | Corrective Measures |
|---|---|
| • Improperly functioning or outdated wireless network adapter driver.<br>• Improperly functioning wireless AP. | • Obtain and install the most recent version of the wireless network adapter driver. |

**Symptom: Incorrect, missing, or stale visible networks**

| Possible Causes | Corrective Measures |
|---|---|
| • Improperly functioning or outdated wireless network adapter driver.<br>• Improperly functioning radio equipment on wireless AP or wireless network adapter.<br>• Malfunctioning wireless network adapter drivers cannot detect and register visible networks. | • Obtain and install the most recent version of the wireless network adapter driver.<br>• Run the Repair tool on the wireless network adapter.<br>**Note**<br>To run Repair, right-click the wireless connection icon in the notification area or in Network Connections, and the click **Repair**. |

**Symptom: Wireless client has associated, but no there is no valid IP address configuration or no network connectivity**

| Possible Causes | Corrective Measures |
|---|---|

| | |
|---|---|
| • Authentication problem.<br>• Incorrect encryption key.<br>• Corrupt, expired, or missing certificates.<br>• Improperly functioning wireless AP. | • Verify that the wireless network configurations between the wireless client and wireless AP are compatible.<br>• If you are using a static wired equivalent privacy (WEP) key, verify that it has been correctly configured.<br>**Note**<br>Due to known security issues with WEP encryption, it is recommended that you use only Wi-Fi Protected Access version 2 (WPA2) (preferred) or WPA.<br>• Verify whether other computers that connect to the wireless AP have the same problem. If all wireless clients of the same wireless AP have the same problem, make sure the wireless AP settings match the **IAS RADIUS Clients** settings configured for the specific wireless AP. Also make sure that the **Wireless Network (IEEE 802.11) Policy** configuration settings for client computers match the wireless AP settings. |

**Symptom: There are no visible wireless networks or the Wireless Networks tab is not present in the Network Connections folder**

| Possible Causes | Corrective Measures |
|---|---|
| • The Wireless ZeroConfig Service is not running.<br>• Improperly functioning or outdated wireless network adapter driver.<br>• On a portable computer, the external switch for the wireless antenna might be turned off. | • Check to see if the Wireless ZeroConfig Service is running by checking the state is **Started** in the Services Microsoft Management Console (MMC) snap-in.<br>• Use the Services console to configure the Wireless ZeroConfig Service to start automatically.<br>• A wireless network adapter driver that fails in the early stages of service startup can cause the Wireless ZeroConfig Service not to initialize on that interface. If this is determined to be the problem, install the most recent version of the driver for that adapter. |

**Quick lists by network type**

The following quick lists are not exhaustive catalogs of connectivity problems. They provide information about the types of conditions that can cause connectivity problems.

For the purposes of this document, network connectivity problems fall into three groups:

- General network connectivity problems
- Domain network connectivity problems
- 802.1X-authenticated network connectivity problems

**General network connectivity problems**

These types of problems can occur on networks ranging from small office/home office (SOHO) workgroup-based networks to enterprise networks.

| Possible Causes | Corrective Measures |
|---|---|

| | |
|---|---|
| A wireless setting mismatch exists between the wireless AP and the wireless client.<br><br>For example, the wireless AP is configured to use WPA2 and the client is configured with WPA-PSK. | For a single computer, manually configure the settings to match.<br><br>For multiple computers, use the **Wireless Network (IEEE 802.11) Policy** to configure settings to match the settings configured on the wireless AP. |
| The wireless adapter is disabled in Network Connections. | Right-click the disabled connection, and then click **Enable**. |
| The external switch that controls the wireless antenna is turned off. | Set the external switch to the On position. |
| The wireless network adapter is malfunctioning. | Install the most recent driver for the adapter. If that fails to fix the problem, replace the wireless adapter, if possible.<br><br>**Note**<br>In cases where the adapter is built into the computer, you can try to install a second wireless adapter, such as a Universal Serial Bus (USB) adapter to test connectivity. If you install a second wireless adapter, it is recommended that you first disable the original wireless connection. In Network Connections, right-click the wireless connection, and then click **Disable**. Install the second wireless adapter, and then attempt to connect to the network. |
| Network clients configured with static IP addresses are configured by using an IP address that is not in the correct IP address range or by using a different subnet mask. | Configure the IP settings with a unique IP address in the correct IP address range, using the correct subnet mask. |
| The DHCP service is enabled on the wireless router to allocate IP addresses to network clients, but one or more network clients are configured with a static IP address. | Configure the **Internet Protocol (TCP/IP)** properties of the wireless adapter to **Obtain an IP address automatically**. |
| The DHCP server is disconnected from the network, powered off, or the service is not running. | In a SOHO network, the DHCP service is typically provided by the wireless router or by Internet Connection Sharing (ICS). Restore the DHCP service. |
| In a SOHO network:<br><br>• In a new wireless network or when replacing your modem or wireless AP, you have not registered your modem with your Internet service provider (ISP), or your router media access control (MAC) address. Modem or router registration varies by ISP.<br><br>• You have not configured the public connection on the router to accept DHCP leases from the ISP network. For example, you have configured the public connection on the wireless router with a static IP address. | • Contact your ISP to register your device.<br><br>• Configure the public interface to accept DHCP leases from the ISP network. |

**Domain network connectivity problems**

In addition to the general network connectivity problems, these types of problems commonly occur on domain networks, ranging from small organizations to enterprise networks.

**Active Directory**

| Possible Causes | Corrective Measures |
|---|---|
| The user does not have an account in the **Active Directory Users and Computers** snap-in. | Create an account for the user. |
| The **Dial-in** properties of the user account or computer account in **Active Directory Users and Computers** is set to **Deny access**. | Set the user and computer account **Dial-in** properties to **Allow access**.<br>**Note**<br>In 802.1X networks that use IAS to authenticate connections, set the user account **Dial-in** properties to **Control access through Remote Access Policy**. |
| The user account is disabled. | In **Active Directory Users and Computers**, in **Users**, right-click the account, and then click **Enable**. |
| The user account has expired. | In **Active Directory Users and Computers**, right-click the account, click **Properties**, and then on the **Account** tab, in **Account expires**, select **Never**, or in **End of** set a new expiration date. |
| The user is attempting a connection at a prohibited time, as specified in the logon hours of the user account (the default setting is **Logon Permitted** for all hours). | In **Active Directory Users and Computers**, in the user account properties, on the **Account** tab, click **Logon Hours**, and then configure the settings to specify the hours that the client is allowed to connect to the network. |
| The user is attempting a prohibited connection by using a computer that is not specified in the **Log On To** setting of the user account properties, or the default setting **All computers** is not selected. | In **Active Directory Users and Computers**, in the user account properties, on the **Account** tab, click **Log On To**, and then either select **All computers**, or select **The following computers**. In **Computer name**, specify the computers that the user is allowed to use to connect to the network. |
| The Domain Name System (DNS) service is stopped or is not configured. | On your DNS server, in the **Services** snap-in, right click **DNS Server**, and then click **Start**. |

**Users and Computers**

| Possible Causes | Corrective Measures |
|---|---|
| The client computer is not a member of the domain. | Join the computer to the domain. |
| The client is attempting to log on to the domain by using non-domain credentials. A common error with new computers or user accounts is that users log on to the computer by using their computer account. | At the log on window, in **Log on to**, select the domain if it is available, and then use the domain user account. For newly joined computers, logon using the domain name and user account in the format *DomainName\UserName*. |

**DHCP**

| Possible Causes | Corrective Measures |
|---|---|
| The DHCP scope is full, and therefore the DHCP server cannot lease addresses to requesting DHCP clients. | If the DHCP scope does not use the full address range, edit the scope to expand the address range. |
| The IP address of the DHCP server was changed and now DHCP clients cannot get IP addresses. | Make sure that the static IP address and subnet mask of the DHCP server are within the addressing scheme of the subnet. |
| The DHCP service is stopped. | On your DHCP server, in the **Services** snap-in, right-click **DHCP Server**, and then click **Start**. |

| | |
|---|---|
| On a newly configured DHCP server:<br>• The DHCP server is not authorized in Active Directory.<br>• The IP address range of the DHCP scope is incorrectly specified.<br>• The DHCP scope is not activated.<br>• The DHCP server is not on the same subnet as the clients.<br>• The DHCP server is offline. | In the **DHCP** snap-in, right-click the domain container, and then click **Authorize**.<br>Set the IP address range and subnet mask in the scope to match the addressing scheme of your subnet.<br>In the **DHCP** snap-in, right-click the domain container, right-click the scope for the subnet that is presenting connectivity problems, and then click **Activate**.<br>Physically connect the DHCP server to the correct subnet.<br>Restart the DHCP server. |

**802.1X-authenticated network connectivity problems**

This section provides examples of configuration problems that are specific to networks that deploy 802.1X-authenticating wireless APs and IAS for 802.1X-authenticated connections. In an 802.1X network, consider the following examples in addition to the examples listed in the previous two sections.

**Active Directory problems**

| Possible Causes | Corrective Measures |
|---|---|
| The Active Directory domain functional level is not raised to **Windows Server 2003**. IAS Remote Authentication Dial-In User Service (RADIUS) settings require the Windows Server 2003 domain functional level. | In the **Active Directory Domains and Trusts** snap-in, click **Action**, and then click **Raise Domain Functional Level**.<br>**Important**<br>If domain controllers on your network are running Windows NT 4.0 and earlier, then do not raise the domain functional level to Windows 2000 native. After the domain functional level is set to Windows 2000 native, it cannot be changed back to Windows 2000 mixed.<br>Likewise, if domain controllers on your network are running Windows 2000 or Windows NT 4.0 and earlier, then do not raise the domain functional level to Windows Server 2003. After the domain functional level is set to Windows Server 2003, it cannot be changed back to Windows 2000 mixed or Windows 2000 native. |
| In **Active Directory Users and Computers**, the dial-in properties of the user account are not configured to **Control access through Remote Access Policy**. | In the **Active Directory Users and Computers** snap-in, in the domain container, open **Users**, right-click the user account, click **Properties**, and then on the **Dial-in tab**, select **Control access through Remote Access Policy**. |
| The IAS remote access policy grants access for members of an Active Directory security group. However, the user is not a member of the security group that is specified in the remote access policy. | In **Active Directory Users and Computers**, in the domain container, open **Users**, right-click the security group that is specified in the applicable IAS remote access policy, click **Properties**. On the **Members** tab, click **Add**, and then in **Enter the object names to select**, type the user account to add the user to the security group. |

| | |
|---|---|
| The authentication method specified in **Wireless Network (IEEE 802.11) Policies** does not match the authentication method specified in the IAS remote access policy.<br><br>For example, if network clients running Windows Vista are configured by **Wireless Network (IEEE 802.11) Policies** to use Protected Extensible Authenticated Protocol Microsoft Challenge Handshake Authentication Protocol version 2 (PEAP-MS-CHAPv2) authentication, but no IAS remote access policy specifies PEAP-MS-CHAPv2 authentication, the mismatch prevents client authentication. | Change the Extensible Authenticated Protocol (EAP) authentication method specified in either the IAS remote access policy or in **Wireless Network (IEEE 802.11) Policies** to match the method deployed for your network. |

**Client**

| Possible Causes | Corrective Measures |
|---|---|
| The Wireless ZeroConfig Service is not running. By default, the Wireless ZeroConfig Service starts automatically. | For an individual computer, manually start the service in the **Services** snap-in.<br><br>For multiple computers, in Group Policy Object Editor, open **Wireless Network (IEEE 802.11) Policies**. In the details pane, right-click the applicable wireless policy, click **Properties**, and then on the **General** tab, select **Use Windows to configure wireless network settings for clients**. |
| When using Extensible Authenticated Protocol-Transport Layer Security (EAP-TLS) authentication, the client does not have a certificate that contains the Client Authentication purpose in the Enhanced Key Usage extension. Instead, the client is configured according to minimum client certificate requirements. | Instruct the user to log on to the network by using a wired Ethernet connection and domain credentials; the enhanced certificate is automatically installed. |

**Certificate Services**

| Possible Causes | Corrective Measures |
|---|---|
| When using EAP-TLS, the user does not have a client certificate. | Instruct the user to log on to the network by using a wired Ethernet connection and domain credentials; the certificate is automatically installed. |
| The client does not have a corresponding root CA certificate that matches the issuing CA of the IAS server certificate. | 1. In Group Policy Object Editor, open **Wireless Network (IEEE 802.11) Policies**.<br><br>2. In the details pane, right-click the applicable wireless policy, and then click **Properties**.<br><br>3. On the **Preferred Networks** tab, in **Networks**, select the corresponding wireless network, and then click **Edit**.<br><br>4. On the **802.1x** tab, in **EAP** type, click **Settings**, and then in **Trusted Root Certification Authorities**, select the certificate that matches the IAS server certificate. |

**IAS (RADIUS)**

| Possible Causes | Corrective Measures |
|---|---|
| The RADIUS shared secret on the wireless AP does not match the shared secret configured for RADIUS clients in IAS. | Configure the wireless AP to use the same shared secret. The shared secret is specified in the **RADIUS Clients** node of the **IAS** snap-in. |

| | |
|---|---|
| The IAS remote access policy properties are configured to reject the user or computer requests. For example:<br>• On the **Settings** tab, the properties of the policy are set to **Deny remote access permission**.<br>• On the **Dial-in Constraints** tab of the remote access policy, time restrictions prohibiting the connection are configured.<br>• On the **Dial-in Constraints** tab, an incorrect media type is specified. | • In the **IAS** snap-in, right-click the applicable remote access policy, click **Properties**, and then click **Grant remote access permission**.<br>• In the **IAS** snap-in, right-click the applicable remote access policy, click **Properties**, click **Edit Profile**. On the **Dial-in Constraints** tab, select **Allow access only on these days and at these times**, and then click **Edit** to specify allowed access times.<br>• In the **IAS** snap-in, right-click the applicable remote access policy, click **Properties**, click **Edit Profile**, and then on the **Dial-in Constraints** tab, do one of the following:<br>  • Clear **Allow access only through these media (NAS-Port-Type)**<br>  • Select **Allow access only through these media (NAS-Port-Type)**, and then select **Wireless - IEEE 802.11**. |
| A mismatch exists between the trusted root CA that issued the RADIUS server certificate specified in the IAS remote access policy, and the trusted root CA specified in the selected EAP type in **Wireless Network (IEEE 802.11) Policies**. | 1. In Group Policy Object Editor, open **Wireless Network (IEEE 802.11) Policies**.<br>2. In the details pane, right-click the applicable wireless policy, and then click **Properties**.<br>3. On the **Preferred Networks** tab, in **Networks**, select the corresponding wireless network, and then click **Edit**.<br>4. On the **802.1x** tab, in **EAP type**, click **Settings**, and then in **Trusted Root Certification Authorities**, select the certificate that matches the IAS server certificate. |
| The vendor-specific attributes (VSAs) for the wireless AP are configured incorrectly. | Check the wireless AP product documentation for VSA usage, and then specify the **IAS Vendor specific attributes** in **IAS**. If you are unsure about the correct VSA setting, select **RADIUS Standard**. |
| The IP address of the wireless AP (RADIUS client) specified in IAS is incorrect. | 1. In the **IAS** snap-in, select **RADIUS Clients**.<br>2. In the details pane, right-click the RADIUS client that corresponds to the wireless AP, and then click **Properties**.<br>3. On the **settings** tab, in **Address (IP or DNS)** type the correct IP address, and then click **Verify**. |
| The IAS server certificate has expired. | For information about requesting an IAS Server certificate, see the Windows Server 2003 Help topic Computer certificates for certificate-based authentication. |
| The IAS service is stopped. | In the **Services** snap-in, right-click **Internet Authentication Service**, and then click **Start**. |

| | |
|---|---|
| EAP is configured differently in the applicable remote access policy than it is in **Wired Network (IEEE 802.11) Policy** in Active Directory. | Configure both the IAS remote access policy and **Wired Network (IEEE 802.11) Policy** to use the EAP method that corresponds with your network deployment. |
| On a newly configured IAS server:<br>• IAS is not registered in Active Directory.<br>• The IAS server does not have a server certificate. | • In the **IAS** snap-in, right-click **Internet Authentication Service**, and then click **Register Server in Active Directory**.<br>• See the Windows Server 2003 Help topic Computer certificates for certificate-based authentication for information about requesting an IAS Server certificate. |

**Wireless AP**

| Possible Causes | Corrective Measures |
|---|---|
| The wireless AP does not have the correct or latest firmware. | Contact the wireless AP manufacturer for the latest firmware. |
| The IP address of the wireless AP is incorrectly configured for the subnet. | Configure the wireless AP with a static IP address and subnet mask according to your network TCP/IP addressing scheme. |
| The wireless AP does not specify the correct IP address of the IAS RADIUS server. | On the wireless AP, configure the RADIUS server IP address to match the IP address of your IAS server. |

**Troubleshooting Windows XP wireless connections: quick list**

Wireless connection problems frequently occur for the following reasons:

- Disabled wireless network adapters.
- Incorrectly configured wireless network settings.
- Insufficient credentials for authentication or missing permissions for authorization.
- Distance, interference, or obstructions between wireless devices.

Because successful troubleshooting depends on your ability to identify the source of the problem, Windows Server 2003 with Service Pack 1 (SP1) includes status and warning reporting to help you isolate and resolve wireless network connection problems.

Follow these steps to solve several common problems associated with wireless connections:

- Many portable computers have a switch that can be used to turn 802.11 wireless network adapters on and off. On a laptop computer, the switch might be on the left side of the computer case. Be sure that the switch is turned on. For more information, see the product documentation for your portable computing device.
- Make sure that the wireless adapter has not been disabled. You can disable a wireless adapter through the user interface (UI) by right-clicking on a wireless adapter icon, and then selecting **Disable**. Wireless adapters that have been disabled in this way will not appear in the notification area and can only be enabled in Network Connections. For more information, see Configuring wireless network settings on client computers.
- Use Wireless Auto Configuration to configure wireless network settings. When enabled, Wireless Auto Configuration allows you to connect to an existing wireless network, change wireless network connection settings, configure a connection to a new wireless network, and specify preferred wireless networks. It also notifies you when new wireless networks are available. When you switch wireless networks, your wireless network adapter settings will be dynamically updated to match the settings of that new network and a network connection attempt will be made. For more information, see Use Windows to configure wireless network settings on a client computer.
- If you are connecting to a wireless network for the first time, Wireless Auto Configuration will configure basic network

settings, if the service is enabled. However, you may need to configure additional settings, such as the data encryption type or Wired Equivalent Privacy (WEP) key, if they are not automatically configured for your account in the Active Directory directory service. For more information, see Define Wireless Network Policies on a Client Computer. You might also need to request account permissions from your network administrator.

- Check to see if the desired wireless network appears in the network list. Right-click the wireless icon, and then click **View Available Wireless Networks**. If the desired wireless network does not appear under **Choose a wireless network**, you might be outside of the broadcast range of that network or the network might be suppressing the beaconing signal. First, try to relocate the wireless device to a location that receives a stronger signal. To refresh the network list and get the most current list of wireless networks that are advertising within reception range of your computer, right-click the wireless icon, click **View available wireless networks**, and then, under **Network Tasks**, click **Refresh network list**.

  **Note**

  - Some infrastructure networks suppress the beaconing signal because they do not want to advertise the availability of their wireless network. In these cases, the network will not appear under **Choose a wireless network**. However, you can connect to these networks if you enter all of the correct configuration information, which you can obtain from the network administrator.

    For more information about configuring wireless network settings, see Use Windows to configure wireless network settings on a client computer, Add, edit, or remove wireless network connections on a client computer, and Define a wireless network connection on a client computer.

- Check to see if there is a wireless warning icon in the notification area. You can click the warning icon to get information about the error as well as possible remedies. If you used **View Available Wireless Network** to open the list of available wireless networks, check for a warning where the wireless network is displayed under **Choose a wireless network**. You can click the warning link text to get information about the warning and possible remedies.

- If you have previously connected successfully to a specific network, but the connection to that network failed, right-click the wireless icon, and then click **Repair**. This will disable, and then enable the wireless adapter.

- Balloon notifications appear in the notification area when the status of a wireless connection changes (for example, when status changes from **Connected** to **Not Connected** because the wireless device has moved out of reception range). If a balloon notification indicates an error, you can click the notification for more information and remedies to correct the problem.

**Status and warning reporting**

Windows Server 2003 SP1 monitors wireless connection status to detect connection errors. Status and connection error information is reported in real time in the following ways:

**Notification area icons**

The wireless icon in the notification area changes appearance to indicate the state of the wireless connection:

| Icon | Wireless connection state |
|---|---|
| | Connected |
| | Connecting |
| | Not connected |
| | Warning |

If the warning icon is displayed, click the icon, and then, on the **General** tab of the **Wireless Network Connection Status** dialog box, under **Connection**, click **More information**.

**Hovering pointer display**

You can hover the mouse pointer over the wireless icon in the notification area and instantly see the connection status and other information:

| Status type | Reported status |
| --- | --- |
| Wireless Network Connection | The name of the network to which the computer is currently connected. This is the same as the service set identifier (SSID). |
| Speed | Connection speed (for example, 11.0 Mbps) |
| Signal Strength | Excellent<br><br>Very good<br><br>Poor |
| Status | Connected<br><br>Limited or no connection<br><br>Not connected<br><br>**Note**<br><br>In the event of a service interruption, the status will display the name of the most recent wireless network connection, but it will indicate that the connection has limited or no connectivity. |

**Balloon notifications**

Balloon notifications will appear in the notification area when the status of a wireless connection changes, regardless of whether the wireless icon has been configured to display in the notification area.

**Example notifications**

When Windows has detected an error, you might receive the following notification:

**The connection has limited or no connectivity. You may not be able to access the Internet or some network resources. For more information, click this message.**

To open the **Wireless Network Connection Status** dialog box, click the balloon. On the **Support** tab, under **Connection Status**, a message similar to the following will be displayed:

**Limited or no connectivity. You might not be able to access the Internet or some network resources. This problem occurred because the network did not assign a network address to the computer.**

**To restart the connection and try to establish full connectivity, click Repair.**

After you click **Repair**, the wireless adapter is restarted, and shortly afterward, you will receive a notification similar to the following:

**Wireless Network Connection is now connected**

**Connected to: Gulliver**

**Signal Strength: Very Good**

The balloon notifications are displayed for a short time only. For this reason, there are alternative ways to access the **Support** tab in the **Wireless Connection Status** dialog box.

**Choose a wireless connection**

Wireless network connection status is also reported in **Choose a wireless connection** in the **Wireless Network Connection** dialog box. To control the connection to wireless networks that appear under **Choose a wireless network**, click **Connect** or **Disconnect**. If you have attempted to connect to a wireless network and the connection attempt failed, a status message such as **Limited or no connectivity** might be displayed for that item. To open the **Wireless Network Connection Status** dialog box, click the message text. On the **Support** tab, under **Connection Status**, a message similar to the following will be displayed:

**Limited or no connectivity. You might not be able to access the Internet or some network resources. This problem occurred because the network did not assign a network address to the computer.**

**To restart the connection and try to establish full connectivity, click Repair.**

**Additional troubleshooting tools**

You can use the following tools to troubleshoot 802.11 wireless network connections and infrared devices:

- **802.11 wireless networks**. To troubleshoot problems related to 802.11 wireless network connections, you can view details about wireless access points and wireless clients in Wireless Monitor. For detailed information about the statistics displayed in Wireless Monitor, see Logging and viewing wireless network activity.

- **Infrared devices**. To troubleshoot problems related to infrared devices, you can use the Input Devices Troubleshooter.

**Note**

- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition, supports infrared networking.

# HyperTerminal

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**HyperTerminal**
HyperTerminal is a program that you can use to connect to other computers, Telnet sites, bulletin board systems (BBSs), online services, and host computers, using either a modem, a null modem cable, or a TCP/IP (Winsock) connection:

- For help with specific tasks, see HyperTerminal How To....
- For general background information, see HyperTerminal Concepts.
- For problem-solving instructions, see HyperTerminal Troubleshooting.

# HyperTerminal How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install HyperTerminal
- Set up a new connection
- Change redial settings
- Change the port settings of the modem
- Change the settings for making a call
- Use a saved connection to call a remote computer
- Send a file to a remote computer
- Wait for or stop waiting for a call using HyperTerminal
- Receive a file from a remote computer
- Save incoming data to a text file
- Use HyperTerminal with Minitel
- View East Asian languages with the VT-UTF8 terminal emulator in Hyperterminal
- Change the backscroll buffer size
- Change the number of columns
- Stop using HyperTerminal as your telnet client

# Install HyperTerminal

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install HyperTerminal**

1. Open Add or Remove Programs in Control Panel.
2. Click **Add/Remove** Windows **Components**.
3. Click **Accessories and Utilities**, then click **Details**.
4. Click **Communications**, then click **Details**.
5. Select the **HyperTerminal** check box, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the Windows Components Wizard, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Change the port settings of the modem
Set up a new connection

# Set up a new connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set up a new connection**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open HyperTerminal.
2. If the **Location Information** dialog box is displayed, complete the information for your location and click **OK**.
3. On the **File** menu, click **New Connection**.
4. In the **Name** box, type a name that describes the connection.
5. In the **Icon** box, click the appropriate icon, and then click **OK**.
6. In the **Connect To** dialog box, choose which port or modem you want to use in the **Connect using** drop-down box.
7. If you are connecting with a modem, enter the information for the phone number you want to dial. If you are connecting via TCP/IP (Winsock), enter the host address and port number, and then click **OK**.
8. If you are using a modem and want to change your dialing properties, click **Dialing Properties**, choose the appropriate location, and click **Edit**.
9. If you are using a modem and want to change your location, click **Dialing Properties**, and click **New**.
10. If the **Port Settings** dialog box is displayed, complete the information, and click **OK**.
11. If you are using a modem, to dial the call, click **Dial**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open HyperTerminal, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then click **HyperTerminal**.
- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.
- You can only change the dialing properties if you have chosen a modem in the **Connect using** drop-down box.
- If you save this connection, it will be saved using the .ht extension. By default, the connections are saved in the Documents and Settings\user name\Start Menu\Programs\Accessories\Communications\HyperTerminal folder.

**Using a command line**

1. Open Command Prompt.

2. On the volume where the operating system is installed, type: **cd Program Files\Windows NT** and then press ENTER.

3. Type:

   **hypertrm.exe/t***telnet address*[ **:***port*]

| Value | Description |
|---|---|
| telnet address | The address or name of the connection you want to create. This can be in standard Internet dotted notation (for example, w.x.y.z) or can be the site's user-friendly name. |
| port | The number of the port that you want the connection to use. Port 23 is the default. |

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

**Notes**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.
- Using the command line to create a new connection creates a TCP/IP (Winsock) connection.
- If you save this connection, it will be saved using the .ht extension. By default the connections are saved in the Documents and Settings\user name\Start Menu\Programs\Accessories\Communications\HyperTerminal folder.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change redial settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change redial settings**

1. Open HyperTerminal.
2. Open a saved connection file or create a new connection. However, do not dial the connection. Instead click **Cancel** when the **Connect** dialog box is displayed.
3. On the **File** menu, click **Properties** and click the **Connect To** tab.
4. Select or clear the **Redial on busy** check box depending on what you want to do.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open HyperTerminal, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then click **HyperTerminal**.
- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the port settings of the modem

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the port settings of the modem**

1. Open HyperTerminal.
2. Open a saved connection file or create a new connection.
3. If the **Connect To** dialog box does not display, on the **File** menu, click **Properties**.
4. On the **Connect To** dialog box (or the **Connect To** tab on the **Properties** dialog box) click **Configure**.
5. Make your changes on the **General** and **Advanced** tabs. Click **OK**, and click **OK** again.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open HyperTerminal, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then click **HyperTerminal**.
- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.
- This procedure applies only to connections using a modem or COM port.
- The changes that you make to the port settings affect only this connection.
- The port settings for your modem are automatically set when you install the modem, and you typically do not need to change these settings. However, you can modify port settings for a connection with special requirements. For example, a server you connect to might require that you disable data compression or reduce the port speed. To get Help for an item in the Connection Preference dialog box, right-click the item, and then click **What's This?**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the settings for making a call

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the settings for making a call**

1. Open HyperTerminal.
2. Create a new connection, or click **Cancel** when the **Connection Description** dialog box is displayed.
3. If you did not create a new connection, open a saved connection.
4. If the **Connect To** dialog box is displayed, make the appropriate changes and click **OK**.
5. To make additional changes, on the **File** menu, click **Properties**.
6. Click the **Connect To** and **Settings** tabs to see the available choices, and make the appropriate changes.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open HyperTerminal, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then click **HyperTerminal**.
- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use a saved connection to call a remote computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use a saved connection to call a remote computer**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open HyperTerminal.
2. If the **Connection Description** dialog box is displayed, click **Cancel**.
3. On the **File** menu, click **Open**.
4. In the **File name** box, type or select the name of the connection you want to use and click **Open**.
5. If the **Connect To** dialog box is displayed, type any needed information, such as the Phone number, and click **OK**.
6. Click **Dial**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open HyperTerminal, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then click **HyperTerminal**.
- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.
- HyperTerminal connections are saved using the .ht extension. By default the connections are saved in the Documents and Settings\user name\Start Menu\Programs\Accessories\Communications\HyperTerminal folder.

**Using a command line**

1. Open Command Prompt.
2. On the volume where the operating system is installed, type: **cd Program Files\Windows NT** and then press ENTER.
3. Type:

   **hypertrm.exe** [**/d**] *connection name*

4. If the **Connect To** dialog box is displayed, type any needed information, such as the Phone number, and click **OK**.
5. Click **Dial**.

| Value | Description |
|---|---|

| | |
|---|---|
| connection name | The fully qualified path and name of a previously saved connection. HyperTerminal connections are saved using the .ht extension. By default the connections are saved in the Documents and Settings\user name\Start Menu\Programs\Accessories\Communications\HyperTerminal folder. |

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Send a file to a remote computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To send a file to a remote computer**

1. Open HyperTerminal.
2. Open a saved connection file or create a new connection.
3. Connect to the remote computer.
4. On the **Transfer** menu, click **Send File**.
5. In the **Filename** box, type the path and name of the file you want to send.
6. In the **Protocol** list, click the protocol your computer is using to send the file.
7. Click **Send**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open HyperTerminal, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then click **HyperTerminal**.
- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.
- You must have an active HyperTerminal session connected prior to performing this procedure.
- Both the sending computer and the receiving computer must be using the same file transfer protocol.
- In most cases, you need to configure the file-transfer software on the remote computer so that it receives the file correctly. For more information, contact the administrator of the remote computer.
- If you use the Zmodem protocol to transfer data, the remote computer will receive the file automatically and will not need to perform a manual receive procedure.
- Be aware that the automatic download feature of the Zmodem protocol can pose a security risk by allowing remote users to send files to your computer without your explicit permission. To avoid this risk, you must select a protocol other than Zmodem or clear the **Allow remote host initiated file transfers** check box on the **Settings** tab of **Connection Properties**.
- Incoming files might contain viruses or malicious programs that could compromise or destroy data on your computer. To mitigate this risk, use virus scanning software and ensure that the file is coming from a reliable and trusted source.
- You can save the protocol that is the recommended default by following these same procedures, but click **Close** instead of **Send** in the last step.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Wait for or stop waiting for a call using HyperTerminal

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To wait for or stop waiting for a call using HyperTerminal**

1. Open HyperTerminal.
2. If the **Connection Description** dialog box is displayed, click **Cancel**.
3. On the **Call** menu, click **Wait for a Call** or **Stop Waiting**, depending on what you want to do.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open HyperTerminal, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then click **HyperTerminal**.
- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.
- HyperTerminal does not automatically host calls when unattended, so you will need to manually interact with the user who is calling you.
- Waiting for a call allows others to connect to your computer and upload files. Take the proper precautions to ensure that only authorized individuals connect to your computer and that you approve of any uploads.
- When you disconnect from a call, you must always follow this procedure again to wait for another call.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Receive a file from a remote computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To receive a file from a remote computer**

1. Open HyperTerminal.
2. Connect to the remote computer using either a new connection or using a saved connection. Alternatively, you can wait for a call and have the remote computer connect to your computer.
3. Use the remote computer's modem file transfer software to send the file to your computer.
4. On the **Transfer** menu on your computer, click **Receive File**.
5. In the **Place received file in the following folder** box, type the path of the folder in which you want to save the downloaded file.
6. In the **Use receiving protocol** list, click the protocol that the remote computer is using to send the file, and then click **Receive**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open HyperTerminal, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then click **HyperTerminal**.
- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.
- You must have an active HyperTerminal session connected prior to performing this procedure.
- If the remote computer is transferring data using the Zmodem protocol and you have allowed remote host initiated file transfers, you do not need to perform this procedure because the Zmodem protocol causes HyperTerminal to receive the file automatically.

  Be aware that the automatic download feature of the Zmodem protocol can pose a security risk by allowing remote users to send files to your computer without your explicit permission. To avoid this risk, you must select a protocol other than Zmodem in the **Receive File** dialog box or clear the **Allow remote host initiated file transfers** check box on the **Settings** tab of **Connection Properties**.
- Incoming files might contain viruses or malicious programs that could compromise or destroy data on your computer. To mitigate this risk, use virus scanning software and ensure that the file is coming from a reliable and trusted source.
- You can save the receiving folder and the protocol that are the recommended defaults by following these same procedures, but click **Close** instead of **Receive** in the last step.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Save incoming data to a text file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To save incoming data to a text file**

1. Open HyperTerminal.
2. Connect to the remote computer using either a new connection or using an saved connection. Alternatively, you can wait for a call and have the remote computer connect to your computer.
3. On the **Transfer** menu, click **Capture Text** or, to send the text file directly to a printer, click **Capture to Printer**.
4. In the **File** box, type a descriptive name for the file, and then click **Start**.
5. Any text typed at the remote computer will now be captured in the specified file, or be sent to the printer.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open HyperTerminal, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then click **HyperTerminal**.
- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.
- When saving incoming data to a text file or sending the data to a printer, HyperTerminal will capture all data transmitted during the connection session. You cannot use HyperTerminal to filter the data.
- To stop capturing the text to a file, on the HyperTerminal **Transfer** menu click **Capture Text**, then click **Stop** or **Pause**.
- To stop capturing the text to a printer, on the HyperTerminal Transfer menu click **Capture to Printer**, which will uncheck this selection.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use HyperTerminal with Minitel

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use HyperTerminal with Minitel**

1. Open HyperTerminal.
2. Open a saved connection file or create a new connection.
3. On the **File** menu, click **Properties**, and then click the **Settings** tab.
4. In the **Emulation** list, click **Minitel**, and then click **OK**.
5. On the **View** menu, click **Font**.
6. In the **Font** list, click **Arial Alternative Symbol** then click **OK**.

**Notes**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open HyperTerminal, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then click **HyperTerminal**.
- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.
- Arial Alternative is the only font that contains the graphic characters you need for the Minitel service. If this font is not an available option, add the Arial Alternative Symbol and Arial Alternative Regular fonts to your computer.
- The function keys used for Minitel emulation are as follows:

| Function key | Minitel key |
|---|---|
| **HOME** | Sommaire |
| **DELETE** or **F2** | Annulation |
| **PAGE UP** or **F3** | Retour |
| **INSERT** or **F4** | Repetition |
| **END** or **F5** | Guide |
| **BACKSPACE** or **F6** | Correction |
| **PAGE DOWN** or **F7** | Suite |
| **ENTER** or **F8** | Envoi |
| **F9** | Connexion/fin |

- When you emulate a Minitel terminal, the **Port Settings** default values change to:
    - Data bits: 7

- Parity: Even
- Stop bits: 1

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View East Asian languages with the VT-UTF8 terminal emulator in Hyperterminal

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view East Asian languages with the VT-UTF8 terminal emulator in Hyperterminal**

1. Open Regional and Language Options in Control Panel.
2. On the **Languages** tab, click **Install files for East Asian languages** and click **Apply**.
3. After the installation of the files for East Asian languages completes, do not restart your computer. Click the **Advanced** tab in the **Regional and Language Options** dialog box.
4. In the **Language for non-Unicode programs** box, select the language you want to view and click **OK**.
5. When prompted about using your existing files, click **Yes**.
6. Restart your computer.
7. After your computer has been restarted, open Regional and Language Options in Control Panel.
8. On the **Regional Options** tab, verify that the correct language (the East Asian language that you want to view) is selected in the **Standard and formats** box.
9. Close the Regional and Language Options dialog box and open HyperTerminal.
10. If the **Connection Description** dialog box is displayed, click **Cancel**.
11. In the **File** menu, click **Properties**.
12. On the **Connect To** tab, click **Configure**.
13. Change the **Port Speed** to match your port setting (this setting will likely be correct by default).
14. In the **Properties** box, click the **Settings** tab and select **VT-UTF8** in the **Emulation** box and click **OK**.
15. In the HyperTerminal **View** menu, click **Font** and select the correct East Asian language font.
16. Connect to the remote computer. For more information, see Related Topics below.

**Notes**

- You must be logged on as an administrator or a member of the Administrators group (or you must have been delegated the proper authority) to complete the first several steps of this procedure, in which you install the files for East Asian languages. After those files are installed and you restart your computer, the remaining steps do not require you to have administrative credentials. Therefore, as a security best practice, consider performing the final steps as a user without administrative credentials.
- To open Regional and Language Options, click **Start**, click **Control Panel**, and then double-click **Regional and Language Options**.
- To open HyperTerminal, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then

click **HyperTerminal**.

- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.

- The East Asian languages include Chinese, Japanese, and Korean. The files for most other languages are installed on your computer automatically by Windows.

- It is recommended that you install these files only if you are going to be entering or receiving text in one or more of these languages. The Chinese, Japanese, and Korean files require about 230 megabytes (MB) of space on your hard disk. In addition to the language files, Input Method Editors (IMEs) are installed for each of the three languages.

- Similar steps can be used to configure HyperTerminal to view other languages as well.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the backscroll buffer size

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the backscroll buffer size**

1. Open HyperTerminal.
2. Open a saved connection file or create a new connection.
3. On the **File** menu, click **Properties**, and click the **Settings** tab.
4. In the **Backscroll buffer lines** box, type the number of communication text lines that you want saved in addition to what is displayed on the screen, and then click **OK**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open HyperTerminal, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then click **HyperTerminal**.
- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.
- The maximum backscroll buffer value is 500 lines.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the number of columns

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the number of columns**

1. Open HyperTerminal.
2. Open a saved connection file or create a new connection.
3. On the **File** menu, click **Properties**.
4. Click the **Settings** tab. In the **Emulation** drop-down box, choose either **VT100**, **VT100J** or **VT-UTF8**.
5. Click the **Terminal Setup** button and as appropriate, either check or clear the **132 column mode** check box. Click **OK**, and click **OK** again.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open HyperTerminal, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then click **HyperTerminal**.
- HyperTerminal is not installed by default. For information on how to install HyperTerminal, see Related Topics.
- This procedure is valid only when emulating a VT100, VT100J or VT-UTF8 terminal.
- The default number of columns is 80.
- You can not change the number of rows displayed by HyperTerminal. VT-UTF8 and Minitel terminal emulation will display 25 rows and all other terminal types will display 24 rows.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Stop using HyperTerminal as your telnet client

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To stop using HyperTerminal as your telnet client

1. Open My Computer.
2. Click the **Tools** menu, and click **Folder Options**.
3. On the **File Types** tab, scroll down the list of file types to **URL: Telnet Protocol**.
4. Click **URL:Telnet Protocol**, and then click **Advanced**.
5. In the **Actions** box, click **Open** and then click **Edit**.
6. Delete the contents of the **Application used to perform action** field, and type:

   **rundll32.exe url.dll,TelnetProtocolHandler %l**

7. Close these dialog boxes by clicking **OK** to save your settings.

### Important

- Take note of the existing entry in the **Application used to perform action** field before replacing that entry. You can then repeat this procedure using the prior data if you want to again use HyperTerminal as your default telnet client.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open My Computer, click **Start**, and then click **My Computer**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# HyperTerminal Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about HyperTerminal:

- HyperTerminal overview
- Understanding HyperTerminal connections
- Understanding HyperTerminal file transfers
- HyperTerminal Resources

# HyperTerminal overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**HyperTerminal overview**

HyperTerminal is a program that you can use to connect to other computers, Telnet sites, bulletin board systems (BBSs), online services, and host computers, using either your modem, a null modem cable or Ethernet connection.

Though using HyperTerminal with a BBS to access information on remote computers is a practice that has become less common with the availability of the World Wide Web, HyperTerminal is still a useful means of configuring and testing your modem or examining your connection with other sites. For more information, see Set up a new connection.

HyperTerminal records the messages passed to and from the computer or service on the other end of your connection. Therefore, it can serve as a valuable troubleshooting tool when setting up and using your modem. To make sure that your modem is connected properly or to view your modem's settings, you can send commands through HyperTerminal and check the results. HyperTerminal has scroll functionality that allows you to look at received text that has scrolled off the screen.

You can use HyperTerminal to transfer large files from a computer onto your portable computer using a serial port rather than going through the process of setting up your portable computer on a network. For more information, see Send a file to a remote computer.

You can use HyperTerminal to help debug source code from a remote terminal. You can also use HyperTerminal to communicate with older character-based computers.

HyperTerminal is designed to be an easy-to-use tool and is not meant to replace other full-feature tools available on the market. You can use HyperTerminal to perform the specific tasks described above, but do not attempt to use HyperTerminal for more complex communication needs. For more information on what HyperTerminal does and does not support, see the HyperTerminal frequently asked questions list at the Hilgraeve Web Site.

Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

# Understanding HyperTerminal connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding HyperTerminal connections**

You can create and save multiple connections within HyperTerminal. Each connection can have its own unique configuration, including phone number and port settings such as bits per second(bps), parity checks, and host TCP/IP address.

As part of the connection configuration, HyperTerminal also allows your computer to emulate a variety of terminal types, such as TTY, ANSI and VTx terminals.

The connection that is currently open within HyperTerminal is displayed in the Hyperterminal title bar.

You can only have one connection open per each HyperTerminal session. You can, however, start multiple HyperTerminal sessions, opening a new connection for each session (provided each connection uses a different communication port). To set up a new connection, see Set up a new connection.

When you first open HyperTerminal, you will be prompted to decide if you want HyperTerminal to be your default telnet client. You also will be able to choose not to see this dialog box again. If you choose to not see the dialog box again, but later do want to set Hyperterminal as your default telnet client, see HyperTerminal Troubleshooting.

HyperTerminal cannot automatically provide your login ID and password when you make a connection. If you provide a password when using HyperTerminal for a Telnet session, be aware that this password will be sent to the remote computer using plain text (as with all telnet connections).

# Understanding HyperTerminal file transfers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding HyperTerminal file transfers**

You can use HyperTerminal to send and receive text and data files to a remote computer. The status of the transfer is displayed in the HyperTerminal window during the transfer. You can also capture the status of a transferred file and send the information directly to a printer. For more information, see Save incoming data to a text file.

You can use **Send File** to send data files as described in Send a file to a remote computer. You can send text files as an alternative to keyboard input using **Send Text File**. This is useful, for example, when you need to send a string of keyboard input to a remote computer for troubleshooting purposes, or need to send a lengthy keyboard input string as part of a connection sequence to a remote computer or router.

For information on receiving a file, see Receive a file from a remote computer.

Be aware that you cannot change the size of the HyperTerminal window to view more or less text than what is currently displayed.

# HyperTerminal Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

This topic provides sources of additional information about HyperTerminal and modems.

- For a list of HyperTerminal frequently asked questions, see the HyperTerminal frequently asked questions list at the Hilgraeve Web Site.
- For more information about modems in general, see Installing and configuring Modems.
- For more information about supported modems, refer to the hardware compatibility information for products in the Windows Server 2003 family, by clicking the appropriate link in Support resources.
- Most modems support the AT command set. If you are uncertain about the exact command set supported by your modem, check the manufacturer's documentation. The modem documentation may also provide information about special commands supported by the modem. The modem manufacturer's Web site is often a good place to find technical information for your modem and the commands it supports.
- Microsoft Product Support Services provides a searchable database of technical support information for Microsoft products. You can search here for general information about HyperTerminal, modems or for information related to other Microsoft products. You can get to the Microsoft Product Support Services Web site by clicking the appropriate link in Support resources.
- For enhancements and updates to Windows software and other Microsoft software that might affect the use of HyperTerminal or your modem, see Windows Update at the Microsoft Web site.
- Microsoft TechNet is a service that contains resources for Information Technology (IT) professionals. This includes access to white papers and articles written about HyperTerminal by support professionals at Microsoft, career and industry information, discussion groups, technical feedback, and software. For more information about TechNet, see the Microsoft Web site.
- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

# HyperTerminal Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- You receive an error when you are performing a file transfer and you are not able to send or receive a file successfully.
- You are unable to connect to a remote computer when using a remote site's user-friendly name.
- You want to use HyperTerminal as your default telnet application, but you are not prompted for that option when you open HyperTerminal.
- The terminal screen size does not change when you maximize HyperTerminal to full screen.
- Information you type is not appearing on the HyperTerminal terminal screen.
- Information you type is appearing double on the HyperTerminal terminal screen.
- ANSI characters are not displaying properly.
- HyperTerminal does not redial when the line is busy.
- After connecting to a remote computer, the terminal screen displays meaningless information.
- You cannot delete characters from the terminal screen.
- The cursor does not blink when you are using HyperTerminal via a Remote Desktop connection.
- You cannot use the traditional Windows control key combinations to perform certain tasks, such as CTRL+C to copy, or CTRL+V to paste.

**You receive an error when you are performing a file transfer and you are not able to send or receive a file successfully.**
Possible Cause

Solution

- The local computer and remote computer are not using the same file transfer protocol.
- Ensure that the file transfer protocol is the same on both the remote and local computer.
- You have excess noise on your phone line.
- Establish a new connection. You might need to use a different phone line.
- The connection to the phone line is interrupted briefly.
- Establish a new connection.
- Your hardware is not working correctly, you are using incorrect drivers, or your modem configuration is incorrect.
- Verify that the hardware is functioning properly and has the latest drivers. Verify that you are using the correct port. Also try your file transfer using different port speeds, baud rates, data bits, parity, stop bits and modulation. These settings

must be the same for both the remote and local computers.

**You are unable to connect to a remote computer when using a remote site's user-friendly name.**
**Cause:** The Domain Name System (DNS) server may not be functioning properly.

**Solution:** Connect to the site using standard Internet dotted notation (for example, w.x.y.z).

**You want to use HyperTerminal as your default telnet application, but you are not prompted for that option when you open HyperTerminal.**
**Cause:** When the dialog box asking you whether to use HyperTerminal as your telnet default client first appeared, you responded **No** and selected **Stop asking me this question**.

**Solution:** Open Registry Editor. In Registry Editor, navigate to the following registry key and change the value to 1:

**HKEY_CURRENT_USER\Software\Microsoft\HyperTerminal\Telnet Check**.

After you change this value, the next time you start HyperTerminal, the dialog box will appear and will ask you whether you want to have HyperTerminal as your default telnet application.

**Notes**

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, back up any valued data on the computer. You can also use the Last Known Good Configuration startup option if you encounter problems after manual changes have been applied.

**The terminal screen size does not change when you maximize HyperTerminal to full screen.**
**Cause:** The HyperTerminal terminal screen size is determined by the font size that you are using. It will size itself to display 24 lines of 80 (or 132) characters of whatever font you have selected.

**Solution:** On the HyperTerminal **View** menu, select **Font**. If you want a larger terminal screen select a larger font size. If you want a smaller terminal screen, select a smaller font size.

**Information you type is not appearing on the HyperTerminal terminal screen.**
**Cause:** The terminal screen displays the information sent from the remote computer, not information entered on your local computer. To view what you type, the remote computer must be configured to echo back your input. There also may be a time lag between when you type the information and when it is displayed on your terminal screen.

**Solution:** Ensure that you have a proper connection with the remote computer and ensure that the remote computer is configured to echo user input.

**Cause:** Neither your computer nor the remote computer is configured to echo the information that is typed.

**Solution:** If the remote computer is not configured to echo user input, you can configure your computer to do so with the following steps:

1. On the HyperTerminal **File** menu, click **Properties**.
2. On the **Settings** tab, click **ASCII Setup**.
3. Check the **Echo typed characters locally** box.

**Information you type is appearing double on the HyperTerminal terminal screen.**
**Cause:** Both your computer and the remote computer are configured to echo back your input.

**Solution:** Either ensure that the remote computer is not configured to echo user input or instead configure your computer to not echo user input. To ensure that your computer is not echoing user input:

1. On the HyperTerminal **File** menu, click **Properties**.

2. On the **Settings** tab, click **ASCII Setup**.

3. Clear the **Echo typed characters locally** box.

**ANSI characters are not displaying properly.**
**Cause:** You are not using the Terminal font.

**Solution:** On the HyperTerminal **View** menu, select **Font**. Click **Terminal** and choose **OK**.

**HyperTerminal does not redial when the line is busy.**
**Cause:** The **Redial on busy** option may not be selected.

**Solution:** On the HyperTerminal **File** menu, select **Properties**. Select the **Connect To** tab and ensure that **Redial on busy** is selected.

**After connecting to a remote computer, the terminal screen displays meaningless information.**
**Cause:** You have not selected the correct terminal emulation type.

**Solution:** On the HyperTerminal **File** menu, select **Properties**. Select the **Settings** tab. In the **Emulation** drop-down box, choose the terminal type of the remote computer. If the remote computer's type is not listed in the drop-down box, it is not supported by HyperTerminal.

**You cannot delete characters from the terminal screen.**
**Cause:** The remote computer that you are connected to has control of the characters displayed on your terminal screen. The remote computer is expecting the cursor to be at particular positions on the screen based on the data that it has already sent to the screen. If you alter that screen locally, you potentially disrupt the interaction between you and the remote computer in ways that the host can not predict or control. Therefore, HyperTerminal does not allow you to delete characters from the screen.

**Solution:** Not Applicable

**The cursor does not blink when you are using HyperTerminal via a Remote Desktop connection.**
**Cause:** The cursor blink option is not available when using HyperTerminal via a Remote Desktop connection. This is done to reduce the screen updates in the Remote Desktop session.

**Solution:** Not applicable

**You cannot use the traditional Windows control key combinations to perform certain tasks, such as CTRL+C to copy, or CTRL+V to paste.**
**Cause:** If you are set to **Terminal Keys** in the properties for this connection, pushing control key combinations will send out terminal commands, not the Windows commands. For example, many hosts use CTRL+V to navigate through their systems.

**Solution:** You can change this setting to **Windows Keys** and the control key combinations will work as in Windows. To do so, on the HyperTerminal **File** menu, click **Properties**. Click the **Settings** tab, and click the **Windows Keys** radio button.

### Important

- When using the **Windows Keys** setting, all function, arrow and control keys will be processed locally. Using the **Terminal keys** setting and then using the menus to perform the necessary functions is the recommended option.

### Notes

- For more information on these topics and other frequently asked questions, see the HyperTerminal frequently asked questions list at the Hilgraeve Web site.

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials. Exceptions are noted.

# Telnet

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Telnet**

By using Telnet Client, you can connect to a remote computer that is running Telnet server software and you can interact with that computer through a console window. For more information about Telnet Client, see Telnet Client.

By using Telnet Server, you can allow users of Telnet client software to log on to your computer and to run character-mode applications on it. For more information about Telnet Server, see Telnet Server.

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Telnet Client**
With Telnet Client, users can connect to a remote Telnet server and run character-mode applications on the remote computer or administer it.

- For general background information, see Telnet Client Concepts.
- For problem-solving instructions, see Telnet Client Troubleshooting.

# Telnet Client Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

Telnet is a member of the TCP/IP family of protocols, and it allows a user to establish a remote session on a server. The protocol supports only alphanumeric terminals -- that is, it does not support mice and other pointing devices, nor does it support graphical user interfaces. Instead, all commands must be entered at the command line.

The Telnet protocol provides very little security. In a Telnet session that does not use NTLM authentication, all data, including passwords, is transmitted between client and server in plaintext. Because Telnet session traffic is not secure, you need to ensure that no sensitive data is sent during a Telnet session.

This section provides general background information about Telnet Client:

- Telnet Client overview
- Using Telnet Client

# Telnet Client overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Telnet Client overview**

Telnet Client uses the Telnet protocol (part of the TCP/IP protocol suite) to connect to a remote computer over a network. Telnet Client allows a computer to connect to a remote Telnet server and run applications on that server.

All members of the Microsoft® Windows Server 2003 family include an improved, command line-oriented version of Telnet Client. You can use the NTLM authentication process to authenticate clients for Telnet connections between computers running Microsoft Windows NT®, Windows 2000, Windows XP, or the Windows Server 2003 family.

# Using Telnet Client

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Telnet Client**

This section contains information on the following:

- Telnet Client authentication
- Telnet commands
- Session mode and command mode

# Telnet Client authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Telnet Client authentication**

You can use your local Windows user name and password or domain account information to access a computer running Telnet Server.

If you do not use the NTLM option for authentication, the user name and password are sent to the Telnet server as plaintext.

If you use NTLM authentication, Telnet Client uses the Windows security context for authentication, and the user is not prompted for a user name and password. The user name and password are encrypted.

Attempts to log on to the Telnet server using NTLM authentication will fail if the password option is set at **User Must Change Password at Next Log on**. To log on successfully, you must log on to the server directly, change your password, and then log on through Telnet Client.

If you connect to a Telnet server using NTLM authentication, you will not be able to access additional network resources because of a limitation of the NTLM authentication. In order to access network resources from a Telnet session, you need to access network drives by providing your user name and password again.

**Note**

- Although authentication might be encrypted, the actual data being transferred can be read by anyone on the network. Because Telnet session traffic is not secure, ensure that no sensitive data is sent or received during a Telnet session.

# Telnet commands

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Telnet commands**

The Telnet commands allow you to communicate with a remote computer that is using the Telnet protocol. You can run Telnet without parameters in order to enter the Telnet context, indicated by the Telnet prompt (`Microsoft Telnet>`). From the Telnet prompt, use the Telnet commands to manage a computer running Telnet Client.

The Telnet Client command prompt accepts the following commands:

| Command | Description |
|---|---|
| **open** | Use **open** *hostname* to establish a Telnet connection to a host. |
| **close** | Use the **close** command to close an existing Telnet connection. |
| **display** | Use the **display** command to view the current settings for Telnet Client. |
| **send** | Use the **send** command to send commands to the Telnet server. The following commands are supported:<br><br>**ao**<br><br>Abort output command.<br><br>**ayt**<br><br>"Are you there?" command.<br><br>**esc**<br><br>Sends the current escape character.<br><br>**ip**<br><br>Interrupt process command.<br><br>**synch**<br><br>Performs the Telnet synch operation.<br><br>**brk**<br><br>Sends a break signal.<br><br>Anything other than one of the commands listed above will be sent as a string to the Telnet server. For example, **send abcd** will send the string **abcd** to the Telnet server, which will echo the string in the Telnet session window. |
| **quit** | Use the **quit** command to close Telnet Client. |
| **set** | Use the **set** command with one of the following arguments to configure Telnet Client for the current session.<br><br>**bsasdel**<br><br>Backspace will be sent as delete.<br><br>**codeset option**<br><br>Available only when the language is set to Japanese. Set the current code set to option, which can be one of the following:<br><br>• Shift JIS |

| | |
|---|---|
| | • Japanese EUC<br>• JIS Kanji<br>• JIS Kanji (78)<br>• DEC Kanji<br>• NEC Kanji<br><br>The same code set should be set on the remote computer. By default, Telnet Client uses a raster font. Before accessing a remote computer using one of these code sets, you must configure Telnet Client to use a TrueType font to ensure that characters will display properly.<br><br>**crlf**<br><br>New-line mode; causes the RETURN key to send 0x0D, 0x0A.<br><br>**delasbs**<br><br>Delete will be sent as backspace.<br><br>**escape** *character*<br><br>Switches from Telnet session mode to the Telnet command mode. While in Telnet command mode, press ENTER to return to Telnet session mode.<br><br>**localecho**<br><br>Turns on localecho.<br><br>**logfile** *name*<br><br>Specifies the name of the file to which the Telnet log is written for this session. If you do not specify the path of the file, it is created in your current directory. Specifying a log file also turns on logging.<br><br>**logging**<br><br>Turns on logging for this session.<br><br>**mode** {**console** \| **stream**}<br><br>The mode of operation.<br><br>**ntlm**<br><br>Turns on NTLM authentication.<br><br>**term** {**ansi** \| **vt100** \| **vt52** \| **vtnt**}<br><br>The type of terminal you want Telnet Client to emulate.<br><br>**?**<br><br>Displays Help information for **set**. |
| **unset** | Use **unset** to turn off an option previously set using the **set** command. |
| **status** | Use the **status** command to determine whether the computer running Telnet Client is connected. |
| **?/help** | Displays Help information. |

For more information about Telnet Server commands, see Telnet Command-line Reference for Telnet Server.

# Session mode and command mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Session mode and command mode**

There are two modes of operation in Telnet Client: Telnet command mode and Telnet session mode. Telnet command mode allows the Telnet terminal to open a connection to a remote host, close a connection to a remote host, display operating parameters, set terminal options, print the status, and quit the program.

For information about how to set Telnet options and to learn how to send Telnet commands, see Telnet Command-line Reference for Telnet Server.

Once connected to a remote host, Telnet Client is in Telnet session mode. This mode is the most common. After logging on, users are given a Command Prompt window. Users are then able to use character-based applications on any remote Telnet server, as if they were logged on to the system directly.

Once connected to a host, you can return from session mode to command mode to change terminal settings. You can change from a Telnet session mode to a Telnet command mode by pressing **CTRL** + **]**; press ENTER to return to the Telnet session mode. For more information about switching modes, see Telnet commands.

**Important**

- **Use a TrueType font in the Command Prompt window when using Telnet with any of the four supported Asian languages**

  Telnet supports the following four Asian languages: Japanese, Simplified Chinese, Korean, and Traditional Chinese. You must use a TrueType font in the Command Prompt window to properly display the characters used in Asian languages. By default, the Command Prompt window displays characters using raster fonts.

  Because each Telnet session creates a new Command Prompt window, you need to permanently set the properties of the Command Prompt window to use the TrueType fonts if you use Telnet with Asian languages on a regular basis.

  1. To set the Command Prompt window font, right-click in the title bar of the Command Prompt window, and then click **Properties**.
  2. Select a TrueType font, and then click **OK**.
  3. To always use the TrueType font you selected, in the **Apply Properties to Shortcut** dialog box, click **Modify shortcut that started this window**.

- This can also be done using the **Save properties for all future windows with the same title** option. If this option is not set, DBCS (Double Byte Character Set) characters will not be displayed properly in the Telnet session.

**Note**

- Although authentication might be encrypted, the actual data being transferred can be read by anyone on the network. Because Telnet session traffic is not secure, ensure that no sensitive data is sent or received during a Telnet session.

# Telnet Client Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
This section contains information on troubleshooting Telnet Client. For troubleshooting information on Telnet Server, see Telnet Server Troubleshooting.

What problem are you having?

- Telnet Client is not restored after Services for UNIX is uninstalled.
- Characters and lines on the Telnet Client display are misaligned when connecting to the computer running Telnet Server.

**Telnet Client is not restored after Services for UNIX is uninstalled.**
**Cause:** Setup attempted to restore the original Telnet files but failed.

**Solution:** Restore the Telnet files from the Windows CD. For example, here are the commands you would use to restore the required files if C:\WINDOWS is the system folder, and D is the source CD:

```
C:\>copy D:\I386\telnet.exe C:\WINDOWS\SYSTEM32

C:\>expand -r D:\I386\tlntsvr.ex_ C:\WINDOWS\SYSTEM32

C:\>expand -r D:\I386\tlntsvrp.dl_ C:\WINDOWS\SYSTEM32

C:\>expand -r D:\I386\tlntsess.ex_ C:\WINDOWS\SYSTEM32
```

**Characters and lines on the Telnet Client display are misaligned when connecting to the computer running Telnet Server.**
**Cause:** This problem can be caused by a mismatch between the size of the Telnet Client window and the maximum size of the command window that Telnet Server can support.

**Solution:** Try reducing the size of the Telnet Client window before reconnecting.

# Telnet Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Telnet Server**
Telnet Server provides ASCII terminal sessions to Telnet clients. Telnet Server supports two types of authentication and supports four types of terminals: ANSI, VT-100, VT-52, and VTNT.

- For tips about using Telnet Server, see Telnet Server best practices.
- For general background information, see Telnet Server Concepts.
- For problem-solving instructions, see Telnet Server Troubleshooting.

# Telnet Server best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **Provide user-level security**

  To control the access that Telnet users have to files on the server, use only the NTFS file system on the system partition. Create a TelnetClients group, add all Telnet users to that group, and then assign file and directory permissions to control the access that members have to the files and directories.

- **Allow users to disconnect before stopping the service**

  Before you stop Telnet Server or uninstall it, send a message to Telnet client sessions that you are about to stop the service. You can then stop the service after the users have had the opportunity to close their sessions.

- **Make sure that the client code page matches the code page of the UNIX terminal**

  If users will be connecting to Telnet Server from computers running an internationalized version of UNIX (such as a version capable of supporting European languages), you should ensure that the code page used by the command shell can display extended characters properly. To set the code page for all users when they log on, edit *systemroot*\system\login.cmd to add the **chcp** command to set the appropriate code page. For example, to support English and Western European UNIX, add the command **chcp 1252**.

# Telnet Server Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

Telnet is a member of the TCP/IP family of protocols, and it allows a user to establish a remote session on a server. The protocol supports only alphanumeric terminals -- that is, it does not support mice and other pointing devices, nor does it support graphical user interfaces. Instead, all commands must be entered at the command line.

The Telnet protocol provides very little security. In a Telnet session that does not use NTLM authentication, all data, including passwords, is transmitted between client and server in plaintext. Because of this limitation, as well as the general recommendation against allowing untrusted users access to security-critical servers, you should run Telnet Server only on computers that store no sensitive data.

This section contains information about:

- Telnet Server overview
- Telnet Server access
- Telnet Server authentication
- Administering Telnet Server

# Telnet Server overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Telnet Server overview**

Telnet Server is a gateway for Telnet clients. When Telnet Server is running on a computer, users can use Telnet clients to connect to it from remote computers. When a Telnet client connects to a computer running Telnet Server, the remote user is asked to enter a user name and password. By default, only user name and password combinations that are valid on the local server can be used to log on to that server.

Once logged on, a user is given a command prompt that can be used as if it had been opened in a command prompt window locally. By default, however, the user cannot use applications that interact with the desktop.

Telnet uses the Telnet protocol (part of the TCP/IP protocol suite) to connect to a remote computer over the network.

Members of the Administrators group can log on to Telnet Server. Access by other users is controlled by membership in the TelnetClients group. By default, this group contains no entries. If you want to allow users who are not members of the Administrators group to log on to Telnet Server, add the appropriate users or groups to the TelnetClients group.

**Telnet licensing**

With each installation of a member of the Microsoft® Windows Server 2003 family, a license provides one installation of Telnet Server. However, several Telnet sessions can exist simultaneously.

By default, Telnet Server supports a maximum of two Telnet clients at a time. However, the administrator can change this value by using the **tlntadmn** command. For detailed information about using the **tlntadmn** command, see Telnet Command-line Reference for Telnet Server. The number of distinct devices that can connect to a computer running Telnet Server is limited by available resources like RAM, virtual memory, and the number of Client Access Licenses (CALs).

### Note

- After you create a TelnetClients group, you must stop and start the Telnet Server service before users can log on.

# Telnet Server access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Telnet Server access**
By default, only members of the Administrators group can log on to Telnet Server. You can give access to your computer running Telnet Server to other users. To allow other users to log on, create a local user group, on your server, called TelnetClients, and add users to that group. If a group with that name exists on your server, only that group's members can log on to Telnet Server.

- **To create a local user group called TelnetClients:** See Create a local group.

- **To grant access to a computer running Telnet Server**

  1. Open Computer Management.

  2. In the console tree, expand **Local Users and Groups**, and click **Groups**.

  3. Double-click the TelnetClients group.

  4. Click **Add...**

  5. Follow the instructions in the **Select Users** box to add users to the TelnetClients group, and then click **OK**.

**Notes**

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- The group name TelnetClients must be spelled exactly as shown.

- After you create a TelnetClients group, you must stop and start the Telnet Server service before users can log on.

# Telnet Server authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Telnet Server authentication**
Authentication is the means by which a user is identified and authorized. Telnet Server supports two methods of authentication: NTLM and plaintext.

If you use NTLM authentication, Windows-based clients use the Windows security context for authentication, and the user is not prompted for a user name and password. The user name and password are encrypted. Sessions that do not use encryption use unencrypted text (also known as plaintext) and are visible across the network.

If you do not use NTLM authentication the user name and password are sent to the computer running Telnet Server as plaintext. Anyone capturing the packets of the authentication process can easily read the password and use it to gain unauthorized access to your intranet. The use of plaintext authentication is therefore highly discouraged.

If **User Must Change Password at Next Logon** is set for a user, an attempt to log on to the computer running Telnet Server will fail. The user must log on to the server directly and change the password, then log on through Telnet.

If you connect to a computer running Telnet Server using NTLM authentication, you will not be able to access additional network resources because of a limitation of the NTLM authentication. In order to access network resources from a Telnet session, you need to access network drives by providing your user name and password again.

NTLM might not be the chosen mode of client authentication. This occurs when your client is:

- A Windows-based client that does not use NTLM by choice
- A UNIX Telnet client

In this scenario, the only other authentication method supported by the computer running Telnet Server is the user name/password method. In this method, the user name and password are sent as plaintext for authentication by the server.

For information about how to set authentication methods, see Telnet Command-line Reference for Telnet Server.

**Note**

- Although authentication data might be encrypted, the actual data being transferred can be read by anyone on the network. Because Telnet session traffic is not secure, ensure that no sensitive data is sent or received during a Telnet session.

# Administering Telnet Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administering Telnet Server**

This section covers:

- Using the tlntadmn command
- Using login.cmd
- Managing Telnet from the command line

# Using the tlntadmn command

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using the tlntadmn command**

You can use the **tlntadmn** command to administer a local or a remote computer that is running Telnet Server. This command is new in Windows XP and the Windows Server 2003 family. For detailed information about using the **tlntadmn** command, see Telnet Command-line Reference for Telnet Server.

**System requirements**

Both the computer you are administering and the computer at which you use the **tlntadmn** command must be running Windows NT, Windows 2000, Windows XP, or a member of the Windows Server 2003 family. If either computer is running Windows NT or Windows 2000, it must also be running Windows Services for UNIX 2.0.

**Security considerations**

To administer a local or a remote computer using the **tlntadmn** command, you must log on to the local computer with administrative credentials. To administer a remote computer, you must also do one of the following:

- log on to the local computer with an account that has administrative credentials on the remote computer
- use the **-u** and **-p** parameters to provide administrative credentials for the remote computer

Use of the **-u** and **-p** parameters is a non-NTLM method of authentication. This method is less secure than NTLM because credentials are sent in plaintext. As a security measure, you cannot use the **-s**, **-k**, and **-m** parameters even if you provide credentials using the **-u** and **-p** parameters. The **-s**, **-k**, and **-m** parameters are used to list a session, end a session, and send a message, respectively.

# Using login.cmd

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using login.cmd**

The program login.cmd is run whenever someone logs on to Telnet Server. You can edit the login.cmd file to change the text that appears when someone logs on, and you can use login.cmd to run other programs.

When Telnet Server is installed, the program is copied to %SystemRoot%\system32\login.cmd. This is what it looks like:

```
@echo off
rem
rem  Default global logon script for the Telnet Server
rem
rem  In the default setup, this command script is run
rem  when the initial command shell is invoked. It, in
rem  turn, will try to invoke the individual user's
rem  logon script.
rem
echo
*====================================================
echo
Welcome to Microsoft Telnet Server.
echo
*================================================
cd /d %HOMEDRIVE%\%HOMEPATH%
```

In the following example, the file has been edited to display the text "Welcome to my Telnet Server," and run **net config** to display information about the server configuration:

```
@echo off
rem
rem  Default global logon script for the Telnet Server
rem
rem  In the default setup, this command script is run
rem  when the initial command shell is invoked. It, in
rem  turn, will try to invoke the individual user's
rem  logon script.
rem
echo
*=================================================
echo
Welcome to my Telnet Server
echo
*=================================================
cd /d %HOMEDRIVE%\%HOMEPATH%net config server
```

# Managing Telnet from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Telnet from the command line**

By using the **tlntadmn** command, you can administer a local or a remote computer running Telnet Server. For a list of **tlntadmn** parameters, see Telnet Command-line Reference for Telnet Server.

For information about other command-line utilities, see Command-line reference A-Z. For more information about manageability, see Management Strategies and Tools.

# Telnet Server Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
This section contains information on troubleshooting Telnet Server. For troubleshooting information on Telnet Client, see Telnet Client Troubleshooting.

What problem are you having?

- Logon failure: The user has not been granted the requested logon type at this computer.
- Access denied: Specified user is not a member of the TelnetClients group.
- Logon failure: The user must change his or her password before logging on the first time.
- Logon failure: Telnet Server allows NTLM authentication only.
- Error while connecting to localhost: Could not open a connection to host on port 23.
- Cannot connect to network drives.
- Users cannot access drive letters mapped by others.
- If you interrupt and then reconnect a Telnet session that is being conducted from a UNIX computer to a Windows-based computer, the cursor might lose alignment with the prompt.

**Logon failure: The user has not been granted the requested logon type at this computer.**
**Cause:** The user does not have permission to log on locally to the computer running Telnet Server.

**Solution:** Ensure that the user, or a group the user belongs to (such as the TelnetClients group), has the right to log on locally. Ensure that the user, or a group that the user belongs to, is not denied the right to log on locally.

**Access denied: Specified user is not a member of the TelnetClients group.**
**Cause:** Users must belong to the TelnetClients group in order to connect to Telnet Server.

**Solution:** Add the user to the TelnetClients group.

**Logon failure: The user must change his or her password before logging on the first time.**
**Cause:** The user's password must be changed.

**Solution:** The user must log on to the computer directly (that is, in person) to change the password.

**Logon failure: Telnet Server allows NTLM authentication only.**
**Cause:** Either the client does not support NTLM authentication and the server requires it, or the client requires NTLM authentication and Telnet Server does not support it.

**Solution:** If the Telnet client does not support NTLM authentication, use a client that does. If that is not possible, enable plaintext authentication on Telnet Server. For maximum security, use only Telnet clients that support NTLM authentication, and enable NTLM authentication and disable plaintext authentication on Telnet Server.

**Error while connecting to localhost: Could not open a connection to host on port 23.**
**Cause:** Telnet Server is not configured to listen on port 23, or Telnet Server is not started.

**Solution:** Ensure that Telnet Server is started and configured to listen on port 23. If that is not possible, specify the configured port after the host name when connecting.

**Cannot connect to network drives.**
**Cause:** NTLM authentication does not allow access to network drives.

**Solution:** Map the network to a drive letter using the **net use /user** command.

**Users cannot access drive letters mapped by others.**

**Cause:** Telnet clients recognize only drive letters mapped during the current Telnet session. Consequently, Telnet users cannot access network drives using drive letters mapped by other Telnet users or by local server users.

**Solution:** Telnet client users must use the **net use /user** command to map network drives to drive letters themselves.

**If you interrupt and then reconnect a Telnet session that is being conducted from a UNIX computer to a Windows-based computer, the cursor might lose alignment with the prompt.**

**Cause:** This problem is caused by the interruption in communication.

**Solution:** If your default shell is the Windows command prompt, type **cls**. If your default shell is the Korn shell or C shell, type **clear**.

# Configuring Communication Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring communication services**

This section covers:

- Telephony

# Telephony

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Telephony**
This implementation of Telephony Application Programming Interface (TAPI) unifies Internet Protocol (IP) and traditional public switched telephone network (PSTN) telephony to support programs that effectively work the same way over intranets, the Internet, and traditional networks. This section provides information for configuring and managing both IP and PSTN telephony servers and clients.

- Before you begin using telephony with this computer, see Telephony Checklists.
- To find features that have been moved in Microsoft® Windows® 2000, Windows XP, and the Windows Server 2003 family, see New ways to do familiar Telephony tasks.
- For tips about using telephony, see Telephony Best practices.
- For help with specific tasks, see Telephony How To....
- For general background information, see Telephony Concepts.
- For problem-solving instructions, see Telephony Troubleshooting.

# Telephony Checklists

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Checklists**

- Checklist: Installing IP telephony (H.323)
- Checklist: Installing IP multicast video conferencing
- Checklist: Setting up a telephony server
- Checklist: Setting up telephony clients

# Checklist: Installing IP telephony (H.323)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Checklist: Installing IP telephony (H.323)**

| Step | Reference |
|---|---|
| Review key concepts. | IP Telephony |
| Confirm that TCP/IP is running on your network. | TCP/IP Core Networking Service |
| (Optional) Confirm that you have an Active Directory domain and that a TAPI application directory partition is available on your network.<br><br>TAPI application directory partitions are not required for H.323 IP telephony, but if a TAPI application directory partition is available on your network, users of TAPI-based programs can specify user names, rather than computer names or IP addresses, when making H.323-based IP telephony calls. | TAPI and Active Directory;Tapicfg;Active Directory |
| Configure H.323 gateways and firewall proxies. | Specify an H.323 gateway or proxy |
| Configure H.323 gatekeepers. | Specify an H.323 gatekeeper |
| Make voice or video IP telephony calls. | Manufacturer's documentation |

# Checklist: Installing IP multicast video conferencing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Checklist: Installing IP multicast video conferencing**

| Step | Reference |
|---|---|
| Review key concepts. | IP Multicast Video Conferencing |
| Confirm that TCP/IP is running on your network. | TCP/IP Core Networking Service |
| Confirm that your network is enabled for multicast. | Enabling IP multicast |
| Confirm that you have an Active Directory domain and that a TAPI application directory partition is available on your network. | TAPI and Active Directory;Active Directory |
| Configure MADCAP on your network for IP multicast telephony.<br>• Install the DHCP server if it is not already installed.<br>• For networks using domains, you must authorize the DHCP service in the domain's directory service database. This prevents users from setting up unauthorized DHCP services.<br>You do not need to do this, however, if the server has been authorized already (for example, if it already functioning as a DHCP server).<br>• To have the DHCP server allocate multicast addresses using the MADCAP protocol, create a new multicast scope. | DHCP;Authorize a DHCP server in Active Directory;Create a multicast Telephony scope |
| Set up multimedia devices on client computers. | Setting up clients for IP telephony;Configure multimedia devices;Eliminating acoustic echo |
| Set up conference rooms. | Setting up conference rooms;Eliminating acoustic echo |
| Make multicast video conference calls. | Manufacturer's documentation. |

# Checklist: Setting up a telephony server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Checklist: Setting up a telephony server**

| Step | Reference |
|---|---|
| Review key concepts. | General Telephony Concepts |
| Confirm that you have an Active Directory domain. | Active Directory |
| For the telephony server, set up or select a computer that is running a Windows Server 2003 operating system and that is in the same domain as the telephony clients or that is in a domain that has a two-way trust relationship with the domain containing the telephony clients. | Trusts |
| Install telephony hardware and software on the server. | Manufacturer's documentation |
| Enable the telephony server. | Enable or disable a telephony server |
| Specify a logon account for the telephony server. (You can create a specific account, such as TAPI_ADMIN.) | Change the Telephony service logon account for a telephony server |
| Designate telephony administrators who are not in the administrator group on the telephony server. | Designate telephony administrators |
| Assign telephony users to lines or phones. | Assign a telephony user to a line or phone |

# Checklist: Setting up telephony clients

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Checklist: Setting up telephony clients**

| Step | Reference |
|---|---|
| Review key concepts. | General Telephony Concepts |
| Confirm that you have an Active Directory domain. | Active Directory |
| (Optional) Upgrade Windows NT 4.0 and Windows 95 clients to TAPI version 2.1 or later, if you have not already done so. | Telephony Resources |
| Install any necessary telephony hardware and software on the clients. | Manufacturer's documentation |
| (Optional) If clients are running Windows 98 or Windows Millennium Edition, enable Windows 98 or Windows Millennium Edition telephony clients. | Enable a Windows 98 or Windows Millennium Edition telephony client |
| On each client, specify the telephony servers to be used by the client. | Specify telephony servers on a client computer; Tcmsetup |
| Configure general dialing rules, area code rules, and calling cards as required for users. | Create a new location |
| Dial and receive phone calls. | Manufacturer's documentation. |

# New ways to do familiar Telephony tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**New ways to do familiar tasks**

The following table lists common tasks for configuring telephony. The user interface for performing these tasks is different in this version of Windows from the way it was in Windows NT 4.0.

**Note**

- There are no significant user interface differences between Windows 2000, Windows XP, and the Windows Server 2003 family for this component.

| If you want to | In Windows NT 4.0 | In this version of Windows use |
|---|---|---|
| **Create a dialing location** | **Telephony** in **Control Panel** | Open Phone and Modem Options. For more information, see Create a new location. |
| **Configure dialing properties for a location** | **Telephony** in **Control Panel** | Open Phone and Modem Options. For more information, see Change dialing properties for a location. |
| **Specify area code rules** | **Telephony** in **Control Panel** | Open Phone and Modem Options. For more information, see Specify area code rules. |
| **Create a calling card** | **Telephony** in **Control Panel** | Open Phone and Modem Options. For more information, see Create a new calling card. |
| **Set up or disable a telephony server** | The **Tcmsetup** command | Open Telephony. For more information, see Enable or disable a telephony server. |
| **Set up or disable a telephony client** | The **Tcmsetup** command | For this task, there is a user interface difference between Windows 2000 and Windows XP and the Windows Server 2003 family.<br><br>If you have telephony servers or clients that run Windows 2000, use the **Tcmsetup** command. For more information, see Specify telephony servers on a client computer.<br><br>If you have telephony servers that run Windows Server 2003 and telephony clients that run Windows XP or a Windows Server 2003 operating system, open Phone and Modem Options. For more information, see Add a telephony service provider. |
| **Assign users to lines or phones** | The **Tcmapp** command | Open Telephony. For more information, see Assign a telephony user to a line or phone. |
| **Add a telephony service provider on a local or remote server** | **Telephony** in **Control Panel** | Open Telephony. For more information, see Add a telephony service provider on a telephony server. |
| **Add a telephony service provider on a client** | **Telephony** in **Control Panel** | Open Phone and Modem Options. For more information, see Add a telephony service provider. |

# Telephony Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Best practices**

- **As a rule, any computer with enough processing power to run a** Windows Server 2003 **operating system can act as a telephony server, linking client computers to hardware, such as a PBX.**

  Other services, especially server-side telephony programs, may have different requirements.

  Remember that, if the telephony server is the PBX, it may make additional processing demands.

- **Obtain service provider components required to communicate with a PBX from a PBX vendor or value-added reseller.**

  TAPI does not supply the service provider components required to communicate with a PBX.

- **Like networking software, a telephony program must be secured to protect privacy and data integrity.**

  The Telephony service must run on a computer that is a member of a Windows Server 2003 domain, and all users must have valid domain accounts. The domain administrator defines which users have permission to communicate with the switch, and the telephony server administrator defines which lines those users can access.

- **Telephony client users must be in the same domain as the telephony server.**

  Make sure that telephony clients are in the same domain as a telephony server or in a domain that has a two-way trust relationship with the domain containing the server. MADCAP servers must also be in the same domain as their client computers.

- **Specify the server on a telephony client or install the Windows Remote Service Provider to make lines or phones available to the client users**

  TAPI is automatically installed on computers running Windows 95, Windows 98, Windows Millennium Edition, Windows NT 4.0, Windows 2000, Windows XP, and Windows Server 2003 operating systems. However, unless your servers are running Windows Server 2003 , and your clients are running Windows XP or a Windows Server 2003 operating system, you must specify a server on the telephony clients before the server's lines are available to the client users.

  For more information, see Specify telephony servers on a client computer.

  If your servers are running Windows Server 2003 , and your clients are running Windows XP or a Windows Server 2003 operating system, you only need to add the Windows Remote Service provider.

  For more information, see Add a telephony service provider.

- **Set up a domain and install Active Directory for IP multicast video conferencing (and optionally, for H.323 IP telephony)**.

  In Windows Server 2003 Active Directory, application directory partitions store and replicate static or dynamic program-specific data. TAPI application directory partitions are not required for H.323 IP telephony, but if one is available on your network, users of TAPI-based programs can specify user names, rather than computer names or IP addresses, when making H.323-based IP telephony calls.

  **Note**

- You can still use Internet Locator Service (ILS) servers in your organization, if ILS is needed to support certain programs, because telephony clients running Windows XP or a Windows Server 2003 operating system can query either ILS servers or TAPI application directory partitions.

For more information about TAPI and Active Directory, see TAPI and Active Directory.

- **If you create a multicast scope, be certain to provide a range of addresses that is large enough for your needs.**

  If a range is not large enough, the scope's pool of addresses will be exhausted. The time-out period must also allow addresses to be reused often enough to keep the pool of addresses from being exhausted. A setting of 30 days is normally sufficient.

  For more information, see Using multicast scopes, Create a multicast Telephony scope, and Enabling IP multicast.

# Telephony How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**How to...**

- Create a multicast Telephony scope
- Manage a TAPI Application Directory Partition
- Manage Telephony Servers
- Manage Telephony Service Providers on a Server
- Manage Telephony Clients and Users
- Change How Phone Calls Are Dialed

# Create a multicast Telephony scope

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To create a multicast scope**

1. Open DHCP.
2. In the console tree, right-click the applicable DHCP server, and then click **New Multicast Scope**.

   **Where?**

   - DHCP/*Applicable DHCP server*

3. On the **Welcome** page of the New Multicast Scope Wizard, click **Next**.
4. Type a name and description for the scope, and then click **Next**.
5. In **IP Address range**, type a valid IP address range for the multicast scope.
6. In **TTL**, specify the number of routers that multicast traffic should pass through on your network.
7. In **Add Exclusions**, add any IP addresses or a range of IP addresses to exclude from the distribution, and then click **Next**.
8. In **Lease Duration**, select a DHCP lease duration for the affected IP addresses, and then click **Next**.
9. In **Activate Multicast Scope**, click **Yes** or **No** to specify whether to activate the multicast scope immediately, and then click **Next**.
10. In **Completing the New Multicast Scope Wizard**, click **Finish**.
11. Repeat the procedure to create any additional scopes.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open DHCP, click **Start**, click **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **DHCP**.
- Provide a range of addresses that is large enough for your needs, and be sure to set a time-out period that will allow addresses to be reused often enough to keep the scope's pool of addresses from being exhausted. A setting of 30 days is normally sufficient.
- If you are running the MADCAP server inside a domain, it might generate warning messages for granting permissions to the DHCP server. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

Authorizing DHCP servers

# Manage a TAPI Application Directory Partition

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Manage a TAPI application directory partition**

- Create a TAPI application directory partition
- Remove a TAPI application directory partition

# Create a TAPI application directory partition

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To create a TAPI application directory partition**

1. Verify that the computer is a domain controller and that the Active Directory directory service is running.

2. Open Command Prompt.

3. At the command prompt, type:

   **tapicfg install /directory:** *PartitionName* [/**server:***DCName*] [**/forcedefault**]

| Value | Description |
|---|---|
| **/directory:** *PartitionName* | Required. Specifies the DNS name of the TAPI application directory partition that is to be created. Note that this name must be a fully qualified domain name. |
| **/server:** *DCName* | Specifies the DNS name of the domain controller on which the TAPI application directory partition is to be created. If the domain controller name is not specified, the name of the local computer is used. |
| **/forcedefault** | Specifies that this directory will be the default TAPI application directory partition for the domain. There can be multiple TAPI application directory partitions in a domain.<br><br>If this application directory partition is the first TAPI application directory partition created on the domain, it is automatically set as the default, regardless of whether you use the **/forcedefault** option. |

**Notes**

- To perform this procedure, you must be a member of the Enterprise Admins group in Active Directory. For more information, see Default local groups and Default groups.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at the command prompt, type:

  **tapicfg help**

- You can also use **tapicfg** to create and remove service connection points that enable telephony clients to efficiently locate TAPI application directory partitions in a domain. For more information, see Related Topics.

- You can also create a TAPI application directory partition by running the Configure Your Server Wizard. If you select **Typical setup for a first server**, a TAPI application directory partition with the name MSTAPI.*DomainName* is automatically created on the first domain controller that is configured in a forest. For more information about the prerequisites for configuring the typical setup for a first server, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Typical setup for a first server

# Remove a TAPI application directory partition

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To remove a TAPI application directory partition**

1. Open Command Prompt.

2. At the command prompt, type:

   **tapicfg remove / directory:** *PartitionName*

| Value | Description |
|---|---|
| **/directory:** *PartitionName* | Required. Specifies the DNS name of the TAPI application directory partition that is to be removed. Note that this name must be a fully qualified domain name. |

## Notes

- To perform this procedure, you must be a member of the Enterprise Admins group in Active Directory. For more information, see Default local groups and Default groups.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at the command prompt, type:

  **tapicfg help**

- If you do not know the name of the TAPI application directory partition, at the command prompt, type **tapicfg show** to view a list of the TAPI application directory partitions that are in the domain. Type **tapicfg show [/defaultonly]** to view the TAPI application directory partition that is the default for the domain.

- You can also use **tapicfg** to create and remove service connection points that enable telephony clients to efficiently locate TAPI application directory partitions in a domain. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Telephony Servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Manage telephony servers**

- Enable or disable a telephony server
- Add a server to the Telephony console
- Delete a server from the Telephony console
- Designate telephony administrators
- Change the Telephony service logon account for a telephony server
- Update information for a telephony server

# Enable or disable a telephony server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To enable or disable a telephony server**

1. Open Telephony.
2. In the console tree, click the server you want to manage.

   **Where?**

   - Telephony/*server*

3. On the **Action** menu, click **Properties**.
4. On the **Setup** tab, do one of the following:

   - To enable the telephony server, select the **Enable telephony server** check box.
   - To disable the telephony server, clear the **Enable telephony server** check box.

5. If you are enabling the telephony server, under **Account Information**, specify a logon account for the Telephony service. For more information, see Related Topics.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Telephony, click **Start**, click **Run**, and then type **tapimgmt.msc**.
- If the **Enable telephony server** check box is unavailable, you need to start the Telephony service first. For more information, see Related Topics.
- This procedure changes whether clients can use the telephony devices on the server. Changes take effect the next time the system attempts to start the Telephony service.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Delete a server from the Telephony console

Update information for a telephony server
Start, stop, pause, resume, or restart a service

# Add a server to the Telephony console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To add a server to the Telephony console**

1. Open Telephony.
2. In the console tree, click **Telephony**.

   **Where?**

   - Telephony

3. On the **Action** menu, click **Add Computer**.
4. In the **Select Computer** dialog box, click **Locations**, and then click the domain where the server is located.
5. In **Enter the object name to select**, enter the name of the telephony server to manage, and then click **OK**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Telephony, click **Start**, click **Run**, and then type **tapimgmt.msc**.
- The telephony server must be enabled on the computer you want to administer. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a server from the Telephony console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To delete a server from the Telephony console**

1. Open Telephony.
2. In the console tree, click the server you want to remove.

   **Where?**

   - Telephony/*server*

3. On the **Action** menu, click **Delete**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Telephony, click **Start**, click **Run**, and then type **tapimgmt.msc**.
- This procedure removes the server from the Telephony console. It does not disable it or prevent it from being used by telephony clients. For the procedure to disable a telephony server, click **Related Topics**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Designate telephony administrators

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To designate telephony administrators**

1. Open Telephony.
2. In the console tree, click the server you want to manage.

   **Where?**

   - Telephony/*server*

3. On the **Action** menu, click **Properties**.
4. On the **Setup** tab, in **Telephony administrators**, click **Add**.
5. In the **Select Users** dialog box, click **Locations**, and then click the domain where the user account is located.
6. In **Enter the object names to select**, enter the name of the user to be designated as a Telephony administrator, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Telephony, click **Start**, click **Run**, and then type **tapimgmt.msc**.
- Use this procedure to enable users who are not administrators for the server to administer the Telephony service.
- If the user's domain is not listed in the **Locations** dialog box, try specifying the domain in **Enter the object names to select** by using the following format:

  *domain\username*

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the Telephony service logon account for a telephony server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To change the Telephony service logon account for a telephony server**

1. Open Telephony.
2. In the console tree, click the server you want to manage.

   **Where?**

   - Telephony/*server*

3. On the **Action** menu, click **Properties**.
4. On the **Setup** tab, in **Account Information**, click **Choose User**.
5. In the **Select User** dialog box, click **Locations**, and then click the domain where the account is located.
6. In **Enter the object name to select**, type the name of the account, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Telephony, click **Start**, click **Run**, and then type **tapimgmt.msc**.
- If the user's domain is not listed in the **Locations** dialog box, try specifying the domain in **Enter the object name to select** by using the following format:

  *domain\username*

# Update information for a telephony server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To update information for a telephony server**

1. Open Telephony.
2. In the console tree, click the server you want to manage.

   **Where?**

   - Telephony/*server*

3. In the **Action** menu, click **Refresh**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Telephony, click **Start**, click **Run**, and then type **tapimgmt.msc**.
- This procedure updates the status of lines and phones, displays new lines and phones, and shows changes made by others administering the Telephony service.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Telephony Service Providers on a Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Manage telephony service providers on a server**

- Add a telephony service provider on a telephony server
- View the status of a telephony service provider's lines or phones
- Export telephony service provider information to a text file
- Enable auto updates for telephony devices
- Configure telephony service providers on a telephony server

# Add a telephony service provider on a telephony server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To add a telephony service provider on a telephony server**

1. Open Telephony.
2. In the console tree, click the server you want to manage.

   **Where?**

   - Telephony/*server*

3. In the **Action** menu, click **Manage Providers**.
4. In the **Telephony Providers** dialog box, click **Add**.
5. In the **Add Provider** dialog box, under **Available telephony providers**, select the telephony service provider that you want to add, and then click **Add**.

   If the telephony service provider you want to add does not appear in this list, you must install the appropriate driver files for the telephony service provider. For more information, see Notes.

6. In the **Telephony Providers** dialog box, review the list of installed telephony service providers to confirm that the provider was added to the list, and then click **Close**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must be designated as a telephony administrator (for information about designating telephony administrators, see Related Topics). If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- After you add a telephony service provider, the Telephony console might not display the lines and phones supported by the service provider until after the computer is restarted.
- If the telephony driver is not listed in the **Available telephony drivers** list in the **Add Provider** dialog box, you must install the driver files in the *Systemroot*\system32 folder. Usually you can use the setup program on a telephony device manufacturer's installation disk. For additional information, see the manufacturer's installation instructions.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View the status of a telephony service provider's lines or phones

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To view the status of a telephony service provider's lines or phones**

1. Open Telephony.
2. In the console tree, click the service provider you want to manage.

**Where?**

- Telephony/*server/service provider*

1. Click **View**.
2. Click **Lines** or **Phones**.

**Notes**

- If the telephony server is not enabled, performing this task does not require administrative credentials. Any user who logs on to the telephony server can view the status of the lines and phones for each telephony service provider on the server. In addition, that user can view the names of all users who are assigned to lines or phones on the server.
- If the telephony server is enabled, to view the status of lines or phones for each telephony service provider on the server you must log on to the telephony server as one of the following:
  - A member of the local Administrators group on the telephony server. (If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.) For more information, see Default local groups and Default groups.
  - A telephony administrator. (For more information about designating telephony administrators, see Related Topics.)
  - A user who is assigned to a line or phone on the telephony server.

  Members of the local Administrators group on the telephony server and telephony administrators can view the names of all users who are assigned to lines or phones on the server. However, a user who is assigned to a line or phone on the server cannot view the names of other users who are assigned to lines or phones on the server. For information about enabling a telephony server, see Related Topics.
- To open Telephony, click **Start**, click **Run**, and then type **tapimgmt.msc**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Export telephony service provider information to a text file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To export telephony service provider information to a text file**

1. Open Telephony.
2. In the console tree, click the service provider you want to manage.

   **Where?**

   - Telephony/*server*/*service provider*

3. On the **Action** menu, click **Export List**.

## Notes

- If the telephony server is not enabled, performing this task does not require administrative credentials. Any user who logs on to the telephony server can export telephony service provider information to a text file. The information that is exported will include a list of telephony lines and phones on the telephony server and the names of users who are assigned to each of the telephony lines or phones.
- If the telephony server is enabled, to view the status of lines or phones for each telephony service provider on the server you must log on to the telephony server as one of the following:
  - A member of the local Administrators group on the telephony server. (If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.)
  - A telephony administrator. (For more information about designating telephony administrators, see Related Topics.)
  - A user who is assigned to a line or phone on the telephony server.

  Members of the local Administrators group on the telephony server and telephony administrators can export the names of users who are assigned to each of the telephony lines or phones on the server. However, a user who is assigned to a line or phone on the server cannot export the names of other users who are assigned to lines or phones on the server. For information about enabling a telephony server, see Related Topics.
- To open Telephony, click **Start**, click **Run**, and then type **tapimgmt.msc**.
- This procedure exports the list of telephony lines or phones to a text file.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable auto updates for telephony devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To enable auto updates for telephony devices**

1. Open Telephony.
2. In the console tree, click the server you want to manage.

   **Where?**

   - Telephony/*server*

3. On the **Action** menu, click **Properties**, and then click the **Auto Updates** tab.
4. Select the **Enable device status auto updates** check box.
5. Next to **Interval**, type the **Hours** and **Minutes** between automatic updates.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Telephony, click **Start**, click **Run**, and then type **tapimgmt.msc**.
- The action enabled by this procedure updates only the status information for lines and phones.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

# Configure telephony service providers on a telephony server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To configure telephony service providers on a telephony server**

1. Open Telephony.
2. In the console tree, click the server you want to manage.

   **Where?**

   - Telephony/*server*

3. On the **Action** menu, click **Manage Providers**.
4. Click the telephony service provider you want to configure, and then click **Configure**.

   If **Configure** is not available, then the telephony service provider has no configurable properties.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must be designated as a telephony administrator (for information about designating telephony administrators, see Related Topics). If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.For more information, see Default local groups, Default groups, and Using Run as.
- To open Telephony, click **Start**, click **Run**, and then type **tapimgmt.msc**.
- The settings you can change depend on the telephony service provider.
- You can also configure telephony service providers on the local computer using **Phone and Modem Options** in Control Panel. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Telephony Clients and Users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Manage telephony clients and users**

- Assign a telephony user to a line or phone
- Remove users from telephony lines or phones
- Specify telephony servers on a client computer
- Add a telephony service provider
- Configure a telephony service provider
- Specify an H.323 gateway or proxy
- Specify an H.323 gatekeeper
- Specify H.323 call control options
- Enable a Windows 98 or Windows Millennium Edition telephony client

# Assign a telephony user to a line or phone

Updated: May 4, 2006

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To assign a telephony user to a line or phone**

1. Open Telephony.
2. In the console tree, click the service provider you want to manage.

   **Where?**

   - Telephony\server\service provider

3. In the details pane, under **Line Name** or **Phone Name**, click the line or phone.
4. On the **Action** menu, click **Edit Users**.
5. In the **Edit Users** dialog box, click **Add**.
6. In the **Select Users** dialog box, click **Locations**, and then click the domain where the user is located.
7. In **Enter the object names to select**, enter the name of the user to be assigned a line or phone, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must be designated as a telephony administrator (for information about designating telephony administrators, see Related Topics). If the computer is joined to a domain, members of the Domain Admins group can perform this procedure only if the Domain Admins group is a member of the Administrators group. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- By default, members of groups with administrative credentials for a telephony server already have access to all telephony lines or phones on that server and therefore do not need to be assigned lines or phones on the server. Members of the local Administrators group can access all lines or phones on that server from any other computer in the domain. By default, members of the Domain Admins group can access all telephony lines and phones on all servers in the domain.
- To open Telephony, click **Start**, click **Run**, and then type **tapimgmt.msc**.
- After you perform this procedure, telephony client programs run by the user will be able to use the line or phone on the telephony server.
- A user added for a phone or line must be in the same domain as the telephony server or in a domain that has a two-way trust relationship with the domain containing the server.
- If the user's domain is not listed in the **Locations** dialog box, try specifying the domain in **Enter the object names to select** by using the following format:

  *domain\username*

- Before a user can use the telephony line or phone, the telephony server must be specified on the client computer. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove users from telephony lines or phones

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To remove users from telephony lines or phones**

1. Open Telephony.
2. In the console tree, click the service provider you want to manage.

   **Where?**

   - Telephony/*server*/*service provider*

3. In the details pane, under **Line Name** or **Phone Name** click the line or phone.
4. In the **Action** menu, click **Edit Users**.
5. In **Assigned Users**, click a user, and then click **Remove**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must be designated as a telephony administrator (for information about designating telephony administrators, see Related Topics). If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Telephony, click **Start**, click **Run**, and then type **tapimgmt.msc**.
- After you perform this procedure, telephony client programs run by the user will be unable to use the line or phone on the telephony server.
- You can remove multiple users from telephony lines or phones at one time by using the **Tsecimp** command. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify telephony servers on a client computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To specify telephony servers on a client computer**

1. Open a Command Prompt window.
2. Type **tcmsetup /c** *server1 server2* **...**

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- The client must be in the same domain as the telephony server or in a fully trusted domain when you run **tcmsetup**.
- In order for TAPI to function correctly, you must add the Windows Remote Service Provider to the client computer or run the **tcmsetup** command. If your telephony clients run Windows XP or a Windows Server 2003 operating system, and your telephony servers run Windows Server 2003, then add the Windows Remote Service Provider to your clients. (The Windows Remote Service Provider enables clients to detect telephony servers.) However, if your telephony clients or servers run Windows NT 4.0 or Windows 2000, you must run **tcmsetup**, as described in this procedure, instead. For more information about adding telephony service providers and using **tcmsetup**, see Related Topics.
- In the **tcmsetup** command-line syntax, *server1 server2* **...** represents the names of one or more telephony servers. Because **tcmsetup** replaces any previous server list, you should include every telephony server that you want to make available to the client when you run **tcmsetup**.
- You may have to restart the Telephony service for this change to take effect. For more information, see Related Topics.
- Before client users can dial out using the phone lines on the telephony server, the telephony server administrator must assign the users to the phone lines. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**

Cmd

# Add a telephony service provider

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To add a telephony service provider**

1. Open Phone and Modem Options in Control Panel.

2. On the **Advanced** tab, click **Add**.

3. In the **Add Provider** dialog box, under **Telephony providers**, click the service provider, then click **Add**.

   If the telephony service provider that you want to add does not appear in this list, you must install the appropriate driver files for the telephony service provider. For more information, see Notes.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

- In order for TAPI to function correctly, you must add the Windows Remote Service Provider to the client computer or run the **tcmsetup** command. If your telephony clients run Windows XP or a Windows Server 2003 operating system, and your telephony servers run Windows Server 2003 , then add the Windows Remote Service Provider to your clients. (The Windows Remote Service Provider enables clients to detect telephony servers.) However, if your telephony clients or servers run Windows NT 4.0 or Windows 2000, you must run **tcmsetup**, as described in this procedure, instead. For more information about adding telephony service providers and using **tcmsetup**, see Related Topics.

- This procedure only adds telephony service providers that are already installed on your hard drive in the *Systemroot*\system32 folder. Use the setup or installation program provided on the manufacturer's disk to install the driver files for a new telephony service provider.

- A manufacturer's setup program normally adds the new telephony service provider to the list on the **Advanced** tab of **Phone and Modem Options**. If a telephony service provider is not listed on the **Advanced** tab after you run the manufacturer's setup program, use this procedure to add the service provider. If it is not listed in the **Add Provider** dialog box, refer to the manufacturer's documentation for further instructions.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure a telephony service provider

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To configure a telephony service provider**

1. Open Phone and Modem Options in Control Panel.
2. On the **Advanced** tab, under **Providers**, click the telephony service provider you want to configure.
3. Click **Configure**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- The settings you can change depend on the service provider. If **Configure** is unavailable, then the service provider does not have any settings that you can change.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify an H.323 gateway or proxy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To specify an H.323 gateway or proxy**

1. Open Phone and Modem Options in Control Panel.
2. On the **Advanced** tab, in **Providers**, click **Microsoft H.323 Telephony Service Provider**, and then click **Configure**.
3. In **Configure H.323 Service Provider**, select one of the following:
   - To specify an H.323 gateway, select the **Use H.323 gateway** check box, and then type the computer name or IP address for the gateway.
   - To specify an H.323 proxy, select the **Use H.323 proxy**, and then type the server name or IP address for the proxy.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- An H.323 gateway connects the IP network with a switched service network, such as the public switched telephone network (PSTN). Your telephony administrator can provide the correct name or IP address to enter here.
- A proxy server acts as a firewall or security barrier between your intranet and the Internet, preventing other people on the Internet from gaining access to confidential information on your internal network or computer. Your telephony administrator can provide the correct name or IP address to enter here.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify an H.323 gatekeeper

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To specify an H.323 gatekeeper**

1. Open Phone and Modem Options in Control Panel.
2. On the **Advanced** tab, in **Providers**, click **Microsoft H.323 Telephony Service Provider**, and then click **Configure**.
3. Under **Calling through a gatekeeper using TAPI 3.1**, select the **Use H.323 gatekeeper** check box, and then type the computer name or IP address (for example, 10.255.255.255) of the gatekeeper that you want to use.
4. Under **Calling through a gatekeeper using TAPI 3.1**, register with the gatekeeper by specifying one or both of the following:
   - To use a telephone number, select the **Log on using my phone number** check box, and then type the telephone number that you want to use.
   - To use an account name, select the **Log on using my account name** check box, and then type the name of the account you want to use.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- An H.323 gatekeeper serves as the central point for all calls within its zone of control. Gatekeepers perform address translation, admissions control, bandwidth control, and zone management functions. In addition, gatekeepers can perform call control, call authorization, bandwidth management, and call management functions.
- If you select the **Use H.323 gatekeeper** check box, any gateway and proxy settings that are specified in the **Configure H.323 Service Provider** dialog box will not be used.
- To use an H.323 gatekeeper, you must register with the gatekeeper by specifying a valid telephone number, account name, or both. Registering with a gatekeeper allows you to receive calls at this computer. If you are not sure which telephone number or account name to use to register with the H.323 gatekeeper, contact your telephony administrator or service provider.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify H.323 call control options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To specify H.323 call control options**

1. Open Phone and Modem Options in Control Panel.
2. On the **Advanced** tab, in **Providers**, click **Microsoft H.323 Telephony Service Provider**, and then click **Configure**.
3. Under **H.323 call control**, in **H.323 call alerting timeout**, type the amount of time, in milliseconds, an incoming call will ring before it is dropped.
4. Under **H.323 call control**, in **H.323 call listening port**, type the number of the port on which this H.323 client will listen for incoming calls, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

# Enable a Windows 98 or Windows Millennium Edition telephony client

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To enable a Windows 98 or Windows Millennium Edition telephony client**

1. On a Windows 98 or Windows Millennium Edition telephony client computer, click **Start**, point to **Settings**, and then click **Control Panel**.
2. Double-click **Network**.
3. (Optional) If **Client for Microsoft Networks** is not in the list of installed network components, click **Add**, and follow the instructions to add it.
4. Click **File and Print Sharing**, confirm that both check boxes are selected, and then click **OK**.
5. Click the **Access Control** tab, click **User-level access control**, then click **OK**.

### Note

- After you complete this procedure, you need to specify a telephony server on the client. To make the telephony resources on the server available to the client users, the server administrator needs to assign the users to telephones or lines on the server. Users must log on to a trusted domain account. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change How Phone Calls Are Dialed

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Change how phone calls are dialed**

- Create a new location
- Change dialing properties for a location
- Specify area code rules
- Specify numbers to dial an outside line
- Create a new calling card
- Modify an existing calling card
- Use a calling card for long distance dialing
- Specify a long distance carrier

# Create a new location

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To create a new location**

1. Open Phone and Modem Options in Control Panel.
2. On the **Dialing Rules** tab, click **New**.
3. On the **General** tab, in **Location name**, type the name of the new location.
4. Specify the characteristics of your telephone line by providing additional information on the **General** tab, the **Area Code Rules** tab, and the **Calling Card** tab.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- See Related Topics for more information about locations or specifying specific elements of a location.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify area code rules

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To specify area code rules**

1. Open Phone and Modem Options in Control Panel.
2. On the **Dialing Rules** tab, click the location to modify, and then click **Edit**.

   To create a new location, click **New**.
3. Click the **Area Code Rules** tab.
4. To add a new area code rule, click **New**.

   To edit an existing rule, click the rule and then click **Edit**.
5. In **Area code**, enter the area or city code.
6. In **Prefixes**, select one of the following:

   - To apply the rule to all prefixes in the area code, select the **Include all the prefixes within this area code** check box.
   - To apply the rule to specific prefixes, select the **Include only the prefixes in the list below** check box, click **Add**, enter one or more prefix, and then click **OK**.
7. In **Rules**, select one or both of the following:

   - To dial a number before the phone numbers that contain these prefixes, select the **Dial** check box, and then type the digits to dial.
   - To dial the area code before the phone number, select the **Include the area code** check box.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify numbers to dial an outside line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To specify numbers to dial an outside line**

1. Open Phone and Modem Options in Control Panel.
2. On the **Dialing Rules** tab, click the location to modify, and then click **Edit**.

   To create a new location, click **New**.
3. On the **General** tab, in **Dialing rules**, enter the numbers required to reach an outside line for local and long-distance calls.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- Do not use this procedure to specify the numbers required before dialing to a different city, area, or country/region, such as 1, 0, 00, or 011. The numbers specified here are to dial local or long distance calls from within a private branch exchange (PBX), such as used by a company or other organization. The dialing rules for a location automatically insert the number required to call a number with a different city, area, or country/region code.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a new calling card

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To create a new calling card**

1. Open Phone and Modem Options in Control Panel.
2. On the **Dialing Rules** tab, click the location to modify, and then click **Edit**.

   To create a new location, click **New**.
3. On the **Calling Card** tab, click **New**.
4. On the **General** tab, enter the following:

| Value | Description |
|---|---|
| **Calling card name** | The name you use to identify the card. |
| **Account number** | The account number provided by the calling card company for the calling card. For some calling cards this is the home or business phone number associated with the account. |
| **Personal Identification Number (PIN)** | Any personal number required to secure your account against unauthorized use. Often a four digit number, this is usually dialed after the account number when you place a call. Some calling cards do not use a PIN. |

5. On the **Long Distance** tab, the **International** tab, and the **Local Calls** tab, type the phone number that is required to access the corresponding service. Include all the digits dialed after you access an outside line.

   - On the **Long Distance** tab, **Access number for long distance calls** is the phone number required to access the calling card service for domestic long distance calls.
   - On the **International** tab, **Access number for international calls** is the phone number required to access the calling card service for international long distance calls.
   - On the **Local Calls** tab, **Access number for local calls** is the phone number required to access the calling card service for local calls. Leave this blank to dial local numbers without using the calling card.
6. On the **Long Distance** tab, the **International** tab, and the **Local Calls** tab, in **Calling card dialing steps**, click the buttons to add the steps that are required to complete a call.

| Click | To dial |
|---|---|
| **Access Number** | The number to access the calling card company. This will dial the access number entered at the top of the tab. |
| **Account Number** | The account number that identifies your account, which was entered on the **General** tab. |
| **PIN** | Your personal identification number, which was entered on the **General** tab, usually dialed immediately after the account number. |

| | |
|---|---|
| **Destination Number** | The country/region code, area code, and phone number. |
| **Wait for Prompt** | Pauses dialing for a dial tone, voice message, or time interval. |
| **Specify Digits** | Any sequence of the digits 0-9, *, and #. |

7. To reposition any step in the order of calling card dialing steps, click the step, and then click **Move Up** or **Move Down**.

   To remove the step, click **Delete**.

### Important

- When you enter a calling card PIN number, this number is displayed in plaintext. Therefore, to enhance security, type this number in a private location whenever possible. If you are not in a private location, take care to ensure that this number is not exposed to another user.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

- If you add **Access Number**, **PIN**, or **Account Number** to the **Calling card dialing steps** and the corresponding field is blank, the program will prompt you to enter the missing value when you click **OK** or **Apply**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modify an existing calling card

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To modify an existing calling card**

1. Open Phone and Modem Options in Control Panel.
2. On the **Dialing Rules** tab, click the location to modify, and then click **Edit**.
3. On the **Calling Card** tab, click the card type you want to modify, and then click **Edit**.
4. Click the **General** tab to change the calling card name, number, or your personal identification number (PIN).
5. Click the **Long Distance**, **International**, or **Local Calls** tab to change the access number or dialing steps for the corresponding type of call.

### Important

- When you enter a calling card PIN number, this number is displayed in plaintext. Therefore, to enhance security, type this number in a private location whenever possible. If you are not in a private location, take care to ensure that this number is not exposed to another user.

### Notes

- To perform this procedure, you must be the user who created the calling card. A calling card that is created by one user cannot be modified by a different user.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- If you add **Access Number**, **PIN**, or **Account Number** to the **Calling card dialing steps** and the corresponding field is blank, the program will prompt you to enter the missing value when you click **OK** or **Apply**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use a calling card for long distance dialing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To use a calling card for long distance dialing**

1. Open Phone and Modem Options in Control Panel.
2. On the **Dialing Rules** tab, click the location to modify, and then click **Edit**.

   To create a new location, click **New**.
3. On the **Calling Card** tab, click the calling card you want to use.

## Notes

- To perform this procedure, you must be the user who created the calling card.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- If you use more than one calling card, you can create a different location for each one. Telephony programs typically allow you to change the location before dialing.
- If you dial digits to access a long distance carrier (a long distance operator), you can use a calling card to specify the dialing sequence. When you create the calling card for a long distance carrier, create a unique location to go with it.
- See Related Topics for procedures to create calling cards or locations.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Dialing rules overview
Create a new calling card
Modify an existing calling card

# Specify a long distance carrier

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**To specify a long distance carrier**

1. Open Phone and Modem Options in Control Panel.
2. On the **Dialing Rules** tab, click **New**.
3. On the **General** tab, type a **Location name** to identify the long distance carrier, and specify the **Country/region**, **Area code**, and any **Dialing rules**.
4. On the **Calling Card** tab, click **New**, and on the **General** tab, in **Calling card name**, type a name to identify the calling card, such as the name of the long distance carrier.
5. On the **Long Distance** tab and the **International** tab, in the access number box, type the corresponding long distance operator number.
6. On the **Long Distance** tab and the **International** tab, in **Calling card dialing steps**, click **Access Number** and the additional steps for dialing long distance and international calls.
7. On the **Local Calls** tab, leave **Access number for local calls** blank, unless an access number is required, and in **Calling card dialing steps**, enter the steps for dialing local calls.

   To dial only the local phone number, click **Destination Number**, and clear the **Dial the area code** check box.
8. Click **OK** to save the new calling card.
9. On the **Calling Card** tab, in **Card Types**, make sure that the new calling card is selected to be used with the location, and then click **OK**.
10. Under **Locations**, leave this location selected if you want this to be the default long distance carrier for telephony programs, and then click **OK**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- This procedure specifies long distance carrier numbers (also called the long distance operator) required for domestic or international long distance calling. This procedure is not normally required to use the default domestic and international long distance operators for a country/region. The country/region selection for a location normally enables programs to use the default numbers.
- The location selected on the **Dialing Rules** tab of **Phone and Modem Options** is the default location for dialing. If you create more than one location, some telephony programs allow you to choose a different location before dialing.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Telephony Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Concepts**

This section provides general background information about Telephony Application Programming Interface (TAPI):

- Telephony overview
- TAPI and Active Directory
- Telephony service providers
- Understanding Telephony
- Using Telephony
- Telephony Resources

# Telephony overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Telephony overview**

Telephony Application Programming Interface (TAPI) integrates telecommunications with the computer. TAPI supports both traditional (or PSTN) and IP telephony to provide voice, data, and video communication. Supported hardware includes sound and video cards, modems, ISDN lines, ATM networks, and cameras. With this, you can communicate over direct connections to local computers, phone lines, LANs, WANs, and the Internet.

In addition to making and receiving calls, programs can use TAPI to provide enhanced telephony features such as caller ID, call routing, voice mail, and video conferencing. Communication programs may identify the caller, recall and display caller information, and even prioritize or route a call, based on customer information.

With TAPI, there is a common standard so that communication programs can control telephony functions for data, fax, and voice calls.

- TAPI manages all signaling between a computer and a telephone network, including basic functions such as dialing, answering, and hanging up a call.
- TAPI includes supplementary functions that are found in PBX, ISDN, and other phone systems, such as hold, transfer, conference, and call park.
- TAPI provides access to features that are specific to certain service providers, with built-in extensibility to accommodate additional telephony features and networks.
- TAPI allows users to make audio and video telephone calls over IP networks using the H.323 protocol and IP multicast video conferencing.
- TAPI includes Quality of Service (QoS) support to improve conference quality and network manageability.

These capabilities enable TAPI to unify IP and traditional telephony and support programs that effectively work the same way over intranets and the Internet as they do over the traditional telephone network. Furthermore, the current version of TAPI provides compatibility with previous versions to support existing telephony programs.

HyperTerminal and Network Connections are communication programs that use TAPI and that are provided with the Microsoft® Windows Server 2003 family. Fax Services, another communication program that uses TAPI, is available on an optional basis. You can also install other Microsoft or non-Microsoft programs to provide additional telephony support. The common interface that TAPI provides enables different communication programs to work together and share communication devices.

# TAPI and Active Directory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**TAPI and Active Directory**

Active Directory is the extensible and scalable directory service for Windows Server 2003 operating systems. TAPI-based programs use Active Directory to facilitate H.323-based IP telephony calls and multicast conferencing.

Active Directory publishes the locations of all TAPI application directory partitions on the network and provides the directory store for TAPI program-specific data. In Active Directory, application directory partitions store and replicate static or dynamic program-specific data. TAPI-based programs can use TAPI application directory partitions to store and retrieve information to facilitate H.323-based IP telephony calls and multicast conferencing.

TAPI provides transparent translation from user or computer names to IP addresses. When you place an H.323-based IP telephony call, you can specify a computer name or a user name, rather than an IP address, because TAPI application directory partitions publish user names, computer names, and IP addresses, and TAPI can translate user or computer names to IP addresses.

For multicast conferencing, TAPI application directory partitions publish information about active users and IP multicast conferences in progress. Information about active users includes the users' names, computer names, and IP addresses. Information about conferences in progress includes the conferences' names, descriptions, times, and originators.

You can create TAPI application directory partitions in one of two ways:

- By using the **Tapicfg** command-line tool. You can also use this command to remove or display TAPI application directory partitions and to set default TAPI application directory partitions. For more information, see Tapicfg.

- By selecting the **Typical setup for a first server** option when running the Configure Your Server Wizard to configure the first domain controller in a domain. When you select this option, the **Tapicfg** command runs transparently to create a TAPI application directory partition called MSTAPI.*DomainName*. This application directory partition is set as the default for the domain. For more information about the prerequisites for using this option, see Typical setup for a first server.

For more information about application directory partitions, see Application directory partitions. For more information about the H.323 IP protocol and the telephony service provider that supports it, see H.323 IP telephony calls.

**Note**

- If Internet Locator Service (ILS) is needed to support certain programs, you can continue to use ILS servers in your organization because telephony clients running Windows Server 2003 operating system can query either ILS servers or TAPI application directory partitions.

# Telephony service providers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Telephony service providers**
The following telephony service providers are supplied with this version of the Windows operating system.

**HID Phone TAPI Service Provider**
The Human Interface Device (HID) Phone TAPI Service Provider allows users of TAPI-based programs to make and receive telephone calls by using universal serial bus (USB) telephone handsets connected to their computers. This service provider is installed with Windows Server 2003 operating systems, and it requires no configuration.

**NDIS Proxy TAPI Service Provider**
The Network Driver Interface Specification (NDIS) Proxy TAPI Service Provider enables TAPI to control NDIS 5 devices. Routing and Remote Access uses this telephony service provider to set up network connections across NDIS WAN devices for My Network Places. This service provider is installed with Windows XP and Windows Server 2003 operating systems. To map addresses for the different types of calls received by the NDIS Proxy TAPI Service Provider on the local computer, see Configure a telephony service provider.

**TAPI Kernel-Mode Service Provider**
The TAPI Kernel-Mode Service Provider allows TAPI to control NDIS 4 devices. Network Connections uses this telephony service provider to set up network connections across NDIS WAN devices for My Network Places. This service provider is installed with Windows XP and Windows Server 2003 operating systems, and it requires no configuration.

**Unimodem 5 Service Provider**
The universal modem driver (Unimodem) provides services for data, fax, and voice modems so that users and program developers will not have to learn or maintain modem AT commands to dial, answer, and configure modems. Unimodem performs these tasks by using files that specify the AT command sets and expected responses for modems. These files usually have an .inf extension. Unimodem supports both data and voice, so a modem can be used for data and fax functions, as a speaker phone, as an answering machine, and so on. This service provider is installed with Windows XP and Windows Server 2003 operating systems.

**Windows Remote Service Provider**
The Windows Remote Service Provider enables a client computer to access and control remote telephony devices connected to a server computer, such as telephones and phone lines. The remote service provider makes the client-to-server link transparent to programs.

The Windows Remote Service Provider resides on the client computer, where it appears as a telephony service provider. When a program makes a TAPI request, the service provider interprets the request and sends it across the computer network to the Telephony service running on the server. The program then uses the telephony service provider for the telephone device installed on the server. By using this solution, clients can share a telephony resource over the network.

The Windows Remote Service Provider is installed with TAPI 2.2 on Windows 2000, Windows Millennium Edition, Windows XP, and Windows Server 2003 operating systems. On Windows 98 and Windows NT Service Pack 4, the Windows Remote Service Provider is included with TAPI 2.1. Windows NT 4.0 and Windows 95 clients need to upgrade to TAPI 2.1.

**H.323 TAPI Service Provider**

The H.323 TAPI Service Provider allows TAPI-supported programs to engage in multimedia calls with any H.323-compliant terminal on the local area network. It is also designed to work well with standard phone or Internet phone gateways. This service provider supports programs that enable computer users to interconnect and communicate with other people over IP-based networks. This service provider is installed with Windows XP and Windows Server 2003 operating systems.

**Multicast Conference TAPI Service Provider**

The Multicast Conference TAPI Service Provider supports IP multicast video conferencing for telephony clients. Using IP multicast, users participate in efficient multicasting, sending data to a single conference IP address instead of copying data to all participants in a conference. This service provider is installed with Windows XP and Windows Server 2003 operating systems.

### Note

- For information about configuring telephony service providers, see Configure telephony service providers on a telephony server.

# Introduction to telephony

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Introduction to telephony**
Telephony Application Programming Interface (TAPI) provides a uniform set of commands for any supported telephony device that is connected to your computer.

**How TAPI works**
When you use a Windows Server 2003 family program to send faxes, connect to a telephone, make a call using IP, join a conference, or perform other TAPI-supported activities, there are three layers of software that enable you to use a telephony device: a program, TAPI, and a telephony service provider.

- A program enables you to make phone calls, send and receive data or faxes, or join conferences. Microsoft and independent software vendors provide programs that incorporate TAPI functionality. Examples include HyperTerminal, which is included with Windows Server 2003 operating systems. Fax Services, another communication program that uses TAPI, is available on an optional basis.

- TAPI provides telephony functions for programs, such as dialing.

- A telephony service provider translates the commands for a telephony device or telephony protocol. Telephony service providers for modems and several telephony protocols are installed with Windows Server 2003 operating systems, and others are provided by independent hardware vendors.

**How TAPI works with telephony hardware**
In place of proprietary solutions that are difficult and expensive to implement, TAPI provides a single set of commands allowing hardware and software to come from different sources. When a telephony program requests an action, TAPI determines which telephony service provider supports the device, and the service provider sends the appropriate commands to the device.

For example, the Unimodem (Universal Modem) 5 Service Provider is installed with Windows Server 2003 operating systems. When an program initiates the dialing of a phone number, TAPI sends the appropriate commands to the Unimodem 5 Service Provider, and it sends the correct sequence of commands for dialing the number on the particular modem attached to the computer. The program does not need to know anything about the modem.

With TAPI, the Windows Server 2003 operating system provides a telephony platform. The Windows Server 2003 operating system is the operator that interconnects computer and telephony resources to direct and manage calls. TAPI-based software can provide solutions ranging from complete small office systems or home office systems to PBX front ends that integrate the computer and telephone networks of an organization.

**How TAPI makes resources available to users**
Network users make calls using lines. They may also use phones for call management and control. These are supported by the telephony service providers. A telephony administrator makes telephony resources on a server, such as lines and phones, available to users.

**Lines**
In telephony, a line is any media stream (data, voice, or video) supported by a telephony service provider. For a modem, the

line represents an actual telephone line. For other devices, it can represent another media stream, such as a gateway to the Internet. Calls are made using a line provided by a telephony service provider. A single line can support more than one call at a time, such as with call waiting and conferencing. The telephony service provider determines how physical devices are represented by telephony lines.

**Phones**
A phone in TAPI represents terminal equipment that is supported by a telephony service provider. In TAPI, a "phone" closely models a physical telephone, but may not be actual hardware. It includes the concepts of a hookswitch, handset, speaker, microphone, display, lamps, and programmable buttons. As with an actual telephone on your desk, a phone may be used without actually making calls to someone else. For example, you can use a telephone handset to listen to or retrieve voice mail messages.

A phone does not have to represent actual hardware; it can be emulated in software. For instance, this type of phone might be a program that uses TAPI or a telephony service provider. A physical phone is not required to manage a media stream and, although all telephony service providers support lines, not all telephony service providers support phones.

**How TAPI supports telephony**
The Windows Server 2003 family supports computer-telephony integration, from simple small office or home-based solutions to full-scale, enterprise-wide solutions. Low-level telephony solutions enable an individual to:

- Use a computer as an answering machine or voice mailbox.
- Use a computer to send and receive faxes.
- Use a microphone and speaker or a speakerphone connected to a multimedia computer as a phone system.
- Log on to a computer from a remote location.

These solutions are typically supported by a direct connection from a desktop computer to a phone line with a modem. Enterprise-wide solutions rely on a network and enable an organization to:

- Use a computer either as a multiline phone system or as a multifunction PBX controller.
- Provide a voice-mail system across your entire enterprise.
- Provide a fax system across your entire enterprise.
- Provide on-demand audio information services that allows callers to retrieve prerecorded or computer-generated text-to-speech information.
- Fax information to customers on demand, based on touch-tone keys or other input.
- Implement automatic, list-based dialing for telemarketing.
- Deliver database information related to a call (such as a customer profile or account information) at the same time it is switched to a desktop.
- Create a single, easy-to-use client program to manage all communications, such as voice, pager, e-mail, and conferencing.
- Provide dial-up access to the network.

On a network, a hardware interface adapter on a server connects the LAN to a public or private telephone network. The adapter is supported by a telephony service provider. Programs running on the server provide calling features such as conferencing, transferring, forwarding, holding, and automatic redialing. The server controls the calls going through the network and out onto the PBX.

Client programs provide voice, video, fax, and data communications for the user. As this section illustrates, the client programs call functions provided by the Telephony service on the client. The Telephony service on the client uses the Windows Remote

Service Provider to communicate over the network with the telephony service providers on the server, and the actual telephony services are provided by the telephony service providers managing telephony devices on the server.

# PSTN telephony

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**PSTN telephony**

The public switched telephone network (PSTN) is a traditional, circuit-switched network which is optimized for real-time voice communication. When you call someone, you close a switch by dialing and establish a circuit with the other party. The PSTN guarantees Quality of Service (QoS) by dedicating the circuit to your call until you hang up the telephone. Whether you and your party are talking or silent, you continue to use the same circuit until you hang up.

Telephony Application Programming Interface (TAPI) enables programs to communicate easily over the traditional telephone network. TAPI provides support for the direct connection to a PSTN network, automatic phone dialing, and interfaces for conference calling, voice mail, and caller ID.

TAPI helps make the Windows Server 2003 family a powerful and flexible platform for developing and using computer-telephony integration (CTI) programs. Programs can build on TAPI's client-server support to provide a graphical interface for system administration and enhanced services, such as voice mail, call queueing, follow-me call forwarding, telephony-computer integration, and speech recognition. Besides enabling individual programs to provide telephony services, TAPI manages the telephony devices, so more than one program using a line can remain active simultaneously. One program can wait for a call while another is dialing out.

In a client-server environment, telephony can be managed like any other network service. You can specify the lines and phones available to particular users and use domain security to control access to telephony resources. Telephony service providers and all stored parameters can be updated across a LAN, making it easy to set up, use, and manage resources without regard to physical location.

# PSTNs, PBXs, and computer networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**PSTNs, PBXs, and computer networks**

In telephony, desktop computers interact with telephony hardware. Most PBXs implement the computer-telephony integration (CTI) link with hardware that connects the PBX to one or more computers. Communication between a PBX and computers is rarely straightforward, because many vendors implement the CTI link differently. Furthermore, there is no standard for encoding data on the CTI link. As a result, computer-based telephony programs often need to understand the switch's proprietary language, which requires a separate driver. By using TAPI, you can use one API that many programs can use to request telephony services, and supply one translator (called a telephony service provider) for each PBX or other piece of telephony hardware.

Windows supplies several telephony service providers. The telephony service provider that enables telephony client-server functionality is the Microsoft Windows Remote Service Provider. Proprietary hardware may require additional telephony service providers, which are normally packaged with the hardware or available from the equipment manufacturer.

**Microsoft Windows client-server components**

TAPI includes the following components that support client-server CTI.

**Server-side components**

The following components are available on the telephony server.

- **Telephony console.** Enables administrators to administer and monitor a telephony server, lines, phones, and users.
- **Telephony service provider.** Translates between the generalized commands created by the Telephony service and the proprietary commands that the hardware uses. Provided by the hardware vendor.
- **Telephony service.** On the server side, communicates with the remote service provider running on the clients. Also communicates with telephony programs running on the server, such as the client manager program.

**Client-side components**

The following components must run on the client or appear on the client.

- **Telephony service.** On the client side, communicates with client-side telephony programs and acts as a link between those programs and the Windows Remote Service Provider.
- **Windows Remote Service Provider.** Communicates over the network with the Telephony service running on the telephony server computer.

Note that these components do not include client-side TAPI-based programs. Some general purpose programs use TAPI. Specialized programs, such as those that manage call centers, are provided by independent software or hardware vendors.

# How TAPI supports programs and hardware

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**How TAPI supports programs and hardware**

Telephony Application Programming Interface (TAPI) supports programs that share the same communication ports and devices. Communication programs use TAPI to communicate with and control the appropriate hardware. TAPI manages the way programs and their call traffic use ports and devices. Telephony service providers provide support for particular devices or classes of devices.

**Telephony service providers**

Telephony service providers are dynamic link libraries (DLLs) that translate the commands for a specific telephony device, carrying out the low-level tasks required to communicate over telephone and IP networks.

**How TAPI makes services available**

TAPI arbitrates requests from different communication programs, so they can run simultaneously while sharing communication ports and devices. Each service provider controls its hardware. For example, one Windows Server 2003 family program can use TAPI functions to make outgoing calls while other programs are waiting for incoming calls.

Although only one program controls any single call, the devices are available to other programs, and users do not have to close other programs that share a communication port.

**Supplied telephony service providers**

The following table lists the telephony service providers that are supplied with Windows Server 2003 operating systems:

| Telephony service providers | Used for |
|---|---|
| HID Phone | Human Interface Device (HID) telephone communications |
| H.323 | IP telephony multimedia communications |
| Multicast Conference | IP telephony multiparty conferencing |
| Unimodem 5 | Modems |
| NDIS Proxy | Connection-oriented network devices using NDIS 5 |
| TAPI Kernel-Mode | Connects network devices using NDIS 4 |
| Windows Remote | Client-server telephony |

For more information about telephony service providers, see Telephony service providers.

**Additional hardware support**
Other service providers can be installed, in addition to telephony hardware or software.

Hardware manufacturers normally supply device drivers for their hardware. To provide telephony services for the hardware, the manufacturers or independent software vendors provide telephony service providers to control the hardware. Each service provider supports at least one device specific to that category of communication, such as a fax board, an ISDN card, a telephone or a modem. Some service providers support several devices, or even an entire class of devices.

For more detailed information about how telephony works, see Telephony Resources.

# IP Telephony

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**IP telephony**
This section covers:

- IP telephony concepts
- H.323 IP telephony calls

# IP telephony concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**IP telephony concepts**
IP telephony refers to telephone communications over TCP/IP networks. In contrast to the PSTN, which consists of analog and digital signals over a circuit-switched network, IP telephony is packet switched. All information to be transmitted over the network is separated into data packets. Each packet has a header containing its source and destination, a sequence number, a block of data content, and an error-checking code. Routers and servers direct these packets over the network until they arrive at their destination. When the packets arrive, the sequence number is used to reassemble the packets in their original order. Unlike PSTN telephony, which dedicates a circuit for a telephone call, the data packets share a circuit with other transmissions.

**How IP telephony works**
IP telephony blends voice, video, and data by using TCP/IP as a common transport, effectively collapsing these separate channels into one. Clients using IP telephony employ either existing multimedia hardware or a phone plugged into a PSTN adapter.

IP telephony supports voice communication, voice and video mail, and video on demand. IP telephony also enables voice and video conferencing over the Internet and existing IP-based LANs and WANs.

**Benefits of IP telephony**
IP telephony provides the following benefits:

- IP telephony moves multimedia traffic over any network that uses IP. This offers users both flexibility in physical media (PSTN lines, xDSL, ISDN, leased lines, coaxial cable, satellite, and twisted pair) and flexibility of physical location.

- IP telephony lowers costs of existing services, such as voice and broadcast video, and broadens means of communication to include audio and video conferencing.

**TAPI support for IP telephony**
Two telephony service providers provide IP telephony support in the Windows Server 2003 family: the H.323 TAPI Service Provider and the Multicast Conference TAPI Service Provider. These service providers support the H.323 and IP multicast video conferencing standards and enable different IP telephony programs to interoperate with each other. Organizations can now take full advantage of the global reach of the Internet or the immediacy of a corporate intranet for real-time communication.

**Quality of Service for IP telephony**
Packet-switched networks such as the Internet do not dedicate a connection between parties, so they cannot guarantee Quality of Service (QoS) as the PSTN does. Historically, they have been used for programs, such as e-mail and file transfer, where variable QoS is acceptable.

Organizations can now design private networks to provide adequate bandwidth and redundant paths between switching points for high quality IP telephony. New software and hardware have improved QoS, and voice over IP on a WAN can be as good as standard PSTN calls, even if the network is congested. For more information about QoS, see QoS overview.

# H.323 IP telephony calls

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**H.323 IP telephony calls**

The H.323 TAPI Service Provider provides H.323 version 1.0 support for TAPI-based programs. H.323 is a comprehensive (ITU-T) standard. It provides for multimedia communication over computer networks that do not provide a guaranteed quality of service, such as IP-based networks and the Internet. The H.323 standard enables any H.323-compliant terminal to operate with another.

H.323 encompasses call control, multimedia streaming, and bandwidth management for point-to-point calls and multipoint conferences over packet-switched networks. It is used for peer-to-peer, two-way delivery of audio and video phone data. It is designed to interact well with PSTN or Internet phone gateways. For conferencing, it works well for a moderate number of participants.

H.323 support defines the format for audio and video information and how audio and video information is packaged for transmission over the network. Standard audio and video codecs encode and decode input and output from audio and video sources to be communicated between nodes on a network.

TAPI 3.1 in Windows XP and the Windows Server 2003 family support H.323 gateways, gatekeepers, and proxies. To implement H.323 gateways and proxies with the H.323 TAPI Service Provider, see Specify an H.323 gateway or proxy. To implement H.323 gatekeepers, see Specify an H.323 gatekeeper.

# IP Multicast Video Conferencing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**IP multicast video conferencing**

This section covers:

- How TAPI supports IP multicast video conferencing
- Security for multicast video conferencing

# How TAPI supports IP multicast video conferencing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**How TAPI supports IP multicast video conferencing**

The DHCP service provides Multicast Address Dynamic Client Allocation Protocol (MADCAP) support required for IP multicast video conferencing. DHCP provides unicast addresses for point to point communications between two networked computers. These addresses are unique and specific to a single network. In contrast, MADCAP provides multicast IP addresses, which are shared by many computers. These enable data to be forwarded to all members of a multicast group. The membership of a multicast group is dynamic, which means individual hosts can join or leave the group at any time.

MADCAP is part of the DHCP service, which is an optional component of the Windows Server 2003 family. Clients that are manually configured or use DHCP to obtain a unicast IP address lease can also use MADCAP to obtain multicast IP address configuration. Although MADCAP is packaged in the DHCP service, the DHCP and MADCAP services are independent of each other. You can use a MADCAP server to provide multicast addresses and run DHCP on other servers to provide DHCP services on your network.

MADCAP is built on a client/server model, where multicast conference hosts request addresses from a MADCAP server.

TAPI application directory partitions provide Active Directory directory services for IP multicast conferencing and H.323 telephony. They also publish IP multicast conferences and user IP mappings for H.323 IP telephony and enable users to join conferences and make IP telephone calls. For more information about TAPI application directory partitions, see Tapicfg and TAPI and Active Directory.

For information about installing IP multicast and video conferencing on your network, see Enabling IP multicast.

# Security for multicast video conferencing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Security for multicast video conferencing**

The TAPI 3.1 conference security system determines who can create, delete, view, and join conferences. Each published conference can be associated with a security descriptor. This specifies object access rights on a user or group basis.

By associating security descriptors with SDP conference descriptors, conference creators can specify who can enumerate and view conference announcements. User authentication is provided by the Windows security subsystem.

For more information, see Security.

# Using Telephony

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Using telephony**

This section covers:

- Dialing rules overview
- Canonical address format for phone numbers
- Telephony hardware requirements
- Setting up clients for IP telephony
- Setting up conference rooms
- Enabling IP multicast
- Eliminating acoustic echo
- Setting up the PSTN server and client
- Managing telephony from the command line

# Dialing rules overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Dialing rules overview**
Telephony API (TAPI) allows you to configure dialing rules for all telephony programs. If you run a TAPI-supported program before configuring dialing, the program normally prompts you for the minimum information required for dialing. To completely configure dialing rules on a computer, use **Phone and Modem Options** in Control Panel, as described in this topic.

**Dial locations**
A dial location is the set of parameters that is used to analyze telephone numbers and determine the correct sequence of numbers to dial. You can create as many dial locations as you need for different dialing requirements.

A dial location can correspond to an actual geographic location, such as an office or hotel room, where you need to include codes for dialing outside of the company or building. If your work takes you to different cities, countries, or regions, you can create a dial location for each area, city, or country/region code.

A dial location can also be created for dialing rules that are not necessarily associated with a geographic location. For example, you can create different dialing rules for different company accounts, calling cards, or long distance services.

Dial location information includes:

- Name
- Country or region
- Area (or city) code
- Dialing rules
- Area code rules
- Calling card information

**Naming and using dial locations**
Dial locations can be named anything that is helpful for remembering them later. The default dial location is the location selected in the **Phone and Modem Options** dialog box. Many telephony programs allow you to select a different dial location before dialing. When a telephony program dials a long distance number, it uses the dialing information provided by the selected dial location to complete the connection.

The available dial locations are listed on the **Dialing Rules** tab of **Phone and Modem Options** in Control Panel. On this tab, you can select the default dial location, create a new dial location, or edit any existing dial location. To create a new dial location, see Create a new location. If you want to edit an existing dial location, see Change dialing properties for a location.

**General dial location rules**
General dial location rules specify the name of a location, the country or region, and the local area code. They also enable you to access outside lines from a PBX for local and long distance calls, disable call waiting (so incoming calls do not interrupt connections), and specify either tone or pulse dialing.

The default rules for dialing local, long distance, and international calls are determined by the country or region that you have selected. Dialing rules specify the long distance operator and international prefix that is dialed before domestic long distance or international phone numbers.

**Area code rules**
Area code rules enable you to change the dialing patterns for calls to numbers in the same country or region, as described in Specify area code rules. The default area code rule for numbers in another area code often requires the program to dial the long distance operator, the area or city code, and then the phone number. For numbers in the same area code, the program

dials only the subscriber's phone number. The default rules are shown in the following table.

| Format and Example | For |
|---|---|
| *LongDistanceOperator* (*AreaOrCityCode*) *Prefix-SubscriberNumber*<br><br>1 (425) 555-0101 | Numbers in other area or city codes |
| *Prefix-SubscriberNumber*<br><br>555-0101 | Numbers in the same area or city code |

Digits dialed in each of these categories may be different for different countries, regions, or locations.

Use area code rules to specify any of the following exceptions to the default rules:

| Format and Example | For |
|---|---|
| (*AreaOrCityCode*) *Prefix-SubscriberNumber*<br><br>(425) 555-0101 | Numbers in another area or city code. |
| (*AreaOrCityCode*) *Prefix-SubscriberNumber*<br><br>(425) 555-0101 | Numbers in the same area or city code. |
| *LongDistanceOperator*<br>*Prefix-SubscriberNumber*<br><br>1 555-0101 | Numbers in the same area or city code. |
| *LongDistanceOperator* (*AreaOrCityCode*)<br>*Prefix-SubscriberNumber*<br><br>1 (425) 555-0101 | Numbers in the same area or city code. |
| *LongDistanceOperator* (*AreaOrCityCode*)<br>*Prefix-SubscriberNumber*<br><br>01 (425) 555-0101 | Numbers in another city or area code, but the long distance operator is not the default for the country or region. |

If you use a different long distance operator than the country/region default for all area codes, it is much easier to use a calling card for the dial location instead of creating an area code rule for every area or city code that you dial. For more information, see "Calling cards" in this topic.

**Specifying more than one rule for an area code**

When different prefixes in an area code are dialed differently, you can specify more than one rule for the area code. Area code rules are applied from top to bottom in the list. If two rules apply to a particular prefix in an area code, the last rule in the list determines the dialing pattern for that prefix.

When you create a new area code rule, it is added to the bottom of the list. To apply multiple rules correctly then, create area code rules in this order:

1. Any default rule that should apply to all unspecified prefixes. (In this case, use the **Include all the prefixes within this area code** option). This rule should appear at the top of the list.

2. Area code rules that list specific prefixes. (Use the **Include only the prefixes in the list below** option).

Most prefixes in an area code follow the default dialing patterns shown here:

| Dial | For |
|---|---|
| *1* (*AreaOrCityCode*) *Prefix-SubscriberNumber* | Numbers in another area or city code. |
| *Prefix-SubscriberNumber* | Numbers in the same area or city code. |

When most prefixes in an area code do not follow the default dialing patterns, create one rule to specify the new default dialing pattern for the area code and create another rule to specify the few exceptions. This is easier than just creating one area code rule that lists the bulk of prefixes for an area code.

For example, suppose you dial most numbers in an area code in the following format:

(*AreaOrCityCode*) *Prefix-SubscriberNumber*

but three prefixes are dialed in this format:

1 (*AreaOrCityCode*) *Prefix-SubscriberNumber*

First, create an area code rule that applies to all prefixes in the area code and, in that rule under **Rules**, select only the **Include the area code** check box. This creates the default rule for the area code. It will apply to all the prefixes that are not specified by the second rule in the list.

Second, create an area code rule that lists the three prefixes that follow the second dialing pattern. In that rule under **Rules**, select both the **Dial** check box (confirm that the adjacent text box says *1*) and the **Include the area code** check box. This creates a rule that applies only to the three prefixes and should appear second in the list.

**Calling cards**

A dial location can use a calling card to specify the sequence of numbers to be dialed for a particular calling card or long distance service. You may also choose to use a calling card to specify a different long distance operator or international operator than the default operator for a country or region.

A calling card records the calling card number and any personal identification number (PIN). It defines the access numbers and dialing steps for local, long distance, and international calls. After you create a new calling card, you can use it with any dial location. To create or use a calling card, see Create a new calling card or Use a calling card for long distance dialing.

If you use two or more long distance services with different access numbers, you can create a calling card for each service and a different dial location to use each calling card. Telephony programs typically permit you to change the dial location before dialing a number. When you dial a number, select the dial location that corresponds to the long distance service that you want to use.

**Important**

- When you enter a calling card PIN number, this number is displayed in plaintext. Therefore, to enhance security, type this number in a private location whenever possible. If you are not in a private location, take care to ensure that this number is not exposed to another user.

**Specify a long distance carrier**

The long distance carrier number, also called the long distance operator, is dialed before the area code or country/region code to dial domestic or international long distance calls. The country/region selection for a dial location usually enables programs to dial the correct long distance carrier numbers for domestic and international calls. If your long distance carrier is not accessed with the default numbers for the country/region selection, then see Specify a long distance carrier.

# Canonical address format for phone numbers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Canonical address format for phone numbers**

The canonical address format is a universal phone number format recognized by the Windows Server 2003 Telephony API (TAPI). The format explicitly identifies the components of a phone number, which TAPI translates according to a country or region's dialing rules. The canonical address format is:

**+***Country/RegionCode* **(***AreaCode***)** *SubscriberNumber*

For example, this is how you would enter a number for a subscriber in the United States of America in canonical address format:

+1 (425) 555-0100

Some address book programs store numbers in canonical address format. If your computer is not dialing a number correctly, you may try saving or entering the number in this format.

**Components**

- **+**

  Indicates that the number is in canonical address format.

- *Country/RegionCode*

  The standard country/region code that identifies the country or region for a phone number. This contains one or more digits from 0 through 9. The country/region code is delimited by the space that follows it.

- **(***AreaCode***)**

  The area or city code for the phone number. This may contain one or more digits from 0 through 9. The area or city code is delimited by parentheses. This component is omitted for countries/regions that do not use area or city codes.

- *SubscriberNumber*

  The number for a phone subscriber. This contains one or more digits from 0 to 9, formatting characters, or the dialing control characters:

- A a B b C c D d P p T t W w * # ! @ $ ?

  The subscriber number should not contain the following characters:

- ( ) ^

  Formatting characters in the subscriber numbers are normally spaces, periods, and dashes. Use formatting characters to make a phone number easier to read. They do not affect dialing, because TAPI discards them.

# Telephony hardware requirements

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Telephony hardware requirements**

To hook up a regular (PSTN) phone line to your local computer, you must have a voice modem. To send and receive faxes in addition to making voice or data calls, you must have a fax modem.

To use IP telephony service providers, your computer must have a sound card, video camera, speakers, and a microphone (or headset).

To support speech and hearing simultaneously, you must have a full-duplex sound card.

To include video communications, you must have a video capture card.

You may need to install other hardware for special telephony programs. For example, to connect trunk lines for a personal computer-based telephony server or cables to connect to a PBX system, you may need expansion cards. For additional information about your telephony hardware requirements, consult your vendor.

To verify hardware compatibility, see the Compatible Hardware and Software section at Support resources.

# Setting up clients for IP telephony

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Setting up clients for IP telephony**
Each client computer must run Windows XP or a Windows Server 2003 operating system and be equipped with a video camera, sound card, speakers, and microphone (or headset).

**Install Windows XP or a Windows Server 2003 operating system**
All of the Windows XP and Windows Server 2003 components required to support TAPI multicast conferencing on a client computer are included with these operating systems.

**Create computer and user accounts**
The client computer should be added to a domain. When the client computer is added to a domain, a computer account is automatically created for it. The user should also have a user account in a domain, and should log on to the computer with this account.

If computer or user accounts for the domain are not created, users will not be able to access TAPI application directory partitions to participate in multicast conferencing. If Internet Locator Service (ILS) servers are being used to support multicast conferencing, users will have to manually add the ILS servers to multicast conferencing programs. The multicast conferencing capabilities are otherwise still available.

**Install a full duplex audio sound card**
Windows XP and Windows Server 2003 operating systems support a wide range of audio devices. Multicast conferencing requires a sound card capable of full duplex audio functions. Such sound cards allow audio to be played back and recorded simultaneously. The manufacturer's documentation should describe the characteristics of your sound card.

**Verify full duplex audio**
If you are uncertain whether your system supports full duplex audio, install and start Sound Recorder and record a long message (about one minute). (Sound Recorder is an audio program that is available on an optional basis. Rewind the recording and start Sound Recorder again, so it appears in two places on the desktop. In the first instance of Sound Recorder, start playing back the recording, and then use the other instance to simultaneously record another message. If you can record and play back simultaneously, then your system supports full duplex audio.

**Eliminate acoustic echo**
Acoustic echo is a common problem with audio conferencing systems. You can eliminate acoustic echo by using an audio headset or by enabling acoustic echo cancellation (AEC). For more information, see Eliminating acoustic echo.

**Install the video camera**
Video cameras designed to connect to your computer capture and transfer video images to the computer. TAPI multicast conferencing components are able to acquire these images using WDM or Video for Windows interfaces that are built into the operating system.

Many of the older video cameras require the use of a video capture card that fits into an ISA or PCI slot inside your computer. Video capture cards connect to the camera with a cable, using connectors built into the back of the capture card. Windows XP and Windows Server 2003 operating systems provide support for many such cameras.

The newer generation of cameras uses Universal Serial Bus (USB) interfaces to eliminate the need for a video capture card. The camera can be directly plugged into a USB port in the back of your computer without switching off or opening up the computer. Windows XP and Windows Server 2003 operating systems automatically detect these cameras, using Plug and Play, and install all the device drivers necessary to make the camera work.

Ensure that drivers are available for the video camera model that you choose. To verify the compatibility of a driver, click the Compatible Hardware and Software link at Support resources.

**Add USB ports to your computer**
Some older computer models may not contain USB ports. This is easily determined by examining the back of the computer for a rectangular female connector that corresponds to the male USB connector on your camera.

Such computers can be upgraded by using PCI cards that have two to four USB ports on the back. Inexpensive cards can be ordered from online computer retail Web sites.

# Setting up conference rooms

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Setting up conference rooms**
On the computer, conference rooms have similar configurations as workstations, but you must provide audio and visual coverage for a group of people.

**Get a good microphone**
Headsets are not practical for canceling echoes in conference rooms. Special equipment that cancels echoes is required, which contains long range microphones and speakers with automatic gain control. Some of these devices can track a speaker walking around a room and automatically adjust the volume before transmitting it to other participants. Several manufacturers produce this equipment. For more information, see Eliminating acoustic echo.

**Install a large screen television**
Your conference rooms may already be equipped with large screen televisions or projection systems. Connect the video output from a computer to these systems to provide an image that is suitably large for viewing by groups of people.

**Set up logon access**
When a participant joins a multicast conference, TAPI automatically determines the name of the user and displays this to other conference participants. This works fine for client workstations, because users usually log on to Windows using their domain accounts. For a video conferencing computer in a conference room, you may want to create a user account that uses the conference room name or location. This allows participants to associate the name of the conference room with its image.

# Enabling IP multicast

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Enabling IP multicast**

To enable multicast conferencing on your network, you must install Active Directory and configure a server with the MADCAP service. The steps are listed in Checklist: Installing IP multicast video conferencing.

For more information about MADCAP and the Microsoft implementation of multicast conferencing, see How TAPI supports IP multicast video conferencing.

**Checking routers on your network**

The Windows Server 2003 family provides the following support for troubleshooting multicast routing and forwarding problems:

- The **mrinfo** command displays the configuration of a multicast router.
- The following **netsh** commands display multicast group tables and troubleshooting information for interfaces.
    - **netsh routing ip show mfe** displays the entries in the multicast forwarding table.
    - **netsh routing ip show mfestats** displays packet statistics and input and output interface information for multicast forwarding entries in the multicast forwarding table.
    - **netsh interface ip show joins** displays the multicast groups locally joined on each interface.
- Although the Windows Server 2003 family does not provide a version of the Mtrace multicasting utility, a multicast router running Windows Server 2003 does respond to **mtrace** command queries from other Mtrace utilities.

For more information about how to use the **mrinfo** command and **netsh** commands for troubleshooting multicast routing and forwarding problems, see Using the IP multicasting utilities. For general information about how to use Netsh, see Netsh overview.

**Configuring routers on your network**

If there is a router on your network and you want to enable multicast conferencing across the router, you may have to configure your router to handle multicast packets. This can involve several steps:

1. Enable multicast for the network (globally).
2. Determine the interfaces on which to use multicast, and enable multicast on those interfaces.
3. Enable multicast routing protocols on specific devices. For example:
    - PIM Sparse mode for links that have limited bandwidth.
    - PIM Dense mode for links that have broad bandwidth.
    - DVMRP
4. Create access lists specifying the range of multicast group addresses allowed to cross the router.
5. Associate access lists with specific interfaces on different routers.

To configure routing services, see Routing. To configure a particular router, refer to the documentation provided by the manufacturer.

# Eliminating acoustic echo

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Eliminating acoustic echo**

Acoustic echo is a common problem with audio conferencing systems. It originates in the local audio loopback that occurs when your microphone picks up audio signals from your the speaker, and sends it back to the other participant along with your voice. The other participant hears this echo of his or her own voice as he or she speaks. For example:

1. Alice and Bob are participating in a call or conference.
2. Alice speaks into her microphone.
3. Bob hears Alice's voice played by his speaker.
4. Bob's microphone also picks up and transmits Alice's voice.
5. Alice can now hear an echo of her own voice, with a slight delay due to the round-trip transmission time.

Acoustic echo can be caused or exacerbated when very sensitive microphones are used, speaker volume is turned up very high, or the microphone and speaker are very close to one another. Besides being annoying, this can prevent normal conversation among participants in a conference.

**Eliminate echo with audio headsets**

One of the easiest ways to completely eliminate acoustic echo is to use audio headsets. These play audio at low volume very close to a conference participant's ears. This prevents the microphone from picking up the audio signal.

Many different audio headsets are available to use with personal computers. These have connectors designed to fit into the audio jacks on sound cards. Many also have built-in microphones that enhance audio quality by staying a constant distance from a person's mouth, even while one moves or changes position.

**Eliminate echo with acoustic echo cancellation**

In Windows XP and Windows Server 2003 operating systems, TAPI 3.1 provides support for acoustic echo cancellation (AEC). During the process of AEC, a digital signal processor electronically compares the speaker signal to the microphone signal, and then subtracts the speaker signal from the microphone signal. In this way, AEC prevents the speaker sound from being fed back into the microphone and transmitted as an echo.

# Setting up the PSTN server and client

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Setting up the PSTN server and client**

Telephony programs can use telephony devices controlled by both local and remote telephony service providers. For remote devices, the telephony server controls user access to lines and phones. The Windows Remote Service Provider on client computers gives users access to telephony devices on remote servers. The following instructions summarize how to set up the telephony server and clients.

**Select a server that is part of a domain**

Make sure that the server that will be used as a telephony server is part of a domain and that the domain is trusted by the telephony users' domains. Add telephony clients to this domain or a fully trusted domain. Clients cannot be logged on to more than one domain at a time. For information about adding local users or groups, see Local Users and Groups overview. For more information about adding users and groups in Active Directory, see Windows interface administrative tool reference A-Z: Active Directory Users and Computers.

**Administer the telephony server**

Log on to the server as an administrator. Administrators of the Telephony service must be in the same domain as the server or in fully trusted domains. Use the Telephony console in the Microsoft Management Console (MMC) to administer the Telephony service on the local computer. To open the Telephony console, see Working with MMC console files.

**Enable the telephony server**

The telephony server is automatically installed with Windows Server 2003 operating systems. To begin using the telephony server, you must first enable it, and then specify the logon account for the Telephony service on the server. You can also specify additional telephony administrators. They do not have to have administrative credentials on the entire server.

Use the Telephony console to enable the telephony server. For more information, see Enable or disable a telephony server.

When you enable the telephony server, enter the user name and password of the domain user account to run the Telephony service on the server. (For more information, see Change the Telephony service logon account for a telephony server.) This account must be in the Administrators group on the server. It must also be in the same domain as the server or in a fully trusted domain. You may want to create a special account in the domain for this purpose. If you do, use an easily recognizable name, such as TAPI_ADMIN.

You should also designate individuals who will administer the telephony server. (For more information, see Designate telephony administrators.) This procedure enables you to allow users who do not have administrative credentials on the telephony server to administer the Telephony service. This procedure does not give users additional administrator rights and permissions on the server. Users who have administrative credentials on the telephony server can administer the Telephony service just as they can administer any other service on the computer. These users must be in the same domain as the telephony server or in fully trusted domains.

**Provide access to Telephony service providers**

Specify which users have access to the telephony service providers on the telephony server. This task is also performed in the Telephony console. You can do this by assigning users to a line or phone belonging to the service providers. (For more information, see Assign a telephony user to a line or phone.) Users need to be in the same domain as the telephony server or in a trusted domain. If you need to delete a user, follow the steps in Remove users from telephony lines or phones.

**Set up the telephony clients**

To use remote PSTN telephony devices on a server, telephony clients must be running TAPI version 2.1 or later. For information about which version of TAPI is included in each Windows operating system, see Telephony Resources.

Computers running Windows 98 or Windows Millennium Edition must have File and Printer Sharing for Microsoft Networks and user-level access control enabled, and they must be running Client for Microsoft Networks. For more information, see Enable a Windows 98 or Windows Millennium Edition telephony client.

For all operating systems, you need to specify the telephony servers to be used by the client. For more information, see Specify telephony servers on a client computer. The clients must be in the same domain as the telephony server or in fully trusted domains.

# Managing telephony from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Managing telephony from the command line**
In addition to the Telephony console, you can use command-line utilities to manage telephony servers and clients. For example, you can use Tapicfg to create, remove, or display a TAPI application directory partition, publish a service connection point for a TAPI application directory partition, or set a default TAPI application directory partition.

You can use Tsecimp to import assignment information from an Extensible Markup (XML) file into a telephony server security file (tsec.ini) and to set up or disable telephony clients.

For information about other command-line utilities, see Command-line reference A-Z. For more information about manageability, see Management Strategies and Tools.

**Note**

- If your telephony clients or servers run Windows NT 4.0 or Windows 2000, you must run **tcmsetup** to set up telephony clients. If your telephony clients run Windows XP or a Windows Server 2003 operating system, and your telephony servers run Windows Server 2003 , you can set up telephony clients by adding the Windows Remote Service Provider to your clients instead. To add the Windows Remote Service Provider, see Add a telephony service provider.

# Telephony Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Resources**
This section includes information about additional telephony resources.

**Service packs and updates**
TAPI 2.2 supports the PSTN client-server telephony functionality provided with Windows NT 4.0 Service Pack 4. TAPI 3.0 and TAPI 3.1 support both PSTN telephony and media stream IP telephony and are compatible with products supported by previous versions of TAPI.

The following table shows the version of TAPI included with each Windows operating system. (Recent releases, service packs, or updates might not appear on this table.)

| Windows release | TAPI version |
|---|---|
| Windows 95 | TAPI 2.0 |
| Windows NT 4.0 | TAPI 2.0 |
| Windows NT 4.0 Service Pack 4 | TAPI 2.1 |
| Windows 98 | TAPI 2.1 |
| Windows Millennium Edition | TAPI 2.2 |
| Windows 2000 | TAPI 2.2, TAPI 3.0 |
| Windows XP | TAPI 2.2, TAPI 3.1 |
| Windows Server 2003 family | TAPI 2.2, TAPI 3.1 |

For the latest Windows updates, including service packs, see the Windows Update section at Support resources.

**Other related Microsoft Web sites**

- To verify hardware compatibility, see Compatible Hardware and Software at Support resources.
- For additional product support, see Microsoft Product Support Services at Support resources.

# Telephony Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Troubleshooting**

This section provides information about troubleshooting telephony in the Windows Server 2003 family.

- Troubleshooting IP telephony
- Troubleshooting PSTN telephony

# Troubleshooting IP telephony

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Troubleshooting IP telephony**
What problem are you having?

- A program fails to get a multicast address from the MADCAP server.
- Programs warn that they are using a local random address allocation when users create conferences.
- A client cannot see all participants in a multicast conference.
- Audio or video does not function correctly in a call or conference.
- There are audio or video device errors during calls or conferences.

**A program fails to get a multicast address from the MADCAP server.**
**Cause:** The server is not reachable from the client, or the server is not set up correctly.

**Solution:** The MADCAP server and client must both be in the same domain. The MADCAP server must be configured correctly.

**See also:** Using multicast scopes; Enabling IP multicast; Checklist: Installing IP multicast video conferencing; Create a multicast Telephony scope.

**Programs warn that they are using a local random address allocation when users create conferences.**
**Cause:** All addresses have been allocated for the scopes assigned for MADCAP.

**Solution:** Expand the size of the MADCAP scope.

**See also:** Using multicast scopes; Enabling IP multicast; Checklist: Installing IP multicast video conferencing; Create a multicast Telephony scope.

**A client cannot see all participants in a multicast conference.**
**Cause:** Servers running Routing and Remote Access may not be configured correctly for multicast telephony.

**Solution:** Check that multicast is enabled in both directions on servers running Routing and Remote Access.

**See also:** Understanding Multicasting; Configure IP Multicast Support; Using the IP multicasting utilities.

**Audio or video does not function correctly in a call or conference.**
**Cause:** Either the audio or video is working incorrectly, or the system is using an older audio or video driver that is incompatible with Windows Server 2003 operating systems. Test audio and video on your computer by doing the following:

- Install and use Sound Recorder to check your microphone and speakers. Sound Recorder is an audio program that is available on an optional basis.
- Use a video capture program to check the video camera and its settings, such as Vidcap32, found in the Platform Software Development Kit (SDK).

**Solution:** Check the audio or video equipment manufacturer's Web site for the latest Windows Server 2003 family-compatible drivers.

**There are audio or video device errors during calls or conferences.**
**Cause:** The audio or video device is being used by another program, or the sound card does not support full-duplex functionality.

**Solution:** If closing another program that is using an audio or video device does not resolve the problem, then check that the

sound card and driver support full-duplex functionality:

- Install and start Sound Recorder, and record a long message (about one minute). (Sound Recorder is an audio program that is available on an optional basis.) Rewind the recording, and start Sound Recorder again, so that it appears in two places on the desktop. In the first instance of Sound Recorder, start playing back the recording you made, and then use the other instance to simultaneously record another message. If you can record and play back simultaneously, then your system supports full-duplex audio.

# Troubleshooting PSTN telephony

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 2008, Windows Server 2008 R2, Windows Server 8 Beta

**Troubleshooting PSTN telephony**
What problem are you having?

- One or more client computers cannot see the telephony server.
- Client computers cannot see lines on the telephony server.
- A client user cannot see lines or phones on the telephony server even though the server is set up correctly and the lines or phones have been assigned to the user.
- A program fails to start after a user canceled out of the telephony location information dialog box.
- A client user cannot see a new line on the telephony server, even though the server administrator has assigned the user to the line.
- A telephony program dials a long distance number incorrectly.

**One or more client computers cannot see the telephony server.**
**Cause:** The server cannot be reached on the network because it is not set up correctly.

**Solution:** Ensure the following:

- The client computers can successfully log on to a domain.
- The client computers can successfully see the server with the **ping** command.
- That the telephony server has been configured correctly.

**See also:** Permit users to log on locally to a domain controller; Diagnose Connections; Routing Tools and Utilities; Manage Telephony Servers.

**Client computers cannot see lines on the telephony server.**
**Cause:** The telephony server has not been set up correctly, or users have not been authorized to access lines on the server.

**Solution:** When a TAPI-based program accesses lines on the telephony server, the user who is running the program process is first authenticated. For the user to see the lines, they must have been assigned to the user. Ensure that the server has been set up correctly and that the user is assigned lines on the server.

**See also:** Manage Telephony Servers; Assign a telephony user to a line or phone.

**A client user cannot see lines or phones on the telephony server even though the server is set up correctly and the lines or phones have been assigned to the user.**
**Cause:** The client computer has not been enabled to use the telephony server.

**Solution:** Use **tcmsetup** on the client computer to specify the telephony server.

**See also:** Specify telephony servers on a client computer; Tcmsetup.

**A program fails to start after a user canceled out of the telephony location information dialog box.**
**Cause:** The program requires TAPI to translate addresses, but address translation requires current telephony location information, which has not been specified.

**Solution:** When the location information dialog box is displayed, the user should enter the country/region, local area code,

external line access settings, and select tone or pulse dialing. The user can instead create a location for telephony.

**See also:** Dialing rules overview; Create a new location.

**A client user cannot see a new line on the telephony server, even though the server administrator has assigned the user to the line.**
**Cause:** When you assign a currently running client user to a line on the telephony server, the new settings will not be available until the user restarts the Telephony service on the client computer.

**Solution:** Stop all client TAPI-based programs on the client so that the Telephony service will shut down. When the client programs restart, they will be able to see the newly allocated lines. If you cannot get TAPI to shut down, restart the client computer.

**See also:** Manage Telephony Clients and Users; Start, stop, pause, resume, or restart a service.

**A telephony program dials a long distance number incorrectly.**
**Cause:** The program is not sending the correct number to TAPI.

**Solution:** Check that the number is entered correctly. If the long distance dialing rules for the country/region code are not being implemented, try entering the phone number in canonical address format:

**+** *Country/RegionCode* **(**AreaCode**)***SubscriberNumber*

This is a universal address format for telephone numbers, and it is recognized by TAPI. The format distinguishes the country/region code, area code, and number, so TAPI will dial according to the dialing rules for the country or region.

**See also:** Canonical address format for phone numbers.

# Managing Bandwidth

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing bandwidth**
This section covers:

- Quality of Service (QoS)
- Windows ATM Services

For information about managing bandwidth with Winsock Direct, see "Windows Server 2003 Network Architecture" at the Microsoft Windows Resource Kits Web site.

# Quality of Service (QoS)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Quality of Service (QoS)**
QoS is a set of standards and mechanisms that ensure quality data transmission for QoS-enabled programs.

- For help installing QoS Packet Scheduler, see Install QoS Packet Scheduler.
- For general background information, see QoS Concepts.

# Install QoS Packet Scheduler

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install QoS Packet Scheduler**

1. Open Network Connections.
2. Click any connection, and then, on the **File** menu, click **Properties**.
3. Click **Install**, click **Service**, and then click **Add**.
4. Click **QoS Packet Scheduler**, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- When you install QoS Packet Scheduler on any network connection, it is installed on every local network connection.
- Install QoS Packet Scheduler on end-systems on which you want to enable traffic shaping, traffic marking, or both. For computers with dial-up connections, install QoS Packet Scheduler if you want to enable Integrated Services over Slow Links (ISSLOW).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

- QoS Resources

# QoS overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**QoS overview**

Quality of Service (QoS) is a set of service requirements that the network must meet in order to ensure an adequate service level for data transmission. These service requirements are based on industry standards for QoS functionality.

QoS allows real-time programs to make the most efficient use of network bandwidth. Because QoS provides some level of guarantee for sufficient network resources, it gives a shared network a level of service similar to that of a dedicated network.

A QoS guarantee indicates a service level that enables a program to transmit data at a specified rate and to deliver it within a specified time frame.

The goal of QoS is a guaranteed delivery system for network traffic, such as Internet Protocol (IP) packets.

# Differentiated Services Code Point (DSCP) overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Differentiated Services Code Point (DSCP) overview**
Differentiated Services Code Point (DSCP) is a field in an IP packet that enables different levels of service to be assigned to network traffic. This is achieved by marking each packet on the network with a DSCP code and appropriating to it the corresponding level of service.

DSCP is the combination of IP Precedence and Type of Service fields. In order to work with legacy routers that only support IP Precedence, DSCP values are used because they are compatible with IP Precedence fields. For more information, see RFC 2474 at the RFC Editor Web site.

**How DSCP works**
Quality of Service (QoS)-enabled programs request a specific service type for a traffic flow through the generic QoS (GQoS) application programming interface (API). The available service types are:

- Guaranteed service

  Guaranteed service provides high quality, quantifiable guarantees with bounded (guaranteed minimum) latency.

- Controlled load service

  Controlled load service provides high quality, quantifiable guarantees without bounded latency.

DSCP is a six-bit field carrying the default values that are displayed in the following table. The equivalent IP Precedence and IEEE 802.1p values are shown in separate columns.

| Service Type | DSCP | IP Precedence | IEEE 802.1p |
|---|---|---|---|
| Network control | 30 | 6 | 7 |
| Guaranteed | 28 | 5 | 5 |
| Controlled load | 18 | 3 | 3 |
| All other traffic | 0 | 0 | 0 |

**Notes**

- The network control service cannot be requested through the GQoS API. However, it can be requested by network management applications that use the traffic control (TC) API.

- Default DSCP values can be edited remotely using Group Policy.

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

# Planning QoS networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Planning QoS networks**
It is recommended that you ensure your network hardware, Windows configuration, programs, and services meet the necessary requirements for Quality of Service (QoS).

**Hardware**
To take advantage of IEEE 802.1p markings, QoS requires that your network adapters and network equipment are 802.1p compliant. Additionally, you may need to configure network hardware for QoS 802.1p markings. For more information about the standards upon which Windows QoS networks are based, see QoS standards (RFCs).

**Windows configuration**
Install QoS Packet Scheduler on end-systems on which you want to enable traffic shaping, traffic marking, or both. For computers with dial-up connections, install QoS Packet scheduler if you want to enable Integrated Services over Slow Links (ISSLOW). For more information, see Install QoS Packet Scheduler.

**Programs and services**
Only programs and services that have been designed to work with QoS can take advantage of QoS functionality. Examples of QoS-aware services and programs are Windows Messenger and NetMeeting.

# QoS Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

This topic covers:

- QoS updated technical information

# QoS standards (RFCs)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**QoS standards (RFCs)**

Request for Comments (RFCs) are an evolving series of reports, proposals for protocols, and protocol standards used by the Internet community. Quality of Service (QoS) standards are defined in RFCs published by the Internet Engineering Task Force (IETF) and other working groups.

The following RFCs cover QoS issues:

| | |
|---|---|
| 2211 | Specification of the Controlled-Load Network Element Service |
| 2212 | Specification of Guaranteed Quality of Service |

For more information about RFCs and how to obtain them, see TCP/IP RFCs.

**Notes**

- For additional information about the most current RFCs related to QoS, see the RFC Editor Web site.
- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

# QoS updated technical information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**QoS updated technical information**
The following Web sites post information about Quality of Service (QoS) issues, Internet engineering standards, and other related topics.

- The Internet Engineering Task Force Web site
- The Transport area of the Active working groups page at the Internet Engineering Task Force Web site

For more information about QoS, see "Quality of Service" at the Microsoft Windows Resource Kits Web site.

**Note**

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

# Windows ATM Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows ATM services**
Asynchronous transfer mode (ATM) is a standardized set of networking technologies that can be used to build high-speed networks that accommodate Quality of Service (QoS) for connections. Microsoft® Windows® ATM services software allows you to participate in ATM networks if you have ATM adapter hardware installed on your computer.

- Before you begin using ATM with this computer, see Checklist: Installing ATM services.
- For tips about using ATM, see ATM Best practices.
- For help with specific tasks, see ATM How To....
- For general background information, see ATM Concepts.
- For problem-solving instructions, see ATM Troubleshooting.

# Checklist: Installing ATM services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Installing ATM services**

| | Step | Reference |
|---|---|---|
| | Review ATM concepts such as cells, the ATM model, and ATM QoS. | Understanding ATM |
| | Review LAN emulation (LANE). | Configuring LAN emulation |
| | Review TCP/IP over ATM. | IP over ATM (IP/ATM) |
| | Install an ATM adapter on this computer. | Install an ATM adapter |
| | (Optional) Configure the LAN emulation client. | Configure a LAN emulation client |
| | (Optional) Set up IP/ATM connections and install and configure the ATM ARP/MARS service. | Enable a simple TCP/IP-over-ATM connection; Install and configure the ATM ARP/MARS service |
| | Configure permanent virtual connections (PVCs). | Create a permanent virtual circuit using ATM |
| | Troubleshoot ATM connections. | ATM Troubleshooting |

# ATM Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **Use the default emulated LAN (ELAN).**

  On computers running Windows Server 2003 operating systems, asynchronous transfer mode (ATM) services are configured with a default *unspecified_ELAN_name* group name. If you plan to implement LAN emulation (LANE), it is recommended that you use the preconfigured, default unspecified ELAN group name.

  When you purchase an ATM switch, check the product specifications to ensure that it is preconfigured with the default, unspecified ELAN group name.

- **Use supported ATM adapters.**

  Before you buy an ATM adapter, confirm that it is designed for Windows ATM. For more information about compatible hardware, see Support resources.

- **Note configuration parameters before you upgrade from Windows NT 4.0 or Windows 2000 to** Windows Server 2003 **operating systems.**

  Before upgrading from Windows NT 4.0 or Windows 2000, note the following configuration information for each of the LAN emulation clients you plan to upgrade.

  - The ELAN name
  - The media type to be emulated on the LAN
  - ATM addresses for the LAN emulation server (LES) and broadcast and unknown server (BUS) associated with the ELAN
  - The maximum allowable packet size for the ELAN

  After you note these configuration parameters, use the LAN emulation configuration server (LECS) interface on your ATM switch to configure ELANs and their associated parameters, as listed and noted above.

  Next, install the Server software and configure the ELAN name for each LAN emulation client (LEC). For information about configuring the ELAN name, see Configure a LAN emulation client.

- **Use only one ATM ARP/MARS per virtual LAN.**

  If your network uses IP/ATM, it is recommended that you configure only one ATM ARP/MARS for each virtual local area network (VLAN) on your network. If you have multiple ARP servers on the same network segment, and your ARP client is configured with the addresses for these servers, the ARP caches could become out of synch. This can render parts of the network unreachable.

# ATM How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install an ATM adapter
- Configure a LAN emulation client
- Create an encapsulated Ethernet permanent virtual circuit
- Enable a simple TCP/IP-over-ATM connection
- Configure an advanced TCP/IP-over-ATM connection
- Install and configure the ATM ARP/MARS service
- Create a permanent virtual circuit using ATM
- View ATM connection information

# Install an ATM adapter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install an ATM adapter**

- In most cases, if your ATM network adapter hardware supports Plug and Play, your adapter is automatically detected and installed. For more information, see Hardware.

## Notes

- After your ATM adapter is recognized and installed, ATM services are installed and available. By default, the connection is set up as a LAN emulation client (LEC). To view or configure additional services, right-click your ATM connection in Network Connections, and then click **Properties**.

- If your ATM hardware does not support Plug and Play detection, contact your adapter vendor for updated installation software and information about installing your adapter. For more information about installing hardware that does not support Plug and Play, see Hardware.

- To provide end-to-end connectivity, you must configure a permanent virtual circuit (PVC) on the ATM adapter at each end station. You must also configure a PVC on each ATM device (for example, router, ATM switch, and DSLAM) connected between the end stations. For information about configuring a PVC on ATM devices, please see the manufacturers' documentation.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure a LAN emulation client

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure a LAN emulation client**

1. Open Network Connections.
2. Click the ATM connection that corresponds to the ATM network adapter installed on this computer.
3. On the **File** menu, click **Properties**.
4. In **This connection uses the following items**, click **ATM LAN Emulation**, and then click **Properties**.
5. Click **Add**, **Edit**, or **Remove** to add, rename, or delete entries in the list of emulated LANs available for use with this ATM connection.

   The ATM LAN emulation client is configured by default to support a simple connection with another device (typically an ATM switch) that is providing LAN emulation services to your network.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer. For more information, see Default local groups and Default groups.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- By default, the LAN emulation client is preconfigured to use the default emulated LAN (ELAN) group name for simple client configuration:

  *<unspecified_ELAN_name>*

  If you do not want to configure a specific ELAN name on your network, use the unspecified ELAN name as the default ELAN group name.

  Where this default ELAN name is not currently configured or supported by other ATM hardware products (such as other switches used on your network), you can do one of the following:

  - Add another supported ELAN name to the list maintained here.
  - Configure a default ELAN on your ATM switches that provide LAN emulation service to your network.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create an encapsulated Ethernet permanent virtual circuit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create an encapsulated Ethernet permanent virtual circuit**

1. Open Network Connections.
2. Click the ATM connection that corresponds to the ATM network adapter installed on this computer.
3. On the **File** menu, click **Properties**.
4. On the **General** tab, click **Install**, click **Protocol**, and then click **Add**.
5. Click **Microsoft Ethernet PVC - RFC2684**, click **OK**, and then click **Close**.
6. In the Network Connections folder, right-click the icon for the connection with the device name **Ethernet ATM Miniport**, and then click **Properties**.
7. On the **General** tab, click **Configure**.
8. On the **Advanced** tab, click **Encapsulation Type**.
9. In **Value**, click an encapsulation type.
10. Click **VCI Number**, and then type a number in **Value**.
11. Click **VPI Number**, type a number in **Value**, and then click **OK** twice to apply the configuration you specified.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer. For more information, see Default local groups and Default groups.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Contact your service provider to determine what encapsulation type to choose and what values to type in for virtual circuit identification (VCI) and virtual path identification (VPI).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable a simple TCP/IP-over-ATM connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable a simple TCP/IP-over-ATM connection**

1. Open Network Connections.
2. Click the ATM connection that corresponds to the ATM network adapter installed on this computer.
3. Click **File**, and then click **Properties**.
4. In **This connection uses the following items**, select the **Internet Protocol (TCP/IP)** check box, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group or the Network Configuration Operators group on the local computer. For more information, see Default local groups and Default groups.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You can use the default TCP/IP settings for quick ATM ARP client configuration for a single-switch network by installing the ARP/MARS server on one system. If you use another ARP/MARS server, the client must be configured with the ATM address of that server.
- In order for the default setup to work, the ATM ARP/MARS service must be running on a server on the network.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**

Create a permanent virtual circuit using ATM

# Configure an advanced TCP/IP-over-ATM connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure an advanced TCP/IP-over-ATM connection**

1. Open Network Connections.
2. Click the ATM connection for the ATM network adapter installed on this computer.
3. On the **File** menu, click **Properties**.
4. In **This connection uses the following items**, select the **Internet Protocol (TCP/IP)** check box, and then click **Properties**.
5. To connect using a permanent virtual circuit (PVC), in **Internet Protocol (TCP/IP) Properties**, specify an IP address for use with this ATM connection. By default, the TCP/IP connection uses a DHCP server to obtain an IP address.
6. Click **Advanced**, and then click the **ATM ARP Client** tab.
7. If you want TCP/IP to be used only over permanent virtual circuits (PVCs) configured using the ATM Call Manager, select **PVC only**. In order for this option to function, you must configure the PVC with an application type of **ATM ARP** in the ATM Call Manager.
8. To connect using a switched virtual circuit (SVC), in **ARP server address list** and **MARS address list**, use **Add**, **Edit**, and **Remove** to add, rename, or delete an address entry or entries for any ATM ARP servers or ATM Multicast Address Resolution Service (MARS) servers on your network. If more than one address is listed, use the **up** and **down** arrow buttons to reorder the list.
9. After you finish configuring these properties, click **OK**.
10. Configure any other advanced TCP/IP properties that this ATM connection will use, such as multiple IP addresses, DNS servers, or WINS servers, and then click **OK**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group or the Network Configuration Operators group on the local computer. For more information, see Default local groups and Default groups.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- For ATM ARP or MARS server lists, you can either use the default address or add entries for other computers and switches on your network. If needed, the entries added to the list can include ATM addresses for other ATM switches that provide comparable ARP/MARS service.
- If you add multiple addresses to the ARP or MARS server address lists, the ATM ARP client tries the first address on the list. If the client fails to connect using that address, it then tries each address in the order that it appears on the list.
- In most cases, default client settings provide rapid configuration, and ATM ARP clients are preconfigured with default ARP/MARS addresses. Advanced client configuration might not be needed.
- Only one ATM ARP/MARS server may use the default address. If clients have difficulty connecting to the server over ATM, you should view the ATM ARP/MARS server Error Log for details.

- By default, the maximum transmission unit is set to 9180. The maximum transmission unit must be the same for all clients using the same server.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install and configure the ATM ARP/MARS service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install and configure the ATM ARP/MARS service**

1. Open Network Connections.
2. Click the ATM connection that corresponds to the ATM network adapter installed on this computer.
3. On the **File** menu, click **Properties**, and then click **Install**.
4. In **Select Network Component Type**, in the list of network component types, click **Protocol**, and then click **Add**.
5. In **Select Network Protocol**, in the list of network protocols, click **ATM ARP/MARS Service**, and then click **OK**.

   The ATM ARP/MARS service is installed with a default configuration. For more information on modifying these default services, see the notes below or see your ATM networking and product documentation.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- The ATM ARP/MARS service is not available on Windows XP.
- It is recommended that you configure only one ATM ARP/MARS for each virtual local area network (VLAN) on your network. If you have multiple ARP servers on the same network segment, and your ARP client is configured with the addresses for these servers, the ARP caches could become out of synch. This can render parts of the network unreachable.
- The ATM ARP/MARS service supports IP-to-ATM address resolution for ATM network hosts active on the same logical IP subnet as this computer. The ATM ARP service supports classical IP over ATM connections, as described in RFC 2225. The MARS service supports multicast IP over ATM connections, as described in RFC 2022.
- By default, this predetermined address is used for simple configuration: `47007900010200000000000000000A03E00000200`. This number is an NSAP address that Microsoft selected to simplify configuration and enhance interoperability of the ATM ARP/MARS service with other computers running ATM services.
- The ATM ARP/MARS service includes a preconfigured default list of IP address ranges for which broadcast and multicast forwarding are provided by the service. This default is known as hubbed mode operation. If the IP address range list is empty, the ATM ARP/MARS service defaults to nonhubbed mode operation. In this mode, the service will not perform any forwarding for multicast group clients.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a permanent virtual circuit using ATM

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a permanent virtual circuit using ATM**

1. Open Network Connections.
2. Click the ATM connection that corresponds to the ATM network adapter for which you want to create a permanent virtual circuit (PVC).
3. On the **File** menu, click **Properties**.
4. In **This connection uses the following items**, click **ATM Call Manager**, and then click **Properties**.
5. In **ATM Call Manager** properties, click **Add**.
6. Review and modify PVC settings as needed:
   - For **Name**, you can either use the default unspecified PVC name or type a name. Both are used only for your reference.
   - For **Virtual path ID**, you can either use the default path of **0** or type a number that should be used to identify the virtual path for the connection.
   - For **Virtual circuit ID**, type a number that identifies the virtual circuit within the specified virtual path for the connection.
   - In **Application type**, click the type of application for use with this PVC. If you configured your IP/ATM connection for PVCs only, you must select the application type **ATM ARP** for this PVC.
7. If needed, click **Advanced** to configure any settings that specify a quality of service for use with the PVC.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer. For more information, see Default local groups and Default groups.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- PVCs are not required and are not typically recommended for building most types of ATM network connections.
- To provide end-to-end connectivity, you must configure a PVC on the ATM adapter at each end station. You must also configure a PVC on each ATM device (for example, router, ATM switch, and DSLAM) connected between the end stations. For information about configuring a PVC on ATM devices, please see the manufacturers' documentation.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# ATM defined

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ATM defined**

Asynchronous transfer mode (ATM) refers to a number of related technologies, including software, hardware, and connection media. ATM differs from other existing LAN and WAN technologies and was specifically designed to support high-speed communication. ATM allows networks to use bandwidth resources at maximum efficiency while maintaining Quality of Service (QoS) for users and programs with strict service requirements.

The basic components of ATM are the computers that are connected to the ATM network and the devices that connect these computers and ensure that data is transferred successfully. The computers that are connected to the ATM network are called *end stations*. Routers, DSLAMs, and ATM switches are examples of devices that connect end stations and ensure that data is transferred successfully.

**Asynchronous** means the available network bandwidth is not divided into fixed channels or slots synchronized by a timing mechanism or clock. Devices that communicate using asynchronous communication are not bound by design in terms of their ability to send and receive information at a precise transmission rate. Instead, the sender and receiver negotiate the rate at which they will communicate based on physical hardware limitations and the ability to maintain a reliable flow of information within the network.

**Transfer mode** refers to the way the information is transferred between sender and receiver. In ATM, the concept of small, fixed-length cells is used to structure and parcel data for transfer. By using cells that contrast directly with the variable-length packet mechanism used by most existing network technologies, ATM assures that connections can be negotiated and managed so that no single data type or connection can monopolize the transfer path.

# Windows ATM services defined

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows ATM services defined**

- An ATM UNI Call Manager that conforms to ATM Forum specifications for signaling over ATM and supports the creation of switched virtual circuits (SVCs) and permanent virtual circuits (PVCs).
- Updated NDIS 5.0 ATM miniport drivers that display the **Designed for Microsoft® Windows®** logo and provide limited support for installed ATM adapter hardware. For more information, see Designed for Microsoft Windows logo.
- A LAN emulation client module that conforms to the ATM Forum LANE 1.0 specification, enabling existing programs and protocols designed for use on Ethernet and Token Ring networks to run without modification over an ATM network.
- An ARP/MARS service that enables the Microsoft TCP/IP stack to resolve ATM addresses to hardware addresses for more direct and efficient use of ATM media. The IP-over-ATM module conforms to RFC specifications for Address Resolution Protocol (ARP) over ATM media, as well as support for a multicast address resolution service (MARS).
- Enhanced support for TAPI-based programs and services.
- Support for raw channel access filtering that can be used in program environments that include DirectStreaming.
- Expanded support for PPP dial-up over ATM media, enabling you to create and use a PPP dial-up connection over any supported ATM adapter that is installed in a computer running a Windows Server 2003 operating system. This feature provides support for ATM over DSL, ATM over cable modem, and other ATM on-demand connectivity possibilities.
- Access to native ATM services with Winsock 2.0 over ATM. Available through the Windows Sockets ATM Service Provider, Winsock 2.0 allows direct access to ATM services from user-mode programs. It also allows programs that use TCP/IP as a transport protocol to run over ATM networks and interoperate with standard LAN-based IP clients.
- Encapsulated Ethernet over a permanent virtual connection (PVC), which enables the transmission of Ethernet packets across a PVC on an ATM network adapter. It accomplishes this by acting as an Ethernet adapter to the TCP/IP protocol and using the PVC on the ATM adapter to transfer Ethernet packets.

# Benefits of ATM

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Benefits of ATM**

ATM provides a flexible and scalable solution to the increasing need for quality of service in networks where multiple information types (such as data, voice, and real-time video and audio) are supported. With ATM, each of these information types can pass through a single network connection.

ATM can provide the following benefits:

- High-speed communication
- Connection-oriented service, similar to traditional telephony
- Fast, hardware-based switching
- A single, universal, interoperable network transport
- A single network connection that can reliably mix voice, video, and data
- Flexible and efficient allocation of network bandwidth

# Understanding ATM

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding ATM**

Asynchronous transfer mode (ATM) refers to a number of related and standardized technologies designed to provide high-speed network communication. For more information on these technologies, see the following sections:

- ATM networks
- Example: Switched virtual circuit (SVC)
- Example: Permanent virtual circuit (PVC)
- Encapsulated Ethernet over PVC
- IP over ATM (IP/ATM)

# ATM networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ATM networks**

ATM networks are made up of three distinct elements: users (endpoint devices), switches, and interfaces.

In ATM networking, two types of interfaces exist to describe how these elements communicate: user-to-network interfaces (UNIs) and network-to-network interfaces (NNIs).

The UNI and NNI specifications provide a standard signaling method for end stations and ATM switches to communicate.

**Note**

- The Windows ATM services Call Manager currently supports ATM Forum UNI 3.1. For more information about Windows ATM services, see Windows ATM services defined

# Example: Switched virtual circuit (SVC)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Example: Switched virtual circuit (SVC)**
The following example shows in detail how an SVC connection is established in an ATM network.

1. An ATM user, End station A, sends a SETUP message on the virtual channel connection reserved for signaling (VPI=0, VCI=5) to its directly connected ATM switch, ATM switch 1.

   The SETUP message contains:

   - The 20-byte ATM address of End station B.
   - Quality of Service (QoS) parameters needed for connection.

2. ATM switch 1 analyzes the SETUP message to determine whether it can find a table entry for End station B's switch address and whether it can support the required QoS parameters for the requested connection.

   If ATM switch 1 can find End station B's switch address and support the required QoS parameters for connection, a CALL PROCEEDING message is sent back to End station A.

   If ATM switch 1 either cannot find End station B's switch address or accommodate the connection, a RELEASE message containing standard error codes is sent back to End station A and the call request is rejected.

3. ATM switch 1 sends the SETUP message (described in Step 1) on the virtual channel connection reserved for signaling (VPI=0, VCI=5) to the next switch in the network, ATM switch 2, on its way to the destination, End station B.

   The SETUP message contains the same ATM address of End station B and all required QoS parameter information as included in Step 1. Additionally, the SETUP message now identifies a new VPI/VCI pair for use between ATM switch 1 and ATM switch 2.

4. ATM switch 2 receives the SETUP message. End station B is determined to be a directly connected endpoint registered to ATM switch 2. If the QoS required for the requested connection can be accommodated, ATM switch 2 sends a CALL PROCEEDING message back to ATM switch 1.

5. The SETUP message reaches its final destination, End station B. End station B can respond in either of two ways:

   - If End station B accepts the call, it sends a CALL PROCEEDING message, followed immediately by a CONNECT message back to ATM switch 2.
   - If End station B rejects the call, it sends a RELEASE message back to ATM switch 2. The RELEASE message is passed through the network back to the original source user (End station A) containing standard error codes that describe the reason for rejection.

6. ATM switch 2 sends a CONNECT ACK message back to End station B, then passes the CONNECT message to ATM switch 1.

7. ATM switch 1 sends a CONNECT ACK message back to ATM switch 2, then passes the CONNECT message to End station A.

8. End station A sends a CONNECT ACK message back to ATM switch 1.

The previous example demonstrates a simplified SVC connection using only two intermediate switches, ATM switch 1 and ATM switch 2. In practice, most SVC connections use many intermediate switches. When more intermediate switches are used, each switch forwards SETUP, CONNECT, and RELEASE messages to its downstream neighbor switch, while relaying acknowledgment messages (CONNECT ACK, RELEASE ACK) back to its upstream neighbor switch.

The result of this connection process is a virtual circuit (VC) in both directions between End stations A and B in which:

- All intermediate switches and ATM user hardware at End stations A and B now support and protectively enforce the QoS communication parameters required for this connection.

- All intermediate switches (in this case, ATM switches 1 and 2) have been programmed with switch table entries for mapping the series of VPI/VCI pairs used for routing ATM cells between End stations A and B.

If any intermediate switch cannot accommodate the requested QoS connection parameters, a RELEASE message is sent back in the direction of the source user. The RELEASE message contains the standard error codes and frees the resources being reserved at each device in the connection path and at the source.

# Example: Permanent virtual circuit (PVC)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Example: Permanent virtual circuit (PVC)**
Besides using switching and call message signaling to create circuits on demand between any two possible users, you can also permanently configure an ATM virtual circuit between any two specified service endpoints on an ATM network.

PVCs are used extensively by public ATM service providers to create and establish a complex ATM-based infrastructure for their internal networks. In many cases, the internal ATM infrastructure of the network is built using PVCs with actual end-to-end connections occurring over SVCs.

PVCs can also be useful in some private ATM networks where the following types of situations exist:

- A large campus LAN migrating to a higher-speed ATM backbone. In backbone configurations, connections typically represent a few static configurable switch paths that infrequently change, so permanent configuration of ATM circuits is acceptable.

- A small WAN with a limited number of sites, each requiring a continuous, dedicated high-speed connection that guarantees a fixed quality of service between site locations. With a circuit permanently established, the ATM switches at both WAN sites do not require the added latency and overhead of using call signaling or connection setup and teardown each time ATM cell traffic data is sent over the network. Sent data can be directly forwarded over PVCs established between each site.

# Encapsulated Ethernet over PVC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Encapsulated Ethernet over PVC**

With encapsulated Ethernet over PVC, you can use an ATM network adapter to send and receive Ethernet packets across a permanent virtual circuit (PVC). Before this technology was developed, you had to install a separate driver for each digital subscriber line (DSL) network adapter to allow an Ethernet network to exchange information with an ATM network. With this technology, you need only provide the virtual path identifier (VPI), the virtual channel identifier (VCI), and the encapsulation type required by your service provider. After you configure these settings, the encapsulated Ethernet PVC transmits data through the ATM adapter. Encapsulated Ethernet over PVC performs the following functions:

- It acts as an Ethernet adapter to the TCP/IP protocol.
- It uses a PVC on the ATM adapter to transfer Ethernet packets.
- It provides a mechanism to transport packets across a DSL.
- It eliminates the need to install different drivers for different DSL network adapters.

**Notes**

- The VPI and VCI must match those configured on your service provider's switch or router.
- For information about creating an encapsulated Ethernet PVC, see Create an encapsulated Ethernet permanent virtual circuit
- For more information about encapsulation, see RFC 2684 on the RFC Editor Web site.
- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

# IP over ATM (IP/ATM)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IP over ATM (IP/ATM)**
This section covers:

- IP/ATM overview
- How IP/ATM works

# IP/ATM overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IP/ATM overview**

IP/ATM is a group of services for communicating over an ATM network that can be used as an alternative to LAN emulation. IP/ATM is handled by two main components: the IP/ATM client and the IP/ATM server. The IP/ATM server includes an ATM ARP server and a multicast address resolution service (MARS). IP/ATM network components can reside on a server or an ATM switch.

The main advantage of using IP/ATM is that it is faster than LANE. With IP/ATM, no additional header information is added to packets as they move through the protocol stack. Once an IP/ATM client has established a connection, data can be transferred without modification.

IP/ATM supports the use of a Dynamic Host Configuration Protocol (DHCP) server in the ATM network.

# How IP/ATM works

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How IP/ATM works**
The three general stages of IP/ATM operation are:

- Client initialization
- Client registration
- Data transfer

**IP/ATM client startup and registration with a static IP address**
The following example describes each step in establishing an IP/ATM connection for a single IP/ATM client with a static IP address:

1. Client A initializes and gets an ATM address from the ATM switch.
2. Client A connects to the ATM ARP/MARS server and joins the broadcast group. Client A's IP-to-ATM address mapping is added to the ATM ARP server database.
3. Client A contacts Client B, an ATM end station connected to the network, and begins data transfer.

**IP/ATM client startup and registration with DHCP**
The following example describes each step in establishing an IP/ATM connection for a single IP/ATM client obtaining an IP address using Dynamic Host Configuration Protocol (DHCP):

1. The client initializes and gets an ATM address from the ATM switch.
2. The client connects to the ATM ARP/MARS server and joins the broadcast group.
3. The client connects to the multicast server and sends a DHCP request. The multicast server broadcasts the DHCP request to all members of the broadcast group. The DHCP server receives the request.
4. The DHCP server sends a DHCP reply to the multicast server, which then broadcasts the reply to the broadcast group.
5. The client receives the DHCP reply and then registers its IP and ATM addresses with the ATM ARP/MARS server.
6. The client is now ready to contact other hosts and begin data transfer.

**Note**

- For more information about DHCP, see DHCP.

**Broadcasting and multicasting**

A broadcast or multicast is used to establish point-to-multipoint connections between the requesting client and multiple end stations on the network. The process of broadcasting and multicasting on IP/ATM can follow two different methods:

- **Direct point-to-multipoint connection**

  If a client needs to send an IP packet to a broadcast or multicast IP address, it sends a request to the MARS to resolve the IP address to a list of clients. The MARS sends a group of addresses to a client, allowing it to set up a point-to-multipoint connection.

- **Point-to-multipoint connection through a multicast server**

  The MARS can also work with a multicast server. The Windows ATM ARP/MARS has an integrated multicast server, which registers one or more multicast groups with the MARS and receives a list of members in each multicast group from the MARS. The MARS updates the multicast server when clients join or leave a multicast group. When a client makes a multicast or broadcast request to the MARS, the MARS returns only the address of the multicast server. The client contacts the multicast server, which creates a point-to-multipoint connection with the multicast group. The multicast server copies and distributes the packets sent by the client that initiated the point-to-multipoint call to end stations on the multicast list.

# Using ATM

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using ATM**

This section covers:

- ATM addressing
- Configuring LAN emulation
- Creating switched virtual circuits
- Creating permanent virtual circuits
- Modifying ATM defaults
- Managing ATM from the command line
- Well-known addresses

# ATM addressing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ATM addressing**

ATM addresses are needed to support the use of switched virtual connections (SVCs) through an ATM network.

At the simplest level, ATM addresses are 20 bytes long and have three distinct parts:

- **Network prefix**

  The first 13 bytes identify the location of a specific switch in the network. The use of this portion of the address can vary considerably depending on its address format. Each of the three standard ATM addressing schemes provides information about ATM switch locations differently. These schemes include the data country/region code (DCC) format, the international code designator (ICD) format, and the E.164 format proposed by the ITU-T for international telephone numbering use in broadband ISDN networks.

- **Adapter media access control address**

  The next 6 bytes identify a physical endpoint, such as a specific ATM adapter card, using a media access control layer address that is physically assigned to the ATM hardware by its manufacturer. The use and assignment of media access control addresses for ATM hardware are identical to how this addressing works for Ethernet, Token Ring, and other IEEE 802.*x* technologies.

- **Selector (SEL)**

  The last byte is used to select a logical connection endpoint on the physical ATM adapter. Although all ATM addresses fit this basic three-part structure, there are significant differences in the exact format of the first 13 bytes, depending on the addressing format or whether the ATM network is for public or private use.

All of the three ATM address formats that are currently in widespread use (DCC, ICD, and E.164) include the following characteristics:

- They comply with the Network Service Access Point (NSAP) addressing plan as proposed by the Open Standards Interconnection (OSI) protocol suite of the International Standards Organization (ISO).

- Each can be used to establish and interconnect privately built ATM networks that support switched virtual connections (SVCs).

# Configuring LAN emulation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring LAN emulation**

The basic services for an emulated LAN reside on the ATM switch and workstations with ATM hardware installed. An edge device is required if you plan to connect an Ethernet or Token Ring network to your emulated LAN.

| LAN emulation (LANE) component | Where the component resides |
|---|---|
| LANE services | The LES, LECS, and BUS typically reside on the ATM switch. |
| LAN emulation client | The LAN emulation client can reside on workstations, ATM switches, and edge devices. |

**Services**

Most of the configuration for LAN emulation is done on the switch running the LAN emulation services. These services include the LAN emulation server (LES), LAN emulation configuration server (LECS), and the broadcast unknown server (BUS). For more information about LAN emulation, see "Asynchronous Transfer Mode" at the Microsoft Windows Resource Kits Web site. For more information about configuring the LANE services on your ATM switch, see the documentation for your ATM switch.

**Client**

The LAN emulation client (LEC) software resides on workstations, ATM switches, and edge devices. The LEC is integrated in Windows Server 2003 operating systems and is installed by default if you have an ATM network adapter installed on your computer. After installation is complete, you can install and configure any network protocol driver that works over Ethernet or Token Ring, such as TCP/IP or IPX/SPX. For information about installing and configuring network protocols on your ATM ELAN connection, see Configure a connection to a remote network. For more information about configuring the LAN emulation client, see Configure a LAN emulation client.

### Note

- The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

# Creating switched virtual circuits

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating switched virtual circuits**
Switched virtual circuits (SVCs) are processed by the ATM Call Manager, which handles virtual circuit creation and management. The ATM ARP client and the LAN emulation client support SVCs. Both the LAN emulation client and ATM ARP client are based on the ATM Forum UNI specification.

**LAN emulation with SVCs**
The LAN emulation client running Windows uses SVCs by default. The client must be configured with a valid emulated LAN name to use SVCs. For more information, see Configure a LAN emulation client.

**IP/ATM with SVCs**
The ATM ARP client running Windows uses SVCs by default. The ATM ARP client must be configured with the address of the ATM ARP/MARS on the subnet. For more information, see Configure an advanced TCP/IP-over-ATM connection.

# Creating permanent virtual circuits

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating permanent virtual circuits**

Permanent virtual circuits (PVCs) are typically used by large service providers or in campus backbones to maintain virtual connections in an ATM network.

The ATM Call Manager is used to manually set up PVCs in an emulated LAN or in an IP/ATM network. Use the ATM Call Manager to define the properties for each PVC, including the PVC definition, program usage, and advanced properties.

| PVC property | Description |
|---|---|
| PVC definition | Define the name, virtual path ID, virtual circuit ID, and ATM adaptation layer (AAL). |
| Program usage | Define the program type for use with the PVC and the basic call-matching characteristics of this PVC. |
| Advanced properties | Define the Quality of Service (QoS) transmit and receive parameters and specific layer protocols for call matching and answer matching. |

For more information, see Create a permanent virtual circuit using ATM.

# Modifying ATM defaults

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Modifying ATM defaults**

When you install an ATM adapter on computers running Windows Server 2003 operating systems, the default LAN emulation client configuration for ATM services is automatically installed. The LAN emulation client is preconfigured to use the following default emulated LAN (ELAN) group name:

```
<unspecified ELAN name>
```

The *unspecified_ELAN_name* is configured for use with Windows ATM services and by other vendors of ATM switching products. It enables simplified configuration of the ATM LAN emulation client service provided with computers running Windows Server 2003 operating systems, with ATM switches that might be providing LAN emulation services for your network.

Where the unspecified ELAN name is not currently configured or supported by default by other ATM hardware products (such as other switches used on your network), you can do one of the following:

- Add another supported ELAN name to the list maintained here.
- Configure the unspecified ELAN name on your ATM switches that provide LAN emulation service to your network.

For more information about changing the settings of your LAN emulation client, see Configure a LAN emulation client.

# Managing ATM from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing ATM from the command line**
From the command line, you can monitor details of connections and addresses registered by ATM Call Manager on an asynchronous transfer mode (ATM) network. The command line function **atmadm** allows you to view more detailed connection information than the user interface, which only monitors simple ATM connectivity.

To monitor ATM connectivity:

1. Click the icon for your ATM adapter in the Network Connections folder.
2. Click **File**, and then click **Properties**.
3. On the General tab, select the **Show icon in taskbar notification when connected** check box.

### Notes

- For specific information about using the ATM command-line utility, see Atmadm.
- When working with the **atmadm** command, you can list commands currently available for use by typing any of the following: **help/?**, **/?/?**, **-?/?**, **?/?**.

# Well-known addresses

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Well-known addresses**

**LANE well-known addresses**
LAN emulation clients (LEC) running Windows are preconfigured with the well-known ATM address and virtual channel defined in the ATM Forum specification for obtaining the LAN emulation configuration server (LECS) address. The LEC uses these addresses in the following order:

1. It can try the well-known LECS address defined in the ATM protocol.

   ```
   47007900000000000000000000000A03E00000100
   ```

2. It can use the well-known virtual channel defined in the ATM protocol.

3. It can query using the integrated local management interface (ILMI).

**IP/ATM preconfigured address**
Windows ATM ARP clients are preconfigured with the ARP/MARS addresses of Windows ATM services. This address is:

This number is a well-known E.164 address that Microsoft has selected to simplify configuration and enhance interoperability of the ATM ARP/MARS with other computers running ATM services and Windows XP Professional or a Windows Server 2003 operating system.

# ATM Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

This section covers:

- ATM standards
- ATM updated technical information

# ATM standards

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ATM standards**
There are three major groups defining implementation standards for ATM in networks: the ATM Forum, the IETF, and the ITU-T.

**ATM Forum**
The ATM Forum is an international not-for-profit group of ATM hardware manufacturers, network software developers, and network service providers, consisting of workgroups that develop and review ATM specifications.

For more information about the ATM Forum and access to ATM Technical Committee specifications, see the ATM Forum Web site.

**Internet Engineering Task Force (IETF)**
The IETF is the standards organization for the Internet. Within the IETF, the IETF IP-over-ATM working group developed standards for IP traffic over ATM networks. The following chart lists RFCs for implementing IP over ATM.

| RFC | Description |
|---|---|
| 2684 | Multiprotocol encapsulation over ATM adaptation layer 5 |
| 1722 | RIP version 2 protocol applicability statement |
| 1754 | IP over ATM Working Group's Recommendations for the ATM Forum's Multiprotocol BOF - Version 1 |
| 1755 | ATM Signaling Support for IP over ATM |
| 2022 | Support for Multicast over UNI 3.0/3.1 based ATM Networks |
| 2225 | Classical IP and ARP over ATM (makes obsolete RFC 1626 and RFC 1577) |

For more information about the IETF and the RFCs regarding IP over ATM, see the IETF Web site.

**International Telecommunication Union, Telecommunication Standardization Sector (ITU-T)**
The ITU-T defines standards for global telecommunication and services. The ITU-T developed B-ISDN and SONET for broadband transport services.

For additional information about the ITU-T and ITU-T recommendations, see the ITU-T Web site.

### Note

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

# ATM updated technical information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ATM updated technical information**

The Personal Support Center at the Microsoft Web site provides additional information about ATM. For more information, see Updated technical information.

For more information about asynchronous transfer mode (ATM), see "Asynchronous Transfer Mode" at the Microsoft Windows Resource Kits Web site.

# ATM Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ATM Troubleshooting**
What problem are you having?

- Host cannot join an emulated LAN.
- Hosts on my IP/ATM network are unreachable.
- A hardware error occurs when my ATM adapter attempts to initialize.

**Host cannot join an emulated LAN.**
**Cause:** The client and switch must be running a user-to-network interface (UNI) based on parameters outlined in ATM Forum UNI 3.1 or 4.0 specifications. Otherwise, the initial point-to-multipoint (PMP) call setup fails and no connection is made. The LAN emulation client (LEC) provided in the Windows Server 2003 family is based on the ATM Forum UNI 3.1 specification.

**Solution:** Use the Atmadm utility to determine if the setup call is failing. The Atmadm utility is used to monitor connections and addresses registered by the ATM Call Manager on an asynchronous transfer mode (ATM) network. You can use it to display statistics for incoming and outgoing calls on ATM adapters. If Atmadm displays few or no packets received on signaling and ILMI VCs, check your switch connectivity. For example:

```
Signaling and ILMI packets sent     = 90718
Signaling and ILMI packets received = 0
```

**See also:** View ATM connection information; Atmadm

**Hosts on my IP/ATM network are unreachable.**
**Cause:** If you have more than one ATM ARP/MARS for each virtual LAN on your network, the ARP caches can become out of synch. This causes clients to be able to only contact clients registered with the same server. Clients registered with another server are unreachable.

**Solution:** Only use one ATM ARP/MARS for each virtual LAN.

**A hardware error occurs when my ATM adapter attempts to initialize.**
**Cause:** Your ATM adapter is running IP/ATM and LAN emulation (LANE) on the same subnet.

**Solution:** IP/ATM and LAN emulation (LANE) must be configured to run on separate subnets.

# Integrating with Other Networks

- For tips about using NWLink or Client Service for NetWare, see Novell NetWare Integration Best Practices.
- For help with specific tasks, see Novell NetWare Integration How To....
- For general background information, see Novell NetWare Integration Concepts.
- For problem-solving instructions, see Novell NetWare Integration Troubleshooting.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# New ways to do familiar Novell NetWare Integration tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

The following table lists common tasks for interoperating with Novell NetWare in Windows. The user interface for performing these tasks is different in this version of Windows from the way it was in Windows NT version 4.0.

**Note**

- There are no significant user interface differences between Windows 2000, Windows XP, and the Windows Server 2003 family for this component.

| If you want to | In Windows NT 4.0 use | In this version of Windows use |
|---|---|---|
| Install and configure the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) | **Network** in Control Panel | Network Connections. For more information, see Install NWLink and Configure NWLink. |
| Install Client Service for NetWare | **Network** in Control Panel | Network Connections. For more information, see Install Client Service for NetWare. |
| Enable or disable NWLink NetBIOS | **Network** in Control Panel | Network Connections. For more information, see Enable direct hosting of IPX. |

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Novell NetWare Integration Best Practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

This section covers:

- Best practices for NWLink
- Best practices for Client Service for NetWare

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Best practices for NWLink

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for NWLink**

**If you do not know what value to use for the internal network number, accept the default value of 00000000.**

- You can determine what internal network number your routers are using by typing **ipxroute config** at a command prompt.
- For more information about setting the internal network number, see Configure NWLink.

**Use automatic frame type detection.**

- You should choose to have the frame type automatically detected rather than setting this value manually. If you must use manual frame type detection, determine what type of frame type you should use before you start configuring the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) by typing **ipxroute config** at a command prompt. In addition, verify that all the server computers on your network that use IPX/SPX are using the same frame type.
- For more information, see Configure NWLink.

**Specify the order that Windows accesses network providers and protocols.**

- By changing your provider order, and by changing the order of protocols bound to those providers, you can improve performance. For example, if your LAN connection is enabled to access NetWare and Microsoft Windows networks and uses TCP/IP and IPX, but your primary connection is to a NetWare network, you can move **NetWare or Compatible Network** to the top of the **Network providers** list on the **Provider Order** tab, and move **NWLink IPX/SPX/NetBIOS Compatible Transport Protocol** to the top of the **File and Printer Sharing for Microsoft Networks** binding on the **Adapters and Bindings** tab.
- For more information about modifying the order of network providers, see Modify the network provider order. For more information about modifying protocol bindings, see Modify the protocol bindings order.

**Only install and enable the network protocols that you need.**

- Limiting the number of protocols on your computer enhances network performance and reduces network traffic.
- If Windows encounters a problem with network connectivity, it attempts to establish connectivity by using every network protocol that is installed. By only installing and enabling the protocols that your system can use, Windows does not attempt to connect with protocols it cannot use, and returns status information to you more efficiently.

**When using direct hosting, if you cannot access a server computer running Windows 95 or Windows 98 from a server running Windows Server 2003 , you must enable NetBIOS over IPX/SPX on the computer running Windows 95 or Windows 98.**

- For more information about enabling NetBIOS, see the Windows 95 or Windows 98 documentation.

**When you use NWLink to connect computers running Windows that use Windows-based networking, ensure that NetBIOS broadcast propagation (type 20 packets) is enabled on all the router interfaces that connect the computers running Windows.**

- You can enable NetBIOS broadcast propagation by using Routing and Remote Access. NetBIOS broadcast propagation is enabled by default.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Best practices for Client Service for NetWare

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for Client Service for NetWare**
**When running Novell Directory Services (NDS) administrative utilities on Windows, you must use NetWare client software.**

- To administer a Novell NDS server from a Windows computer using NDS utilities, you need to run the client software from Novell, not Client Service for NetWare.

**When changing a user's NetWare password, synchronize the password for both NetWare and Windows resources.**

- You can use the **Change Password** dialog box that is available by pressing CTRL+ALT+DELETE. User names and passwords should be the same for all NetWare servers.

**When connecting to NetWare resources on NDS trees, confirm that you are using the proper default tree and context.**

- For more information, see Set a default tree and context.

**Use the 32-bit version of command prompt.**

- If you are running Client Service for NetWare and use a command prompt, you should use the 32-bit version (that is, Cmd.exe), which is available on the **Programs** menu, not the 16-bit version (that is, Command.com).

**Follow the best practices for NWLink.**

- For more information about the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink), see Best practices for NWLink.

### Important

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Novell NetWare Integration How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install and Configure Client Service for NetWare
- Install and Configure NWLink
- Use NetWare Resources

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Install and Configure Client Service for NetWare

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Install and configure Client Service for NetWare**

- Install Client Service for NetWare
- Set a preferred server
- Set a default tree and context
- Set print options

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

# Install Client Service for NetWare

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install Client Service for NetWare**

1. Open Network Connections.
2. Right-click a local area connection and then click **Properties**.
3. On the **General** tab, click **Install**.
4. In the **Select Network Component Type** dialog box, click **Client**, and then click **Add**.
5. In the **Select Network Client** dialog box, click **Client Service for NetWare**, and then click **OK**.

### Important

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

### Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You must be a member of the Administrators group to install Client Service for NetWare.
- When you install Client Service for NetWare, it is installed for all your connections. For connections that you do not want Client Service for NetWare installed, right-click that connection, click **Properties** and, on either the **General** or **Networking** tab, clear the **Client Services for NetWare** check box.
- To confirm that Client Service for NetWare is working properly, at a command prompt, type **net view /network:nw**. You should see a list of available NetWare servers.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set a preferred server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set a preferred server**

1. Open Client Service for NetWare.
2. Click **Preferred Server**, and in **Select Preferred Server**, enter the preferred server.

### Important

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

### Notes

- To open Client Service for NetWare, click **Start**, click **Control Panel**, and then double-click **CSNW**. To use Client Service for NetWare, you must first install it.
- You should set a default tree and context only in an NDS environment; otherwise, you can set a preferred server.
- If you do not want to set a preferred server, click **None**. You are then attached to the nearest available NetWare server, and your interaction with the NetWare network is through that server. If you do not set a preferred server, and do not select **None**, then you are prompted to set one each time you log on. You can set a preferred server at any time.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set a default tree and context

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set a default tree and context**

1. Open Client Service for NetWare.
2. Click **Default Tree and Context**, and in **Tree** and **Context**, type your tree and context.

### Important

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

### Notes

- To open Client Service for NetWare, click Start, click Control Panel, and then double-click CSNW. To use Client Service for NetWare, you must first install it.
- You should set a default tree and context only in an NDS environment; otherwise, you can set a preferred server.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set print options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set print options**

1. Open Client Service for NetWare.
2. Under **Print Options**, do one or more of the following:
   - To eject a page at the end of each document, select the **Add Form Feed** check box.
   - To receive notification when a document prints, select the **Notify When Printed** check box.
   - To print a banner page before each document, select the **Print Banner** check box.
3. Under **Login Script options**, to run a login script from the Netware server, select **Run Login Script**.

### Important

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

### Notes

- To open Client Service for NetWare, click **Start**, click **Control Panel**, and then double-click **CSNW**.
- To use Client Service for NetWare, you must first install it.
- You must be a member of the Administrators group to set print options.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install and Configure NWLink

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Install and configure NWLink**

- Install NWLink
- Configure NWLink
- Enable direct hosting of IPX

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

# Install NWLink

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install NWLink**

1. Open **Network Connections**.
2. Right-click a local area connection and then click **Properties**.
3. On the **General** tab, click **Install**.
4. In the **Select Network Component Type** dialog box, click **Protocol**, and then click **Add**.
5. In the **Select Network Protocol** dialog box, click **NWLink IPX/SPX/NetBIOS Compatible Transport Protocol**, and then click **OK**.

### Important

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

### Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You must be a member of the Administrators group to install NWLink.
- When you install NWLink, it is installed for all your connections. If you do not want NWLink installed for a certain connection, right-click that connection, click **Properties** and, on either the **General** or **Networking** tab, clear the **NWLink IPX/SPX/NetBIOS Compatible Transport Protocol** check box.
- To confirm that NWLink is working properly, at a command prompt, type **ipxroute config**. You should see a table with information about the bindings for which NWLink is configured.

**See Also**
**Concepts**
Use NetWare Resources
Install and Configure Client Service for NetWare
Install and Configure NWLink

# Configure NWLink

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure NWLink**

1. Open **Network Connections**.
2. Right-click a local area connection and then click **Properties**.
3. On the **General** tab, click **NWLink IPX/SPX/NetBIOS Compatible Transport Protocol**, and then click **Properties**.
4. On the **General** tab, type a value for **Internal network number**, or leave this setting at the default value of **00000000**.
5. Do one of the following:

- Click **Auto frame type detection**, and then click **OK**.
- Click **Manual frame type detection**, and do the following:
    - Click **Add**.
    - In the **Manual Frame Detection** dialog box, in **Frame type**, click a frame type.
    - In **Network number**, type a network number, and then click **OK**.
    - Repeat these steps for each frame type you want to include, and then click **OK**.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- These instructions are for advanced users. New users should accept default values unless told otherwise by their network administrator.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- To configure NWLink, you must first install the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol and be a member of the Administrators group.
- Additional tunable parameters for NWLink are stored in the registry. In most situations, you should not need to modify the defaults. You should use this procedure only if you want to bind NWLink to a different network adapter or to manually change the frame type.
- By default, NWLink automatically detects the frame type used by the network adapter to which it is bound. If NWLink detects no network traffic or if multiple frame types are detected in addition to the 802.2 frame type, NWLink sets the frame type to 802.2.

  You can determine which external network number, frame type, and internal network number your routers are using by typing **ipxroute config** at a command prompt.

Best practices for NWLink

# Enable direct hosting of IPX

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable direct hosting of IPX**

1. Open Network Connections.
2. Right-click a local area connection, and then click **Properties**.
3. In the list of installed components, clear the **NWLink NetBIOS** check box.

### Important

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

### Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- To enable direct hosting of IPX, you must first install the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink).
- You must be a member of the Administrators group to enable direct hosting of IPX.
- When you clear the **NWLink NetBIOS** check box, the component is disabled for all IPX interfaces. However, you can clear the **NWLink IPX/SPX/NetBIOS Compatible Transport Protocol** check box on a per-interface basis.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**Concepts**
Install and Configure Client Service for NetWare
Install and Configure NWLink
Use NetWare Resources

# Use NetWare Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use NetWare resources**

- Connect to a NetWare resource
- Connect to a printer attached to a NetWare server
- View NetWare resources
- View current network connections
- Change your NetWare password

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

# Connect to a NetWare resource

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to a NetWare resource**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open **My Network Places**.
2. Do one of the following:
   - Double-click **NetWare or Compatible Network**.
   - Double-click **Entire Network**, and then double-click **NetWare or Compatible Network**.

     Windows Explorer displays Novell Directory Services (NDS) trees with a tree icon and individual NetWare computers with a computer icon.
3. Double-click a tree or volume to see the contents. You can then double-click those contents to see other computers or volumes.
4. Do one of the following:
   - When you find the volume or folder that you want to access, double-click the volume or folder to expand it.
   - To map a local drive to the volume or folder, click the volume or folder, and then, on the **Tools** menu, click **Map Network Drive**. Follow the instructions in the Map Network Drive wizard.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

**Notes**

- To open My Network Places, click **Start**, and then click **My Computer**. Under **Other Places**, click **My Network Places**.
- When you map a network drive, you are connected by default under the user name and password you used to log on. To connect under a different user name, follow the instructions in the Map Network Drive wizard.
- To view or connect to NetWare resources, you must first install Client Service for NetWare and the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol.

**Using a command line**

1. Open **Command Prompt**.

2. To connect to an individual NetWare volume, at the command prompt type: **net use** *drive**UNCname*|*NetWareName*

   For example, to use the Universal Naming Convention (UNC) naming syntax to redirect drive G to the \Data\Mydata directory of the Thor volume on a server called Nw4, type**: net use G\\nw4\thor\data\mydata**

   The following message indicates that your user name and password cannot be authenticated:

   ```
   The password is invalid for server name\volume name[\directory name...]
   ```

3. To connect with a valid user name and password, at the command prompt, add your user name and password to the command line by typing: */user: UserName Password*

   For example, to use drive G to connect as Annie with the password Marshmallow to the \Data\Mydata directory within the Thor volume on a server called Nw4, type: **net use G\\nw4\ thor\data\mydata /user:annie marshmallow**

4. To connect to a Novell Directory Services (NDS) tree, at the command prompt, type: **net use***drive:*\\ *TreeName\volume.OrgName.OrgName [/u:UserName.OrgName.OrgName [password]]*

| **Value** | **Description** |
|---|---|
| *TreeName* | Name of the tree volume. |
| *OrgName* | Tree location to which you want to connect. |
| *UserName.OrgName.OrgName* | The user name and context for this tree (unless it is your default tree). |

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

**Notes**

- To open a command prompt, click **Start**, point to **All Programs**, point to **Accessories**, and then click **Command Prompt**.
- To view or connect to NetWare resources, you must first install Client Service for NetWare and the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol.
- When you connect to NetWare file servers, **net use** is equivalent to the NetWare **map** command on MS-DOS-based NetWare workstations.
- You can connect to Novell Directory Services (NDS) trees and individual NetWare volumes that use bindery-style security. NetWare server volumes, directories, and print queues are represented by Universal Naming Convention (UNC) names and use the same command syntax as Windows-based networks.
- You can type the path to an NDS resource with or without labels (that is, **cn**=, **ou**=, and **o**=).
- When you use a command prompt to connect to NetWare file resources, you can use the next available drive letter by replacing the drive letter with an asterisk (*) in the syntax. For example: **net use ***: *UNCname or NetWarename*
- If you want to be prompted for a password, you can replace the password in the command line with an asterisk (*). When you type your password at the prompt, it does not appear on the screen.
- If you are running Client Service for NetWare and use a command prompt, you should use the 32-bit version (that is, Cmd.exe), which is available on the **Programs** menu, not the 16-bit version (that is, Command.com).
- To view the complete syntax for net use, at a command prompt, type:

**net use /?**

# Connect to a printer attached to a NetWare server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To connect to a printer attached to a NetWare server

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open **Printers and Faxes**.
2. Double-click **Add Printer**, and then click **Next**.
3. Follow the remaining instructions in the Add Printer wizard.

### Important

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

### Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- To view or connect to NetWare resources, you must first install Client Service for NetWare and the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol.
- If a printer driver is not available locally for a NetWare printer, you are prompted to install one.

#### Using a command line

1. Open **Command Prompt**. To redirect output from a port to a print queue, at the command prompt type: **net use***ServerName \\PrintQueue*

   For example, to redirect output from LPT1 to the NetWare print queue called Memos on the server Nw4, type: **net use lpt1 \\nw4\memos**

   This is equivalent to the NetWare capture **q=memos s=nw4 l=1** command line.

2. To send files that do not require formatting to LPT1, redirect output with **net use**, and then, at the command prompt, type: **copy** *FileName ServerName*

   For example: **copy myfile.txt lpt1**

3. To copy a file directly to a print queue, redirect output with **net use**, and then, at the command prompt type: **copy***FileName \\PrintQueue*

   For example: **copy myfile.txt \\nw4\memos**

4. To connect to a printer in a Novell Directory Services (NDS) tree, at the command prompt, type: **net use drive:** *\\TreeName\printer.OrgName.OrgName [/u:UserName.OrgName.OrgName [password]]*

| Value | Description |
| --- | --- |
| *TreeName* | Name of the tree *volume*. |
| *OrgName* | Tree location to which you want to connect. |
| *UserName.OrgName.OrgName* | The user name and context for this tree (unless it is your default tree). |

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

**Notes**

- To open a command prompt, click **Start**, point to **All Programs**, point to **Accessories**, and then click **Command Prompt**.
- To view or connect to NetWare resources, you must first install Client Service for NetWare and the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol.
- You can type the path to a NDS resource with or without labels (that is, **cn=**, **ou=**, **o=**).
- When you run any application that writes directly to a predefined port, the **net use** command works like the NetWare **capture** utility, associating the NetWare print queue with the port.
- If you are running Client Service for NetWare and use a command prompt, you should use the 32-bit version (that is, Cmd.exe), which is available on the **Programs** menu, not the 16-bit version (that is, Command.com).

# View NetWare resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view NetWare resources**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open **My Network Places** and do one of the following:

   - Double-click **NetWare or Compatible Network**.
   - Double-click **Entire Network**, and then double-click **NetWare or Compatible Network**.

   Windows Explorer displays Novell Directory Services (NDS) trees with a tree icon and individual NetWare computers with a computer icon.

2. Double-click a tree or volume to see the contents. You can then double-click those contents to see other computers or volumes.

### Important

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

### Notes

- To open My Network Places, click **Start**, and then click **My Computer**. Under **Other Places**, click **My Network Places**.
- To view or connect to NetWare resources, you must first install Client Service for NetWare and the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol.

**Using a command line**

- Open **Command Prompt** and do one of the following:

  - To display a list of NetWare file servers, at the command prompt, type**: net view /network:nw**
  - To display volumes on a specific NetWare file server, at the command prompt, type: **net view ***NWServerName***/network:nw**

    For example, to view the volumes on the NetWare server Nw4, type: **net view \\nw4 /network:nw**

  - To display the contents of a directory on a NetWare file server running bindery security, at the command prompt, type: **dir ***DirectoryPath*
  - To display the contents of a directory on a NetWare file server running Novell Directory Services (NDS), enclose the directory path in quotation marks.

For example, at the command prompt, type: **dir "***NDStree******volume.unit.group***"**

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

**Notes**

- To open a command prompt, click **Start**, point to **All Programs**, point to **Accessories**, and then click **Command Prompt**.
- To view or connect to NetWare resources, you must first install Client Service for NetWare and the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol.
- **Net view**performs the same function as the NetWare **slist** utility.
- You can type the path to an NDS resource with or without labels (that is, **cn**=, **ou**=, **o**=).
- If you are running Client Service for NetWare and use a command prompt, you should use the 32-bit version (that is, Cmd.exe), which is available on the **Programs** menu, not the 16-bit version (that is, Command.com).

View current network connections

# View current network connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To view current network connections

- Using the Windows interface to view all network connections
- Using the Windows interface to view NetWare connections only
- Using a command line

#### Using the Windows interface to view all network connections

- Open **My Computer**.

### Notes

- To open My Computer, click **Start**, and then click **My Computer**.
- My Computer displays a red X over any disconnected network drives.

#### Using the Windows interface to view NetWare connections only

- Open Windows Explorer, right-click **My Network Places**, and then click **Who Am I?**

### Important

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

### Notes

- To open Windows Explorer, click **Start**, point to **All Programs**, point to **Accessories**, and then click **Windows Explorer**.
- To show or hide desktop icons, right-click somewhere on the desktop, click **Properties**, click the **Desktop** tab, click **Customize Desktop**, and then, under **Desktop icons**, select the check box next to the icon you want to display, or clear the check box next to the icon you want to hide.

#### Using a command line

1. Open Command Prompt.
2. At the command prompt, type: **net use**

### Important

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

### Notes

- To open a command prompt, click **Start**, point to **All Programs**, point to **Accessories**, and then click **Command Prompt**.

- To view or connect to NetWare resources, you must first install Client Service for NetWare and the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol.

- If you are running Client Service for NetWare and use a command prompt, you should use the 32-bit version (that is, Cmd.exe), which is available on the **Programs** menu, not the 16-bit version (that is, Command.com).

- To view the complete syntax for **net use**, at a command prompt, type: **net use /?**

# Change your NetWare password

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change your NetWare password**

- On a NetWare bindery server
- On a NetWare Novell Directory Services (NDS) tree

**On a NetWare bindery server**

1. Open **Command Prompt**.
2. Change to the drive for the NetWare server, and then type:

   **cd \public**

3. Type the following, where *NetWareServer* is the name of the NetWare server for which you want to change your password:

   **setpass***NetWareServer*

4. When prompted for each, type your old password, a new password, and the new password again.

   A message confirms that you have successfully changed your password.

5. If prompted, type **y** to change your password on other NetWare servers that also use your old password.

   Or, to leave your old password unchanged on the other NetWare servers, type **n**.

### Important

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

### Notes

- To open a command prompt, click **Start**, point to **All Programs**, point to **Accessories**, and then click **Command Prompt**.
- To view or connect to NetWare resources, you must first install Client Service for NetWare and the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol.
- To change your password on more than one server, connect to all the servers before you type **setpass**.
- If you are running Client Service for NetWare and use a command prompt, you should use the 32-bit version (that is, Cmd.exe), which is available on the **Programs** menu, not the 16-bit version (that is, Command.com).

**On a NetWare Novell Directory Services (NDS) tree**

1. Press CTRL+ALT+DELETE.
2. Click **Change Password**.

3. In **Log on to**, click **NetWare or Compatible Network**.

4. In **Old Password**, type your current password.

5. In **New Password**, type your new password and, in **Confirm New Password**, type your new password again.

### Important

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

### Notes

- Your password changes on all NDS trees to which you are currently connected. If the old password you specify does not match your current password on any of those trees, you are prompted to type the old password for those trees.

- To view or connect to NetWare resources, you must first install Client Service for NetWare and the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol.

# Novell NetWare Integration Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section covers:

- Novell NetWare integration overview
- The NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink)
- Install Client Service for NetWare

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Novell NetWare integration overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Novell NetWare integration overview**

The Microsoft® Windows® Server 2003 family and Microsoft® Windows® XP provide several services that enable computers running Windows to coexist and interoperate with Novell NetWare networks and servers. Some of these services are included with the Windows Server 2003 family and Windows XP. Other services are available as separate products.

- **NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink)**

  Included with the Windows Server 2003 family operating systems and Windows XP is the Windows implementation of the IPX/SPX protocol. NWLink supports connectivity between computers running Windows and computers running NetWare and compatible systems. You can also use NWLink as a protocol that connects Windows-based computers and computers running MS Client for DOS. For more information about NWLink, see The NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink).

- **Client Service for NetWare**

  Included with the Windows Server 2003 family and Windows XP, Client Service for NetWare makes direct connections from workstations to file and printer resources on NetWare servers. With Client Service for NetWare, you can access servers running either Novell Directory Services (NDS) or bindery security. Logon script support is also included.

- **Microsoft Directory Synchronization Services**

  Included with Services for NetWare (a separate product), Microsoft Directory Synchronization Services (MSDSS) can perform a one-time migration of directory objects or synchronize directory objects from both Novell Directory Services (NDS) and Bindery environments with Microsoft Active Directory.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# The NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink)**
This section covers:

- NWLink overview
- Understanding NWLink
- Using NWLink

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# NWLink overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NWLink overview**
NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) is an implementation of Novell's Internetwork Packet Exchange/Sequenced Packet Exchange (IPX/SPX) and NetBIOS protocols. Windows clients can use NWLink to access client and server applications running on Novell NetWare servers. NetWare clients can use NWLink to access client and server applications running on Windows servers. With NWLink, computers running Windows can communicate with other network devices, such as printers, that use IPX/SPX. You can also use NWLink in small networks that only use Windows and other Microsoft client software.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Understanding NWLink

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding NWLink**

The NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) is a Network Driver Interface Specification (NDIS)-compliant, native 32-bit implementation of Novell's IPX/SPX protocol. NWLink supports two networking application programming interfaces (APIs): NetBIOS and Windows Sockets. These APIs allow communication among computers running Windows and between computers running Windows and NetWare servers.

The NWLink transport driver is an implementation of the lower-level NetWare protocols, which include IPX, SPX, RIPX (Routing Information Protocol over IPX), and NBIPX (NetBIOS over IPX). IPX controls addressing and routing of packets of data within and between networks. SPX provides reliable delivery through sequencing and acknowledgments. NWLink provides NetBIOS compatibility with a NetBIOS layer over IPX.

**Interoperating with NetWare resources**

Depending on what platform you are using and what resources that you want to access, you may need to use NWLink in conjunction with other tools. The following table lists several interoperability options that use NWLink.

| Platform | Running | Can connect to |
|---|---|---|
| Windows | NWLink | Client/server applications running on a NetWare server |
| Windows | NWLink and Client Service for NetWare | NetWare servers for file and print services |
| NetWare client | IPX with NetBIOS, Named Pipes, or Windows Sockets support | Computers running Windows (with NWLink installed) running IPX applications such as Microsoft SQL Server |
| NetWare client | IPX | Servers running Windows Server 2003 (with NWLink installed) for file and print services |

For a Windows client to access file and print resources on a NetWare server, Client Service for NetWare must be installed on the Windows client in addition to NWLink. For more information, see Novell NetWare integration overview.

**Interoperating with Microsoft resources**

By default, the file and print sharing components of Windows use NetBIOS over IPX to send file and print sharing messages.

Alternatively, you can disable NetBIOS so that the file and print sharing messages are sent directly over IPX. This is known as direct hosting. While direct hosting may be more efficient, it causes an interoperability issue: A direct hosting client can only connect to a direct hosting server. Direct hosting clients include computers running Microsoft Network Client for MS-DOS, Windows for Workgroups, Windows 95, and Windows 98. Direct hosting servers include computers running Microsoft Network Client for MS-DOS, and all Windows-based computers.

The following table lists several interoperability options that use IPX.

| Platform | Running | Can connect to |
|---|---|---|
| Microsoft Network Client for MS-DOS<br><br>Windows for Workgroups<br><br>Windows 95<br><br>Windows 98 | IPX only (direct hosting) | File and print shared resources on computers running:<br><br>Microsoft Network Client for MS-DOS<br><br>Windows for Workgroups<br><br>Windows 95<br><br>Windows 98<br><br>Windows NT<br><br>Windows 2000 |

| | | |
|---|---|---|
| Microsoft Network Client for MS-DOS<br>Windows for Workgroups Windows 95<br>Windows 98<br>Windows NT<br>Windows 2000 | NetBIOS over IPX | File and print shared resources on computers running:<br>Microsoft Network Client for MS-DOS<br>Windows for Workgroups<br>Windows 95<br>Windows 98<br>Windows NT<br>Windows 2000 |

**Important**

- You cannot use direct hosting of IPX to gain access to resources on any computer acting as a direct host server from a computer running Windows. Computers running Windows do not include a direct hosting client for NWlink. For example, while you can connect by using direct hosting of IPX to resources on a computer running Windows from a computer running Windows 95 or Windows 98 (where NetBIOS is disabled by default for performance reasons), you cannot connect by using direct hosting of IPX to the computer running Windows 95 or Windows 98 from the computer running Windows. For detailed instructions about enabling direct hosting, see Enable direct hosting of IPX.

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.

- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.

- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Using NWLink

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using NWLink**
This section covers:

- Installing NWLink
- Configuring NWLink
- Routing and NWLink

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Installing NWLink

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Installing NWLink**
You can install the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) when you install a Windows Server 2003family operating system, or you can install NWLink later. You must be logged on as a member of the Administrators group to install and configure NWLink.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Configuring NWLink

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring NWLink**
This section covers:

- Setting the frame type
- Setting the external and internal network numbers

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Setting the frame type

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting the frame type**

The frame type defines the way in which the network adapter, in a computer running Windows, formats data to be sent over a network. To communicate between a computer running Windows and NetWare servers, you need to configure the IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) on the computer running Windows with the same frame type as the one used by the NetWare servers.

The following table lists the topologies and frame types supported by NWLink.

| Topology | Supported frame type |
|---|---|
| Ethernet | Ethernet II, 802.3, 802.2, and Sub Network Access Protocol (SNAP), which defaults to 802.2 |
| Token ring | 802.5 and SNAP |
| Fiber Distributed Data Interface (FDDI) | 802.2 and 802.3 |

**Note**

- On Ethernet networks, the standard frame type for NetWare 2.2 and NetWare 3.11 is 802.3. Starting with NetWare 3.12, the default frame type was changed to 802.2.

You can choose to automatically detect or manually configure the frame type. However, the frame type is automatically detected when NWLink is loaded. If multiple frame types are detected in addition to the 802.2 frame type, NWLink defaults to the 802.2 frame type.

If the frame type is manually configured, a computer running Windows can use multiple frame types simultaneously.

For more information about configuring the frame type, see Configure NWLink.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Setting the external and internal network numbers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting the external and internal network numbers**

The IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) uses two types of IPX network numbers for routing purposes: external network numbers, referred to as the **Network number** in the **Manual Frame Detection** dialog box, and internal network numbers, referred to as the **Internal network number** in the **NWLink IPX/SPX/NetBIOS Compatible Transport Protocol Properties** dialog box. Both are hexadecimal numbers, with 1 to 8 digits (1 to FFFFFFFE).

The external network number is associated with physical network adapters and networks. To communicate with each other, all computers on the same network that use a given frame type must have the same external network number. If your computer has multiple network adapters that are connected to different networks, you must assign an external network number to each configured frame type and network adapter combination on your computer. If you do not know the appropriate numbers to use, see your NetWare documentation. If you do not set an external network number, the number is automatically detected by the Windows operating system.

The internal network number, also called a virtual network number, identifies a virtual network inside a computer. On a server computer running Windows, programs advertise themselves as being located on the virtual network, not a physical network. When you assign internal network numbers, you gain more efficient routing to the programs in a computer with multiple network adapters that are connected to multiple, interconnected networks. By default, the internal network number is 00000000. However, in each of the following situations, you need to manually assign a unique, nonzero internal network number:

- Your computer is acting as a server (running Windows) for a program that uses the NetWare Service Advertising Protocol (SAP), such as SQL Server or SNA Server.
- Your computer is acting as an IPX router that uses the Windows routing.

For more information about setting the external and internal network numbers, see Configure NWLink.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Routing and NWLink

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Routing and NWLink**
This section covers:

- Using the Routing Information Protocol
- Using the Service Advertising Protocol
- Using Ipxroute

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Using the Routing Information Protocol

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using the Routing Information Protocol**
In networks that use only the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink), routing information is propagated by using the Routing Information Protocol (RIP). NWLink uses the Routing Information Protocol over IPX (RIPX) to determine the best router to use when forwarding IPX traffic to another IPX network.

**RIPX and NWLink**
RIPX is used to determine the frame type and external network number for each interface that is configured for autodetection. When NWLink loads, it sends out a RIPX request to discover the frame type and external network number. IPX routers (and NetWare servers) respond to the request with packets that use the IPX router frame type and contain the external network number of the local network.

**RIPX and routers**
When the IPX host determines the IPX network number of the destination, it compares the destination IPX network number with its own attached external network number. If they are different, the IPX host must forward the IPX packet to an IPX router. To determine the best router to use to forward the IPX traffic, the IPX host sends out a RIP request for the destination IPX network number. All IPX routers on the network of the IPX host that have a route to the destination network number send back a response to the IPX host. The IPX host chooses the best response and forwards the IPX packet to the router that sent the best response.

When the Windows Routing and Remote Access service is installed, the computer running Windows acts as a RIP-based IPX router. RIPX is used to listen for route announcements and periodically send route announcements to maintain an IPX routing table.

For more information about routing with Windows, see Checklist: Installing and configuring the router.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Using the Service Advertising Protocol

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using the Service Advertising Protocol**

The NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) uses the Service Advertising Protocol (SAP) to locate the nearest server upon startup and to locate either all services or all services of a specific type. When the Windows Routing and Remote Access service is installed, the computer running Windows also uses SAP to listen for SAP advertisements and periodically make SAP advertisements to maintain a table of available services on the network. If you have installed Routing and Remote Access, you can run just SAP advertising and routing by disabling all other functions of the Routing and Remote Access.

The SAP Agent is a network service that allows services on a server running Windows Server 2003 to advertise themselves by using periodic SAP advertisements. Without the SAP Agent, the services on a computer running Windows are unavailable to computers running NetWare client software as well as computers running Windows that are configured to use just the NWLink protocol.

You can manually install the SAP Agent by using the properties of a connection, but is usually automatically installed when a service that uses the SAP Agent is installed. An example is Microsoft Exchange Server. To make the computer running Microsoft Exchange Server available to computers running NetWare client software and computers running Windows that are configured to use just the NWLink protocol, the Microsoft Exchange Server setup program automatically installs the SAP Agent. Once installed, the Microsoft Exchange Server service uses the SAP Agent to periodically advertise its presence and location so that it can be contacted by Microsoft Exchange clients on an IPX network.

When Routing and Remote Access is running, you can configure SAP settings per network adapter, such as whether to forward broadcasts from one adapter to another or whether to disable SAP over an adapter. These settings are configured through the Routing and Remote Access console. You cannot configure the SAP Agent.

The following table summarizes the relationship between the SAP Agent and Routing and Remote Access.

| Status of Routing and Remote Access/SAP Agent | Routing method |
|---|---|
| Neither SAP Agent nor Routing and Remote Access is running | Services are not advertised/routed. |
| SAP Agent is running (but not Routing and Remote Access) | SAP Agent advertises/routes services. |
| Routing and Remote Access is running (but not SAP Agent) | Routing and Remote Access advertises/routes services. |
| Both SAP Agent and Routing and Remote Access are running | Routing and Remote Access advertises/routes services. |

**Note**

- You do not need to install the SAP Agent service separately when Routing and Remote Access is running, since Routing and Remote Access assumes the responsibilities of the SAP Agent.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Using Ipxroute

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Ipxroute**

You can modify the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) settings that affect routing with the Ipxroute.exe command-line utility (the **ipxroute** command). The Ipxroute utility provides the same functionality as the Route.exe command-line utility that is supplied by Novell for its MS-DOS-based clients.

The Ipxroute utility manages the source routing variables of NWLink. Ipxroute.exe is installed only if the NWLink transport protocol is bound to a network adapter.

The Ipxroute utility changes these settings for the current session only. When you log off, the settings are lost. To permanently change NWLink settings, you must set them in the registry.

For information about the **ipxroute** command, see Ipxroute.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Client Service for NetWare

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Client Service for NetWare**
This section covers:

- Client Service for NetWare overview
- Using Client Service for NetWare

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Client Service for NetWare overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Client Service for NetWare overview**
A user who works locally on a computer running Windows can use Client Service for NetWare to gain direct access to NetWare file and print resources, both on Novell Directory Services (NDS) trees and on servers with bindery security.

Client Service for NetWare depends on and works with the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink). NWLink is an implementation of the Internetwork Packet Exchange (IPX), Sequenced Packet Exchange (SPX), and NetBIOS transport protocols used by the NetWare network. The Microsoft implementations of these protocols can coexist seamlessly with other protocols on the same network adapter.

**Note**

- Client Service for NetWare does not support the IP protocol and therefore cannot be used to interoperate with NetWare 5.*x* in an IP-only environment. To do this, you must load the IPX protocol onto the NetWare 5.*x* server, or use a redirector that is compatible with NetWare core Protocol (NCP) and supports native IP.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Using Client Service for NetWare

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Client Service for NetWare**
This section covers:

- Installing Client Service for NetWare
- Configuring Client Service for NetWare
- Connecting Directly to NetWare Resources

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Installing Client Service for NetWare

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Installing Client Service for NetWare**

You have the option to install client service for NetWare when you install a Windows Server 2003 operating system, or you can install Client Service for NetWare later. You must be logged on as a member of the Administrators group to install and configure Client Service for NetWare. For more information about installing Client Service for NetWare after you have already installed a Windows Server 2003 operating system, see Install Client Service for NetWare.

During installation of Client Service for NetWare, the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) is installed if it is not already on the server. For more information about NWLink, see The NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink).

By default, the NetWare network is placed first in the network search order.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Before you install Client Service for NetWare on a computer, remove any existing client software that is compatible with NCP, including NetWare client software, from the computer.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Configuring Client Service for NetWare

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring Client Service for NetWare**
When you first log on after Client Service for NetWare is installed, you are prompted to set your default tree and context or your preferred server. The tree and context define the position of the user object for the user name you use to log on to a Novell Directory Services (NDS) tree. A preferred server is the NetWare server to which you are automatically connected when you log on, if your network does not use NDS.

You can have either a default tree and context or a preferred server, but not both. (In NDS environments, you set a default tree and context.) If you select a default tree and context, you can still access NetWare servers that use bindery security.

For more information, see Set a preferred server and Set a default tree and context. To change your tree and context at a later time, you can use Client Service for NetWare (in Control Panel).

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Connecting Directly to NetWare Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connecting directly to NetWare resources**
Novell Directory Services (NDS) trees (as well as NetWare servers running bindery security) appear under NetWare or Compatible Network in Windows Explorer. You can double-click a tree name to expand it, and then double-click any container object to expand its contents and structure. You can connect to and assign a local drive to any volume, folder, or directory map object anywhere in the tree hierarchy (for which you have credentials). For more information, see Connect to a NetWare resource.

To connect to an NDS printer, you can use the Add Printer wizard, just as you would to connect to any network printer. For more information, see Connect to a printer attached to a NetWare server.

If you have a default tree and context, once you have logged on, you do not need to log on again or supply another password to access any volume in your default tree. If you access another tree, you are prompted to supply a full context (including user name) for that tree.

This section covers:

- Changing the NetWare password
- Using logon scripts
- Managing NetWare file attributes
- Running NetWare utilities and programs that can use NetWare

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Changing the NetWare password

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Changing the NetWare password**
Users who use client service for NetWare to directly access NetWare resources can change their passwords on NDS trees on the network. For more information, see Change your NetWare password.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Using logon scripts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using logon scripts**

When a user, running Client Service for NetWare to directly access NetWare resources, first makes a connection to a particular NetWare server, the user's logon script (if any) runs.

### Note

- If you are running Client Service for NetWare and use a command prompt, you should use the 32-bit version (Cmd.exe), which is available on the **Programs** menu, not the 16-bit version (Command.com). While running Client Service for NetWare, if you run a batch file (such as a logon script) that opens an instance of the command prompt, the batch file should begin with the command **#cmd**, not **#command**.

### Important

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Managing NetWare file attributes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing NetWare file attributes**

When you use a computer running Client Service for NetWare to directly access NetWare servers, you can use NetWare utilities (such as the **filer** and **rights** commands), to set attributes that are not supported by the mapping of Windows-to-NetWare file rights. For more information about other supported utilities, see Running NetWare utilities and programs that can use NetWare.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Running NetWare utilities and programs that can use NetWare

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Running NetWare utilities and programs that can use NetWare**

On servers running Windows Server 2003 and Client Service for NetWare, you can run some standard NetWare utilities from a command prompt and many programs that can use NetWare. Client Service for NetWare does not support NetWare 4.*x* or 5.*x* utilities. In addition, for some administrative functions, you must use the management tools included with your Windows Server 2003 family operating system.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Novell NetWare Integration Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Client Service for NetWare does not start.
- Client Service for NetWare starts, but no servers are found.
- Client Service for NetWare starts, but only some resources are found.
- Cannot use the NetWare map command to connect to file or print resources.
- The network does not start when you start your computer.
- A computer running the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) cannot connect to other computers.

**Client Service for NetWare does not start.**
**Cause:** One of the required services or protocols might be unavailable.

**Solution:** Try to start Client Service for NetWare manually. If that fails, use Event Viewer to look at the system log and troubleshoot the problem.

**See also:** Event Viewer

**Client Service for NetWare starts, but no servers are found.**
**Cause:** The frame type or SAP might be configured incorrectly.

**Solution:** Try the following:

- View the network adapter load line in the Autoexec.ncf file of the NetWare server to verify that you are using the correct frame type for the server. For example, suppose a network adapter load line for a server is:

  ```
  load 3C503 FRAME=ETHERNET_802.3 NAME=ETH
  ```

  In this case, the server is bound to a 3Com 503 Ethernet adapter that accepts the raw 802.3 frame format.

  To see the frame type that is set for your network adapter, start Network Connections in Control Panel. If the frame type is detected automatically and the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) detects any frames of type 802.2 or no frames at all, NWLink sets the frame type to 802.2. If the network adapter receives frames of type 802.2, but your NetWare network uses a different frame type, you must set the frame type manually.

  To determine which frame type your routers are using on a server running Windows Server 2003 , at a command prompt, type:

  **ipxroute config**

- If you cannot see NetWare file server resources, ensure that SAP is enabled on all the router interfaces that connect the computers running Windows and the server computers running NetWare software. (A Windows remote access server, which is a server running Windows Server 2003 and the Routing and Remote Access service, is an IPX router.) You can enable SAP on an interface by using Routing and Remote Access.

**See also:** Configure NWLink

**Client Service for NetWare starts, but only some resources are found.**
**Cause:** The tree and context or SAP might be configured incorrectly.

**Solution:** Try the following:

- In a Novell Directory Services (NDS) environment, verify that you are using the correct tree and context.
- For each IPX router, view the SAP service table and verify that all of the services that should be learned from SAP are present. If some of the services are not present, you should verify that SAP filtering is not preventing the propagation of these services. The SAP service table is not the same as running the NetWare **slist** command or running an NDS query for a list of all the servers in the tree.

**See also:** View routing tables

**Cannot use the NetWare map command to connect to file or print resources.**
**Cause:** You might be using the wrong command prompt, or the default environment size of the command prompt window might be too small.

**Solution:** The default environment for 16-bit programs is too small to accommodate the mapping table created by the **map** command. Designate the 32-bit command prompt (that is, Cmd.exe) as the permanent command interpreter, and reset the default environment size allocated to the command prompt window. An environment of 4,096 bytes is large enough to accommodate the **map** command, the mapping table, and the command interpreter.

To make these changes to the environment, type the following line in Config.nt:

**shell=%systemroot%\system32\cmd.exe /e:4096**

This line sets Cmd.exe as the command interpreter for the window as long as it remains open or until you run another **shell** command. The line also permanently allocates 4,096 bytes of environment space to 16-bit programs you run in the window.

**The network does not start when you start your computer.**
**Cause:** You might have duplicate computer names.

**Solution:** You must specify a computer name that is not the same as the name of another computer on the network or the same as the name of a workgroup or a domain on the network.

**A computer running the NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) cannot connect to other computers.**
**Cause:** Routing might be configured incorrectly.

**Solution:** Try the following:

- Verify that you have NetBIOS broadcast propagation (type 20 packets) enabled on all the router interfaces between the computers. (A Windows remote access server, which is a server running Windows Server 2003 and the Routing and Remote Access service, is an IPX router.) You can enable NetBIOS broadcast propagation in Routing and Remote Access.
- Verify that you do not have more than eight routers between the computers running Windows.

**Important**

- Client Service for NetWare is not available on 64-bit versions of Windows Server 2003 and Windows XP.
- Gateway Service for NetWare is included in Windows 2000 Server. It is not included in the Windows Server 2003 family.
- Computers running operating systems in the Windows Server 2003 family cannot be IPX routers.

# Services for Macintosh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Services for Macintosh**
Services for Macintosh lets x86-based and Apple Macintosh clients share files and printers and remotely connect to a Microsoft® network. The three components of Services for Macintosh are: File Server for Macintosh, Print Server for Macintosh, and the AppleTalk Protocol.

- Before you install Services for Macintosh, see Services for Macintosh Checklists.
- To find features that have been moved in the Microsoft® Windows Server 2003 family, see New ways to do familiar Services for Macintosh tasks.
- For tips about using Services for Macintosh, see Services for Macintosh Best practices.
- For help with specific tasks, see Services for Macintosh How To....
- For general background information, see Services for Macintosh Concepts.
- For problem-solving instructions, see Services for Macintosh Troubleshooting.

**Notes**

- This feature is not included on computers running the Microsoft Windows Server 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.
- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Services for Macintosh Checklists

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklists**

This section provides checklists to help you do the following tasks:

- Checklist: Installing and configuring File Server for Macintosh
- Checklist: Installing and configuring Print Server for Macintosh
- Checklist: Installing and configuring AppleTalk networking and routing
- Checklist: Installing and configuring remote access for Macintosh

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Checklist: Installing and configuring File Server for Macintosh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Installing and configuring File Server for Macintosh**

| Step | Resource |
|---|---|
| Prepare for installation.<br>• Ensure that there is an NTFS partition on each computer that will share files with a Macintosh computer.<br>• Ensure that an installation compact disc for your operating system or a network location with installation files for your operating system is available. | Macintosh-accessible volumes |
| Install File Server for Macintosh. | Install File Server for Macintosh |
| Install the client component of Services for Macintosh on the Macintosh client computers. | Install authentication files on the Macintosh client |
| Configure File Server for Macintosh. | Create a new logon message for Macintosh clients \| Set session limits for Macintosh clients \| Make new extension associations for x86-based and Macintosh files |
| Configure Macintosh-accessible volumes. | Create a Macintosh-accessible volume \| Set security options for Macintosh volumes |
| Set security on volumes. | Set security options for Macintosh volumes \| Set permissions on a Macintosh-accessible volume or folder |

# Checklist: Installing and configuring Print Server for Macintosh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Installing and configuring Print Server for Macintosh**

| Step | Reference |
|---|---|
| Ensure that an installation compact disc for your operating system or a network location with installation files for your operating system is available. | |
| Install Print Server for Macintosh. | Install Print Server for Macintosh |
| Create a printer on the computer running Services for Macintosh. | Create a printer |
| *(optional)* Create a user account for Macintosh print jobs. | Set up a user account for Macintosh print jobs |
| *(optional)* Capture printers. | Capture or release an AppleTalk printing device |
| *(optional)* Create high and low priority printers. | Prioritize print jobs |
| *(optional)* Create printing pools. | Creating printing pools |

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Checklist: Installing and configuring AppleTalk networking and routing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Installing and configuring AppleTalk networking and routing**

| Step | Reference |
|---|---|
| Review key concepts. | AppleTalk network media;<br>AppleTalk networks;<br>Phase 2 AppleTalk networks |
| Install and configure the AppleTalk Protocol. | Install the AppleTalk protocol and routing;<br>Configure AppleTalk protocol;<br>Configure AppleTalk routing. |
| Assign network numbers and zones. | Assigning AppleTalk network numbers and ranges;<br>Assigning AppleTalk zones |
| Seed the network. | Working with AppleTalk seed routers |
| Create a router record. | AppleTalk routing information;<br>Creating an AppleTalk router record |

# Checklist: Installing and configuring remote access for Macintosh

Updated: January 21, 2005

| Review key remote access concepts | Remote Access |

# New ways to do familiar Services for Macintosh tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

The following table lists common tasks for configuring Services for Macintosh. The user interface for performing these tasks is different in this version of Windows from the way it was in Windows NT version 4.0.

**Note**

- There are no significant user interface differences between Windows 2000, Windows XP, and the Windows Server 2003 family for this component.

| If you want to | In Windows NT 4.0 use | In this version of Windows use |
|---|---|---|
| Configure File Server for Macintosh | MacFile menu in File Manager | Computer Management, System Tools, Shared Folders. |
| Administer File Server for Macintosh | MacFile in Control Panel or MacFile menu in Server Manager | Computer Management, System Tools, Shared Folders. |
| Create an AppleTalk printer | The Printers folder (add an AppleTalk printer) | Printers, Add Printer. |
| Configure AppleTalk Protocol properties | Network utility in Control Panel | Network Connections, right-click Local Area Connection, Properties, AppleTalk Protocol. |
| Set up user accounts for Macintosh users | User Manager for Domains | Local Accounts or Active Directory Users and Computers |
| Enable AppleTalk users to remotely dial in | Not available in 4.0. | Routing and Remote Access. If you have AppleTalk and remote access, this feature is installed by default. |

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Services for Macintosh Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **Avoid sharing the root directory of hard drives**

  While it is easy to share the root directory of a hard drive, it makes troubleshooting the volume much more difficult. When a volume is not working, you can move it to a new directory and delete the old volume and directory. Once the old volume is moved, you can rename the new volume with the old name. This is extremely fast and easy to do, but it will not work on root volumes.

- **Verify routing**

  Verify with your network administrator that your routers are routing AppleTalk if you want communication across the LAN. Also verify, if you will be seeding your network with a computer running Services for Macintosh, all ranges must match for the range. There can be no overlapping between segments and each segment's seed router must contain identical range numbers. Also, it is more efficient for a router to seed an AppleTalk network than it is for a computer running Services for Macintosh.

- **Using POSIX file names**

  Do not use POSIX file names in the same directory tree that Macintosh users can access through Macintosh-accessible volumes. The POSIX subsystem is case-sensitive (that is, you can create one file called accounts, one called ACCOUNTS, one called Accounts, and so on.).

- **Do not share the interrupt setting for the LocalTalk card**

  The interrupt setting used for the LocalTalk card should not be shared with any other device.

# Services for Macintosh How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install and Configure Services for Macintosh
- Set up Macintosh Client Software
- Manage Macintosh-accessible Volumes
- Associate Windows File Types with Macintosh File Types
- Administer Macintosh Clients
- Manage AppleTalk Printing
- Manage Remote Access for Macintosh

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Install and Configure Services for Macintosh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Install and configure Services for Macintosh**

- Install Print Server for Macintosh
- Install File Server for Macintosh
- Install the AppleTalk protocol and routing
- Install remote access for Macintosh
- Configure AppleTalk protocol
- Configure AppleTalk routing
- Configure remote access for Macintosh

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Install Print Server for Macintosh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install Print Server for Macintosh**

1. Open the Windows Components wizard.
2. In **Components**, click **Other Network File and Print Services** (but do not select or clear its check box), and then click **Details**.
3. Select the **Print Services for Macintosh** check box.

   To install File Server for Macintosh, you can also select the **File Services for Macintosh** check box.
4. Click **OK**, and then click **Next**.

## Notes

- To open the Windows Components Wizard, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.
- Certain Windows components require configuration before they can be used. If you installed one or more of these components but did not configure them, when you click **Add/Remove Windows Components**, a list of components that need to be configured is displayed. To start the Windows Components Wizard, click **Components**.
- If you have not already installed the AppleTalk protocol, the protocol is installed automatically when you install Print Server for Macintosh.
- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Install File Server for Macintosh
Install the AppleTalk protocol and routing

# Install File Server for Macintosh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install File Server for Macintosh**

1. Open the Windows Components wizard.
2. In **Components**, click **Other Network File and Print Services** (but do not select or clear its check box), and then click **Details**.
3. Select the **File Services for Macintosh** check box.

   To install Print Server for Macintosh, you can also select the **Print Services for Macintosh** check box.
4. Click **OK**, and then click **Next**.

## Notes

- To open the Windows Components Wizard, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.
- Certain Windows components require configuration before they can be used. If you installed one or more of these components but did not configure them, when you click **Add/Remove Windows Components**, a list of components that need to be configured is displayed. To start the Windows Components Wizard, click **Components**.
- You must have an NTFS partition installed before you install File Server for Macintosh.
- When File Server for Macintosh and TCP/IP are installed, the Apple Filing Protocol (AFP) over TCP/IP is enabled automatically.
- If you have not already installed the AppleTalk protocol, the protocol is installed automatically when you install File Server for Macintosh.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

Install the AppleTalk protocol and routing
Checklist: Installing and configuring File Server for Macintosh

# Install the AppleTalk protocol and routing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install the AppleTalk protocol and routing**

1. Open Network Connections.
2. Right-click any **Local Area Connection** icon, and then click **Properties**.
3. On the **General** tab, click **Install**.
4. In **Select Network Component Type**, click **Protocol**, and then click **Add**.
5. In **Select Network Protocol**, click **AppleTalk Protocol**, and then click **OK**.

## Notes

- To open Network Connections, click **Start**, point to **Settings**, and click **Network Connections**.
- There are two additional AppleTalk networking components in Services for Macintosh: File Server for Macintosh and Print Server for Macintosh. To fully integrate all three AppleTalk networking components, see Related Topics.
- Installing the AppleTalk protocol on a LAN connection installs and enables it for all LAN connections on your computer. To uninstall AppleTalk, right-click the connection icon, click **Properties**, and clear the **AppleTalk Protocol** check box.
- You can install the AppleTalk protocol without installing File Server for Macintosh or Print Server for Macintosh. For example, you can install the AppleTalk protocol for routing purposes only, or for dial-up (AppleTalk over PPP) purposes only, without needing to install or run File Server for Macintosh or Print Server for Macintosh.
- By installing Print Server for Macintosh, you automatically install the AppleTalk network protocol.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install remote access for Macintosh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install remote access for Macintosh**

1. Open Routing and Remote Access.
2. Right-click your server, and then click **Configure and Enable Routing and Remote Access**.
3. Follow the instructions in the Routing and Remote Access Server Setup Wizard.

## Notes

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.
- You must install AppleTalk on your computer before you can install remote access for Macintosh.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure AppleTalk protocol

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure AppleTalk protocol**

1. Open Network Connections.
2. Right-click **Local Area Connection**, and then click **Properties**.
3. Select the **AppleTalk Protocol** check box, and then click **Properties**.

   AppleTalk protocol properties, such as a default adapter type and a default zone, are configured per connection.
4. If you want to use this connection as the default adapter, select the **Accept inbound connections on this adapter** check box. This is the default behavior.
5. In **This system will appear in zone**, select a zone for the system.

## Notes

- To open Network Connections, click **Start**, point to **Settings**, and click **Network Connections**.
- You cannot clear the **Accept inbound connections on this adapter** check box by clicking it. If you want to stop an adapter from accepting inbound connections and you have a second adapter installed, you can clear the check box by making the second adapter accept inbound connections. Because only one adapter at a time can be bound to AppleTalk, the first adapter stops accepting inbound connections. If you want to clear the check box but you have no other adapters installed, you must uninstall AppleTalk.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Remote Access

# Configure AppleTalk routing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure AppleTalk routing**

1. Open Routing and Remote Access.
2. Under **Routing and Remote Access**, double-click your server and right-click **AppleTalk Routing**.
3. Click **Enable AppleTalk Routing**.
4. In the **Adapters** list, right-click an adapter, and then click **Properties**.
5. Configure seed routing, network number allocation, and the zone list as appropriate for the computer.

### Note

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure remote access for Macintosh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure remote access for Macintosh**

1. Open Routing and Remote Access.
2. Right-click your server, and then click **Properties**.
3. On the **AppleTalk** tab, configure remote access options as appropriate for the computer, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.
- You must install AppleTalk on your computer before you can configure remote access for Macintosh.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Remote Access Overview

# Set up Macintosh Client Software

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up Macintosh client software**

- Gain access to authentication files
- Install authentication files on the Macintosh client

# Gain access to authentication files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To gain access to authentication files**

1. On the **Macintosh Apple** menu, double-click **Chooser.**
2. Double-click the **AppleShare** icon, and then click the AppleTalk zone in which the computer running Services for Macintosh resides.
3. On the list of file servers, click the name of the computer running Services for Macintosh, and then click **OK**.
4. Click **Registered User** or **Guest**, as appropriate, and then click **OK**.
5. Click the Microsoft UAM volume, and then click **OK**.
6. Close the **Chooser** dialog box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install authentication files on the Macintosh client

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install the authentication files on the Macintosh client**

1. Open Chooser, click **AppleShare**, select the AppleTalk zone in which the computer running Services for Macintosh is located, and then select that file server. Continue to connect and select the Microsoft UAM volume as the item you want to use.

2. On the Macintosh Desktop, double-click the Microsoft UAM volume to open it.

3. Double-click **MS UAM Installer**.

### Note

- When Macintosh users connect to the computer running Services for Macintosh, authentication will be offered.

  How this is done depends on the Macintosh system the user is running. If a Macintosh computer is running System 7.1 or later and the plaintext and guest options are disabled at the server level, users will be given only one choice: Microsoft Authentication. Earlier systems will show both choices: Microsoft Authentication and plaintext password protection in the form of the Apple standard UAMs, even if the plaintext and guest logon options have been disabled and are unavailable to clients.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Macintosh-accessible Volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage Macintosh-accessible volumes**

- Create a Macintosh-accessible volume
- View a list of Macintosh-accessible volumes
- Modify Macintosh-accessible volumes
- Set permissions on a Macintosh-accessible volume or folder
- Set security options for Macintosh volumes
- View current users of volumes
- Disconnect Macintosh users and volumes
- Remove a Macintosh-accessible volume

# Create a Macintosh-accessible volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a Macintosh-accessible volume**

1. Open Computer Management.
2. In the console tree, right-click **Shares**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Shares

3. Click **New Share**.
4. In Share a Folder Wizard, click **Next**.
5. In **Folder path**, type the drive letter and path to the folder you want to make accessible to Macintosh users and click **Next**.

   Or, click **Browse** to find the folder and click **Next**.

6. In **Share name**, type the name and, optionally, in **Description**, type a description of the Windows share.
7. Select the **Apple Macintosh users** check box and click **Next**.
8. In **Permissions**, click a standard permission set or click **Customize** to set more specific permissions.
9. Click **Finish**.

## Notes

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- A Macintosh-accessible volume is a folder on a computer running Services for Macintosh that is made available to Macintosh clients. Once a Macintosh-accessible volume has been created for Macintosh users and a shared folder created for users of x86-based computers, both types of users can exchange files. Macintosh clients need to run AppleTalk to access AppleTalk printers.
- By default, the folder is shared out to Microsoft Windows users only. If you share out the folder only to Macintosh users, then default permissions for these users are read-only. You can, however, change their permissions using the **Security** tab.
- All Macintosh-accessible volumes must be created on an NTFS partition or on a CDFS volume. If you specify a CDFS volume, the Macintosh-accessible volume will provide read-only access.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View a list of Macintosh-accessible volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view a list of Macintosh-accessible volumes**

1. Open Computer Management.

2. In the console tree, click **Shares**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Shares

3. Look in the **Type** column for Macintosh. This indicates the volumes on this computer that Macintosh users can use over the network.

   If the **Type** column isn't displayed, right-click **Shares**, point to **View**, and then click **Detail**.

**Note**

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modify Macintosh-accessible volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To modify Macintosh-accessible volumes**

1. Open Computer Management.
2. In the console tree, click **Shares**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Shares

3. Double-click the Macintosh-accessible volume you want to modify.
4. In the **Properties** dialog box, on the **General** and **Security** tabs, you can change the volume's properties.

## Notes

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can view the list of all shares on the computer running Services for Macintosh as well as modify the properties of each.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set permissions on a Macintosh-accessible volume or folder

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set permissions on a Macintosh-accessible volume or folder**

1. Open Computer Management.
2. In the console tree, click **Shares**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Shares

3. Right-click the volume or folder, and then click **Properties**.
4. On the **Security** tab, under **Permissions**, select the appropriate permissions.

**Note**

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set security options for Macintosh volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set security options for Macintosh volumes**

1. Open Computer Management.
2. In the console tree, double-click **Shares**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Shares

3. Right-click the volume you want to change, and then click **Properties**.
4. On the **General** tab, select one or more of the **SFM Volume Security** options.

   - **Password.** Enter the password for this volume.
   - **This volume is read-only.** Changes can not be made to files in the volume.

**Note**

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View current users of volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view current users of volumes**

1. Open Computer Management.
2. In the console tree, click **Sessions**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Sessions

## Notes

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- **Sessions** does not dynamically update the list of users. To see the latest list of users, press F5, or right-click **Sessions**, and then click **Refresh**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disconnect Macintosh users and volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disconnect Macintosh users and volumes**

1. Open Computer Management.
2. In the console tree, right-click **Sessions**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Sessions

3. Click **Disconnect All Sessions**.

**Caution**

- Send a message to users before disconnecting them or the volumes they are using. Otherwise, they might lose data.

**Note**

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove a Macintosh-accessible volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove a Macintosh-accessible volume**

1. Open Computer Management.
2. In the console tree, click **Shares**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Shares

3. Right-click the Macintosh volume you want to remove.
4. Click **Stop Sharing**.

**Notes**

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- Removing a Macintosh-accessible volume does not delete the corresponding folder on the computer running Services for Macintosh. Removing a volume makes it unavailable only to Macintosh users.
- If Macintosh users are currently connected, use **Send Message** to warn them. Users are likely to lose data if you remove a volume that's being used.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Associate Windows File Types with Macintosh File Types

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Associate Windows file types with Macintosh file types**

- Make new extension associations for x86-based and Macintosh files
- Add a file creator and type for Macintosh files
- Edit a description of a Macintosh file type
- Delete a file type and its extension associations

# Make new extension associations for x86-based and Macintosh files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make new extension associations for x86-based and Macintosh files**

1. Open Computer Management.
2. In the console tree, right-click **Shared Folders**.

   **Where?**

   - Computer Management/System Tools/Shared Folders

3. Click **Configure File Server for Macintosh**.
4. On the **File Association** tab, in **Files with MS-DOS Extension**, type an extension or select one by clicking the arrow.

   If the extension is already associated with a file type and file creator, it will be selected in the association list **With Macintosh Creator and Type**.

5. In the association list **With Macintosh Creator and Type**, click a creator and type to which you want to associate this extension.
6. To associate the extension with the selected creator and type, click **Associate**.

## Notes

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- Extension-type associations ensure that users will see the correct icon on their computers for a file stored on the computer running Services for Macintosh. For example, Macintosh users will see a Macintosh-style icon for a Microsoft Excel file, and Windows users will see the Windows-style icon for the same Microsoft Excel file.
- For a list of extension-type associations, see "Services for Macintosh" at the Microsoft Windows Resource Kits Web site. You can create new associations or add, edit, or delete existing file creators and types.
- When you add a new extension-type association, it affects only files that are subsequently created on the server, not currently existing files. You can associate multiple extensions with a Macintosh file type and creator. However, you can associate only one file type and creator with an extension.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a file creator and type for Macintosh files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a file creator and type for Macintosh files**

1. Open Computer Management.
2. In the console tree, right-click **Shared Folders**.

   **Where?**

   - Computer Management/System Tools/Shared Folders

3. Click **Configure File Server for Macintosh**.
4. In the **Properties** dialog box, click the **File Association** tab, and then click **Add**.
5. Type the **Creator** and **File Type**, or select them by clicking the arrow, and then, optionally, add a description.

## Notes

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- The new creator and type is added to the file association list.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a new logon message for Macintosh clients**

1. Open Computer Management.
2. In the console tree, right-click **Shared Folders**.

   **Where?**

   - Computer Management/System Tools/Shared Folders

3. Click **Configure File Server for Macintosh**.
4. On the **Configuration** tab, in **Logon message**, type the message you want Macintosh users to see when they log on to the computer running Services for Macintosh.

### Note

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set session limits for Macintosh clients

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set session limits for Macintosh clients**

1. Open Computer Management.
2. In the console tree, right-click **Shared Folders**.

   **Where?**

   - Computer Management/System Tools/Shared Folders

3. Click **Configure File Server for Macintosh**.
4. On the **Configuration** tab, under **Sessions**, click **Unlimited**.

   Or, click **Limited to**, and then type a number.

## Notes

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- Setting session limits determines the number of simultaneous connections Macintosh clients can make to the computer running Services for Macintosh.
- The number of simultaneous connections is limited only by the network media. However, limiting the connections can result in performance increases by the computer running Services for Macintosh.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the name of the computer running File Server for Macintosh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the name of the computer running File Server for Macintosh**

1. Open Computer Management.
2. In the console tree, right-click **Shared Folders**.

   **Where?**

   - Computer Management/System Tools/Shared Folders

3. Right-click **Configure File Server for Macintosh**.
4. In **Server Name for AppleTalk Workstations**, type a new name for the server, and then click **OK**.
5. In **Services and Applications**, click **Services**, and then right-click **File Server for Macintosh**.
6. Click **Restart**.

### Note

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage AppleTalk Printing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage AppleTalk printing**

- Share a printer with Macintosh users
- Capture or release an AppleTalk printing device
- Stop and restart Print Server for Macintosh
- Create a printer
- Set up a user account for Macintosh print jobs
- Prioritize print jobs

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Share a printer with Macintosh users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To share a printer with Macintosh users**

1. Open Printers and Faxes.
2. Right-click a printer, and then click **Properties**.
3. On the **Sharing** tab, click **Shared as**, and type a name.
4. On the **General** tab, in **Location**, type the place where users can find their print jobs.

   For example, you can type the room number where the shared printer is located.

## Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- Macintosh users can gain access to any printing device on a computer running Services for Macintosh. Unlike clients running Windows XP and Windows 2000, those running Windows NT 4.0 need to run AppleTalk to access Macintosh volumes and AppleTalk printers.
- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**

# Capture or release an AppleTalk printing device

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To capture or release an AppleTalk printing device**

1. Open Printers and Faxes.
2. Right-click a printer, and then click **Properties**.
3. On the **Ports** tab, click the port, and then click **Configure Port**.
4. Either select or clear the **Capture this AppleTalk printing device** check box, and then click **OK**.

## Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- If you want an AppleTalk printing device to be reserved for users of the computer running Services for Macintosh, it must be captured. Capturing gives spooling capabilities to all users who connect to the corresponding printer through the computer running Services for Macintosh.
- Releasing a captured printing device enables any Macintosh client to print to an AppleTalk printer directly. However, the print jobs will not be under the administrator's control.
- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Stop and restart Print Server for Macintosh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To stop and restart Print Server for Macintosh**

1. Open Computer Management.
2. In the console tree, click **Services**.

   **Where?**

   - Computer Management/Services and Applications/Services

3. Right-click **Print Server For Macintosh**.
4. Click **Stop** or **Start** as appropriate.

**Notes**

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You would want to stop and restart Print Server for Macintosh to remove a printing device, for example.
- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a printer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a printer**

1. Open Printers and Faxes.
2. In the **Printers** dialog box, double-click **Add Printer**.
3. Follow the Add Printer wizard instructions and select **Local Printer** (select the **Automatically detect my printer** check box if the printer is directly attached to the computer on which you are creating the printer), and then click **Next**.
4. Click **Create a new port**, click **AppleTalk Printing Devices**, and then click **Next**.
5. Expand the AppleTalk zone where the printer you want to connect to is located, and then select the printer.
6. Complete the Add Printer wizard.

## Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- The printer name can contain up to 32 characters. This name will appear in the title bar of the printer window. By default, it is the name that network users (except MS-DOS users) will see when they share the printer.
- Select the **Share this printer** option during setup. In **Share Name**, specify the printer name that you want MS-DOS clients to see.
- When you are selecting a destination, if the printing device is physically connected to the computer running Services for Macintosh, select the appropriate port.

  If the printing device is on a network, click **Add Port**. In the **Printer Ports** dialog box, click **AppleTalk Printing Devices**, and then click **OK**. In the **Available AppleTalk Printing Devices** dialog box, select a zone and a printer, and then click **OK**.
- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set up a user account for Macintosh print jobs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set up a user account for Macintosh print jobs**

1. Open Computer Management.
2. In the console tree, click **Services**.

   **Where?**

   - Computer Management/Services and Applications/Services

3. Double-click **Print Server For Macintosh**.
4. On the **Log On** tab, click **This Account**, and then type the name of the user account, or click **Browse**.
5. To require a password for Macintosh users of the computer running Services for Macintosh, in **Password** type a password, and then confirm it.

## Notes

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Prioritize print jobs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To prioritize print jobs**

1. If necessary, create two (or more) printers and share them.
2. Open Printers and Faxes.
3. Right-click a printer, and then click **Properties**.
4. On the **Advanced** tab, in **Priority**, select a priority.

   Higher priority jobs will print before lower priority jobs. For example, a priority-1 job will print before a priority-2 job.

## Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Remote Access for Macintosh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage remote access for Macintosh**

- Configure remote access protocols for Macintosh clients
- Configure user authentication for Macintosh remote access
- Configure plaintext password authentication for Macintosh remote access
- View AppleTalk and MacFile events

# Configure remote access protocols for Macintosh clients

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure remote access protocols for Macintosh clients**

1. Open Routing and Remote Access.
2. Right-click the server name, click **Configure and Enable Routing and Remote Access**, and then follow directions in the Routing and Remote Access Server Setup Wizard.
3. Click **Remote access server**.
4. After the wizard finishes, open Routing and Remote Access again, and then right-click the server name.
5. Click **Properties**, and then click the **PPP** tab to configure PPP settings.

## Notes

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.
- If you need to add the server, right-click **Server Status**, then click **Add Server**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure user authentication for Macintosh remote access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure user authentication for Macintosh remote access**

1. Open Routing and Remote Access.
2. Right-click your server, and then click **Properties**.
3. On the **Security** tab, configure remote access options as appropriate for the computer, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group. As a security best practice, consider using the Run As command rather than logging on with administrative credentials. If you have logged on with administrative credentials, you can also open Routing and Remote Access by clicking **Start**, clicking **Control Panel**, double-clicking **Administrative Tools**, and then double-clicking **Routing and Remote Access**. For more information, see Default local groups, Default groups, and Using Run as.
- For Macintosh clients logging in as guest, ensure that the **Unauthenticated access** check box on the Security tab is selected.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure plaintext password authentication for Macintosh remote access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure plaintext password authentication for Macintosh remote access**

1. Open MMC.
2. In the **File** menu, click **Add/Remove Snap-in**.
3. Click **Add**, click **Group Policy Object Editor**, and then click **Add**.
4. In the Select Group Policy Object wizard, click **Finish**, and then click **Close**.
5. In the **Add/Remove Snap-in** dialog box, click **OK**.
6. In the **Console Root**, double-click **Local Computer Policy**, and then double-click **Computer Configuration**.
7. Double-click **Windows Settings**, and then double-click **Security Settings**.
8. Double-click **Account Policies**, and then click **Password Policy**.
9. Right-click **Store password using reversible encryption for all users in the domain**, and then click **Properties**.
10. On the **Security** tab, click **Enabled**. Click **Apply** and then **OK**.

### Note

- To open MMC, click **Start**, click **Run**, and then type **mmc**.

# Services for Macintosh Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

You can use Services for Macintosh to share files and printers between x86-based and Apple Macintosh clients.

After the AppleTalk protocol is set up, a computer running Services for Macintosh can also function as an AppleTalk router. Routing capability is supported for AppleTalk Phase 2.

With Services for Macintosh, Macintosh computers need only the Macintosh operating system software to function as clients; no additional software is required. You can, however, set up and distribute the optional Microsoft® user authentication module (MSUAM), which lets Macintosh users securely log on to the computer running Services for Macintosh using the same logon method as Microsoft Windows® users. For information about MSUAM, see Services for Macintosh Authentication.

Services for Macintosh simplifies administration by maintaining just one set of user accounts instead of separate user accounts (one on the Macintosh server and another on the computer running Services for Macintosh).

This section provides general background information about File Server for Macintosh and Print Server for Macintosh:

- Understanding Services for Macintosh
- Using AppleTalk Networking

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Understanding Services for Macintosh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Services for Macintosh**

Services for Macintosh is made up of three parts:

- **File Server for Macintosh** (also called MacFile) which lets you designate a folder as a Macintosh-accessible volume, ensures Macintosh file names are legal NTFS names, and handles permissions.
- **Print Server for Macintosh** (also called MacPrint) which lets all network users send print jobs to a spooler on the computer running Services for Macintosh and continue working; they don't have to wait for their print jobs to finish.
- **AppleTalk protocol** is the layer of AppleTalk Phase 2 protocols that delivers data to its destination on the network.

This section contains information on:

- AppleTalk Networking and Routing
- Files
- Printing Benefits
- Security for Services for Macintosh users

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# AppleTalk Networking and Routing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AppleTalk networking and routing**
A computer running Services for Macintosh can provide routing and seed routing support. An AppleTalk router broadcasts routing information, such as network addresses, and keeps track of and directs data packets on AppleTalk networks. Seed routers perform these functions and also seed the physical networks on which they reside. Seeding a network means establishing and initializing the network address information for that network.

You can install an unlimited number of network adapters on a computer running Services for Macintosh in order to add to an AppleTalk internet.

For more information on AppleTalk networking and routing, see:

- AppleTalk network media
- AppleTalk networks
- Phase 2 AppleTalk networks
- AppleTalk routing information
- Working with AppleTalk seed routers
- Making a router plan
- Assigning AppleTalk network numbers and ranges
- Assigning AppleTalk zones
- Creating an AppleTalk router record
- AppleTalk over PPP

# AppleTalk network media

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AppleTalk network media**

As you plan how to physically connect your Macintosh and x86-based computers, the first thing to consider is network media. Each network media type has its own method of cabling and network topology, and each requires different network hardware.

You can choose among three types of media:

- Ethernet (Fast, Gigabit)
- Token ring
- LocalTalk

Ethernet is the most common network media in x86-based networking.

In token ring, all computers are connected in a ring or star topology where a token passing scheme is used to send messages. FDDI, although not as common, is based on token ring and is designed to be used with fiber-optic cabling.

LocalTalk, an early media, was used in AppleTalk networking.

# AppleTalk networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AppleTalk networks**

Because AppleTalk networks differ from x86-based networks, you must consider some special concepts and issues when you set up an AppleTalk network.

One important concept is the internet. (Note that this is a different concept than the Transmission Control Protocol/Internet Protocol [TCP/IP] Internet.) Most large AppleTalk networks are not single physical networks in which all computers are attached to the same network cabling system. Instead, they are internets, which are multiple smaller physical networks connected by *routers*.

Routers maintain a map of the physical networks on the internet and forward data received from one physical network to other physical networks. Routers are necessary so that computers on different physical networks can communicate with one another. They also reduce network traffic on the internet by isolating the physical networks. In other words, routers only send data that is usable by a network.

Some routers on the network are seed routers. A seed router initializes and broadcasts routing information about one or more physical networks. This information tells routers where to send each packet of data. Each physical network must have one or more seed routers that broadcast the routing information for that network.

Not all routers are seed routers. Routers that are not seed routers maintain a map of the physical networks on the internet and forward data to the correct physical network. Seed routers perform these functions too, but they also initialize the routing information, such as network numbers and zone lists, for one or more physical networks.

A computer running Services for Macintosh can function as a seed router or as a nonseed router. If it is a seed router, it must be the first server you start so that it can initialize the other routers and nodes with network information. If it is a nonseed router, it cannot be started until a seed router has initialized all ports. You can also use dedicated hardware routers on your network.

# Phase 2 AppleTalk networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Phase 2 AppleTalk networks**
There are two types of AppleTalk networks: Phase 1 and Phase 2.

AppleTalk Phase 1 was the original AppleTalk protocol architecture designed to support networking for small workgroups. Phase 1 could only support a single physical network that had just one network number and one zone.

AppleTalk Phase 2 enhances the routing and naming services of AppleTalk. This means improved network traffic and better router selection. You can now create AppleTalk networks that support more than 254 nodes and have multiple zones.

You must use Phase 2 to run Services for Macintosh.

Phase 2 includes these features:

- enhancements to routing and naming services, such as the ability to support AppleTalk networks with more than 254 nodes
- support for multiple zones per network
- improved network traffic and better router selection
- support for token ring, LocalTalk, Ethernet, and FDDI

LocalTalk networks have a single network number; EtherTalk and TokenTalk networks can be assigned a network range, allowing for more nodes on the network.

**AppleTalk zones**
Each LocalTalk network must be in a single zone; each EtherTalk and TokenTalk network can have multiple zones, and individual nodes on a network can be configured to be in any one of the network's associated zones.

**Number of nodes per network**
A *node* is any type of device on the network. Each client, printer, server, and router is a node on an AppleTalk network.

LocalTalk networks can have as many as 254 nodes (but are actually limited to 32 or fewer nodes because of media capacity); EtherTalk and TokenTalk networks can have as many as 253 nodes for every number in the network range, for a maximum of 16.5 million nodes.

### Caution

- Although EtherTalk and TokenTalk support 16.5 million nodes, do not specify this many nodes; network media cannot physically accommodate this many nodes.

### Notes

- Help and Support uses the terms *Ethernet* and *token ring* in descriptions of network media. For discussions on the implementation of an AppleTalk network on Ethernet or token ring, EtherTalk and TokenTalk are used. For more information, refer to an AppleTalk manual.
- AppleTalk Phase 2 is not available on Macintosh platforms released before Macintosh Plus. It requires the installation of AppleTalk file V53. AppleTalk file V53 is installed automatically when you install either EtherTalk 2.0 or TokenTalk 2.0.

# AppleTalk routing information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AppleTalk routing information**

AppleTalk routing information includes:

- A network number or network range associated with each physical network.
- The zone name or zone list associated with each physical network.
- The default zone for the network (if the network has multiple zones).

The *network number* or *network range* is the address or range of addresses assigned to the network. A network number is unique and identifies a particular AppleTalk physical network. By keeping track of network numbers and network ranges, routers can send incoming data to the correct physical network. A network number can be any number from 1 through 65,535.

LocalTalk networks can have only a single network number; EtherTalk, TokenTalk, and Fiber Distributed Data Interface (FDDI) networks can have network ranges.

A zone is a logical grouping that simplifies browsing the network for resources, such as servers and printers. It is similar to a Windows Server 2003 domain as far as browsing is concerned. In LocalTalk networks, each physical network can be associated with only one zone. However, for EtherTalk, TokenTalk, or FDDI, you have more flexibility in assigning zones. Each EtherTalk, TokenTalk, or FDDI network can have one or more zones associated with it, and each zone can include servers and printers on one or more physical networks. This allows you to group servers and printers logically into zones so that users can easily locate and access the servers and printers, no matter what physical networks they are on.

Each Macintosh client on the network is assigned to a single zone. However, each client can access servers and printers in any zone on the network. Zones make accessing network resources simpler for users. When users use the Chooser to view the network, they see only the resources in a single zone at a time, preventing them from having to navigate through huge numbers of resources on large networks to find the resources that they need. You can put the clients, servers, and printers used by a single group into a single zone so that users will see only the resources they typically use but will still be able to access resources in other zones when required.

A zone list includes all the zones associated with that network. One of these zones is the network's default zone, to which the Macintosh clients on that network are assigned by default. Users can configure the client to be in a different zone, however.

# Working with AppleTalk seed routers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Working with AppleTalk seed routers**

When you install and set up Services for Macintosh, you must specify whether the computer running Services for Macintosh will seed each physical network to which it is attached. For example, a computer running Services for Macintosh attached to three physical AppleTalk networks might serve as a seed router on two of the networks but not on the third.

For networks that the server will seed, specify the routing information. The computer running Services for Macintosh will then function as a seed router, seeding the routing information that you provided. If you specify that a server will not seed a network (that is, if you make it a nonseed router), the port will be seeded by another AppleTalk router attached to it.

**Using multiple seed routers on a network**

To make your network more reliable in case of system failure and power outages, you can install multiple seed routers on the same physical network.

When you install multiple seed routers for a particular network, all the seed routers must seed the same information for that network. When the network starts, the first seed router that starts on the network becomes the actual seed router. Although only one server seeds zone and range information at a time, all other seed routers continue to act as routers.

If the first seed router to start on a network has different routing information than the other seed routers that start later, the information established by the first seed router is used. If a seed router that started subsequently has different information and is running Services for Macintosh, the conflicting information is ignored and an event is written to Event Viewer. If a server that is seed routing stops responding or is shut down, one of the waiting seed routers starts seeding the network zone and range information.

# Making a router plan

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Making a router plan**

After you have diagrammed your network, make a router plan that shows the location and type of each seed router for the network.

To make a router plan, determine:

- The expected number of AppleTalk devices on present and projected Ethernet networks.
- The quantity of network numbers sufficient to satisfy capacity requirements. (Up to *n* * 253 devices can be supported, where *n* is the number of network numbers in the range.)

**Router seeding plan example**

| Cable ID | Network range | Zone list | Seed devices |
|---|---|---|---|
| Ethernet #1 | 16-25 | **Finance** Accounts Payable Accounts Receivable | Server 1 Server 3 |
| Ethernet #2 | 32-37 | **Marketing** Marketing Exec | Server 5 |
| Ethernet #3 | 768 | **Engineering** | Server 6 |
| LocalTalk #1 | 1024 | Finance | Server 3 |
| LocalTalk #2 | 1280 | Marketing | Server 5 |

**Notes**

- In the **Zone list** column, bold formatting indicates the network's default zone.
- Seed device information can indicate the server name, the type of dedicated hardware router, or the location, depending on your needs.

# Assigning AppleTalk network numbers and ranges

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Assigning AppleTalk network numbers and ranges**

Follow these guidelines when you decide how to assign network numbers and network ranges:

- Use network numbers that leave room for expansion.

  For example, if your first AppleTalk zone has a network range of 1024-1099, then make the range of your second AppleTalk zone 1400-1450. This will leave plenty of room for growth of the first AppleTalk network.

- Network numbers are essentially arbitrary. The important thing is for them to be unique and not to overlap (if in a range) with other ranges.

- Base your network ranges on the number of nodes you expect to have in the future on each network.

  Base the extent of a network range on the number of AppleTalk nodes expected on the physical network. The total number of possible AppleTalk nodes is 253 times the number of network numbers in the range.

  For example, a network range of 101 through 103 permits 759 nodes (3 * 253 = 759); a network range of 120 to 129 permits 2530 nodes (10 * 253 = 2530) on a network. Leave room for more nodes than are currently connected.

For more information, see AppleTalk routing information, Configure AppleTalk protocol, Assigning AppleTalk zones, and Working with AppleTalk seed routers.

# Assigning AppleTalk zones

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Assigning AppleTalk zones**

AppleTalk zones are identified by zone names. Follow these guidelines when you decide how to assign zone names:

- You can assign one or more zone names to each Ethernet network. An asterisk (*) cannot be a zone name.
- For each Ethernet network, decide which zone will be the default zone.
- The number of zones your internet has depends on the size of the internet you are planning. If your internet is small, a single zone can be adequate. But if you have a single Phase 2 Ethernet network that spans a large geographic area or contains large numbers of AppleTalk devices (such as printers and servers), use multiple zones to make it easier for users to find the devices they need.

# Creating an AppleTalk router record

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating an AppleTalk router record**

To keep information about your internet for maintenance purposes, create a router record. Include the following information:

- Router location.
- Physical location.
- If the router is a computer running Services for Macintosh, record the server computer name.
- Router type and version.
- The physical networks connected to the router, with the following information for each:
    - Cabling identification.
    - Network media type.
    - Network numbers.
    - Zone names.
    - Default zone.
    - Whether this router is a seed router for the networks attached to it.

# AppleTalk over PPP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AppleTalk over PPP**

Macintosh users can dial in to a computer running Services for Macintosh by using a PPP client that supports AppleTalk Control Protocol (ATCP). ATCP is installed automatically if remote access and AppleTalk Protocol are installed. The AppleTalk protocol is installed automatically with File Server for Macintosh and Print Server for Macintosh. You can also install AppleTalk protocol separately. The version of ATCP that comes with Services for Macintosh includes the following features:

- Addresses are dynamically allocated.
- Clients are not forced to change their passwords.

ATCP client callback functionality is identical to other dial-up client types. Callback ensures that only users from specific locations can access the dial-up server. This saves toll charges for the user. In addition, ATCP clients can specify their number to be called back at the time they dial in, if their account is callback-enabled. To do this, users specify their user name as *username@phonenumber*. For example, a user named Jeff Smith, whose account is configured for callback, wants to be called back at 5550123. He can enter JeffSmith@5550123 as his user name, and he will be called back at that number.

Guest account authentication and access authorization are the same for ATCP as for any other dial-up method.

ATCP requires that user passwords be saved in reversibly encrypted plaintext format on the dial-up server. (By default, passwords are not stored on the dial-up server in plaintext format.) Because of this requirement, existing users who want to use the ATCP protocol must have their passwords converted to plaintext format. First the administrator must enable the dial-up server to store passwords in plaintext format. For existing accounts, the administrator can then either delete and re-create the accounts or change the password for the accounts. The passwords are then stored in plaintext format, and users can dial in using the ATCP protocol.

All account passwords created after enabling plaintext password storage will be saved in plaintext format.

You can store passwords on a per-user or domain-wide basis. So for ATCP clients, and for Apple Encrypted passwords to work, the administrator must configure encrypted plaintext password storage for each user.

**Note**

- Do not statically configure client addresses, because addresses are dynamically allocated.

# Files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Files**

This section contains information on:

- Macintosh-accessible volumes
- File sharing
- How shared files appear to users
- Cross-platform applications
- Macintosh file forks
- How file names are translated
- Macintosh file administration

# Macintosh-accessible volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Macintosh-accessible volumes**

A computer running Services for Macintosh can store files so that users of both x86-based and Macintosh computers can gain access to them. Users of x86-based computers look for shared files in a shared folder on the computer running Services for Macintosh. Macintosh users look for shared files in the same folder; however, they see the folder as a volume, with familiar folders and files.

A Macintosh user shares a file with users of x86-based computers by storing that file in a Macintosh-accessible volume on the computer running Services for Macintosh. Likewise, a Macintosh user can mount a Macintosh-accessible volume on the desktop to use files stored in shared folders by users of x86-based computers.

All Macintosh-accessible volumes must be created on an NTFS partition or on a Compact Disc File System (CDFS) volume. If you specify a CDFS volume, the Macintosh-accessible volume will provide read-only access.

# File sharing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**File sharing**

With Services for Macintosh, both users of x86-based computers and Macintosh users can easily share files stored on a server. On a computer running File Server for Macintosh, files are stored in shared folders or in Macintosh volumes. For a file to be accessible to x86-based clients, it must be in a shared folder (or in a subfolder of a shared folder). Each server can have one or more shared folders. Each shared folder on a server is assigned a unique name.

With File Server for Macintosh, Macintosh users cannot automatically gain access to all shared folders. To make a folder (and consequently its subfolders, which may or may not be shared for users who are not using Macintosh computers) available to Macintosh users, the administrator must designate the folder as a *Macintosh-accessible volume*.

### Notes

- Some users of x86-based computers are familiar with the terms *volume* and *volume labels* as they relate to a hard disk partition. In the context of Services for Macintosh, a volume is either a folder designated as both a shared folder and a Macintosh-accessible volume (meaning that both types of clients can gain access to the files in the volume) or a folder available only to Macintosh users on the network. The only exception to this convention is CD-ROM or Compact Disc File System (CDFS) volumes.

- Macintosh volume names that are created on a computer running a member of the Windows Server 2003 family cannot exceed 12 characters. To create volumes with longer names, use the command-line utility Macfile.exe. For example, to add a volume called Landscape Design on the magnolia server using the Trees folder on drive E:, type:

  macfile volume /add /server:\\magnolia /name:"Landscape Design" /path:e:\trees

# How shared files appear to users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How shared files appear to users**

Shared files appear as expected to users of x86-based computers and to Macintosh computer users. For example, when an MS-DOS user views these shared files, the file names follow the MS-DOS standard naming convention, whether or not they were created that way by a Macintosh user. When a Macintosh user views the files, they appear as Macintosh files on the Macintosh client itself or on Macintosh servers running AppleShare.

Within a folder that is both a shared folder and a Macintosh-accessible volume, users of networked x86-based computers see folders and files. In fact, this is what is actually stored on the server hard disk. To Macintosh users, the volume appears to contain Macintosh files and folders. When Macintosh users browse through the files available on the server, they see icons that represent each file and folder.

Macintosh files and folders can have Macintosh file names, including long names and names containing spaces and other characters. They are not limited to the 8.3 naming convention of the file allocation table (FAT) file system used with the MS-DOS system and some OS/2 computers. File Server for Macintosh and the NTFS file system translate the names so that users can see them.

# Cross-platform applications

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cross-platform applications**

Many applications have separate (cross-platform) versions for Macintosh and x86-based computers. With Services for Macintosh, Macintosh and x86-based clients can use cross-platform applications to modify the same files.

For example, a person who uses an x86-based version of Microsoft Excel can create a spreadsheet file and store the file on the server in a shared folder that is also configured as a Macintosh-accessible volume. A Macintosh user who opens that shared folder can double-click the file icon, and Microsoft Excel for Macintosh starts and opens the file. The Macintosh user can modify the file and save it. When the user of the x86-based computer opens the file, the modified version of the file appears.

File Server for Macintosh uses extension-type associations to display x86-based files with the correct icon when the Macintosh user is viewing the files in the Finder.

File Server for Macintosh comes with extension-type associations already defined for many applications. These can be extended or modified.

# Macintosh file forks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Macintosh file forks**

Each Macintosh file has two parts, or *forks*: a data fork and a resource fork. The data fork contains the actual data of the file. The resource fork contains Macintosh operating system information about the file, such as code, menu, font, and icon definitions.

When a Macintosh file is shared on a computer running Services for Macintosh, the two forks are saved in a single NTFS file.

# How file names are translated

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How file names are translated**

There are two things to be aware of regarding file-name translation when running Services for Macintosh:

- How Macintosh file names are maintained and presented to various users.
- How the longer NTFS names (more than 32 characters) are presented to Macintosh users.

When a Macintosh user creates a file or a folder on the server and gives it a name, File Server for Macintosh checks it for illegal NTFS characters. If the file name contains illegal NTFS characters, File Server for Macintosh replaces the illegal characters. Otherwise, the original Macintosh name is the same as the NTFS name. Macintosh users see the name as it was created. Windows users see the same name with any illegal characters replaced.

After File Server for Macintosh has replaced illegal NTFS characters, names that are too long for MS-DOS users are shortened to six characters, a tilde (~), and a unique number. Extensions are preserved.

Users creating long NTFS file names (up to 256 characters) should name files with 31 characters (the Macintosh limit) or fewer so that Macintosh users can readily decipher the file names.

Summary:

- A file created using the FAT file naming convention appears as created to NTFS users and Macintosh users.
- A file created using the 31-character limit of the Macintosh system appears as created (except with illegal characters replaced) to NTFS users. MS-DOS users see a short name.
- A file created using the NTFS 256-character limit appears as created to Macintosh users if it has 31 or fewer characters. Otherwise, it appears to both MS-DOS and Macintosh users in the shortened form.

**Note**

- Because MS-DOS users refer to files created by Macintosh users by the translated short names, Macintosh users should give the FAT standard names (eight characters plus an optional period and three-character extension) to files and folders that will also be used by MS-DOS users. This way MS-DOS users won't have to decipher short names. Macintosh users can use long file and folder names if no MS-DOS users need to access those files.

# Macintosh file administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Macintosh file administration**

In Windows NT 4.0 and earlier, the Macfile program handled Macintosh file administration, including the creation of Macintosh volumes, passwords, security options, user limits, and permissions. You accessed the **Macfile** menu from Control Panel, File Manager, and Server Manager.

On computers that are running Services for Macintosh, Macintosh volumes and files are centrally administered through the Microsoft Management Console (MMC) Shared Folders snap-in. Both Macintosh and non-Macintosh files are administered by using Shared Folders. This improves the integration of Macintosh file management with non-Macintosh files.

**Note**

- You can still use the command-line version of Macfile (Macfile.exe) to administer servers, volumes, files, and folders.

# Printing Benefits

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Printing benefits**

Users gain three major printing benefits with Print Server for Macintosh:

- Macintosh users can print PostScript jobs to non-PostScript printers directly connected to the computer running Services for Macintosh. To the Macintosh user, these printers appear like the standard LaserWriter.
- Users of x86-based computers can send print jobs to PostScript printers on an AppleTalk network, and they can check print jobs from their clients.
- Macintosh and x86-based print jobs are spooled before they go to the printer. So both Macintosh users and users of x86-based computers can send jobs to the printer and then continue working at their computers. This means that users do not have to wait for their jobs to print before using their computers to do other tasks or wait for a printer to be available.

For more information on printing, see:

- Print Server for Macintosh
- Printing device vs. printer
- Sharing printers among Macintosh and x86-based clients
- Capturing AppleTalk printers
- Avoiding LaserPrep wars

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Print Server for Macintosh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Print Server for Macintosh**
When Services for Macintosh is set up, several AppleTalk services (such as Print Server for Macintosh) become integrated with the operating system. Print Server for Macintosh makes printers connected to the computer running Services for Macintosh available to Macintosh clients, and it makes AppleTalk PostScript printers (with LaserWriter drivers) available to x86-based clients.

When Print Server for Macintosh receives print jobs, it sends them to a spooler, which is a portion of the print server hard disk. The spooler then sends the print job to the specified printing device; for example, to a printing device on the AppleTalk network. This enables Macintosh users, as well as users of x86-based computers, to submit print jobs and continue working on their computers without waiting for the print job to finish.

Print Server for Macintosh also translates all incoming PostScript files if the print request is to a non-PostScript printer attached to the computer running Services for Macintosh. A Macintosh client (but not a Windows-based client) can send a PostScript job to any printer that is connected to a computer that is running Services for Macintosh.

Whether printing devices are attached to the computer running Services for Macintosh or are located elsewhere on the AppleTalk network, the Printers folder displays a list of print jobs for the respective printers you created to represent the devices. By default, each list presents jobs in first-in, first-out (FIFO) order. You can change the priority of jobs, however, and specify permissions for the printer and times for print jobs to run.

### Notes

- This implementation of PostScript Routing Information Protocol (RIP) supports 300 dpi and Postscript level 1.
- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Printing device vs. printer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Printing device vs. printer**
Before setting up printers, it's important to understand the distinction between a printing device and a printer that you create using the Add Printer wizard:

- A printing device is the hardware that actually does the printing.

- A printer you create using the Add Printer wizard is a software interface between the document and the printing device. You use the printer you create to send jobs to the printing device, according to the specified priority (for example, on a first-come, first-served basis).

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Sharing printers among Macintosh and x86-based clients

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Sharing printers among Macintosh and x86-based clients**
Without Print Server for Macintosh, Macintosh clients typically send print jobs to AppleTalk printing devices (usually PostScript devices), and x86-based clients send print jobs to non-PostScript devices. Print Server for Macintosh lets both types of clients send print jobs to either type of printing device. In addition, both types of users get the benefit of spooling when they print through the computer running Services for Macintosh.

Users of x86-based computers specify printers on a computer running Services for Macintosh and send print jobs to them as usual, whether the printing device is attached to the server itself or located elsewhere on the network. Similarly, Macintosh users have the familiar Chooser interface to use for connecting to printers that are set up for both AppleTalk printing devices and those attached to a computer running Services for Macintosh.

To get these printing benefits, set up Print Server for Macintosh, and create a user account (such as MACUSERS).

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Capturing AppleTalk printers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Capturing AppleTalk printers**

When you set up a printer on an AppleTalk network to be used with Services for Macintosh, you can specify whether Print Server for Macintosh will *capture* the printer, that is, prevent the printer from accepting print jobs from any source other than Print Server for Macintosh. Capturing gives you complete control over the printer.

If a printer will be used exclusively by users of x86-based computers, you should capture it. Doing so ensures that users do not accidentally bypass the print server and send print jobs directly to the printer or reset the printer, which might cause spooler problems. You will also avoid LaserPrep Wars.

Note that if a source other than Print Server for Macintosh prints jobs on the printer, you should not capture the printer. For example, don't capture printers if you use Apple LaserShare (which provides spooled printing for Macintosh clients) or if you use a minicomputer that sends print jobs from minicomputer users to the printer.

If a printer is not captured and multiple sources send jobs to that printer, no jobs will be interrupted; however, while the printer is printing a job from one source, it will appear busy to the other sources.

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Avoiding LaserPrep wars

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Avoiding LaserPrep wars**

A condition known as *LaserPrep wars* causes slow printing performance with some AppleTalk networks. Services for Macintosh solves this problem.

LaserPrep wars occur when a network has Macintosh clients that use two or more versions of Chooser Packs, which include a PostScript preparation file (also called a LaserPrep file) and a PostScript driver. A printer can use only one version of the LaserPrep file at a time. When a Macintosh user sends a print job to the printer, the Macintosh computer checks for the printer's version of the LaserPrep file. If the printer currently has a different version than the Macintosh client uses, the Macintosh client sends its version of the LaserPrep file along with the print job and instructs the printer to load that file as the printer's resident LaserPrep file.

Because Macintosh computers with different LaserPrep file versions send print jobs to a printer, different versions of the LaserPrep file are loaded and unloaded on the printer. The printer must load and unload versions of the LaserPrep file and then print a startup page each time a different LaserPrep file becomes resident. This causes performance problems and can reduce the life cycle of the printer.

For example, suppose a Macintosh user whose client uses Chooser Pack version 6.0 sends a document to the printer. The LaserPrep version 6.0 file is made resident on the printer. Then, if the next document sent to the printer comes from a client using Chooser Pack version 7.0, the printer must reset, load LaserPrep 7.0, and print a new startup page before printing the document.

Print Server for Macintosh solves the LaserPrep wars problem by sending the LaserPrep file with each job. This extra effort actually improves overall performance: The printer never has to spend time making a LaserPrep resident or printing a startup page.

Note that for printers on an AppleTalk network, LaserPrep wars are guaranteed to be avoided only if the printer is captured. If the printer is not captured, users who send print jobs directly to the printer, bypassing Print Server for Macintosh, can initiate LaserPrep wars.

LaserPrep wars are always prevented when printers are attached directly to a computer that is set up with Print Server for Macintosh.

### Note

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Security for Services for Macintosh users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security for Services for Macintosh users**
With Services for Macintosh, network security is enforced for Macintosh clients in the same way it is enforced for x86-based clients. File Server for Macintosh translates user identification, authentication (passwords), and permissions so that the integrity of the server is maintained regardless of the type of client used.

For more information on network security, see:

- Accounts for Macintosh clients
- Services for Macintosh Passwords
- Services for Macintosh Authentication
- Services for Macintosh Permissions

# Accounts for Macintosh clients

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accounts for Macintosh clients**

Services for Macintosh uses the same user accounts database as any member of the Windows Server 2003 family. If you already have Windows Server 2003 family accounts created for the people who will be using Macintosh computers on the network, you don't need to create additional accounts. Create accounts only for users who don't already have accounts on the computer running File Server for Macintosh and Print Server for Macintosh.

One aspect of the Windows Server 2003 family user accounts, the user's *primary group*, applies only to Services for Macintosh. The user's primary group is the group the user works with most, and it should be the group with which the user has the most resource needs in common. When a user creates a folder on a server, the user becomes the owner. The owner's primary group is set as the group associated with the folder. The administrator or owner can change the group associated with the folder.

# Services for Macintosh Passwords

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Passwords**
A Macintosh user logs on to a computer running Services for Macintosh in one of three ways:

- As a guest.
- As a user with a plaintext password.
- As a user with an encrypted password.

**Guest logons**
To allow Macintosh clients to connect to a server running Services for Macintosh without providing user credentials, you need to enable guest logons. To do so, you need to enable the guest account in the Computer Management snap-in. The guest account is disabled by default in the Windows Server 2003 family. For more information on enabling guest accounts, see Default local groups, Local user accounts, and Create a local user account.

Once the guest account has been enabled, you can set guest permissions on a volume. To do this, use the options available in the **Permissions for Guests** box in the **Security** tab of the **Microsoft UAM Volume Properties** dialog box.

For more information on how to set guest permissions on Macintosh volumes, see Set permissions on a Macintosh-accessible volume or folder. To understand how permissions work, see Access Control.

**Plaintext passwords**
Plaintext password protection is part of the AppleShare client software on Macintosh computers. It provides less security than encrypted password protection because the passwords are sent over computer networks and can be detected by *sniffers* (network monitors that can look for passwords). Moreover, the AppleShare passwords can contain no more than eight characters, making them relatively easy to guess with conventional methods like dictionary attacks. Plaintext password protection is offered for Macintosh users who use the standard AppleShare client software or System 7 File Sharing.

**Encrypted passwords**
An encrypted password is more secure than a plaintext password. The Windows Server 2003 family encrypts passwords and stores them so that they cannot be directly stolen from the client itself. Encrypted passwords can contain up to 14 characters. File Server for Macintosh offers encrypted passwords to Macintosh clients.

# Services for Macintosh Authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authentication**

With Services for Macintosh, Macintosh computers need only the Macintosh operating system to function as clients; no additional software is required. You can, however, set up and distribute the Microsoft user authentication module (MSUAM), which lets Macintosh clients securely log on to computers running Services for Macintosh using the same method as Windows clients.

The Apple standard UAM provides only minimal encryption and so user passwords can be easily intercepted on the local area network (LAN) or Internet. MSUAM is a stronger password encryption method used to log on to a computer running Services for Macintosh. MSUAM encrypts passwords and stores them on the computer running Services for Macintosh. You can either set up, or instruct Macintosh users to set up, the authentication file for MSUAM on their Macintosh computers over the network. Although MSUAM is not required, it provides secure encrypted authentication to servers running Services for Macintosh.

If MSUAM is set up on a client computer, the **Require strong authentication (NTLMv2)** check box is selected by default. Selecting this check box requires users to authenticate to servers that implement NTLMv2. This setting prevents users from authenticating to servers that are running Windows NT 4.0 without Service Pack 3 and other operating systems that cannot authenticate using NTLMv2. However, users can clear the **Require strong authentication (NTLMv2)** check box to allow themselves to authenticate to servers that do not implement NTLMv2. Using NTLMv2 helps eliminate man-in-the-middle attacks in which an attacker tries to force authentication using the less secure Lan Manager (LM) Authentication protocol.

The default setting for NTLMv2 authentication is restored every time users log off. If users clear the **Require strong authentication (NTLMv2)** check box, a message box appears, warning them of the security risk of doing so. However, users can still clear the check box and authenticate using a weaker protocol, putting your network at risk.

With MSUAM, users can also specify a domain when they log on or change their passwords. This feature ensures that, if they have accounts in multiple domains, the correct one will be used. (To specify a domain, users type *DomainName******UserName*in **Name**.)

Different versions of the Mac OS use different default authentication methods. Ensure that you check the appropriate Mac OS documentation before you configure authentication methods for Macintosh users. For information on authentication and remote access security in the Windows Server 2003 family, see Remote Access Security.

# Services for Macintosh Permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Permissions**

Access to network files and folders is controlled with permissions. Using the Windows Server 2003 family security system, you specify which users can access shares, folders, and files, and how these resources can be used. The Macintosh-style permissions differ in that they can be set for folders only, not files. However, NTFS permissions still apply to both files and folders that are shared as Macintosh accessible volumes.

Services for Macintosh ensures a consistent file-level security for x86-based and Macintosh clients by translating file permissions, which adds a level of security to your network. A Macintosh user sets permissions according to the Macintosh scheme; File Server for Macintosh translates these to the Windows Server 2003 family permissions. The reverse is also true: The Windows Server 2003 family permissions set by x86-based clients are translated to Macintosh-style permissions for Macintosh users.

Both the Administrators and Server Operators groups can administer File Server for Macintosh and Print Server for Macintosh. The Windows Server 2003 family Administrator account always has full permissions on volumes that are running File Server for Macintosh. Server Operators group membership is sufficient for common administrative tasks. You need not log on with administrative credentials to perform these tasks.

For more information on permissions, see:

- Types of permissions
- How file-level permissions are handled
- Translating permissions between x86-based clients and Macintosh clients
- Setting permissions from a Macintosh or x86-based computer
- Volume passwords

# Types of permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Types of permissions**

Users and administrators of x86-based networks use the Windows Server 2003 family permissions. Macintosh users set Macintosh-style permissions on the folders they create.

On a computer running a member of the Windows Server 2003 family, new files and subfolders inherit permissions from the folder in which they are created.

Macintosh files inherit the permissions set on folders. Any Windows Server 2003 family permission specified for a file will be recognized by File Server for Macintosh, even though the Macintosh user won't see any indication in the Finder that these permissions exist. There are four types of Macintosh-style permissions:

- *Cannot Move, Rename, Or Delete* prohibits these actions on a folder.
- *Make Changes* lets a user modify the contents of files in the folder, rename files, move files, create new files, and delete existing files.
- *See Folders* lets a user see what folders are contained in the folder.
- *See Files* lets a user see what files are in the folder and read those files.

A Macintosh user cannot give these permissions to multiple users and groups. Instead, permissions can be assigned to three categories of user.

- **Owner.** The user who created the folder.
- **User/Group.** Similar to the Windows Server 2003 family group associated with the folder. Every folder on a server can have one group associated with it at any one time. The group can be a special group such as *users* or *administrators*, or it can be any other group on the server.
- **Everyone.** All other users of the server, including user accounts with guest access.

The Macintosh security scheme assumes that every folder on a server falls into one of three types: *private information* (accessible only by the owner of the folder); *group information* (accessible by a single workgroup); and *public information* (accessible by everyone).

For example, consider a folder containing information that all members of a certain group should see, but that only one person can change. The person allowed to change the information should be the *Owner* of the folder and should have See Files, See Folders, and Make Changes permissions. The workgroup that uses the folder should be the *Group* associated with the folder and should have only See Files and See Folders permissions. Because no one else needs to see the folder's contents, the *Everyone* category should not be selected.

Although a folder's owner will often be a member of the group associated with the folder, this need not be the case.

With both Macintosh-style and Windows-style permissions, users' access to folders can be defined differently for each folder and subfolder within a tree. For example, you could give a user See Files, See Folders, and Make Changes permissions for one folder, only See Files permission for a subfolder of that folder, and no permissions for another subfolder.

# How file-level permissions are handled

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How file-level permissions are handled**

With a member of the Windows Server 2003 family, users of x86-based computers can assign permissions separately for each file within a folder. The Macintosh computer, however, does not support file-level permissions. When a file has file-level permissions, those permissions apply to Macintosh users only if the permissions are more restrictive than those assigned for the folder that contains the file.

For example, if a Macintosh user has See Files, See Folders, and Make Changes permissions for a folder, the user can read and make changes to files in the folder. However, if that user has only Read permissions for any particular file in that folder, the user can only read that file. Because of the Read file-level permission, the user cannot make changes to the file.

# Translating permissions between x86-based clients and Macintosh clients

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Translating permissions between x86-based clients and Macintosh clients**

Services for Macintosh translates permissions so that those set by a user of an x86-based computer are translated into the equivalent Macintosh permissions, and vice versa. When a user of an x86-based computer sets permissions for a folder, or when a Macintosh user sets permissions for a folder, permissions are translated according to the following table:

| Windows Server 2003 family permissions | Macintosh permissions |
|---|---|
| Read | See Files, See Folders, or both |
| Write, Delete | Make Changes |

**Note**

- Permissions set within Macintosh networks behave differently from those set from within the Windows Server 2003 family networks, including Macintosh-style permissions. From the Macintosh computer, a right assigned to everyone overrides more restrictive rights set on the owner or a group. From an x86-based computer, permissions assigned to everyone do not override permissions set on the owner or group.

# Setting permissions from a Macintosh or x86-based computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting permissions from a Macintosh or x86-based computer**

A folder's owner can set permissions for the folder. Both the folder's owner and the server administrator can use an x86-based computer to set Windows Server 2003 family permissions for folders on the server. The folder's owner can set permissions for the folder from an x86-based computer because the owner of every folder has the P (Change Permission) permission for that folder.

# Volume passwords

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Volume passwords**
Services for Macintosh provides an extra level of security through Macintosh-accessible *volume passwords*. A volume password is a password you assign to a Macintosh-accessible volume when configuring it. Any Macintosh user who wants to use the volume must type the volume password. Users of x86-based computers do not need to know the volume password to access the folder that corresponds to the Macintosh-accessible volume.

**Notes**

- Volume passwords are optional.
- Volume passwords are case-sensitive.
- When you create a new Macintosh-accessible volume, the default is to have no volume password.
- Because of a constraint with the System 6 and System 7 Finder, you cannot automatically mount a volume with a volume password at startup or by double-clicking an alias. You also cannot automatically mount a volume if the user originally connected to the volume with the Microsoft user authentication module (UAM).

For more information on network security options for users of Services for Macintosh, see Security for Services for Macintosh users.

# Using AppleTalk Networking

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using AppleTalk networking**

This section contains information on:

- Administering Services for Macintosh
- Services for Macintosh Printing
- Services for Macintosh Macintosh-accessible Volumes

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Administering Services for Macintosh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administering Services for Macintosh**
This section contains information on:

- Managing Services for Macintosh from the command line
- Stopping, starting, pausing, and resuming services
- Viewing the event log
- Setting up user accounts for Macintosh users

# Managing Services for Macintosh from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Services for Macintosh from the command line**

In addition to using Computer Management, you can also use command-line utilities to manage both File Server for Macintosh and Print Server for Macintosh. For example, use Services for Macintosh commands to start or stop File Server for Macintosh or Print Server for Macintosh. You can also use the Macfile commands to manage File Server for Macintosh servers, volumes, directories, and files.

For information about other command-line utilities, see Command-line reference A-Z. For more information about manageability, see Management Strategies and Tools. For more information about Services for Macintosh, see Administer Macintosh Clients.

# Stopping, starting, pausing, and resuming services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Stopping, starting, pausing, and resuming services**

When you set up Services for Macintosh, two services are automatically started: File Server for Macintosh and Print Server for Macintosh. (The AppleTalk Protocol is also started.) At times, you might need to stop these services, as shown in the following table:

| Service | Stop the service to |
|---|---|
| Print Server for Macintosh (MacPrint) | Install another printer driver, to configure a printer, or to immediately see the result of deleting, creating, or changing a printer.<br><br>Stop it to remove the Print Server for Macintosh service. |
| File Server For Macintosh (MacFile) | Change the server name that Macintosh users will see or to remove File Server for Macintosh.<br><br>Pause it when you want to make changes to the server attributes but want to allow current users to continue working. If this service is paused, no new Macintosh users can log on to the computer running Services for Macintosh. |
| AppleTalk Protocol | Change router parameters and the default networking zone and to remove AppleTalk Protocol (which automatically stops File Server for Macintosh and Print Server for Macintosh). |

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Viewing the event log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing the event log**

To check events on the computer running Services for Macintosh, use Event Viewer, which is available in the Administrative Tools folder in Control Panel. If File Server for Macintosh and Print Server for Macintosh are running, you can see events that involved File Server for Macintosh, Print Server for Macintosh, or the AppleTalk Protocol.

# Setting up user accounts for Macintosh users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting up user accounts for Macintosh users**

User accounts are created for Macintosh users just as they are created for Windows users. A guest account is automatically created when you install Services for Macintosh. By default, both local guests and guests accessing the server through a client on the network (including a Macintosh client) are allowed. This means that if users log on without a regular user account and password, they will be logged on as a guest.

Guests have some access to shared resources. Guests can do everything that those with a user account can do except keep a local profile on their computers; lock their computers; and create, delete, and modify local groups on their computers.

The guest account cannot be deleted, but it can be disabled. If it is disabled, no network users, including Macintosh users, can log on without a user account and password.

# Services for Macintosh Printing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Printing**
This section contains information on:

- Creating a printer
- Setting up a user account for Macintosh print jobs
- Using printers on the AppleTalk network
- Prioritizing print jobs
- Creating printing pools

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Creating a printer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating a printer**

After you have physically attached a printing device to a computer (either directly or on a network), use the Add Printer wizard to create a printer that represents it. You can create more than one printer representing the same printing device.

For example, if you have a printing device in your office but also share it with others over a network, you might want to create two printers representing the printing device. You can create a printer for yourself that is not shared over the network and a second printer that is shared. Then it's easy to control the use of the shared printer. You can set permissions on the shared printer, ensuring that only members of your department can print to it. Or you can set a low priority for it, ensuring that documents you send to the printer will always print before documents sent by those who share it.

Another common example is to create a printer that spools to a printing device at night and another printer that spools to the same printing device during the day.

To create a printer, you must be logged on with sufficient permissions. Members of the Administrators, Server Operators, and Print Operators groups can create printers.

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Setting up a user account for Macintosh print jobs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting up a user account for Macintosh print jobs**

After setting up Services for Macintosh, you should create a user account that will be used by all Macintosh clients when printing jobs to captured AppleTalk printing devices or to other devices on the computer running Services for Macintosh. You should also configure Print Server for Macintosh to use this account.

After it is created, the user account (for example, MACUSERS) appears in the list of names that is displayed in the properties dialog box of the print server. You can give specific rights to this user account, just as you would any user account, including Print and No Access.

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Using printers on the AppleTalk network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using printers on the AppleTalk network**

With Services for Macintosh, both x86-based and Macintosh clients can send print jobs to printing devices or spoolers on the AppleTalk network.

The printing device must appear as a LaserWriter in the Chooser, and there must be an appropriate driver for the printing device.

Macintosh clients use printers just as they normally do, through the Chooser. If an AppleTalk printer has been set up, it can be captured so that Macintosh clients cannot access it directly. This causes Macintosh print jobs to go through the computer running Services for Macintosh and to be spooled along with print jobs from x86-based clients.

To allow any Macintosh client to print to an AppleTalk printer directly, disable the capture setting. However, if you do this, the print jobs will not be under the administrator's control.

When an AppleTalk printer is released, any Macintosh user on the AppleTalk network can use the device directly.

A printing device on AppleTalk can be captured when Print Server for Macintosh is set up and a printer is created for it. It must remain captured so that all Macintosh clients send print jobs through the computer running Services for Macintosh. If a printing device has been released, you can recapture it.

You can select another spooler instead of an actual device. However, use this type of configuration with caution. It is possible to create an endless loop of print spooling with this method.

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Prioritizing print jobs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Prioritizing print jobs**

You can create multiple printers that all send print jobs to a single printing device. Each printer has a print-priority level associated with it. If you create two printers and associate them with a single printing device, jobs routed to the printer with the higher priority (lower number) print first.

It's a good idea for users of x86-based computers to create a group that corresponds to each printer. For example, users in Group 1 might have access rights to a priority-1 printer, users in Group 2 might have access rights to a priority-2 printer, and so on. This lets you prioritize print jobs according to the users submitting their jobs.

For Macintosh users, you must create one user account for all incoming print jobs to the computer running Services for Macintosh. Consequently, all Macintosh users sending print jobs through the computer running Services for Macintosh will have the same access rights.

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Creating printing pools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating printing pools**

When you create a printer, you can associate it with more than one printing device in order to form a *printing pool*. To set up a pool, you create a printer and assign it as many output ports as you have identical printing devices. Printing pools have the following characteristics:

- All devices in the pool share the same print property settings and act as a single unit. For example, stopping one device pauses them all.
- Print destinations can be of the same type or mixed (serial, parallel, and network).
- When a job arrives for the printing pool, the spooler on the computer running Services for Macintosh checks the destinations to see which device is idle. The first port selected gets checked first, the second port second, and so on. If your pool consists of a different type of port, make sure you select the fastest port first (network, then parallel, and then serial).
- A printing pool can contain a mixture of printer interface types, but the printing devices must all use the same printer driver.

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Services for Macintosh Macintosh-accessible Volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Macintosh-accessible volumes**
This section contains information on:

- Creating a Macintosh-accessible volume
- Creating a Macintosh-accessible volume on a CDFS
- Configuring Macintosh-accessible volumes
- Creating folders in a volume
- Setting permissions for volumes and folders
- Removing a Macintosh-accessible volume

# Creating a Macintosh-accessible volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating a Macintosh-accessible volume**

Just as you can create a shared folder for users of x86-based computers, you can use Shared Folders to designate a folder as a Macintosh-accessible volume. If the folder is to be accessed by x86-based clients as well as Macintosh clients, share the folder by selecting the **Microsoft Windows** check box in the Create Shared Folder wizard. If you do not need to share the files with users of x86-based computers, you can create a volume on a folder. That is, it does not have to be a shared folder.

**Note**

- You cannot designate any folder within a Macintosh-accessible volume as another Macintosh-accessible volume.

# Creating a Macintosh-accessible volume on a CDFS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating a Macintosh-accessible volume on a CDFS**

To Create a Macintosh-accessible volume on a CDFS volume, follow the same procedure you used to create one on an NTFS-partitioned drive. Note that the CDFS disk is read-only. This means that Services for Macintosh will interpret all security options as See Files and See Folders (read-only).

# Configuring Macintosh-accessible volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring Macintosh-accessible volumes**

With the Windows Server 2003 family, you can share folders on the server in any combination. For example, you can share a single folder twice with two different share names, and you can share a folder with one share name and then share a subfolder of that folder with another share name.

However, different rules apply when you use Services for Macintosh to configure Macintosh-accessible volumes. You cannot configure two folders in the same folder tree as volumes.

This means that, when configuring Macintosh-accessible volumes, you cannot configure:

- A single folder twice as two different volumes.
- A folder as a volume if it exists anywhere in the folder tree under another folder configured as a volume.
- A folder as a volume if one of its subfolders, or any subfolder of one of its subfolders, is configured as a volume.

All Macintosh-accessible volumes must be on an NTFS partition or a Compact Disc File System (CDFS) volume. (The CDFS volumes are read-only.) The number of volumes visible to the user is determined by the length of the volume names, which must all fit in a buffer in order to be displayed. (The size of the buffer is determined by an underlying AppleTalk Protocol.) Volume names can have a maximum of 27 characters. Try to strike a balance between clearly naming volumes so that users can identify them easily and keeping the names short so that all of the volume names can be displayed.

**Note**

- Use this formula to determine the number of Macintosh-accessible volume names that can be displayed:

  $N * (M+2) <= 4624$

  where $N$ is the number of volumes and $M$ is the average length of the names in bytes.

# Creating folders in a volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating folders in a volume**

From a computer running Services for Macintosh, you can create folders for a Macintosh-accessible volume or folders for Macintosh clients, just as you would create other folders on Macintosh or Windows-based computers.

On a computer running Services for Macintosh, the folders appear in Windows Explorer as subfolders of the volume. To create another subfolder, you click the **File** menu, point to **New**, and click **Folder**.

On a Macintosh computer, you create folders using the **New Folder** command on the **File** menu. You view and use folders in the Macintosh-accessible volume just as you would any other volume, by using the **View** menu to see the folders organized by Name, Date, Icon, Size, and so forth.

You cannot, however, designate a folder within a Macintosh-accessible volume as another Macintosh-accessible volume.

# Setting permissions for volumes and folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting permissions for volumes and folders**

Just as you set permissions on shared folders to control which users of x86-based computers have access to the folder, you control who can use Macintosh-accessible volumes by setting permissions. Permissions also control the kind of access granted to users. For example, permissions dictate which users can make changes to a folder and which ones can read the content of the folder but not alter it in any way.

**Note**

- Macintosh files inherit the permissions set on folders; you cannot set permissions on files directly.

# Removing a Macintosh-accessible volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Removing a Macintosh-accessible volume**

If you want to make a volume unavailable to Macintosh users, you must remove it. Removing the volume does not delete the files contained in the volume, nor does it delete its status as a shared directory if it has been designated as such for users of x86-based computers. Removing only removes its status as a Macintosh-accessible volume.

# Services for Macintosh Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
Troubleshooting provides solutions for problems that might occur on a computer running Services for Macintosh. This includes problems that both users and administrators might encounter.

For more information on troubleshooting, see:

- Administrator and user issues and solutions
- Printing issues and solutions

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Administrator and user issues and solutions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administrator and user issues and solutions**
What problem are you having?

- A Macintosh-accessible volume is unavailable to a user.
- A Macintosh user's password has expired without notification.
- Users have forgotten their passwords.
- An "incorrect password" message is displayed, even though the password was entered correctly.
- The computer running Services for Macintosh appears in the Chooser on Macintosh clients and then disappears. The appearances are erratic and unpredictable.
- Cannot find a file or folder.
- Cannot save a file with an 8.3 file name from the Macintosh computer.
- Cannot find a server.
- Cannot see any zones within the Chooser on a Macintosh computer.
- The Microsoft user authentication module volume cannot be found.
- The view of a folder is erased or does not match the view selected in the View menu.
- A file is now displayed with the default Windows icon instead of the correct icon.
- A user of an x86-based computer cannot see the contents of a folder.
- A Macintosh user did not receive a server message.
- A user cannot automatically connect to a Macintosh-accessible volume using an alias.

**A Macintosh-accessible volume is unavailable to a user.**
**Cause:** The volume might be configured as a private volume. A private volume is any volume for which the primary and Everyone groups have no access permissions. Only the volume's owner has permissions. In this case, only the owner has access to the volume.

**Solution:** To make the volume accessible to users, the owner should give the primary or Everyone group at least one permission for the volume.

**Cause:** If the Macintosh-accessible volume is on a CDFS volume, and it appears in the Chooser but cannot be selected, the CD-ROM on which it was created might not be in the disk drive.

**Solution:** Be sure that the correct CD-ROM is in the disk drive and that the drive door is closed.

**A Macintosh user's password has expired without notification.**
**Cause:** Users will be notified that their passwords have expired only if the Microsoft user authentication module (MSUAM) files are installed on their clients. If they are using the Apple standard UAM, they will be told only that their logon attempts failed and to try again later. For more information on installing the Macintosh client software, see the Teachtext ReadMe file in the MSUAM volume or see Authentication and Services for Macintosh Concepts.

**Solution:** Install the MSUAM files on the user's client computer.

**Users have forgotten their passwords.**
**Cause:** If users have not logged in for an extended period of time, or the password they used was too complex, they may forget their password.

**Solution:** Assign the users new passwords.

**An "incorrect password" message is displayed, even though the password was entered correctly.**
**Cause:** Users might have two accounts, with different passwords, on separate domains.

**Solution:** Have users enter the domain and then the account name in Name when they log on. For example:

Domain1\user2A

**The computer running Services for Macintosh appears in the Chooser on Macintosh clients and then disappears. The appearances are erratic and unpredictable.**
**Cause:** Two physical AppleTalk networks have been given the same network numbers. The server started first works as expected. When the second server is started, it appears in the Chooser on one Macintosh client, and then disappears and appears in the Chooser on a different client. The order of appearance is unpredictable.

**Solution:** Check the network numbers used for each physical network. When you find the duplicates, change one so that all physical networks use unique network numbers. After you make the change, restart the AppleTalk Protocol on the server on which you made the change. If you find no duplicates, see if your network has a bridge that is filtering packets. It might be filtering out the requests from the second server to find a unique address.

**Cause:** Zones and network numbers are no longer in correspondence. This situation could occur if you recently changed zone names.

**Solution:** When you change the name of a zone, you must shut down the routers directly connected to the networks in question for 10 to 15 minutes before restarting. This allows the other routers to discard old zone information.

**Cannot find a file or folder.**
**Cause:** The user might not have the necessary permissions for the folder that contains the file or folder in question.

**Solution:** The administrator or the owner of the folder can reset permissions to allow the user to access the folder.

**Cannot save a file with an 8.3 file name from the Macintosh computer.**
**Cause:** A file might already exist with that name. However, Macintosh users cannot see it.

**Solution:** Give the file a different name.

**Cannot find a server.**
**Cause:** There may be a problem with the cable system between the client and the server.

**Solution:** Follow these steps:

1. Be sure the cable system between the client and the server is correct. Be sure the network connection, layout, and cable termination conform to the specifications of the cable system you are using.

2. Start with the client that can't find the server. If the cable system is LocalTalk, ensure that the LocalTalk connector box is firmly attached to the printer port on the back of the Macintosh client, not the modem port.

   If the cable system is not LocalTalk, ensure that the network connector is securely connected to its port. In Control Panel, double-click the Network icon to review other network settings.

3. Determine whether other clients are having the same problem.

   If they are, check the cables and connections at the server, and ensure that the server is operating properly. If the server is not the source of the problem, proceed to step 4.

4. Check for breaks in the cable system. If the missing server is on a local network, check each client between the client that can't find the server and the server until you find the server in the Chooser. The break in the cable system is between the client that shows the server in the Chooser and the one that does not.

   If the missing server is on a different physical network on the internet, use your router seeding plan and server

information table to determine which client is the first one beyond the router that links the two networks. Test that client, and then test each client beyond it (in the direction of the server) until the server appears in the Chooser.

If the server was visible at the first client, work backward toward your own network, testing the client adjacent to each router until the server fails to appear in the Chooser. Isolate the break by testing the clients on this network.

5. When you have isolated the network break, check the network cables and connections at that location to make sure all are securely attached, and try again to display the server in the Chooser. If necessary, try replacing cables or connectors.

**Cannot see any zones within the Chooser on a Macintosh computer.**
**Cause:** There might be router problems.

**Solution:** Check for the following:

- The Macintosh computer might be running on an AppleTalk Phase 2 network without the correct Ethernet driver.
- The router might be using Phase 1 and the rest of the internet is using Phase 2.
- The Macintosh computer is configured for one type of network media (such as LocalTalk) but is actually on a network that uses a different media type (such as Ethernet or token ring).

If the problem persists, make sure all routers are configured properly.

**The Microsoft user authentication module volume cannot be found.**
**Cause:** When the computer running Services for Macintosh was installed, there might have been insufficient disk space for the Microsoft user authentication module (UAM) volume. Or the computer running Services for Macintosh might have been installed without an NTFS partition.

**Solution:** You can create the volume by typing and entering the following at the command prompt: **setup /i oemnxpsm.inf /c uaminstall**. This command line copies UAM files to the AppleShare folder in the first NTFS partition and sets up registry values for this volume in the Registry Editor.

**The view of a folder is erased or does not match the view selected in the View menu.**
**Cause:** The Finder occasionally cannot show the correct view of a folder.

**Solution:** The folder owner must log on to the server, connect to the Macintosh-accessible volume, and, on the **View** menu, select a view (such as View By Icon, View By Name, and so on). The selected view then remains in effect.

**A file is now displayed with the default Windows icon instead of the correct icon.**
**Cause:** The application that uses that type of data file might have been removed from the Macintosh computer.

**Solution:** If the file had no resource fork, use the Apple ResEdit utility to reset the file type and file creator of the file. Use this utility only if you are experienced with it.

**A user of an x86-based computer cannot see the contents of a folder.**
**Cause:** The user of the x86-based computer does not have sufficient permissions to view the contents of the folder.

**Solution:** Use the computer running Services for Macintosh to make sure the user has Read permission, or the folder owner can use a Macintosh computer to give the user of the x86-based computer both the See Files and See Folders permissions. (A user of an x86-based computer must have both these permissions to get the Read permission.)

**A Macintosh user did not receive a server message.**
**Cause:** The Macintosh user is running a version of the AppleTalk Filing Protocol that is older than version 2.1.

**Solution:** Make sure that the user upgrades to version 3.0 of AppleShare, which allows users to receive messages.

**A user cannot automatically connect to a Macintosh-accessible volume using an alias.**
**Cause:** Macintosh clients can be configured to automatically connect to volumes when the client is started or when the user double-clicks an alias to an object on a volume. However, automatic connection to volumes is not supported by the Macintosh system software if the volume is configured with a volume password, or if the user originally used the Microsoft user authentication module (MSUAM) to connect to the volume.

**Solution:** If the volume has a password, you can mount it through the Chooser and then use the alias. Or you can specify that it be opened at system startup time when you mount the volume. If you are using MSUAM to log on to the server, you must

mount the volume through the Chooser and then use the alias.

# Printing issues and solutions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Printing issues and solutions**
What problem are you having?

- AppleTalk printers don't appear in the Printers Folder Available AppleTalk Printer dialog box.
- Messages consistently appear while documents are being printed.
- The PostScript message "Offending command" appears at the end of the printed document or elsewhere.
- Print jobs fail to print.
- Macintosh extended characters (such as bullets, smart quotes, and copyright and trademark symbols) are changed into other characters on the LaserWriter II.

**AppleTalk printers don't appear in the Printers Folder Available AppleTalk Printer dialog box.**
**Cause:** Clicking the AppleTalk zone name does not display the printers in that zone.

**Solution:** You must double-click the zone name in this dialog box.

**Messages consistently appear while documents are being printed.**
**Cause:** The printer needs to be reset.

**Solution:** Reset the printing device by turning it off and then on again.

**The PostScript message "Offending command" appears at the end of the printed document or elsewhere.**
**Cause:**

- A user or administrator might have canceled the print job while it was spooling.
- A user is spooling to a PSTODIB printing device, and it has PostScript level 2 elements or is a PostScript level 2 document.

**Solution:** No action is necessary, and you can reprint the file as desired.

**Print jobs fail to print.**
**Cause:** If one of the printing devices is turned off, all printing devices can stop printing.

**Solution:** Check each printing device that prints jobs for these printers.

**Macintosh extended characters (such as bullets, smart quotes, and copyright and trademark symbols) are changed into other characters on the LaserWriter II.**
**Cause:** If the LaserWriter hasn't been set correctly, printing problems can occur, regardless of how you set the COM port in Control Panel. This problem affects Macintosh computers more frequently than x86-based computers because Macintosh computers use extended characters more often than other clients do.

**Solution:** Set the communications port for the LaserWriter correctly, referring to the owner's manual for the printing device.

**Note**

- Print Server for Macintosh is not available on the 64-bit versions of the Windows operating systems.

# Internet and E-mail Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet and E-mail Services**
This section covers:

- Using Internet Explorer
- Using Windows Media Services
- Using the FrontPage Server Extensions 2002
- UDDI Services overview
- E-mail Services
- Background Intelligent Transfer Service

**Note**

- In the Windows Server 2003 family, you can implement enhanced security settings for Internet Explorer for all users and reduce the exposure of your server to Web sites that might pose a security risk. For more information, see Internet Explorer Enhanced Security Configuration.

# Using Internet Explorer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Internet Explorer**

With Internet Explorer, you can search for and view information on your corporate network or the World Wide Web. You can type the address of the Web page you want to visit into the address bar, or click an address from your list of Favorites. Internet Explorer also lets you search the Internet for people, businesses, and information about subjects that interest you.

In the Windows Server 2003 family, you can implement enhanced security settings for Internet Explorer for all users and reduce the exposure of your server to Web sites that might pose a security risk. For more information, see Internet Explorer Enhanced Security Configuration.

To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.

**Note**

- For information about using Internet Explorer, click the **Help** menu in Internet Explorer.

# Using Windows Media Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Windows Media Services**

With Windows Media Services, you can manage, deliver, and archive Windows Media content, including streaming audio and video, over an intranet or the Internet. Windows Media Services includes server components such as Windows Media Services Administrator for the Web. Windows Media Services is not installed by default.

**To install Windows Media Services**

1. Open the Windows Components Wizard.
2. In the Windows Components Wizard, select the **Windows Media Services** check box, and then click **Details**.
3. In the **Windows Media Services** dialog box, select the **Windows Media Services Administrator for the Web** check box.

## Notes

- To open the Windows Components Wizard, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.
- To open Windows Media Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Windows Media Services**.
- Windows Media Services and Windows Media Services Administrator for the Web are not included with Windows Server 2003, Web Edition, and the Itanium-based versions of the Windows operating systems.
- For more information about using Windows Media Services and Windows Media Services Administrator for the Web, in Windows Media Services Administrator for the Web, click **Help**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Using the FrontPage Server Extensions 2002

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using the FrontPage Server Extensions 2002**

The Microsoft FrontPage Server Extensions 2002 are a set of programs that work with Microsoft Internet Information Services to support administering, authoring, and browsing a FrontPage-extended Web site. Users running the FrontPage client can then create and manage professional-looking Web sites, whether they're creating a personal Web page or a corporate Internet or intranet site. FrontPage Server Extensions 2002 gives you, as the administrator, tools for managing site security, organizing your content into subwebs, and checking site usage.

Microsoft FrontPage Server Extensions 2002 are not installed by default during Windows Setup.

**To install Microsoft FrontPage Server Extensions 2002**

1. Open **Add or Remove Programs** in Control Panel.
2. Click **Add/Remove Windows Components**.
3. In the Windows Components Wizard, double-click **Application Server**, and then select **Internet Information Services**.

### Notes

- To open FrontPage 2002 Server Extensions, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Information Services**.
- Once installed, the Microsoft FrontPage Server Extensions 2002 will run the next time you restart your server with Internet Information Services enabled.

# UDDI Services overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**UDDI Services overview**

Universal Description, Discovery, and Integration (UDDI) is an industry specification for publishing and locating information about Web services. The Windows Server 2003 family includes UDDI Services, an optional component that provides UDDI capabilities for use within an enterprise or between business partners. UDDI Services is a standards-based XML Web service that enables enterprise developers to efficiently publish, discover, share, and reuse Web services directly through their development tools and business applications.

Built on the Microsoft .NET Framework, UDDI Services is a reliable and scalable solution that provides easy integration with enterprise technologies and tools. Information Technology (IT) managers can leverage native support for standard categorization schemes, Microsoft SQL Server, and Active Directory authentication. As a UDDI version 1.0 and 2.0 API-compliant service, UDDI Services also includes a Web interface that is translated into all of the languages that are supported by the Windows Server 2003 family.

UDDI Services product documentation is available in the UDDI Services Help. To view product documentation, install UDDI Services, and then see Windows Server 2003 Product Help. For information about installing UDDI Services, see Using UDDI Services.

**Notes**

- This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.
- To open UDDI Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **UDDI Services**.
- To run UDDI Services, you must also run Microsoft Internet Information Services (IIS).
- For additional planning, installation, configuration, troubleshooting, development, or other UDDI Services resources, see Enterprise UDDI Services at the Microsoft Web site.

# Using UDDI Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using UDDI Services**
Universal Description, Discovery, and Integration (UDDI) is an industry specification for the description and discovery of Web services. The UDDI specification builds on the Simple Object Access Protocol (SOAP), Extensible Markup Language (XML), and HTTP/S protocol standards developed by the World Wide Web Consortium (W3C) and Internet Engineering Task Force (IETF). UDDI Services is an optional component of the Windows Server 2003 family that provides UDDI capabilities within an enterprise.

UDDI Services is not installed by default during setup of a Windows Server 2003 operating system.

**UDDI Services requirements checklist**
Before you install and deploy UDDI Services, make sure your system meets the following hardware and software requirements.

**Hardware requirements**
In addition to the Windows Server 2003 family minimum requirements, UDDI Services requires:

- 128 megabytes (MB) of RAM minimum
- 80 MB free disk space (plus additional storage for UDDI Services data)

**Software requirements**
You must use one of the following Microsoft operating systems to host UDDI Services:

- Windows Server 2003, Standard Edition
- Windows Server 2003, Enterprise Edition
- Windows Server 2003, Datacenter Edition

**Installing UDDI Services**
When you first install UDDI Services, all components are selected by default. By deselecting components, you can decrease or disable UDDI Services functionality. If you are unfamiliar with UDDI Services components or deployment options, complete the default installation, and then view the Deploying and Installing UDDI Services topic in Windows Server 2003 Product Help.

**To install UDDI Services, or add or remove a component**

1. Open the Windows Components Wizard.
2. In the Windows Components Wizard, select the **UDDI Services** check box, and then follow the instructions to install, remove, or add components to UDDI Services.

After you have installed UDDI Services, open UDDI Services.

### Notes

- To open the Windows Components Wizard, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.
- To open UDDI Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **UDDI Services**.
- To run UDDI Services, you must also run Microsoft Internet Information Services (IIS).
- You can use Administrative Tools to administer local or remote installations of UDDI Services.

- If you have already installed UDDI Services, see Windows Server 2003 Product Help.

- After installing and configuring UDDI Services, you can view the Web-based user interface on any server to which you have installed the user interface subcomponent. For example, **http://*serverName*/uddi/**, or if you are using a secure sever, **https://*serverName*/uddi/**.

- For more information about UDDI Services, see UDDI Services overview.

- For additional planning, installation, configuration, troubleshooting, development, or other UDDI Services resources, see UDDI Enterprise Services at Microsoft Web site.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# E-mail Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**E-mail Services**
With E-mail Services, you can install components on your computer to configure it as a mail server. E-mail Services includes the Post Office Protocol 3 (POP3) service and the Simple Mail Transfer Protocol (SMTP) service, which retrieve and transfer e-mail, respectively. To provide e-mail services to users, such as sending and receiving e-mail, administrators can create mailboxes on the server.

This section covers:

- Simple Mail Transfer Protocol (SMTP) service
- POP3 Service

# Simple Mail Transfer Protocol (SMTP) service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Simple Mail Transfer Protocol (SMTP) service**
The Simple Mail Transfer Protocol (SMTP) service, which transfers e-mail, is installed as part of E-mail Services, along with the POP3 service.

SMTP controls how e-mail is transported and then delivered across the Internet to the destination server. The SMTP service sends and receives e-mail between servers, whereas the POP3 service retrieves e-mail from the mail server to the user's computer. For more information, see the SMTP documentation Microsoft SMTP Service.

For more information about configuring the SMTP service for use with the POP3 service, see Simple Mail Transfer Protocol (SMTP) and Configure the Simple Mail Transfer Protocol Service.

**Managing the SMTP service**
You can manage the SMTP service from the Internet Information Services (IIS) Microsoft Management Console (MMC) snap-in. To open the IIS snap-in, click **Start**, and then click **Run**. In **Open**, type **inetmgr**, and then click **OK**. If the IIS snap-in does not appear, verify that you have installed IIS.

# POP3 Service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**POP3 service**
The POP3 service is an e-mail service that retrieves e-mail. Administrators can use the POP3 service to store and manage e-mail accounts on the mail server.

When the POP3 service is installed on the mail server, users can connect to the mail server and retrieve and download e-mail to their local computer using an e-mail client that supports the POP3 protocol (such as Microsoft Outlook). The POP3 service is used with the Simple Mail Transfer Protocol (SMTP) service, which sends outgoing e-mail.

- Before proceeding, see Checklist: Installing and configuring the POP3 service.
- For tips about using the POP3 service, see Best practices for POP3 service.
- For help with specific tasks, see How To... For E-Mail Services.
- For general background information, see E-mail Services Concepts.
- For problem-solving instructions, see Troubleshooting E-mail services.

# Checklist: Installing and configuring the POP3 service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Installing and configuring the POP3 service**

| Step | Reference |
|---|---|
| Read recommended topics. | Best practices for POP3 service;<br><br>POP3 service overview;<br><br>E-mail concepts;<br><br>Name resolution for TCP/IP |
| Choose and configure the mail server running the POP3 service with a Domain Name System (DNS) name. It is recommended that you choose a name that reflects the role of the server, such as mailserver1. | Rename a computer |
| Contact your Internet Service Provider (ISP). | Contacting your Internet Service Provider |
| Configure TCP/IP for static addressing on the mail server on which the POP3 service is installed. | Configure TCP/IP for static addressing |
| Install the POP3 service. | Install e-mail services |
| Read "POP3 service authentication methods" and determine which method is best for your deployment. | POP3 Service Authentication Methods |
| Configure the POP3 service to use the authentication method you have chosen. | Set the authentication method |
| Create a domain. | Create a domain |
| Create a mailbox. | Create a mailbox |
| Configure all e-mail clients to use the POP3 service. In addition, if you are using Secure Password Authentication (SPA), you should now configure your e-mail clients to use SPA. | Configure E-mail Clients |
| Manage your mail server. | POP3 service administration tools |

# Best practices for POP3 service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Set the mail store on a volume other than the one on which the operating system is installed.**

- Because the mail store can potentially use large amounts of disk space, you should either set a disk quota limit on the volume of the mail store (to control its disk space usage) or set it to use a volume other than the one where the operating system is installed. This will prevent the possibility of the operating system running out of disk space if the mail store becomes too large. For more information, see Set the mail store. For more information on disk quotas, see Configuring disk quotas for the POP3 service.

**Set the Badmail directory on a volume other than the one on which the operating system is installed.**

- When an e-mail is undeliverable, the Simple Mail Transfer Protocol (SMTP) service returns it to the sender with a non-delivery report (NDR). If the NDR cannot be delivered to the sender, a copy of the message is put in the Badmail directory. To prevent the possibility of the operating system running out of disk space (if the Badmail directory becomes too large), you must move the SMTP Badmail directory to a volume other than the one on which the operating system is installed.

**Use an NTFS file system partition for the mail store and implement disk quotas.**

- NTFS file system partitions provide greater directory and folder security. This enhances the protection of e-mail stored on the local hard disk.

- Disk quotas can prevent the mail store from using an excessive or unanticipated amount of disk space. This is important because excessive or unanticipated use of disk space can adversely affect the performance of the server on which the POP3 service is running.

**Allocate adequate disk space for the mail store.**

- To ensure that you allocate adequate disk space for the mail store, estimate the amount of disk space it will need based on the number of users on the server, the volume of e-mail they will receive, and the average size of the e-mail they will receive.

**Use strong passwords to protect your mail server.**

- Strong passwords protect your mail server from unauthorized access. For more information about passwords, see Strong passwords.

# How To... For E-Mail Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Set Up the POP3 Service
- Change Service Settings
- Manage E-mail Domains
- Manage Mailboxes
- Configure the Simple Mail Transfer Protocol Service
- Configure E-mail Clients

# Set Up the POP3 Service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up the POP3 service**

- Install e-mail services
- Set the authentication method
- Set the mail store

# Install e-mail services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install e-mail services**

1. Open Add or Remove Programs.
2. Click **Add/Remove** Windows **Components**.
3. Scroll down and select the **E-mail Services** check box.
4. Click **Next**, and then complete the wizard.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Add or Remove programs, click **Start**, click **Control Panel**, and then double-click **Add or Remove programs**.
- You can also install e-mail services using the Configure Your Server Wizard. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Set Up the POP3 Service

Mail server role: Configuring a mail server

# Set the authentication method

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the authentication method**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. In the console tree, right-click the *computer_name* node and click **Properties**.

   **Where?**

   - POP3 Service/*computer_name*

3. In **Authentication Method**, click the drop-down menu, and then click the authentication method you want to use.

### Important

- You can change the authentication method only if there are no existing domains defined. If there are existing domains, the option to change the authentication method is disabled.

  If you change this parameter, you must stop and restart the POP3 service and the IIS Admin service. For more information on how to change the POP3 service state and start and stop the IIS Admin service, see Related Topics.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- If the computer on which the POP3 service is running is either a member of an Active Directory domain or a domain controller, the default authentication method is Active Directory integrated authentication. If the computer is not in a domain, the default is local Windows accounts authentication.
- If the computer on which the POP3 service is running is a domain controller, the available authentication methods are Active Directory integrated authentication and encrypted password file authentication. If the computer on which the POP3 service is running is a member server in an Active Directory domain, all three authentication methods are available. Otherwise, the available authentication methods are local Windows accounts authentication and encrypted password file authentication.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

**Using a command line**

1. Open Command Prompt.

2. Type:

   **winpop set** {**authentication**|**auth**} {**1**|**2**|**3**}

| Value | Description |
|---|---|
| **winpop set** {**authentication**\|**auth**} | Sets the type of authentication to be used by the POP3 service. The **auth** command provides the same functionality as **authentication**. |
| {**1**\|**2**\|**3**} | Specifies the authentication method POP3 uses to verify users who connect to the mail server. The available authentication methods vary, depending on the configuration of your server.<br>● If the computer on which the POP3 service is running is an Active Directory domain controller, the values are as follows:<br>**1** - Active Directory integrated authentication<br>**2** - Encrypted password file authentication<br>● If the computer on which the POP3 service is running is an Active Directory member server, the values are as follows:<br>**1** - Active Directory integrated authentication<br>**2** - Local Windows accounts authentication<br>**3** - Encrypted password file authentication<br>● Otherwise, the following values apply:<br>**1** - Local Windows accounts authentication<br>**2** - Encrypted password file authentication |

**Important**

- You can change the authentication method only if there are no existing domains defined. If there are existing domains, the option to change the authentication method is disabled.

  If you change this parameter, you must stop and restart the POP3 service and the IIS Admin service. For more information on how to change the POP3 service state and start and stop the IIS Admin service, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- If the computer on which the POP3 service is running is either a member of an Active Directory domain or a domain controller, the default authentication method is Active Directory integrated authentication. If the computer is not in a domain, the default is local Windows accounts authentication.

- If the computer on which the POP3 service is running is an Active Directory domain controller, the available authentication methods are Active Directory integrated authentication and encrypted password file authentication. If the computer on which the POP3 service is running is a member server in an Active Directory domain, all three authentication methods are available. Otherwise, the available authentication methods are local Windows accounts authentication and encrypted password file authentication.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

- To view the complete syntax for this command, at a command prompt, type:

  **winpop set help**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set the mail store

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the mail store**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. In the console tree, right-click the *computer_name* node, and then click **Properties**.

   **Where?**

   - POP3 Service/*computer_name*

3. In **Root Mail Directory**, type the path to the mail store; for example, C:*mailstore*. The maximum value is 260 characters.

**Important**

- If you change this parameter, you must stop and restart the POP3 service and the IIS Admin service. For more information on how to change the POP3 service state and start and stop the IIS Admin service, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- You cannot set the mail store to the root directory of the hard disk, for example C:\, or to a directory in which files are currently in use.
- It is recommended that you locate the mail store on a NTFS file system partition.
- The default mail store is *system_drive*:\Inetpub\mailroot\Mailbox.
- The mail store must be a directory on the local file system or a Universal Naming Convention (UNC) path; mapped drives are not supported.
- If you change the mail store from its default location or from a previous location, and there is stored e-mail, you must manually move the folders in which the e-mail is stored to the new location.
- If you transfer the mail store to a new directory, you must move the mail store directory to ensure the directory retains the correct ownership; copying the mail store will not work.
- If you move the mail store to a new location or restore it from a backup, you must reset the permissions on the directory

using the **winpop set mailroot** command.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

- Because the mail store can potentially use large amounts of disk space, you should either set a disk quota limit on the volume of the mail store (to control its disk space usage) or set it to use a volume other than the one where the operating system is installed. This will prevent the possibility of the operating system running out of disk space if the mail store becomes too large. For more information on disk quotas, see Configuring disk quotas for the POP3 service.

**Using a command line**

1. Open Command Prompt.

2. Type:

   **winpop set mailroot***path_to_mail_store*

| Value | Description |
|---|---|
| **winpop set mailroot** | Sets the mail store for the server. |
| *path_to_mail_store* | Specifies a directory on the local file system or a Universal Naming Convention (UNC) path. The maximum allowable value is 260 characters. |

**Important**

- If you change this parameter, you must stop and restart the POP3 service and the IIS Admin service. For more information on how to change the POP3 service state and start and stop the IIS Admin service, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You cannot set the mail store to the root directory of the hard disk (for example C:\), or to a directory in which files are currently in use.

- It is recommended that you locate the mail store on a NTFS file system partition.

- The default mail store is *system_drive*:\Inetpub\mailroot\Mailbox.

- The mail store must be a directory on the local file system or a Universal Naming Convention (UNC) path; mapped drivers are not supported.

- If you change the mail store from its default or from a previous location, and there is stored e-mail, you must manually move the folders in which the e-mail is stored to the new location.

- If you move the mail store to a new location or restore it from a backup, you must reset the permissions on the directory using the **winpop set mailroot** command.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local

computer, to perform this procedure.

- To view the complete syntax for this command, at a command prompt, type:

  **winpop set help**

- Because the mail store can potentially use large amounts of disk space, you should either set a disk quota limit on the volume of the mail store (to control its disk space usage) or set it to use a volume other than the one where the operating system is installed. This will prevent the possibility of the operating system running out of disk space if the mail store becomes too large. For more information on disk quotas, see Configuring disk quotas for the POP3 service.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change Service Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Change service settings**

- Configure the mail server to require Secure Password Authentication
- Change the POP3 service state
- Set the port
- Set the event logging level
- Set the number of sockets
- Set the number of threads
- Connect to a remote server running the POP3 service

# Configure the mail server to require Secure Password Authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure the mail server to require Secure Password Authentication**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. In the console tree, right-click the *computer_name* node and click **Properties**.

   **Where?**

   - POP3 Service/*computer_name*

3. Select **Require Secure Password Authentication (SPA) for all client connections**.

### Important

- If you change this parameter, you must stop and restart the POP3 service. For more information on changing the POP3 service state, see Related Topics.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- SPA supports only Active Directory integrated authentication and local Windows accounts authentication.
- If you enable SPA, users' e-mail clients must also be configured to use SPA. For more information, see Related Topics.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.
- Configuring the mail server to require Secure Password Authentication affects only the POP3 service and not the Simple Mail Transfer Protocol (SMTP) service.

**Using a command line**

1. Open Command Prompt.
2. Type:

**winpop set sparequired** {**0**|**1**}

| Value | Description |
|---|---|
| **winpop set sparequired** | Specifies whether Secure Password Authentication is required for all client connections. |
| {**0**\|**1**} | Specifies whether secure authentication is required from all e-mail clients.<br><br>The default is 0, which specifies that SPA is not required. 1 requires SPA from all e-mail clients and prevents e-mail clients from authenticating by using plaintext authentication. |

**Important**

- If you change this parameter, you must stop and restart the POP3 service. For more information on changing the POP3 service state, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- SPA supports only Active Directory integrated authentication and local Windows accounts authentication.
- If you enable SPA, users' e-mail clients must also be configured to use SPA. For more information, see Related Topics.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.
- To view the complete syntax for this command, at a command prompt, type:

  **winpop set help**

- Configuring the mail server to require Secure Password Authentication affects only the POP3 service and not the Simple Mail Transfer Protocol (SMTP) service.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the POP3 service state

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the POP3 service state**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. In the console tree, right-click *ComputerName*, point to **All Tasks**, and then click the state you want, as described in the table.

   **Where?**

   - POP3 Service/*computer_name*

| Service state | Description |
|---|---|
| Start | Starts the POP3 service from a stopped or paused state and allows POP3 clients to connect to the mail server and retrieve e-mail. |
| Stop | Stops the POP3 service. All current connections are terminated. |
| Pause | Pauses the POP3 service so that no new connections will be accepted. Existing connections are not affected. |
| Resume | Resumes the POP3 service from a paused state to allow POP3 clients to connect to the server and retrieve e-mail. |
| Restart | Restarts the POP3 service. All current connections are terminated. |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **net** {**start**|**stop**} **pop3svc**

| Value | Description |
| --- | --- |
| **net** {**start**\|**stop**} | Starts or stops a service. |
| **pop3svc** | Specifies the POP3 service. |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

- To view the complete syntax for this command, at a command prompt, type:

  **net start /help**

  **net stop /help**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set the port

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To set the port

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open POP3 service.
2. In the console tree, right-click the *computer_name* node and click **Properties**.

   **Where?**

   - POP3 Service/*computer_name*

3. In **Server Port**, type an appropriate port number from 1 to 65535.

### Important

- If you change this parameter, you must stop and restart the POP3 service. For more information on changing the POP3 service state, see Related Topics.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- The port used by the POP3 service is configured by default to 110, the Internet standard for the POP3 protocol. If you change the port from 110, you must notify users to configure their e-mail clients to reflect the change.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **winpop set port***port_number*

| Value | Description |
|---|---|

| | |
|---|---|
| **winpop set port** | Sets the port that POP3 service monitors for clients. |
| *port_number* | Specifies any valid port number from 1 to 65535. |

**Important**

- If you change this parameter, you must stop and restart the POP3 service. For more information on changing the POP3 service state, see Related Topics.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

- The port used by the POP3 service is configured by default to 110, the Internet standard for the POP3 protocol. If you change the port from 110, you must notify users to configure their e-mail clients to reflect the change.

- To view the complete syntax for this command, at a command prompt, type:

# Set the event logging level

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the event logging level**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. In the console tree, right-click the *computer_name* node, and then click **Properties**.

   **Where?**

   - POP3 Service/*computer_name*

3. In **Logging level**, click the drop-down menu, and then click the logging level you want, as described in the following table.

| POP3 event logging level | Description |
|---|---|
| None | No events are logged. |
| Low | Only critical events are logged. |
| Medium | Critical and warning events are logged. |
| High | Critical, warning, and informational events are logged. |

**Important**

- If you change this parameter, you must stop and restart the POP3 service and the IIS Admin service. For more information on how to change the POP3 service state and manage the IIS Admin service, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

**Using a command line**

1. Open Command Prompt.

2. Type:

   **winpop set logging** {**0**|**1**|**2**|**3**}

| Value | Description |
|---|---|
| **winpop set logging** | Sets the event logging level for the POP3 service. For example, to log only critical events type: **winpop set logging 1**. |
| {**0**\|**1**\|**2**\|**3**} | Specifies the level at which events are logged.<br><br>**0** - No events are logged.<br><br>**1** - Only critical events are logged.<br><br>**2** - Critical and warning events are logged.<br><br>**3** - Critical, warning, and informational events are logged. |

**Important**

- If you change this parameter, you must stop and restart the POP3 service and the IIS Admin service. For more information on how to change the POP3 service state and manage the IIS Admin service, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

# Set the number of sockets

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the number of sockets**

1. Open Command Prompt.
2. Type:

   **winpop set socketmin** *number_of_sockets*

   or

   **winpop set socketmax***number_of_sockets*

   or

   **winpop set socketthreshold***number_of_sockets*

   or

   **winpop set socketbacklog***number_of_sockets*

   or

   **winpop set socket***socketbacklog socketmax socketmin socketthreshold*

| Variable | Description | Numeric value for ***number_of_sockets*** |
|---|---|---|
| **winpop set socketmin** | Sets the minimum number of sockets that the POP3 service can create (*socketmin*). The default setting is 10. | The value of *number_of_sockets* for this parameter must be from 1 to 32,000 and less than *socketmax*. |
| **winpop set socketmax** | Sets the maximum number of sockets the service can create (*socketmax*). Once *socketmax* has been reached, any new connection attempts are held in a queue (determined by *socketbacklog*) until an existing connection is disconnected. The default value is 50. | The value of *number_of_sockets* for this parameter must be from 1 to 32,000 and greater than *socketmin* + *socketthreshold*. |
| **winpop set socketthreshold** | Sets the number of new sockets that the POP3 service can create at a time. Once *socketmin* is reached, *n* number of new sockets are created (if there are still remaining sockets available), where *n* is the value of *socketthreshold*. | The value of *number_of_sockets* for this parameter must be from 1 to 99, or 0 if *socketmin* = *socketmax*. |
| **winpop set socketbacklog** | Sets the number of connections that are held in a queue once *socketmax* has been reached (determined by *socket backlog*). Connection requests that occur after *socketmax* has been reached, and are less than *socketmax*+*socketbacklog*, are accepted, but do not receive any response until a new socket becomes available. Once *socketbacklog* is filled, new connection attempts are denied. | The value of *number_of_sockets* for this parameter must be from 0 to 100. |

| | | |
|---|---|---|
| **winpop set socket** | Sets all the socket values. You must provide a numeric value for each of the four four variables. | Each numeric value should follow the specifications for each variable, as described previously in this table; for example, **winpop set socket 5 40 10 5**. |

**Important**

- Do not change these parameters unless it is necessary to do so. Changing these parameters can adversely affect the performance of the POP3 service.

- If you change these parameters, you must stop and restart the POP3 service. For more information on changing the POP3 service state, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

# Set the number of threads

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the number of threads**

1. Open Command Prompt.
2. Type:

   **winpop set threadcount***number_of_threads*

| Value | Description |
|---|---|
| **winpop set threadcount** | Sets the number of threads for the POP3 service. This value is based on the number of CPUs that are installed on the computer on which the POP3 service is running. |
| *number_of_threads* | Specifies the number of CPUs installed on the computer on which the POP3 service is running. This value must be from 1 to 32. |

**Important**

- Do not change this parameter unless it is necessary to do so. Changing this parameter can adversely affect the performance of the POP3 service.
- If you change this parameter, you must stop and restart the POP3 service. For more information on changing the POP3 service state, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. # Connect to a remote server running the POP3 service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to a remote server running the POP3 service**

1. Open POP3 service.
2. In the console tree, right-click **POP3 Service**, and then click **Connect**.
3. Do one of the following:
   - In **Server Name**, type the name of the computer to which you want to connect, and then click **OK**.
   - Or, click **Browse** to view the list of computers available on your network, select the appropriate computer, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, point to **Administrative Tools**, and then click **POP3 Service**.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.
- To connect to a remote mail server running the POP3 service, your computer must also have the POP3 service installed and be on the same local network.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a domain**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. In the console tree, right-click the *computer_name* node, point to **New**, and then click **Domain**.

   **Where?**

   - POP3 Service/*computer_name*

3. In **Domain name**, type the name of the domain to be created, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- Contact your Internet Service Provider (ISP) for domain naming requirements and conventions. For information about this, see Related Topics.
- The POP3 service supports top-level and third-level domain names. For example, example.com and mailserver.example.com are both supported.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **winpop add***domain_name*

| Value | Description |
|---|---|
| **winpop add** | Creates a new domain and adds it to the existing POP3 service directory structure. |

| | |
|---|---|
| *domain_name* | Specifies the name of the domain you want to create, for example, *example.com*. |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- Contact your Internet Service Provider (ISP) for domain naming requirements and conventions. For information about this, see Related Topics.
- The POP3 service supports top-level and third-level domain names. For example, example.com and mailserver.example.com are both supported.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.
- To view the complete syntax for this command, at a command prompt, type:

  **winpop help**

# Delete a domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a domain**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. In the console tree, click *ComputerName*, right-click the domain you want to delete, and then click **Delete**.
3. When the confirmation box appears, click **Yes** to delete the domain, all of the mailboxes stored in that domain, and all mail stored in that domain.

### Caution

- Deleting a domain will delete all of the mailboxes in that domain, the corresponding mail store directories, and all e-mail stored in those directories.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- You cannot delete a domain while a user in that domain is connected to the server running the POP3 service.
- If you are using local Windows accounts or Active Directory integrated authentication, and you have created user accounts, the user accounts are not deleted when the corresponding mailboxes are deleted.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **winpop delete***domain_name*

| Value | Description |
|---|---|
| **winpop delete** | Deletes an existing domain. |

| | |
|---|---|
| *domain_name* | Specifies the name of the domain you want to delete, for example, *example.com*. |

**Caution**

- Deleting a domain will delete all of the mailboxes in that domain, the corresponding mail store directories, and all e-mail stored in those directories.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- If you are using local Windows accounts or Active Directory integrated authentication, and you have created user accounts, the user accounts are not deleted when their corresponding mailboxes are deleted.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

- To view the complete syntax for this command, at a command prompt, type:

  **winpop help**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# List domains

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To list domains**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. In the console tree, click the *computer_name* node. All domains on that server appear in the details pane.

   **Where?**

   - POP3 Service\computer_name

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, point to **All Programs**, point to **Administrative Tools**, and then click **POP3 Service**.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **winpop list**

| Value | Description |
|---|---|
| **winpop list** | Lists all POP3 service domains. |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local

computer, to perform this procedure.

- To view the complete syntax for this command, at a command prompt, type:

  **winpop help**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Lock a domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To lock a domain

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open POP3 service.
2. In the console tree, click the *computer_name* node.

   **Where?**

   - POP3 Service/*computer_name*

3. In the details pane, right-click the domain you want to lock, and then click **Lock**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- When you lock a domain, you prevent all members of the domain from retrieving their e-mail. Incoming e-mail for the domain is still received and delivered to the appropriate mailbox directory in the mail store. The service will also continue to send outgoing mail.
- When a domain is locked, individual mailboxes cannot be unlocked; the entire domain must be unlocked.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **winpop lock***domain_name*

| Value | Description |
|---|---|
| **winpop lock** | Locks all mailboxes in a domain, which prevents users from downloading mail using the POP3 service. |

| | |
|---|---|
| *domain_name* | Specifies the domain you want to lock; for example, example.com |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- When you lock a domain, you prevent all members of the domain from retrieving their e-mail. Incoming e-mail for the domain is still received and delivered to the appropriate mailbox directory in the mail store. The service will also continue to send outgoing mail.

- When a domain is locked, individual mailboxes cannot be unlocked; the entire domain must be unlocked.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

- To view the complete syntax for this command, at a command prompt, type:

  **winpop help**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Unlock a domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To unlock a domain**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. In the console tree, click the *computer_name* node to display the list of domains.

   **Where?**

   - POP3 Service/*computer_name*

3. In the details pane, right-click the locked domain you want to unlock, and then click **Unlock**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- When a domain is locked, individual mailboxes cannot be unlocked; the entire domain must be unlocked.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **winpop unlock***domain_name*

| Value | Description |
|---|---|
| **winpop unlock** | Unlocks a locked domain to permit users to download e-mail again using the POP3 service. |
| *domain_name* | Specifies the name of the domain that you want to unlock, for example, *example.com* |

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group

might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- When a domain is locked, individual mailboxes cannot be unlocked; the entire domain must be unlocked.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

- To view the complete syntax for this command, at a command prompt, type:

  **winpop help**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View domain statistics

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view domain statistics**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. In the console tree, click the domain you for which you want to view statistics.

   **Where?**

   - POP3 Service/*computer_name/domain_name*

   The domain statistics appear in the details pane.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- Depending on the number of domains and mailboxes on the server running the POP3 service, this procedure might require considerable CPU resources.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **winpop stat**

| Value | Description |
|---|---|
| **winpop stat** | Displays statistics for the domain, including total number of mailboxes in the domain, lock/unlock status of the domain, total number of messages, and disk usage. |

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group

might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- Depending on the number of domains and mailboxes on the server running the POP3 service, this procedure might require considerable CPU resources.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

- To view the complete syntax for this command, at a command prompt, type:

  **winpop help**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Mailboxes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage mailboxes**

- Create a mailbox
- Delete a mailbox
- List mailboxes
- Lock a mailbox
- Unlock a mailbox
- Change a password
- View mailbox statistics
- Create a quota file
- Migrate an encrypted password file user account to an Active Directory user account

# Create a mailbox

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a mailbox**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. In the console tree, click the *computer_name* node.

   **Where?**

   - POP3 Service/*computer_name*

3. In the details pane, right-click the domain in which you want to create a new mailbox, point to **New**, and then click **Mailbox**.
4. Check the **Create associated user for this mailbox** box if you are using local Windows accounts authentication or Active Directory integrated authentication, unless a user account already exists with the same name as the mailbox you want to create. If the check box is already selected, clear it only if an account already exists with the same name as the mailbox you want to create.
5. In **Mailbox Name**, type a name for the mailbox.
6. In **Password**, type the password for the mailbox, and then retype it in **Confirm Password**.

**Important**

- If you are using Active Directory integrated authentication and have multiple POP3 e-mail domains, when creating mailboxes, you should consider whether the mailbox you are creating has the same name as an existing mailbox in another POP3 e-mail domain.

  Each mailbox is associated with an Active Directory user account, which has both a user logon name and pre-Windows 2000 user logon name. The user logon name is the name of the Active Directory user account and the POP3 mailbox. Usually, the pre-Windows 2000 user logon name is the same as the user logon name. If you try to create a mailbox and user account when an existing user account has the same pre-Windows 2000 user logon name, a naming conflict will occur.

  Active Directory does not support multiple accounts with the same pre-Windows 2000 user logon name. If there is a naming conflict, the mailbox name and e-mail address will not be affected, but the account's pre-Windows 2000 logon name will be modified to prevent any naming conflict with the existing account. If you are using Secure Password Authentication and a naming conflict has occurred, the pre-Windows 2000 logon name must be used for e-mail client authentication.

  To determine the modified logon name, go to the **Active Directory Users and Computers** snap-in located in the **Administrative Tools** menu. Go to the **Users** folder, right-click the user account and then click **Properties**. Click the **Account** tab and the modified account name will be displayed in **User logon name (pre-Windows 2000)**. You must note the pre-Windows 2000 logon name and provide it to the user. For more information about configuring e-mail

clients to use Secure Password Authentication, see Related Topics.

- Depending on your authentication method, certain characters are not allowed in mailbox names. Periods are allowed, but they must not be either leading or trailing. The following example illustrates the correct use of a period:

  john.someone@example.com

  The following table lists the characters that are prohibited for each type of authentication.

| Authentication method | Prohibited characters |
|---|---|
| Active Directory integrated authentication | @ ( ) / \ [ ] : ; , " < > * = \| ? + |
| Local Windows accounts authentication | @ ( ) / \ [ ] : ; , " < > * = \| ? + |
| Encrypted password file authentication | @ ( ) / \ [ ] : ; , " < > * = \| ? |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.

- The **Create associated user for this mailbox** option is only available if the server is using Active Directory integrated authentication or local Windows accounts authentication.

- The maximum length for a mailbox name is 20 characters for local Windows accounts authentication and 64 characters for encrypted password file authentication or Active Directory integrated authentication. The minimum length is 1 character.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

**Using a command line**

1. Open Command Prompt.

   - If you are using Active Directory integrated authentication or local Windows accounts authentication, type:

     **winpop add***username@domain_name* [**/createuser:***new_user's_password*]

   - If you are using encrypted password file authentication, type:

     **winpop add***username@domain_name***/createuser:***new_user's_password*

| Value | Description |
|---|---|
| **winpop add** | Creates a mailbox in the domain. |
| *username@domain_name* | Specifies the user name for the corresponding mailbox and domain name in which to create the mailbox. |

| | |
|---|---|
| **/createuser** | Creates a corresponding user in the Active Directory or local computer.<br><br>If you are using Active Directory integrated or local Windows accounts authentication, you must use this command when creating a mailbox, unless a user account exists already with the same as the mailbox you want to create.<br><br>If you are using encrypted password file authentication, **/createuser** is still required even though a user account is not created. If you have configured your server with this option as a default, this parameter will have no effect. |
| *new_user's_password* | Specifies the password that will be used to access the mailbox. |

**Important**

- If you are using Active Directory integrated authentication and have multiple POP3 e-mail domains, when creating mailboxes, you should consider whether the mailbox you are creating has the same name as an existing mailbox in another POP3 e-mail domain.

  Each mailbox is associated with an Active Directory user account, which has both a user logon name and pre-Windows 2000 user logon name. The user logon name is the name of the Active Directory user account and the POP3 mailbox. Usually, the pre-Windows 2000 user logon name is the same as the user logon name. If you try to create a mailbox and user account when an existing user account has the same pre-Windows 2000 user logon name, a naming conflict will occur.

  Active Directory does not support multiple accounts with the same pre-Windows 2000 user logon name. If there is a naming conflict, the mailbox name and e-mail address will not be affected, but the account's pre-Windows 2000 logon name will be modified to prevent any naming conflict with the existing account. If you are using Secure Password Authentication and a naming conflict has occurred, the pre-Windows 2000 logon name must be used for e-mail client authentication.

  To determine the modified logon name, go to the **Active Directory Users and Computers** snap-in located in the **Administrative Tools** menu. Go to the **Users** folder, right-click the user account and then click **Properties**. Click the **Account** tab and the modified account name will be displayed in **User logon name (pre-Windows 2000)**. You must note the pre-Windows 2000 logon name and provide it to the user. For more information about configuring e-mail clients to use Secure Password Authentication, see Related Topics.

- Depending on your authentication method, certain characters are not allowed in mailbox names. Periods are allowed, but they cannot be either leading or trailing. The following example illustrates the correct use of a period:

  john.someone@example.com

  The following table lists the characters that are prohibited for each type of authentication.

| **Authentication method** | **Prohibited characters** |
|---|---|
| Active Directory integrated authentication | @ ( ) / \ [ ] : ; , " < > * = \| ? + |
| Local Windows accounts authentication | @ ( ) / \ [ ] : ; , " < > * = \| ? + |
| Encrypted password file authentication | @ ( ) / \ [ ] : ; , " < > * = \| ? |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- The maximum length for a mailbox name is 20 characters for local Windows accounts authentication and 64 characters for encrypted password file authentication or Active Directory integrated authentication. The minimum length is 1 character.

- To view the complete syntax for this command, at a command prompt, type:

  **winpop help**

# Delete a mailbox

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To delete a mailbox

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open POP3 service.
2. In the console tree, click the domain containing the mailbox you want to delete.

   **Where?**

   - POP3 Service/*computer_name*/*domain_name*

3. In the details pane, right-click the mailbox you want to delete, and then click **Delete**.
4. If the mailbox has an associated Active Directory or local Windows accounts user, a dialog box appears. To delete the user account from the Active Directory or local computer Security Accounts Manager (SAM), select **Also delete the user account associated with this mailbox**.

### Caution

- Deleting a mailbox deletes the mail store directory for the mailbox and all e-mail that is stored in that directory.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **winpop delete** *username@domain_name* **/deleteuser**

| Value | Description |
|---|---|

| | |
|---|---|
| **winpop delete** | Deletes a mailbox from a domain.<br><br>If there is a corresponding user in the Active Directory or local computer Security Accounts Manager (SAM), a prompt appears, confirming the deletion of the user entry in addition to the mailbox. |
| *username@domain_name* | Specifies the mailbox name at the corresponding domain, for example, someone@example.com. |
| **/deleteuser** | Deletes the corresponding user from the Active Directory or SAM. |

**Caution**

- Deleting a mailbox deletes the mail store directory for the mailbox and all e-mail that is stored in that directory.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

- To view the complete syntax for this command, at a command prompt, type:

  **winpop help**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# List mailboxes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To list mailboxes**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. In the console tree, click the appropriate domain. The list of mailboxes appears in the details pane.

   **Where?**

   - POP3 Service/*computer_name*/*domain_name*

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **winpop list***domain_name*

| Value | Description |
|---|---|
| **winpop list** | Lists all mailboxes in the domain. |
| *domain_name* | Specifies the name of the domain for which you want a mailbox list, such as: example.com. |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

- To view the complete syntax for this command, at a command prompt, type:

  **winpop help**

# Lock a mailbox

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To lock a mailbox**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. To display the list of mailboxes, in the console tree, click the appropriate domain.

   **Where?**

   - POP3 Service/*computer_name*/*domain_name*

3. In the details pane, right-click the mailbox you want to lock, and then click **Lock**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- When a mailbox is locked, it continues to receive incoming e-mail, which is delivered to the mail store. The user is unable to connect to the server and retrieve e-mail, however.
- While a mailbox is locked, the only restriction is that the user cannot connect to the server. An administrator can still perform all administrative tasks, such as deleting a mailbox or changing the password for a mailbox.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **winpop lock***username@domain_name*

| Value | Description |
|---|---|
| **winpop lock** | Locks the specified mailbox account to prevent the user from retrieving e-mail. |

| | |
|---|---|
| *username@domain_name* | The mailbox account that you want to lock; for example, someone@example.com |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

- When a mailbox is locked, it continues to receive incoming e-mail, which is delivered to the mail store. The user is unable to connect to the server and retrieve e-mail, however.

- While a mailbox is locked, the only restriction is that the user cannot retrieve e-mail from the mail server. An administrator can still perform all administrative tasks, such as deleting a mailbox or changing the password for a mailbox.

- To view the complete syntax for this command, at a command prompt, type:

  **winpop help**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Unlock a mailbox

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To unlock a mailbox**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. In the console tree, click the appropriate domain to display the list of mailboxes.

   **Where?**

   - POP3 Service/*computer_name*/*domain_name*

3. In the details pane, right-click the mailbox you want to unlock, and then click **Unlock**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- If an individual mailbox is locked because it is part of a locked domain, you cannot unlock it.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **winpop unlock***username@domain_name*

| Value | Description |
|---|---|
| **winpop unlock** | Unlocks the specified mailbox account if it has been previously locked. |
| *username@domain_name* | Specifies the mailbox account that you want to unlock. |

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group

might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- If an individual mailbox is locked because it is part of a locked domain, you cannot unlock it.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.
- To view the complete syntax for this command, at a command prompt, type:

  **winpop help unlock**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change a password

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change a password**

1. Open Command Prompt.

2. Type:

   **winpop changepwd***username@domain_namenew_password*

| Value | Description |
|---|---|
| **winpop changepwd** | Changes the password of a mailbox account. |
| *username@domain_name* | Specifies the mailbox account for the password you want to change. |
| *new_password* | Specifies the new password for the mailbox account you want to change |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- Depending on your authentication method there are other ways you can change a user's password.

  If you are using Active Directory integrated authentication you can use the Active Directory Users and Computers snap-in to change a user's password.

  If you are using local Windows accounts authentication you can use the Computer Management snap-in to change a user's password.

  For more information, see Related Topics.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

- To view the complete syntax for this command, at a command prompt, type:

  **winpop help**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View mailbox statistics

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view mailbox statistics**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open POP3 service.
2. In the console tree, click the appropriate domain.

   **Where?**

   - POP3 Service/*computer_name*/*domain_name*

   Mailbox statistics appear in the details pane.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **winpop stat***domain_name*

| Value | Description |
|---|---|
| **winpop stat** | Displays statistics for the domain, including the number of messages in account, the lock/unlock status of the mailbox, size of account, and whether the user is currently connected. |
| *domain_name* | Specifies the domain that you want to view statistics for, for example, *example.com*. |

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

# Create a quota file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a quota file**

1. Open Command Prompt.

2. Type:

   **winpop createquotafile***username@domain* [**/user:***username*]

| Value | Description |
|---|---|
| **winpop createquotafile** | Specifies to create a quota file. |
| *username@domain* | Specifies the user for which a quota file should be created. |
| **/user:** *username* | Specifies to use an existing user account's quota file as a reference to create the quota file. |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.

- If you are using Active Directory integrated authentication or local Windows accounts authentication, a quota file is created by default when a mailbox is created.

- To view the complete syntax for this command, at a command prompt, type:

  **winpop help**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Migrate an encrypted password file user account to an Active Directory user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To migrate an encrypted password file user account to an Active Directory user account**

1. Open Command Prompt.
2. Type:

   **winpop migrateToAD***UserName@DomainName*

| Value | Description |
|---|---|
| **winpop migrateToAD** | Migrates an encrypted password file user account to an Active Directory user account. The encrypted password file user account's password becomes the Active Directory user account's password. |
| *UserName@DomainName* | Specifies the existing encrypted password file user account. |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure.
- The user's mailbox is not migrated. For the new Active Directory user account to be able to send and receive e-mail, you must change the authentication method to Active Directory integrated authentication and create a new mailbox for the Active Directory user account.
- To view the complete syntax for this command, at a command prompt, type:

  **winpop help**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure the Simple Mail Transfer Protocol Service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure the Simple Mail Transfer Protocol service**

- Start or stop the Simple Mail Transfer Protocol service
- Configure the Simple Mail Transfer Protocol service for e-mail relaying
- Configure e-mail clients for e-mail relaying

# Start or stop the Simple Mail Transfer Protocol service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start or stop the Simple Mail Transfer Protocol service**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Services.
2. In the details pane, right-click **Simple Mail Transfer Protocol (SMTP)**, and then click the appropriate service state.

### Note

- To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **net** {**start**|**stop**} **smtpsvc**

| Value | Description |
|---|---|
| **net** {**start**\|**stop**} | Starts or stops a service. |
| **smtpsvc** | Specifies the Simple Mail Transfer Protocol (SMTP) service. |

### Notes

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- To view the complete syntax for this command, at a command prompt, type:

  **net** {**start**|**stop**} **/?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure the Simple Mail Transfer Protocol service for e-mail relaying

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure the Simple Mail Transfer Protocol service for e-mail relaying**

1. To open Internet Information Services (IIS), click **Start**, click **Run**, type **inetmgr**, and then click **OK**. If the Internet Information Services (IIS) snap-in does not appear, verify that you have installed IIS.

2. In the console tree, right-click **Default SMTP Virtual Server**, and then click **Properties**.

   **Where?**

   - Internet Information Services/*computer_name*/Default SMTP Virtual Server

3. Click **Access**, click **Authentication**, select **Integrated Windows Authentication**, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open IIS Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Internet Information Services (IIS) Manager**.

- This procedure is necessary only if you are using Active Directory integrated authentication or local Windows accounts authentication, and you want to enable e-mail relaying. If you are using encrypted password file authentication, see the topic on Simple Mail Transfer Protocol (SMTP) in Related Topics for information about e-mail relaying.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure e-mail clients for e-mail relaying

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure e-mail clients for e-mail relaying**

1. Click **Start**, point to **All Programs**, and then click **Outlook Express**.
2. Click **Tools**, and then click **Accounts**.
3. Click the **Mail** tab, click your POP3 service mail server, and then click **Properties**.
4. In **Outgoing Mail Server**, click **My server requires authentication**, click **Settings**, and then select **Log on using**.
5. In **Account name**, type the name of your POP3 mailbox without the domain. For example, if your mailbox is someone@example.com, you would type:

   **someone**

6. In **Password**, type the password for your POP3 mailbox, and then click **OK**.

## Notes

- For this procedure, you must use Active Directory integrated or local Windows accounts authentication. If you are using encrypted password file authentication and want to configure e-mail relaying, see the topic on Simple Mail Transfer Protocol (SMTP) in Related Topics.
- This procedure uses Outlook Express as an example. If you are not using Outlook Express, check the documentation for your e-mail client for information about configuring e-mail clients to authenticate to the Simple Mail Transfer Protocol (SMTP) service.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

- Configure Outlook Express for Secure Password Authentication

# Configure Outlook Express for e-mail services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure Outlook Express for e-mail services**

1. Click **Start**, point to **All Programs**, and then click **Outlook Express**.
2. On the **Tools** menu, click **Accounts**.
3. Click **Add**, and then click **Mail**.
4. Follow the instructions in the **Internet Connection Wizard** until you reach the **Internet Mail Logon** page.
5. In **Account name**, type your POP3 service user name, followed by the domain, for example, someone@example.com.
6. In **Password**, type the password associated with your POP3 service e-mail account.
7. If your mail server is configured to require SPA, select **Log on using Secure Password Authentication (SPA)**, and then complete the wizard.

### Important

- You must perform this procedure on e-mail clients that will use the POP3 service.

### Notes

- If you are using an e-mail client other than Outlook Express, see your product documentation for information about how to configure your e-mail client to use the user name and domain name.
- Be sure to update your e-mail client and client operating system with the latest service pack available.
- For additional information about configuring Outlook Express for Secure Password Authentication (SPA), see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Outlook Express for Secure Password Authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure Outlook Express for Secure Password Authentication**

1. Click **Start**, point to **All Programs**, and then click **Outlook Express**.
2. On the **Tools** menu, click **Accounts**.
3. In **Internet Accounts**, click the **Mail** tab, click the name of your POP3 e-mail account, and then click **Properties**.
4. Click the **Servers** tab, and then click **Log on using Secure Password Authentication**.
5. In **Account name**, type your POP3 service user name not including the domain. For example, if your e-mail address is someone@example.com, you would type:

   **someone**

   and then click **OK**. If a naming conflict occurred when the mailbox was created, the user name is the pre-Windows 2000 logon name. For more information about the pre-Windows 2000 logon name, see Notes.

## Notes

- Secure Password Authentication (SPA) only supports Active Directory integrated authentication and local Windows accounts authentication.
- Be sure to update your e-mail client software and client operating system with the latest service pack available.
- If you are using an e-mail client other than Outlook Express, check your product documentation for information about how to configure your e-mail client to use Secure Password Authentication (SPA) (also known as NTLM Authentication).
- If a dialog box prompts you for your credentials after you configure Outlook Express for SPA, enter your credentials, as described in the following table:

| Value | Description |
|---|---|
| **User Name** | Your user name, not including the domain. For example, if your e-mail address is someone@example.com, you would type:<br>**someone**<br>If a naming conflict occurred when the mailbox was created, the user name is the pre-Windows 2000 logon name. |
| **Password** | Your password. |
| **Domain** | For Active Directory integrated authentication, this is the network basic input/output system (NetBIOS) name of the domain. For local Windows accounts authentication, this is the name of the local computer. |

- If you are using Active Directory integrated authentication and Secure Password Authentication and a naming conflict occurred when the mailbox was created, the pre-Windows 2000 logon name must be used for e-mail client authentication. To determine the modified logon name, go to the **Active Directory Users and Computers** snap-in in **Administrative Tools**. Go to the **Users** folder, right-click the user account, and then click **Properties**. Click the **Account** tab and the modified account name will appear in **User logon name (pre-Windows 2000)**. You must note the pre-Windows 2000 logon name and provide it to the user.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# E-mail Services Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

The following topics provide background information about the POP3 service:

- POP3 service overview
- Understanding the POP3 Service
- Using the POP3 Service

# POP3 service overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**POP3 service overview**

The POP3 service is an e-mail service that retrieves e-mail. Administrators can use the POP3 service to store and manage e-mail accounts on the mail server.

When the POP3 service is installed on the mail server, users can connect to the mail server and retrieve e-mail to their local computer using an e-mail client that supports the POP3 protocol (such as Microsoft Outlook). The POP3 service is used with the Simple Mail Transfer Protocol (SMTP) service, which sends outgoing e-mail.

**E-mail transfer and retrieval overview**

The diagram illustrates how e-mail is transferred from sender to recipient, and how it is then retrieved to the recipient's local computer.

The sender's client computer connects to the Internet through an Internet Service Provider (ISP). Using an e-mail client, the sender sends an e-mail. The e-mail is picked up according to the SMTP protocol and is transferred to the sender's ISP, which then routes the e-mail out onto the Internet.

The e-mail moves through the Internet and is relayed through a varying number of intermediate servers on its way to the recipient. When the e-mail reaches the recipient's ISP, it is dropped into the recipient's mailbox.

When the recipient's computer connects to the recipient's ISP, the e-mail is then transferred from the ISP to the recipient's e-mail client on the local computer, according to the POP3 protocol. The POP3 service is the mechanism that allows users to retrieve their e-mail from the mail server.

# Understanding the POP3 Service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding the POP3 service**
The POP3 service is an e-mail service that retrieves e-mail. Administrators can use the POP3 service to store and manage e-mail accounts on the mail server.

When the POP3 service is installed on the mail server, users can connect to the mail server and retrieve and download e-mail to their local computer. They do so by using an e-mail client that supports the POP3 protocol (such as Microsoft Outlook). The POP3 service is used with the Simple Mail Transfer Protocol (SMTP) service, which sends outgoing e-mail.

# E-mail concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**E-mail concepts**

**Components of the POP3 e-mail system**

The three components of the POP3 e-mail system are the POP3 e-mail client, the Simple Mail Transfer Protocol (SMTP) service, and the POP3 service. These are each described in the following table.

| Component | Description |
|---|---|
| POP3 e-mail client | The POP3 e-mail client software that is used to read, compose, and manage e-mail.<br><br>The POP3 e-mail client retrieves e-mail from the mail server and transfers it to the user's local computer so it can then be managed by the user. An example of an e-mail client that supports the POP3 protocol is Microsoft Outlook Express. |
| SMTP service | The e-mail transfer system that routes e-mail from the sender to the recipient using the SMTP protocol.<br><br>The POP3 service uses the SMTP service as the e-mail transfer system. E-mail is composed by the user on a POP3 e-mail client. Then, after the user connects to the mail server using an Internet or network connection, the SMTP service picks up and transfers the e-mail across the Internet to the recipient's mail server. |
| POP3 service | The e-mail retrieval system that downloads e-mail from the mail server to the user's local computer using the POP3 protocol.<br><br>The POP3 protocol controls the connection between a user's POP3 e-mail client and the server where e-mail is stored. |

Administrators manage the POP3 service on three organizational levels: mail servers, e-mail domains, and mailboxes. These are described in the following table.

| Category | Description |
|---|---|
| Mail server | The computer where the POP3 service is installed. Users connect to it to retrieve their e-mail. |
| E-mail domains | The e-mail domain must be a registered domain name and it must match the Mail eXchanger (MX) record created by your Internet Service Provider (ISP). |
| Mailboxes | Each mailbox corresponds to a user who is a member of the e-mail domain, such as someone@example.com. The user's mailbox corresponds to a directory in the mail store in which the user's e-mail is stored until it is retrieved. |

**A POP3 e-mail system**

In the diagram, e-mail is sent to someone@example.com, as illustrated by step 1. The e-mail is picked up by the SMTP service and is sent out on the Internet (step 2).

The e-mail domain, example.com, is then resolved to a mail server on the Internet, mailserver1.example.com (step 3). Mailserver1.example.com is a mail server running the POP3 service that receives incoming e-mail for the e-mail domain, example.com.

In step 4, the e-mail for someone@example.com is received by mailserver1.example.com and is moved into the mail store directory (step 5), where e-mail intended for someone@example.com is stored.

In step 6, the user, someone, checks for e-mail by connecting to the mail server running the POP3 service. The POP3 protocol transmits the user and password authentication credentials for the user, someone. The POP3 service verifies these credentials, and then either accepts or denies the connection.

If the connection is accepted, all of the e-mail for the user, someone, that is being stored in the mail store is downloaded from the mail server to someone's local computer (step 7). The mail is usually then deleted from the mail store.

**Network security**

The POP3 and SMTP protocols are not encrypted. If someone gains access to the network on which the server running the POP3 service is running, they could potentially read users' e-mail.

To increase network security, implement Internet Protocol security (IPSec).

IPSec is a framework of open standards for ensuring private, secure communications over Internet Protocol (IP) networks through the use of cryptographic security services. For more information about IPSec, see Internet Protocol Security (IPSec).

# POP3 protocol

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**POP3 protocol**

The Post Office Protocol 3 (POP3) is a standard protocol for retrieving e-mail. The POP3 protocol controls the connection between a POP3 e-mail client and a server where e-mail is stored. The POP3 service uses the POP3 protocol for retrieving e-mail from a mail server to a POP3 e-mail client.

The POP3 protocol has three process states for handling the connection between the mail server and the POP3 e-mail client: the authentication state, the transaction state, and the update state.

During the authentication state, the POP3 e-mail client that is connected to the server must be authenticated before users can retrieve their e-mail. If the user name and password that are provided by the e-mail client match those on the server, the user is authenticated and proceeds to the transaction state. If not, the user receives an error message and is not allowed to connect to retrieve e-mail.

To prevent any damage to the mail store after the client has been authenticated, the POP3 service locks the user's mailbox. New e-mail that is delivered to the mailbox after the user has been authenticated (and the mailbox has been locked) is not available to download until after the connection has been terminated. Also, only one client can connect to a mailbox at a time; additional connection requests to the mailbox are rejected.

During the transaction state, the client sends POP3 commands and the server receives and responds to them according to the POP3 protocol. Any client requests the server receives that do not comply with POP3 protocol are ignored, and an error message is sent back.

The update state closes the connection between the client and server. It is the last command the client transmits.

After the connection is closed, the mail store is updated to reflect the changes made while the user was connected to the mail server. For example, after the user successfully retrieves e-mail, the retrieved e-mail is marked for deletion and then deleted from the mail store, unless the user's e-mail client is configured to do otherwise.

# Simple Mail Transfer Protocol (SMTP)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Simple Mail Transfer Protocol (SMTP)**
Simple Mail Transfer Protocol (SMTP) controls the way e-mail is transported and delivered across the Internet to the destination server. SMTP receives and sends e-mail between servers. The SMTP service is installed by default with the POP3 service to provide complete e-mail services.

The SMTP service is automatically installed on the computer where the POP3 service is installed to allow users to send outgoing e-mail. When you create a domain using the POP3 service, the domain is also added to the SMTP service to allow mailboxes in that domain to send outgoing e-mail. The SMTP service on the mail server receives incoming mail and transfers the e-mail to the mail store.

**E-mail relay**
E-mail relay occurs when users who are not members of the e-mail domain use a mail server with SMTP to send e-mail. SMTP mail servers that are not configured to prevent open relay are often abused by those who want to send large volumes of unsolicited commercial e-mail. The Microsoft SMTP service is configured by default to prevent e-mail relaying.

If you want to enable e-mail relay, however, you have the following two options, depending on which authentication method you are using:

- If you are using Active Directory integrated authentication or local Windows accounts authentication, you can configure the mail server to require authentication before accepting outgoing e-mail.

  For more information on configuring the mail server, see Configure the Simple Mail Transfer Protocol service for e-mail relaying. If you configure the SMTP service to authenticate users trying to send outgoing mail, you must also configure the users' e-mail clients. For more information about configuring e-mail clients to allow relaying, see Configure e-mail clients for e-mail relaying.

- If you are using encrypted password file and want to configure e-mail relaying, you must configure the mail server to allow relay based on either Internet Protocol (IP) address or e-mail domain name.

**Note**

- When an e-mail is undeliverable, the Simple Mail Transfer Protocol (SMTP) service returns it to the sender with a non-delivery report (NDR). If the NDR cannot be delivered to the sender, a copy of the message is put in the Badmail directory. To prevent the possibility of the operating system running out of disk space (if the Badmail directory becomes too large), you must move the SMTP Badmail directory to a volume other than the one on which the operating system is installed.

# POP3 Service Authentication Methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**POP3 service authentication methods**

The POP3 service provides three different authentication methods for verifying users connecting to the mail server.

You must choose an authentication method before creating any e-mail domains on the mail server. You can change the authentication method only if there are no existing e-mail domains on the mail server.

The following table describes when to use each authentication method:

| Authentication method | When to use this authentication method |
|---|---|
| Local Windows accounts authentication | • Your mail server is not a member of an Active Directory domain;<br>-AND-<br>• You want to store user accounts on the server on which the POP3 service is installed. |
| Active Directory integrated authentication | • Your mail server is a domain controller or a member of an Active Directory domain. |
| Encrypted password file authentication | • Your mail server is not using Active Directory;<br>-OR-<br>• You do not want to have user accounts for the POP3 service on the local computer. |

For more information about the POP3 service authentication methods, see the following topics:

- Local Windows accounts authentication
- Active Directory integrated authentication
- Encrypted password file authentication

**Notes**

- If the computer on which the POP3 service is running is either a member of an Active Directory domain or a domain controller, the default authentication method is Active Directory integrated authentication. Otherwise, the default is local Windows accounts authentication.
- If the computer where the POP3 service is running is a domain controller, the available authentication methods are Active Directory integrated authentication and encrypted password file authentication. If the computer where the POP3 service is running is a member server in an Active Directory domain, all three authentication methods are available. Otherwise, the available authentication methods are local Windows accounts authentication and encrypted password file authentication.

# Local Windows accounts authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Local Windows accounts authentication**
If you are not using Active Directory, but you want to create user accounts on the local computer where the POP3 service is installed, you can use local Windows accounts authentication to link the POP3 service into the local system user accounts.

Use local Windows accounts authentication if:

- Your mail server is not a member of an Active Directory domain.

  -and-

- You want to have user accounts on the same local computer as the POP3 service.

Local Windows accounts authentication integrates the POP3 service into the local computer's Security Accounts Manager (SAM). With Security Accounts Manager, users who have user accounts on the local computer can use the same user name and password to be authenticated by both the POP3 service and the local computer.

You can use local Windows accounts authentication to support multiple domains on the server, but user names across domains must be unique. For example, you cannot have a user named someone@example.com and a user named someone@northwindtraders.com.

**POP3 Users Security Accounts Manager group**
If a mailbox is created with a corresponding user account, the user account is added to the "POP3 Users" local group. Members of the "POP3 Users" group cannot log on locally to the server even though they have a user account on the server.

The restriction on local logon is enforced through the computer's local security policy. It increases server security by restricting local logon rights only to authorized users. Being unable to log on locally to the server does not affect the users' ability to use the POP3 service.

For more information on local groups and modifying local group membership, see Local Users and Groups.

For more information on local security policy, see Local Security Policy.

**E-mail client authentication**
Local Windows accounts authentication supports both plaintext and Secure Password Authentication (SPA) e-mail client authentication.

Because plaintext transmits the user's credentials in an unsecured, unencrypted format, the use of plaintext is not recommended. SPA, however, does require that e-mail clients transmit both the user name and password using secure authentication; it is therefore recommended over plaintext authentication. For more information, see Configure the mail server to require Secure Password Authentication.

### Note

- To install Active Directory on the computer where the POP3 service is installed, see the section on upgrading from local Windows accounts to Active Directory integrated authentication in Active Directory integrated authentication. Installing Active Directory on a member server without following the recommended procedure might cause the POP3 service to work incorrectly.

# Active Directory integrated authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Active Directory integrated authentication**

You can use Active Directory integrated authentication to incorporate the POP3 service into your existing Active Directory domain. If mailboxes are created that correspond to existing Active Directory user accounts, users can use their existing Active Directory domain user name and password to send and receive e-mail. For more information about Active Directory, see Active Directory.

Use Active Directory integrated authentication if:

- The server on which you want to install POP3 service is a member of an Active Directory domain or is an Active Directory domain controller.

You can use Active Directory integrated authentication to support multiple POP3 e-mail domains, and you can use the same user name across different POP3 e-mail domains. For example, you can have a user named someone@example.com and a user named someone@northwindtraders.com.

If you use Active Directory integrated authentication and have multiple POP3 e-mail domains, when you create a mailbox, be sure to consider whether the new mailbox has the same name as an existing mailbox in another POP3 e-mail domain. Each mailbox is associated with an Active Directory user account that has both a user logon name and pre-Windows 2000 user logon name. The user logon name is the name of the Active Directory user account and the POP3 mailbox.

Usually, the pre-Windows 2000 user logon name is the same as the user logon name. If, however, you try to create a mailbox and user account when there is an existing user account with the same pre-Windows 2000 user logon name, a naming conflict will occur. Active Directory does not support multiple accounts with the same pre-Windows 2000 user logon name.

If a naming conflict occurs, the mailbox name and e-mail address are not affected, but the account's pre-Windows 2000 logon name is modified to prevent any naming conflict with the existing account.

If you use Secure Password Authentication and a naming conflict has occurred, the pre-Windows 2000 logon name must be used for e-mail client authentication. To determine the modified logon name, go to the **Active Directory Users and Computers** snap-in located in the **Administrative Tools** menu. Go to the **Users** folder, right-click the user account, and then click **Properties**. Click the **Account** tab. The modified account name will appear in **User logon name (pre-Windows 2000)**.

You must note the pre-Windows 2000 logon name and provide it to the user. For more information about configuring e-mail clients to use Secure Password Authentication, see Configure Outlook Express for Secure Password Authentication.

**E-mail client authentication**

Active Directory integrated authentication supports both plaintext and Secure Password Authentication (SPA) e-mail client authentication. Because plaintext transmits the user's credentials in an unsecured, unencrypted format, however, the use of plaintext authentication is not recommended. SPA does require e-mail clients to transmit both the user name and password using secure authentication; it is therefore recommended over plaintext authentication. For more information, see Configure the mail server to require Secure Password Authentication.

**Upgrading from local Windows accounts to Active Directory integrated authentication**

If you are upgrading your mail server to a domain controller, and you were using local Windows accounts authentication, you must complete the steps described in the following table before you can configure the POP3 service for Active Directory integrated authentication.

| Step | Reference |
|---|---|
| Delete all existing e-mail domains in the POP3 service. | For more information on deleting e-mail domains, see Delete a domain. |
| Change the authentication method to Active Directory integrated. | For more information on changing the authentication method, see Set the authentication method. |

| | |
|---|---|
| Recreate the domains and associated mailboxes. | • For more information on creating e-mail domains, see Create a domain<br>• For more information on creating mailboxes, see Create a mailbox. |

**Notes**

- Installing Active Directory on a member server without following the recommended procedure can prevent the POP3 service from working correctly.
- If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to administer the POP3 service.

# Encrypted password file authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Encrypted password file authentication**
Encrypted password file authentication is ideal for large scale deployments where there is not an existing Active Directory deployment, and there will potentially be too many accounts to manage easily from a single local computer.

Use encrypted password file authentication if:

- You are not using Active Directory.

  -Or-

- You do not want to create users on the local computer.

With encrypted password file authentication, you can use an identical user name across different domains, but you cannot assign the same user name to multiple mailboxes within a domain. For example, you cannot have two mailboxes named someone@example.com, but you can have someone@example.com and someone@northwindtraders.com.

Encrypted Password file authentication creates an encrypted file with the user's password, which is then stored in the user's mailbox directory on the server. During authentication, the password the user supplies is encrypted and compared to the encrypted file stored on the server. If the encrypted password matches the encrypted password stored on the server, the user is authenticated.

**Migrating encrypted password file user accounts to Active Directory user accounts**
You can migrate user accounts created under encrypted password file authentication to Active Directory user accounts using the winpop.exe command-line tool. For more information, see Migrate an encrypted password file user account to an Active Directory user account.

**E-mail client authentication**
Encrypted Password file authentication supports both plaintext and Authenticated POP (APOP) e-mail client authentication. Plaintext transmits the user's credentials in an unsecured, unencrypted format. Therefore, the use of plaintext authentication is not recommended.

Because APOP e-mail client authentication requires e-mail clients to transmit both the user name and password using secure authentication, it is recommended over plaintext authentication. For more information, see Configure the mail server to require Secure Password Authentication.

# Mail store

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Mail store**
The mail store is a directory or Universal Naming Convention (UNC) path where the POP3 service stores all e-mail until users retrieve it to their client computer.

The basic structure of the mail store, or mail root, is a directory on the local hard disk where all e-mail is stored.

When a domain is created, the POP3 service creates a corresponding directory in the directory that has been designated for the mail store. For each user with a mailbox in that domain, POP3 creates a directory in the domain directory. E-mail that a user receives is stored as an individual file within the user's directory until the user retrieves it using a POP3 e-mail client.

The following is an example of the path to an e-mail message in the mail store:

C:\inetpub\mailroot\mailbox\example.com\P3_someone.mbx\P347865.eml

where mailroot corresponds to the mail store directory, example.com to the domain directory, P3_somone.mbx to the directory for a mailbox named someone and P347865.eml to a single saved e-mail message.

The directory and file permissions for each directory in the mail store are identical. When you configure the mail store, the permissions are set so that only local or domain administrators and the local network service, which the POP3 service is configured to run under, are assigned permissions to the directories. No other user is assigned read/write permissions.

The mail store's functionality depends on having adequate hard disk space available. To ensure the mail store's functionality, you should develop a disk-space requirement estimate based on the number of users on the server, the volume of e-mail that they will receive, and the average size of the e-mail they will receive.

In addition, you can protect the server from situations where the mail store's disk usage might increase unexpectedly by implementing disk quotas. Disk quotas monitor and control disk space that is used on NTFS file system volumes. For more information, see Configuring disk quotas for the POP3 service.

**Notes**

- Because the mail store can potentially use large amounts of disk space, you should either set a disk quota limit on the volume of the mail store (to control its disk space usage) or set it to use a volume other than the one where the operating system is installed. This will prevent the possibility of the operating system running out of disk space if the mail store becomes too large. For more information, see Set the mail store. For more information on disk quotas, see Configuring disk quotas for the POP3 service.

- The mail store must be configured to use either a directory on the local hard disk or a UNC path; other storage options, such as mapped drives, are not supported.

- You cannot set the mail store to the root directory of the hard disk, for example C:\, or to a directory in which files are currently in use.

- If you restore the mail store from a backup or move it to a new location, you must reset the permissions on the mail store directory using the command-line procedure described in Set the mail store.

- If you transfer the mail store to a new directory, you must move the mail store directory to ensure the directory retains the correct ownership; copying the mail store will not work.

- Physical access to a server is a high security risk. To maintain a more secure environment, restrict physical access to the server where the mail store resides.

# Using the POP3 Service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using POP3 service**

This section provides information on how to use the POP3 service:

- Contacting your Internet Service Provider
- POP3 service administration tools
- POP3 service commands overview
- Configuring disk quotas for the POP3 service
- Remote administration of POP3 service

# Contacting your Internet Service Provider

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Contacting your Internet Service Provider**

Before installing and configuring the POP3 service, you must contact your Internet Service Provider (ISP) and complete the steps described in the following table.

| Step | Description | Additional reference |
|---|---|---|
| Register an e-mail domain name. | The e-mail domain name must be a registered domain name, and it must match the MX record created by your ISP. If you do not have have an e-mail domain name, contact your ISP for assistance registering a domain name. | |
| Have your ISP create a Mail eXchanger (MX) record for your e-mail domain that matches the name of your mail server running the POP3 service. | An MX record provides e-mail routing to a mail exchanger host for e-mail sent to the domain name.<br><br>For example, in the domain example.com, the mail server might be mailserver1.example.com.<br><br>The ISP would create an MX record for example.com that points to mailserver1.example.com.<br><br>An e-mail that is sent to someone@example.com is routed to mailserver1.example.com. This is the server where the POP3 service is running and to which users connect to retrieve e-mail. | To change the name of your server to a title that reflects its role (for example, mailserver1), see Rename a computer. |
| Obtain information to configure your mail server for static addressing. | Your ISP must provide a separate static IP address for each mail server on which you intend to install the POP3 service.<br><br>To obtain a static Internet Protocol (IP) address, you must also obtain the subnet mask, default gateway, and preferred Domain Name System (DNS) server from your ISP. Each mail server must then be configured to use an individual static IP address. | For more information on how to configure your mail server with a static IP address, see Configure TCP/IP for static addressing. |

# POP3 service administration tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**POP3 service administration tools**
The POP3 service provides three methods for local administration and two methods for remote administration.

**Local administration**
You can administer the POP3 service on the local computer from the Microsoft Management Console (MMC) snap-in, the command line, or the Web Interface for Remote Administration. For more information, see Using Web Interface for Remote Administration.

**Remote administration**
You can administer the POP3 service on a remote computer from the Microsoft Management Console (MMC) snap-in or the Web Interface for Remote Administration. You can also set up Terminal Services on the remote computer, which would then make the same local computer administration options available. For more information, see Remote administration of POP3 service.

**Configuring and managing the POP3 service**
The following tables describe the administrative options you can use to configure and manage the POP3 service.

- General service settings
- Domain administration options
- Mailbox administration options
- Service state settings

**General service settings**
For information on how to configure these settings, see Set Up the POP3 Service and Change Service Settings.

| Service parameter | Description |
|---|---|
| Port | Specifies the port on which the POP3 service monitors for POP3 e-mail clients and responds to connection requests. Do not change the port from its default of 110 unless you have a specific need to do so. You must also inform all users if you are using a nonstandard port because most POP3 e-mail clients configure port 110 as the default for a POP3 connection. |
| Event logging level | Specifies how much information is stored by the POP3 service in Event Viewer. Logging information is useful for auditing and troubleshooting. The logging levels are:<br>• None - No logging.<br>• Low - Only critical events are logged.<br>• Medium - Critical and warning events are logged.<br>• High - Critical, warning, and informational events are logged. |

| | |
|---|---|
| Authentication | Specifies the authentication method used to verify users who connect to the mail server. The POP3 service supports three authentication methods:<br>• Local Windows accounts authentication<br>• Active Directory integrated authentication<br>• Encrypted password file authentication<br><br>For more information, see POP3 Service Authentication Methods. |
| Mailroot | Specifies the directory on the local hard disk where e-mail is stored. For more information, see Mail store. |
| Sockets | Specifies the number of sockets.<br><br>A socket receives the network request from the e-mail client and then handles the transaction. Each time a POP3 e-mail client connects to the mail server, a socket is used. The POP3 service has four configurable settings that control the sockets: maxsockets, minsockets, backlogsockets, and thresholdsockets.<br><br>For example, on a system where maxsockets has been set to 20, up to 20 simultaneous connections can be made. If minsockets has been set to 10, when the POP3 service starts, 10 sockets are created immediately. The minsocket value determines how many connection requests the service can respond to on startup, and, based upon the number of sockets to create on startup, how much memory is initially allocated to the service.<br><br>New sockets are created based upon the value of thresholdsockets. If thresholdsockets is 5, when the number of available sockets on the server is less than 5, 5 new sockets are created. This increases the total sockets on the system to 15. When the 5 new sockets are filled, 5 additional sockets are created.<br><br>This process continues until maxsockets is reached. If maxsockets is 20, when 20 sockets are created and filled, the value of backlogsockets determines how many subsequent connections are accepted, but not responded to. If backlogsockets is 5, the server will accept a total of 25 connections: the 20 connections that fill the available sockets and 5 additional connections that are queued until a socket is available. Connection attempts subsequent to maxsockets + backlogsockets are denied. |
| Threads | Specifies the number of threads.<br><br>A thread is a sequence of program code that is scheduled to run on the processor. A process can have several threads running simultaneously. The operating system coordinates this process by assigning each thread a scheduling priority. With the POP3 service, you can change the number of threads created per processor by configuring the thread count setting. The number of threads per processor multiplied by the number of processors equals the number of simultaneous requests the POP3 service can process.<br><br>The number of threads per processor can affect performance when traffic is high. Adding more threads can increase throughput, but adding too many threads will decrease server performance. The default settings are appropriate for most typical environments. For high-load environments, such as dedicated mail servers, the administrator should experiment with the number of threads for best results. |
| Quotas | Specifies disk quotas that are implemented.<br><br>You can implement disk quotas to control the amount of hard disk space allocated for each user's mailbox. Disk quotas are important because they ensure that the server is protected from situations where the mail store might suddenly and rapidly increase in size. For more information, see Configuring disk quotas for the POP3 service. |

**Domain administration options**

For information on how to set these options to manage a domain, see Manage E-mail Domains.

| **Domain administration** | **Description** |
|---|---|

| | |
|---|---|
| Lock/Unlock | Locks or unlocks a domain. Unlocking the domain allows all users in the domain to retrieve their e-mail; locking the domain prevents them from doing so.<br><br>When a domain is locked, incoming e-mail for the domain is still received and delivered to the appropriate user directory in the mail store, and outgoing mail is still sent. All users attempting to download mail from the server are denied a connection, however.<br><br>While a domain is locked, you can still perform administrative tasks such as deleting a domain. If a user is connected to the mail server when the domain is locked, the mailbox remains unlocked until the user disconnects, after which the mailbox is locked. |
| Stat | Displays mailbox statistics, including number of messages in a mailbox, lock/unlock status, size of directory, and whether a user is currently connected |
| List | Lists all mailboxes in the domain. |
| New domain | Creates a new domain and adds it to the existing POP3 directory structure. |
| Delete a domain | Deletes an existing domain. If you delete an existing domain, you also delete all mailboxes and stored e-mail for that domain from the mail store. |

**Mailbox administration options**

For information on how to set these options to manage mailboxes, see Manage Mailboxes.

| **Mailbox administration** | **Description** |
|---|---|
| New mailbox | Creates a new mailbox in an existing domain. To receive e-mail, every user in the domain must have a unique mailbox. Both Active Directory integrated authentication and local Windows accounts authentication support creating an associated user for each mailbox to link POP3 authentication with the existing domain or local computer. |
| Delete a mailbox | Deletes a mailbox and removes the mailbox from the domain. After a mailbox has been deleted, all e-mail sent to that mailbox is returned to the sender as nondeliverable receipt. When you delete a mailbox, you can specify that the corresponding user account also be deleted. |
| Lock or unlock a mailbox | Locks or unlocks a mailbox.<br><br>When the mailbox is unlocked, the user can connect to the server and retrieve e-mail. When it is locked, the mailbox continues to receive incoming e-mail, which is delivered to the mail store, but the user is not allowed to connect to the server and retrieve e-mail. The administrator can still perform administrative tasks, however, such as deleting a mailbox or changing a mailbox's password.<br><br>If a user is connected to the mail server when the mailbox is locked, the mailbox remains unlocked until the user disconnects, after which the mailbox is locked. |
| Change a mailbox password | Resets the mailbox password. If a user loses or forgets his or her password, you must reset the mailbox password to something new; it is impossible to reveal an existing password. |

**Service state settings**

The POP3 service is a Windows service with full support for Start, Stop, Pause, Resume, and Restart commands. For more information on how to change the POP3 service state, see Change the POP3 service state.

| **Service state** | **Description** |
|---|---|
| Start | Starts the POP3 service from a stopped or paused state and allows POP3 clients to connect to the server and retrieve e-mail. |
| Stop | Stops the POP3 service. All current connections are terminated. |
| Pause | Pauses the POP3 service so that no new connections are accepted. Existing connections are not affected. |

| | |
|---|---|
| Resume | Starts the POP3 service from a paused state to allow POP3 clients to connect to the server and retrieve e-mail. |
| Restart | Restarts the POP3 service. All current connections are terminated. |

# POP3 service commands overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**POP3 service commands overview**

You can use the POP3 service command application, Winpop.exe, to manage the POP service and modify parameter settings. With Winpop.exe, you can use all the POP3 service parameters available in the POP3 service Microsoft Management Console (MMC) snap-in, as well as additional administrative settings that are only configurable using Winpop.exe.

For more information, see:

- Winpop

# Configuring disk quotas for the POP3 service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring disk quotas for the POP3 service**

**Important**

- You can configure disk quotas only on NTFS file system partitions.

You can use disk quotas to control and limit the amount of disk space individual mailboxes on the mail server can use. This ensures that individual mailboxes, and the mail store in general, do not use excessive or unanticipated amounts of disk space and adversely affect the performance of the server where the POP3 service is running.

For example, if the mail server suddenly receives a large volume of unsolicited e-mail, the mail store expands rapidly and might use all of the available disk space on the hard disk. If you implement quotas, the mail store only expands to the quota limit that you specified. As a result, no more mail is accepted by the server, and the rest of the server still functions normally.

If you are using Active Directory integrated authentication or local Windows accounts authentication, the e-mail delivered to a POP3 service mailbox will have file ownership assigned to the mailbox user by default. A quota file is created in the mailbox directory that contains the security identifier (SID) of the user account associated with the mailbox. File ownership is then assigned to the user account that corresponds to the SID contained in the quota file. The SID is also used by the NTFS file system disk quota system to enforce the quota limits specified on the user account matching the SID. All e-mail transferred to the mailbox's mail store directory is marked with the SID contained in the quota file; this marks the e-mail so it can be monitored by the quota system.

For more information, see Disk Quotas.

**createquotafile command**

If you are using encrypted password file authentication, there is no valid user account for the mailbox that the quota system can use. You can use the **createquotafile /user** command, however, to manually associate a given mailbox with a valid user account that is configured to have a disk quota. This association is for disk quota purposes only and is separate from mailbox authentication. If you are using Active Directory integrated authentication or local Windows accounts authentication, a quota file is created by default when you create a mailbox.

For more information about the **createquotafile** command, see Create a quota file.

**Configuring domain disk quotas**

Although quotas are designed to be implemented on a per-mailbox basis, you can create a domain-wide disk quota.

To create a disk quota for a domain, you must create a new mailbox and user account with an associated quota. The quota file for the new mailbox functions as a template that you can then copy into all of the other mailbox directories in the domain to create a domain-wide quota policy.

The following table describes the steps for creating a domain disk quota.

| Step | Reference |
|---|---|
| Create a new mailbox and user account. When you create the new mailbox, you must also create an associated user account for the mailbox. This account will be used to create a domain-wide quota. Other accounts in the domain can be configured to reference this account and its associated quota. All accounts associated with this account will have their disk usage aggregated under a single quota limit, which will create a domain-wide quota limit. | Create a mailbox |
| Enable disk quotas for the partition on which the mail store is configured. | Enable disk quotas |
| Create a quota to be used as the domain quota and assign it to the domain quota account. | Add new quota entries |

| | |
|---|---|
| Do one of the following:<br>• Copy the quota file from the mail store directory of the domain account to the corresponding mail store directory of all the mailboxes in the domain.<br>• Or, using the **winpop createquotafile** command and the **/user:** switch, associate one or more accounts in the domain with the domain account and its quota. For more information on the **createquotafile** command, see Create a quota file. | N/A |

**Notes**

- When a mailbox quota is exceeded, the user is not notified. E-mail intended for the user is not accepted, and a Non-Delivery Report (NDR), a notice that the e-mail was not delivered to the recipient, is returned to the sender.
- Be sure that users configure their e-mail client to delete from the server any e-mail that has been successfully retrieved. If users leave successfully retrieved e-mail on the server, they can quickly exceed their quota. Users are likely to be unaware of the disk usage and impact of old e-mail stored on the server.
- You cannot set quota limits on the accounts of Administrators or members of the Administrators group.

# Remote administration of POP3 service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote administration**
There are three approaches you can use to administer the POP3 service remotely: remote Web administration, Terminal Services, and Microsoft Management Console.

- **Remote Web administration**

  You can use the Web to connect remotely to a server running the POP3 service. The POP3 service is integrated into the Web Interface for Remote Administration. You can use a Web browser to exert full administrative control of a computer over the Internet. For more information, see Using Web Interface for Remote Administration.

  **Note**

  - This content is not available in this preliminary release.
  - This content is not available in this preliminary release.

- **Remote administration using Terminal Services**

  You can use a Terminal Services client to connect remotely to a server that is running the POP3 service. With Terminal Services, you have full administrative control over the computer and the POP3 service. For more information, see Remote Administration using Terminal Services.

- **Remote administration using Microsoft Management Console (MMC)**

  Using the POP3 service MMC snap-in, you can connect to another computer that is running the POP3 service. For security reasons, to manage the POP3 service on a remote computer, you must be a member of the Administrators group on the remote computer, or you must have been delegated the appropriate authority. For more information about connecting to a remote server, see Connect to a remote server running the POP3 service.

**Note**

- To perform this procedure on a remote computer, you must be a member of the Administrators group on the remote computer, or you must have been delegated the appropriate authority.

# Troubleshooting E-mail services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Users are unable to connect to the POP3 server to retrieve or send e-mail
- I am using local Windows accounts authentication. The POP3 service will not start after I install Active Directory on the member server.
- Users are unable to access their mailboxes after the mail store directory is restored from a backup or moved to a new location, or event ID 1022 appears in the event log.
- I am using local Windows accounts authentication and a remote mail store. A security identifier (SID) appears instead of an account name as the owner of the files in the remote mail store.
- Deleting a user account from the Active Directory Users and Computers snap-in does not delete the user's corresponding POP3 mailbox.
- When using Secure Password Authentication and Active Directory integrated authentication, users are unable to connect.
- I am unable to perform administrative tasks when using Active Directory integrated authentication, or the following error message appears:"The specified domain either does not exist or could not be contacted."

**Users are unable to connect to the POP3 server to retrieve or send e-mail**
**Cause:** The user's e-mail client has not been configured correctly, or the user has incorrect logon credentials.

**Solution:** Review the procedures to configure e-mail clients.

- If you are not using Secure Password Authentication, see Configure Outlook Express for e-mail services.
- If you are using Secure Password Authentication, see Configure Outlook Express for Secure Password Authentication.

**I am using local Windows accounts authentication. The POP3 service will not start after I install Active Directory on the member server.**
**Cause:** When Active Directory is installed on a computer, the local Security Accounts Manager (SAM) is disabled. Local Windows accounts authentication depends upon SAM, however. Without SAM, the POP3 service will not start if it is configured to use local Windows accounts authentication.

**Solution:** After you install Active Directory on the server, configure the POP3 service to use Active Directory integrated authentication as described in the following table:

Step

Reference

Delete all existing e-mail domains in the POP3 service.

For more information on deleting e-mail domains, see Delete a domain.

Change the authentication method to Active Directory integrated.

For more information on changing the authentication method, see Set the authentication method.

Recreate the domains and associated mailboxes.

- For more information on creating e-mail domains, see Create a domain.

- For more information on creating mailboxes, see Create a mailbox.

**See also:** Active Directory integrated authentication.

**Users are unable to access their mailboxes after the mail store directory is restored from a backup or moved to a new location, or event ID 1022 appears in the event log.**
**Cause:** The discretionary access control list (DACL) that is set on the mail store directory and all subdirectories has been lost.

**Solution:** Reset the DACL on the mail store directory. The DACL will then be propagated to all subdirectories.

1. Open Command Prompt.

2. Type:

   **winpop set mailroot***path_to_mail_store*

   **Note**

   - The **set mailroot** command might take a while to complete if the mail store is large.

**See also:** Mail store.

**I am using local Windows accounts authentication and a remote mail store. A security identifier (SID) appears instead of an account name as the owner of the files in the remote mail store.**
**Cause:** The SID displayed corresponds to a user account on the computer on which the POP3 service is running. Because that account does not exist on the remote computer, there is no user account to be referenced, and the SID appears instead.

**Solution:** This is a known issue.

**Deleting a user account from the Active Directory Users and Computers snap-in does not delete the user's corresponding POP3 mailbox.**
**Cause:** The Active Directory Users and Computers snap-in is designed to function this way.

**Solution:** To delete both the user account and the POP3 mailbox, use the POP3 service snap-in. For more information, see Delete a mailbox.

Or, if you delete the user account from the Active Directory Users and Computers snap-in, you can delete the POP3 mailbox manually.

To delete a mailbox manually, go to the directory that is configured to be the mail store. Delete the directory that corresponds to the POP3 mailbox.

For more information on how to determine the directory that corresponds to the POP3 mailbox, see Mail store.

**When using Secure Password Authentication and Active Directory integrated authentication, users are unable to connect.**
**Cause:** The user's logon credentials are incorrect.

**Solution:** Verify that the user is using the correct logon name and password. If a naming conflict occurred when the user's mailbox was created, the user must use the pre-Windows 2000 logon name as his or her user name when connecting to the server running the POP3 service. For more information about naming conflicts, see Active Directory integrated authentication.

- To verify the user's logon name, go to the **Active Directory Users and Computers** snap-in located in the **Administrative Tools** menu. Go to the **Users** folder, right-click the user account and then click **Properties**. Click the **Account** tab. The user name that must be used will appear in **User logon name (pre-Windows 2000)**.

- If the user's password is incorrect, and the user does not remember the correct password, reset the password and provide the user with a new password. For more information, see Change a password.

**I am unable to perform administrative tasks when using Active Directory integrated authentication, or the following error message appears:"The specified domain either does not exist or could not be contacted."**
**Cause:** You are not logged on to the Active Directory domain. If you are using Active Directory integrated authentication, you

must log on to the Active Directory domain, not the local computer, to administer the POP3 service.

**Solution:** Log on to the Active Directory domain using your administrator credentials.

# Background Intelligent Transfer Service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Background Intelligent Transfer Service**
Background Intelligent Transfer Service (BITS) helps you transfer large amounts of data without degrading network performance. It does this by transferring data in small chunks, utilizing unused bandwidth as it becomes available, and reassembling the data at the destination. BITS is supported on Microsoft® Windows Server 2003 family operating systems and on Microsoft® Windows 2000 Servers.

BITS downloads and uploads both file names, as Universal Resource Locators (URLs), and data. Any transfers that are interrupted by network disconnections or by computer shutdowns and restarts resume when network connectivity is re-established.

BITS Server Extensions is part of Internet Information Services (IIS) and has the following components:

- BITS management console snap-in, for configuring and managing BITS by using Microsoft Management Console (MMC).
- BITS server extension ISAPI, which is used for BITS data transfer.

If you want client computers to be able to use BITS to upload files to a server, you must configure an IIS server with BITS Server Extensions installed and activated.

For more information, see the following topics and Web sites:

- To install BITS Server Extensions, see Install BITS Server Extensions.
- To configure BITS Server Extensions, see Configure BITS Server Extensions.
- To review BITS-specific security information, see Background Intelligent Transfer Service Concepts.
- To review the BITS PSDK, see Background Intelligent Transfer Service.

# Background Intelligent Transfer Service Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This topic describes how to use BITS notifications, and also provides security-related information for BITS.

**Using BITS notifications**

BITS Server Extensions provides a way to notify Web applications of the arrival of data from a client computer to the server, and for that server to generate a reply to the client computer. You can configure this mechanism for each virtual directory on the server by using controls in the **Allow notifications** section of the **BITS Server Extensions** tab.

When **Allow notifications** is checked, two controls become available for configuration: **Notification type** and **Notification URL**.

**Notification type** requires that you select either **Send the file name** or **Send the data**.

- **Send the file name** passes only the name of the file and tells the server the location the location of that uploaded file, as well as where to record a reply. Your application is responsible for opening the request (uploaded) data file and for creating any response data.

- **Send the data** passes all of the data and replies directly between the server and application and specifies the locations for the data and replies.

When BITS Server Extensions receives all of the uploaded data from the application on the client computer, it generates a notification reply in the **Notification URL** that you specify. For **Send the file name**, BITS writes the response to a URL. For **Send the data**, BITS writes the data and response to a temporary file for the client computer to download.

BITS uses IIS security mechanisms. BITS notifications are generated solely in the security context specified for the client system. This context is set in **Authentication Methods**, which is accessed from the **Directory Security** tab of the **Properties** page for the virtual directory.

**Securing virtual directories**

IIS allows a user to set Run script and Execute permissions for a virtual directory separately from Write permissions. Customarily, administrators disallow writing to the virtual directory to prevent clients from uploading executable scripts or programs to a directory and then executing them.

However, when a virtual directory has been enabled for BITS uploads, clients can write to this directory by means of BITS uploads, even though write permissions on the virtual directory have been disallowed. To protect the server, BITS Server Extensions disables all Run script and Execute permissions on a virtual directory that has been upload-enabled for BITS. To keep the virtual directory secure, BITS Server Extensions does not respond to any client requests for uploading data until permissions are disabled. If these permissions are enabled at any time, BITS Server Extensions denies all upload requests until the permissions are disabled again. Whenever BITS Server Extensions denies a request, it writes an IIS log entry.

For more information about securing virtual directories, see the online Help.

**Using BITS with SSL**

BITS Server Extensions is installed with a default configuration that does not secure BITS traffic during data replication. If you want to use BITS to transfer sensitive data, you should do so over a secure connection, such as Secure Sockets Layer (SSL).

For general information about SSL, see the online Help.

# Install BITS Server Extensions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install BITS Server Extensions**

1. Click **Start** and then click **Control Panel**.

2. Select **Add or Remove programs** and then click **Add or Remove Windows Components**.

3. From the **Windows Components Wizard**, select **Application Server**, and then click **Details**.

4. In the **Application Server** dialog box, check **Internet Information Services (IIS)**, and then click **Details**.

5. In the **Internet Information Services (IIS)** dialog box, check **Background Intelligent Transfer Service (BITS) Server Extensions**.

   By default, both the BITS server extension ISAPI and the BITS management console snap-in are installed. To deselect either one, click **Details** in the Internet Information Services (IIS) dialog box to open the Background Intelligent Transfer Service (BITS) server extension dialog box.

6. Close the **IIS** and **Application Server** dialog boxes to return to the **Windows Component Wizard**. Then click **Next** to begin the installation of BITS Server Extensions as part of Application Server. The wizard completes the installation.

## Notes

- To install BITS Server Extensions, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate credentials. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **runas** command to perform this procedure. For Windows 2000 Server family products, see the online Help documentation or go to Windows 2000 product Documentation and select Help for the appropriate product.

- You might need your Windows Server 2003 family CD available when you install BITS Server Extensions, in case the installation process requires additional files.

- You can install BITS on Windows 2000 Server by installing the Platform SDK Redistributables for Windows 2000. Windows 2000 Server uses IIS 5. For help using IIS 5, see Windows 2000 Server Documentation for Internet Information Services.

- To install BITS on a client computer, open the SUPPORT\TOOLS directory on the Windows XP Professional CD, disk image, or network directory, and double-click **SUPTOOLS.EXE**. The BITS tool file is Bitsadmin.exe.

- Internet Information Services is installed on the server you are using when the console opens. If you want to connect to another computer, add that computer in the **Connect to Computer** dialog box by right-clicking **Internet Information Services** in the console tree and selecting **Connect**.

# Configure BITS Server Extensions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure BITS Server Extensions**

1. Click **Start**, click **Administrative Tools**, and then click **Internet Information Services (IIS) Manager**.
2. Click to expand the nodes under the server where BITS Server Extensions is installed, and then click to expand **Web Sites**.
3. Right-click the virtual directory for which you want to configure BITS Server Extensions, and then select **Properties**.
4. In the **Properties** dialog box, select the **BITS Server Extensions** tab.

The following sections explain the settings on the **BITS Server Extensions** tab.

- Allow clients to transfer data to this virtual directory
- Custom settings
- Enable server farm support
- Allow notifications
- Schedule Cleanup
- Run Cleanup Now

**Allow clients to transfer data to this virtual directory**
Enables uploads from BITS clients into the virtual directory. If this check box is not checked, BITS clients attempting an upload are denied access.

### Use default settings

Precludes configuring BITS Server Extensions for the virtual directory. The remaining settings cannot be configured unless you select **Customize settings**.

### Note

- Configuration settings can be inherited. If the directory is a subdirectory of another virtual directory and the parent virtual directory defines a custom configuration, the configuration of the parent virtual directory is used instead of the default settings.

### Customize settings

Allows you to configure this property page according to the settings specified in **Custom settings**.

**Custom settings**
Permits selection of maximum file size and allows you to specify a time limit after which incomplete jobs can be deleted.

### Maximum file size

Defines the maximum size of a file that can be uploaded in a single BITS job. If this setting is not enabled, clients can upload files of any size.

### Delete incomplete jobs after

If enabled, permits incomplete upload files to be deleted by the cleanup process if no progress has been made within the

specified time period. Deletions are performed only when the cleanup process is scheduled to run, or when you manually run a cleanup. See **Schedule Cleanup** for information about scheduling the cleanup process. See **Run Cleanup Now** for information about manually running a cleanup.

#### Enable server farm support

If enabled, instructs the client to try to reconnect to the server of choice instead of the original upload URL used by the client. Server farms can be configured two ways: by using a shared volume for the upload virtual directory, or by using server local storage for the uploaded files. If you want to use local storage, this option enables the client computer to reconnect to the same server computer in the server farm. Uploading to server farms and using local storage are not recommended without enabling and configuring **Enable server farm support**.

### Reconnect to IP address

Specifies the public IP address to use for reconnecting to this server. A server usually has two IP addresses. One points outward and is reachable by client systems. The other belongs to the inner (protected) network. You should specify the outward-pointing IP address here.

### Notes

- You can specify a DNS name here only if each computer in your Web farm has an independent DNS name that can be resolved by client computers.
- **Enable server farm support** must be checked in order to configure this setting.

### Use original IP address after

Specifies the amount of time during which a client computer must reconnect to the server specified in **Reconnect to IP address**. If the client computer does not connect to the server during this time, the client computer must attempt to connect to the original DNS name specified in the upload URL.

#### Allow notifications

Enables notifications for this virtual directory. Both Notification type and Notification URL settings are required if this setting is enabled. For additional information about the notification settings on the **BITS Server Extensions** tab on the **Properties** page for the virtual directory, see **Using BITS notifications** in Related Topics.

### Notification type

You can send either the file name or the data. If **Send the file name** is selected, the server passes the path for the completed upload file to the URL specified by the Notification URL setting. The server returns a file to the client computer as a response. If **Send the data** is selected, the server passes the entire upload file to the URL specified by the Notification URL as a POST. The response is sent to the client computer.

### Notification URL

Specifies the URL to pass the completed upload file to via a POST request if the Notification type is either Send the file contents or Send the file name. The URL can be absolute or self-relative. If the URL is self-relative, the original request URL is used as the base.

#### Schedule Cleanup

Configures the frequency with which BITS Server Extensions scans the virtual directory for incomplete upload files. If an incomplete file is found, it is checked against the time-out value set in **Delete incomplete jobs after**. If the time-out period has elapsed since progress was made on this file, the upload is cancelled and any partial file contents are deleted. This setting is not affected by IIS property inheritance and applies only to the virtual directory.

#### Run Cleanup Now

Immediately starts a cleanup by scanning the virtual directory for incomplete upload files. If an incomplete file is found, it is checked against the time-out value set in **Delete incomplete jobs after**. If the time-out period has elapsed since progress was made on this file, the upload is cancelled and any partial file contents are deleted. To remove all incomplete files from this virtual directory, set the time-out value to 0 before running the cleanup.

### Notes

To install BITS Server Extensions, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate credentials. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **runas** command to perform this

procedure. For Windows 2000 Server family products, see the online Help documentation or go to Windows 2000 Product Documentation and select Help for the appropriate product.

- After you configure settings on the **BITS Server Extensions** tab and click **Apply** or **OK**, a security message appears, indicating that BITS will shut down all Run script and Execute permissions for this virtual directory. When you click **OK**, the **Run Cleanup Now** button becomes enabled. For more information about this security message, see **Setting permissions on virtual directories** in Related Topics.

- BITS Server Extensions must be in the Allowed state in order to function. To determine the state, expand **Web Service Extension** in the IIS console tree. Locate the extension state in the right panel. Click **Allowed** if the extension is in the Prohibited state.

- For information about virtual directories, see Help for Internet Information Services.

# Backup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Backing up and restoring data**

Backup is a utility that you can use to back up and restore user data.

- Before backing up data, see Checklists for Backing Up and Restoring Data.
- For tips on backing up and restoring data, see Best practices for Backup.
- For help with specific tasks, see Backup How To ....
- For general background information, see Backup Concepts.
- For problem-solving information, see Backup Troubleshooting.
- For more information about the recovery options that are available, see Repair overview.

# Checklists for Backing Up and Restoring Data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklists**

- Checklist: Backing up data
- Checklist: Restoring data

# Checklist: Backing up data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Backing up data**

| Step | Reference |
|---|---|
| Review key concepts and prepare to back up data. | Backup Concepts |
| Verify that you are logged on as a member of the Backup Operators group or Administrators group. | Identify members of a local group |
| Verify that you can connect to all shared folders on other computers that need to be backed up. Note: you cannot back up another computer's System State or another domain controller. | |
| If you are using an external storage device, verify that it is compatible with products in the Windows Server 2003 family. Confirm that it is connected directly to the computer that is performing the backup and that the computer is turned on. | Check the hardware compatibility information in Support resources. |
| If you are backing up to a tape, insert the required tape into the tape drive. If you are backing up to a disk drive, verify that there is enough available space. | |
| If you are backing up an Encrypted File System (EFS), first back up the designated recovery agent's EFS private key (the PKCS #12 file) to ensure the successful recovery of encrypted data in case of a disaster such as a system failure. | Export a certificate with the private key |
| To back up files manually, use the Backup or Restore Wizard or click the **Backup** tab in the Backup UI to select files to backup. | Back up files to a file or a tape |
| To back up files automatically, use the schedule feature in backup. | Schedule a backup |

# Checklist: Restoring data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Restoring data**

| Step | Reference |
|---|---|
| Verify that you are logged on as a member of the Backup Operators group or Administrators group. | Identify members of a local group |
| Verify that you can connect to all shared folders on other computers that need to be restored. | |
| Insert the required tape(s) into the tape drive or library. | |
| If you are restoring the System State to a running domain controller, start the server in Directory Services Restore Mode. | Follow the steps in Start the computer in Safe Mode, and then click **Directory Services Restore Mode**. |
| To restore files manually, click the **Restore and Manage Media** tab to select files to restore or use the Backup or Restore Wizard. | Restore files from a file or a tape |
| If you are restoring an Encrypted File System (EFS) on a system where the private key for the encrypted data is somehow inaccessible (for example, on a computer that is not part of a network) or is corrupted or lost, import the designated recovery agent's EFS private key (the PKCS #12 file). | Import a certificate |

# Best practices for Backup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for Backup**

- **Develop backup and restore strategies and test them.**

  With a good plan, you can quickly recover your data if it is lost.

- **Train appropriate personnel.**

  In minimum-security and medium-security networks, assign backup rights to one user and restore rights to a different user. Train personnel with restore rights to perform all of the restore tasks if the administrator is unavailable.

  In a high-security network, make sure that only administrators can restore files.

- **Back up all data on the system and boot volumes and the** System State**.**

  Back up the data on all volumes and the System State data at the same time. This precaution prepares you for the unlikely event of a disk failure.

- **Create an Automated System Recovery backup set.**

  Always create an Automated System Recovery (ASR) backup set when the operating system changes, for example, whenever you install new hardware and drivers or apply a service pack. With an ASR backup set, you can more easily recover from a system failure. Also, backup all data volumes at the same time; ASR protects only the system, so data volumes must be backed up separately.

- **Create a backup log.**

  Always choose to create a backup log for each backup and print them for reference. Keep a book of logs to make it easier to locate specific files. The backup log is helpful when restoring data; you can print it or read it from any text editor. Also, if the tape containing the backup set catalog is corrupted, the printed log can help you locate a file.

- **Retain copies.**

  Keep at least three copies of the media. Keep at least one copy off-site in a properly-controlled environment.

- **Perform trial restorations.**

  Perform a trial restoration periodically to verify that your files were properly backed up. A trial restoration can uncover hardware problems that do not show up when you verify software.

- **Secure devices and media.**

  Secure both the storage device and the backup media. It is possible for someone to access the data from a stolen medium by restoring the data to another server for which they are an administrator.

- **Back up your server cluster effectively.**

  To be able to effectively restore your server cluster in the event of application data or quorum loss, or individual node or complete cluster failure, follow these steps when preparing backups:

  1. Perform an Automated System Recovery (ASR) backup on each node in the cluster.

2. Back up the cluster disks from each node.

3. Back up each individual application (for example, MS Exchange or MS SQL Server) running on the nodes.

For more information, see Backing up and restoring server clusters. For more information on backing up applications in a cluster, see the documentation for that application.

- Schedule a backup

# Back up files to a file or a tape

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To back up files to a file or a tape**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled. You can use this wizard or go to the next step to work in **Advanced Mode**.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. Click the **Backup** tab, and then on the **Job** menu, click **New**.

4. Select the files and folders you want to back up by clicking the box to the left of a file or folder.

5. In **Backup destination**, do one of the following:

   - Choose **File** if you want to back up files and folders to a file. This is selected by default.
   - Choose a tape device if you want to back up files and folders to a tape.

6. In **Backup media or file name**, do one of the following:

   - If you are backing up files and folders to a file, type a path and file name for the backup (.bkf) file, or click the **Browse** button to find a file.
   - If you are backing up files and folders to a tape, choose the tape you want to use.

7. Select any backup options you want, such as the backup type and the log file type, by clicking the **Tools** menu, and then clicking **Options**. When you have finished selecting backup options, click **OK**.

8. Click **Start Backup**, and then make any changes to the **Backup Job Information** dialog box.

9. If you want to set advanced backup options such as data verification or hardware compression, click **Advanced**. When you have finished setting advanced backup options, click **OK**.

10. Click **Start Backup** to start the backup operation.

**Caution**

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

**Notes**

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- If the Backup or Restore Wizard does not start by default, you can still use it to back up files by clicking **Wizard Mode** on the **Welcome** tab.

- To back up and restore Microsoft SQL Server database files, it is recommended that you use the built-in backup and restore utilities that SQL has. For more information, see the Microsoft SQL Server documentation.

- Some tape drives may not support hardware compression.

- System State data contains most elements of a system's configuration, but it might not include all of the information that you require to recover your system from a failure. Therefore, it is recommended that you back up all boot and system volumes, including the System State, when you back up your system.

- You can only back up the System State data on a local computer. You cannot back up the System State data on a remote computer.

- Backup does not support the use of backup media such as CD-RW (compact disc rewritable), CD-R (compact disc recordable), and DVD-R (digital video disc recordable). To save backups to this type of media, back up to a file and copy that file to the CD. You can use Backup to restore from a CD.

- Backup files usually have the extension .bkf. You can use any extension you like, but it is highly recommended that you use .bkf, which has file associations that will ensure that the backup file is recognizable.

- Backup operators and administrators can back up and restore encrypted files and folders without decrypting the files or folders.

- If you have Windows Media Services running on your computer, and you want to back up the files associated with these services, see "Running Backup with Windows Media Services" in the Windows Media Services online documentation. You must follow the procedures outlined in the Windows Media Services online documentation before you can back up or restore files associated with Windows Media Services.

**Using a command line**

1. Open Command Prompt.

2. To backup to a file or tape, type:

   **ntbackup backup***@bks file name***/J** {"*backup job name*"} **/F** {"*file name*"} **/T** {"*tape name*"} **/P** {"*pool name*"} **/G** {"*guid name*"} **/N** {"*media name*"} **/A**

| Value | Description |
|---|---|
| *@bks file name* | Specifies the name of the backup selection file (.bks file) to be used for this backup operation. The @ character must precede the name of the backup selection file. A backup selection file contains information on the files and folders you have selected for backup. You have to create the file using the graphical user interface (GUI) version of Backup. Alternatively, you could supply the path to the drive or file to backup, for example, D:\. |
| **/J** {"*backup job name*"} | Specifies the job name to be used in the backup report. The job name usually describes the files and folders you are backing up in the current backup job. |

| | |
|---|---|
| **/F** {"*file name*"} | Specifies the logical disk path and file name of the backup file. You must not use the following switches with this switch: **/P /G /T**. |
| **/T** {"*tape name*"} | Overwrites or appends to this tape. |
| **/P** {"*pool name*"} | Specifies the media pool from which you want to use media. This is usually a subpool of the Backup media pool, such as 4mm DDS. If you select this value, you must not use the following switches: **/A /G /F /T** |
| **/G** {"*guid name*"} | Overwrites or appends to this tape. Do not use this switch in conjunction with **/P**. |
| **/N** {"*media name*"} | Specifies the new tape name. You must not use **/A** with this switch. |
| **/A** | Performs an append operation. Either **/G** or **/T** must be used in conjunction with this switch. Do not use this switch in conjunction with **/P**. |

For information on additional file and tape backup options, see the Ntbackup.

**Examples:**
To backup drive D: to file C:\backup.bkf, with job name "Backup Job 1" type the following at the command line:

**ntbackup.exe backup D:\ /j "Backup Job 1" /f "C:\Backup.bkf"**

For a tape backup, to create a backup job named "Backup Job 1" that backs up all the files and folders listed in the backup selection file c:\backup.bks to a tape drive, type:

**ntbackup backup @C:\backup.bks /n "Media created 11/5/2001 at 1:25 PM" /d "Set created 11/5/2001 at 1:25 PM" /j "Backup Job 1" /p "4mm DDS"**

**Important**

- If you don't specify options at the command prompt, they will default to those specified in the Backup application.
- Before using the command line to perform backup operations, it is recommended that you use the user interface to create the initial backup selection file, settings and a scheduled task. You can then use that scheduled task to view the command syntax. Copy the information from the scheduled task, make any changes that are necessary to create a script or command line syntax, then delete the scheduled task if it is not needed otherwise.
- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.
- To back up and restore Microsoft SQL Server database files, it is recommended that you use the built-in backup and restore utilities that SQL has. For more information, see the Microsoft SQL Server documentation.
- Some tape drives may not support hardware compression.

**Notes**

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To view the complete syntax for this command, at a command prompt, type:

  **ntbackup /?**

- If you do not specify the other Backup options, **ntbackup** will use the default values of the Backup program for the backup type, verification setting, logging level, hardware compression, and any other settings.

- System State data contains most elements of a system's configuration, but it might not include all of the information that you require to recover your system from a failure. Therefore, it is recommended that you back up all boot and system volumes, including the System State, when you back up your system.

- You can only back up the System State data on a local computer. You cannot back up the System State data on a remote computer.

- Backup files usually have the extension .bkf. You can use any extension that you want, but it is highly recommended that you use .bkf, which has file associations that will ensure that the backup file is recognizable.

- Backup operators and administrators can back up and restore encrypted files and folders without decrypting the files or folders.

- If you have Windows Media Services running on your computer, and you want to back up the files associated with these services, see "Running Backup with Windows Media Services" in the Windows Media Services online documentation. You must follow the procedures outlined in the Windows Media Services online documentation before you can back up or restore files associated with Windows Media Services.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Back up System State data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To back up System State data**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled. You can use this wizard or go to the next step to work in **Advanced Mode**.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. Click the **Backup** tab, then click the box next to **System State** and any other items you would like to backup. It is recommended that you backup all boot and system volumes along with the System State.

## Notes

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.
- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.
- If the Backup or Restore Wizard does not start by default, you can still use it to back up the System State data by clicking **Wizard Mode** on the **Welcome** tab.
- System State data contains most elements of a system's configuration, but it might not include all of the information that you require to recover your system from a failure. Therefore, it is recommended that you back up all boot and system volumes, including the System State, when you back up your system.
- You can only back up the System State data on a local computer. You cannot back up the System State data on a remote computer.

**Using a command line**

1. Open Command Prompt.

2. To backup the System State data, type:

   **ntbackup backup systemstate**

| Value | Description |
|---|---|
| **systemstate** | Specifies that you want to back up the System State data. When you select this option, the backup type will be forced to copy. |

For information on additional backup options, see the Ntbackup.

For example, to create a backup job named "Backup Job 1" that backs up the System State data to the file C:\backup.bkf, type:

**ntbackup backup systemstate /J "Backup Job 1" /F "C:\backup.bkf"**

All other options will default to those specified in the Backup program.

### Notes

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- System State data contains most elements of a system's configuration, but it might not include all of the information that you require to recover your system from a failure. Therefore, it is recommended that you back up all boot and system volumes, including the System State, when you back up your system.

- To view the complete syntax for this command, at a command prompt, type:

  **ntbackup /?**

- If you do not specify the other Backup options, **ntbackup** will use the default values of the Backup program for backup type, verification setting, logging level, hardware compression, and any other settings.

- You can only back up the System State data on a local computer. You cannot back up the System State data on a remote computer.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Schedule a backup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To schedule a backup**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled. You can use this wizard or go to the next step to work in **Advanced Mode**.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. Click the **Backup** tab, and then on the **Job** menu, click **New**.

4. Select the files and folders you want to back up by clicking the box to the left of a file or folder.

5. Select **File** or a tape device in **Backup destination**.

6. In **Backup media or file name**, type a path and file name for the backup file, or select a tape.

7. Select any backup options you want, such as the backup type and the log file type, by clicking the **Tools** menu, and then clicking **Options**. When you have finished selecting backup options, click **OK**.

8. On the **Job** menu select **Save Selections** to save your selections as a backup job file (.bks).

9. Click **Start Backup** and make any changes you want to the **Backup Job Information** dialog box.

10. If you want to set advanced backup options such as data verification or hardware compression, click **Advanced**. When you have finished selecting advanced backup options, click **OK**.

11. Click **Schedule** in the **Backup Job Information** dialog box.

12. In the **Set Account Information** dialog box, enter the user name and password that you want the scheduled backup to run under.

13. In the **Scheduled Job Options** dialog box, in **Job name**, type a name for the scheduled backup job, and then click **Properties** on the **Schedule data** tab to set the date, time, and frequency parameters for the scheduled backup. When you have finished, click **OK**, and then click **OK** again.

**Caution**

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

**Notes**

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- If you are scheduling a tape backup, you may have to use Removable Storage to make sure that your tape is available in the Backup media pool. For more information on Removable Storage, see Related Topics.

- You must have the Task Scheduler service running before you can schedule a backup. To do this, open the command prompt window and type **net start schedule**. You can also use Services in the Computer Management administrative tool to start, stop, and view the status of services.

- System State data contains most elements of a system's configuration, but it might not include all of the information that you require to recover your system from a failure. Therefore, it is recommended that you back up all boot and system volumes, including the System State, when you back up your system.

- If you want to back up your System State data, you must select **System State** in **Click to select the check box for any drive, folder, or file that you want to back up**.

- You can only back up the System State data on a local computer. You cannot back up the System State data on a remote computer.

- You can change the settings of a scheduled backup job after you schedule it by clicking the **Schedule Jobs** tab and then clicking the backup icon that is displayed on the calendar.

- In the **Scheduled Job Options** dialog box, you can delete a scheduled backup from the Task Scheduler by clicking **Delete**.

- Backup operators and administrators can back up and restore encrypted files and folders without decrypting the files or folders.

- If you have Windows Media Services running on your computer, and you want to back up the files associated with these services, see "Running Backup with Windows Media Services" in the Windows Media Services online documentation. You must follow the procedures outlined in the Windows Media Services online documentation before you can back up or restore files associated with Windows Media Services.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Restore Data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Restore data**

- Restore files from a file or a tape
- Restore System State data

# Restore files from a file or a tape

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To restore files from a file or a tape**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. Click the **Restore and Manage Media** tab, select the files and folders you want to restore by clicking the box to the left of a file or folder.

4. In **Restore files to**, do one of the following:

   - Click **Original location** if you want the backed up files and folders to be restored to the folder or folders they were in when they were backed up. Skip to step 6.

   - Click **Alternate location** if you want the backed up files and folders to be restored to a folder that you designate. This option will preserve the folder structure of the backed up data; all folders and subfolders will appear in the alternate folder you designate.

   - Click **Single folder** if you want the backed up files and folders to be restored to a folder that you designate. This option will not preserve the folder structure of the backed up data; the files will appear only in the folder that you designate.

5. If you selected **Alternate location** or **Single folder**, type a path for the folder under **Alternate location**, or click the **Browse** button to find the folder.

6. On the **Tools** menu, click **Options**, click the **Restore** tab, and then do one of the following:

   - Click **Do not replace the file on my computer** if you do not want the restore operation to copy over files that are already on your hard disk.

   - Click **Replace the file on disk only if the file on disk is older** if you want the restore operation to replace older files on your disk with newer files from your backup.

   - Click **Always replace the file on my computer** if you want the restore operation to replace files on your disk regardless of whether the backup files are newer or older.

   - Click **OK** to accept the restore options you have set.

7. Click **Start Restore**.

8. If you want to change any of the advanced restore options, such as restoring security settings and junction point data, click **Advanced**. When you are done setting advanced restore options click **OK**.

9. Click **OK** to start the restore operation.

**Caution**

- Choosing **Always replace the file on my computer** might cause you to lose data if a file you are working on is contained in the backup.

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- You can also use the Restore Wizard to restore files by clicking **Restore Wizard** on the **Tools** menu.

- To back up and restore Microsoft SQL Server database files, it is recommended that you use the built-in backup and restore utilities in SQL. For more information, see the Microsoft SQL Server documentation.

- To restore the System State data on a domain controller, you must first start your computer in Directory Services Restore Mode. This will allow you to restore the SYSVOL directory and the Active Directory directory service database.

- You can only restore the System State data on a local computer. You cannot restore the System State data on a remote computer.

- Backup operators and administrators can back up and restore encrypted files and folders without decrypting the files or folders.

### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Restore System State data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To restore System State data**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. Click the **Restore and Manage Media** tab, click the box next to **System State**. This will restore the System State data along with any other data you have selected for the current restore operation.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- You can also use the Restore Wizard to restore the System State data by clicking **Restore Wizard** on the **Tools** menu.

- If you are restoring the System State data to a domain controller, you must choose whether you want to perform a primary restore, an authoritative restore or a nonauthoritative restore. The default method of restoring the System State data to a domain controller is nonauthoritative (normal). In this mode, any component of the System State that is replicated to with another domain controller, such as the Active Directory directory service or the File Replication service (including the SYSVOL directory), will be brought up to date by replication after you restore the data. For example, if the last backup was performed a week ago, and the System State is restored using the default restore method (nonauthoritative), any changes made subsequent to the backup operation will be replicated from the domain controllers.

  In some cases, you may not want to replicate the changes that have been made subsequent to the last backup operation. In other words, there may be instances where you want all replicas to have the same state as the backed up data. To achieve this state, you must perform an authoritative restore.

  For example, you have to perform an authoritative restore if you inadvertently delete users, groups, or organizational units from the Active Directory directory service, and you want to restore the system so that the deleted objects are recovered and replicated. To do this, you need to run the Ntdsutil utility after you have restored the data but before you restart the domain controller. This utility lets you mark objects as authoritative, which will ensure that any replicated or distributed data that you have restored is properly replicated or distributed throughout your organization. The Ntdsutil command line utility can be run from the command prompt. Help for the Ntdsutil utility can also be found at the command prompt by typing **ntdsutil /?**. For more information , see Related Topics.

- To restore the System State data on a domain controller, you must first start your computer in a special startup option called Directory Services Restore Mode. This will allow you to restore the SYSVOL directory and Active Directory directory service database. To access Directory Services Restore Mode, press F8 during startup and select it from the list of startup options. For more information on startup options, see Related Topics.

- You can only restore the System State data on a local computer. You cannot restore the System State data on a remote computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set backup options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set backup options**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. Click the **Tools** menu, then click **Options**.

4. On the **General** tab, set the options you want.

**Notes**

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

| Item | Description |
|---|---|
| Compute selection information before backup and restore operations | Estimates the number of files and bytes that will be backed up or restored during the current backup or restore operation. This information is calculated and displayed before the backup or restore begins. |
| Use the catalogs on the media to speed up building restore catalogs on disk | Specifies that you want to use the on-media catalog to build the on-disk catalog for restore selections. This is the fastest way to build an on-disk catalog. However, if you want to restore data from several tapes, and the tape with the on-media catalog is missing or you want to restore data from media that is damaged, do not select this option. Backup will then scan your entire backup set (or as much of it as you have) and build an on-disk catalog. This could take several hours if your backup set is very large. |
| Verify data after the backup completes | Checks for disk errors that may have occurred while files were being copied to tape. This might substantially increase the time it takes to perform a backup. It is recommended that you only verify backups of data files; system backups are difficult to verify due to the large number of changes that happen to system files on a continual basis. Some data files that were in use during the backup might also cause verification errors, but you can generally ignore these errors. If there are a large number of verification errors, there may be a problem with the media or the file you are using to back up data. If this occurs, use different media or designate another file and run the backup operation again. |
| Back up the contents of mounted drives | Backs up the data that is on a mounted drive. If you select this option, and you back up a mounted drive, the data that is on the mounted drive will be backed up. If you do not select this option, and you back up a mounted drive, only the path information for the mounted drive will be backed up. |

| | |
|---|---|
| Show alert message when I start Backup and Removable Storage is not running | Displays a dialog box when you start Backup and Removable Storage is not running. Backup will then start Removable Storage automatically. If you primarily back up data to a file, and you save the file to a floppy disk, a hard disk, or any type of removable disk, do not check this box. If you primarily back up data to a tape, or other media that is managed by Removable Storage, check this box. |
| Show alert message when I start Backup and there is recognizable media available | Displays a dialog box when you start Backup and there is new media available. If you primarily back up data to a file, and you save the file to a floppy disk, a hard disk, or any type of removable disk, do not check this box. If you primarily back up data to a tape or other media that is managed by Removable Storage, check this box. For more information on media pools and Removable Storage, see Related Topics. |
| Show alert message when new media is inserted | Displays a dialog box when new media is detected by Removable Storage. If you primarily back up data to a file and you save the file to a floppy disk, a hard disk, or any type of removable disk, do not check this box. If you primarily back up data to a tape, or other media that is managed by Removable Storage, check this box. |
| Always allow use of recognizable media without prompting | Automatically moves new media that is detected by Removable Storage to the Backup media pool. If you usually back up data to a file, and you save the file to a floppy disk, a hard disk, or any type of removable disk, do not check this box. If you want all new media to be available to the Backup program only, and no one is using Removable Storage to manage new media, check this box. |

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Using batch files to back up data

# Set the backup type

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To set the backup type

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. Click the **Tools** menu, then click **Options**.

4. On the **Backup Type** tab, in **Default Backup Type**, select the type of backup you want to perform.

### Notes

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- There are five backup types: copy, daily, differential, incremental, and normal. For more information about these backup types, see Related Topics.

#### Using a command line

1. Open Command Prompt.

2. To set the backup type, type:

   **ntbackup backup /M** {*backuptype*}

Backup type must be one of the following: normal, copy, differential, incremental, or daily. For information on additional backup options, see the Ntbackup.

For example, to create a normal backup job named "Backup Job 1" that backs up the System State data to the file C:\backup.bkf, type:

**ntbackup backup systemstate /M normal /J "Backup Job 1" /F "C:\backup.bkf"**

### Notes

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to

prevent losing data. Some file systems might not support all of the features of other file systems.

- To view the complete syntax for this command, at a command prompt, type:

  **ntbackup /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Exclude file types from a backup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To exclude file types from a backup**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. Click the **Tools** menu, then click **Options**.

4. On the **Exclude Files** tab, do one of the following:

   - Click **Add new** under the **Files excluded for all users** list if you want to exclude files that are owned by all users.

   - Click **Add new** under the **Files excluded for user** list if you want to exclude only files that you own.

5. In the **Add Excluded Files** dialog box, do one of the following:

   - If you want to exclude a registered file type, click the file type in **Registered file type**.

   - If you want to exclude a custom file type, enter a period and then the one, two, or three letter file extension in **Custom file mask**.

6. Type a path in **Applies to path** if you want to restrict the excluded file type to a specific folder or hard disk drive, and then click **OK**.

## Notes

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- If you restrict excluded files to a specific path (folder), the files will be restricted from all subfolders of that path unless you clear the **Applies to all subfolders** check box.

- You can change how a file is excluded from a backup set by clicking the file in **Files excluded for all users** or **Files excluded for user**, and then clicking **Edit**. The **Add Excluded Files** dialog box appears.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set advanced backup options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set advanced backup options**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. Click the **Backup** tab and select the files and folders you want to back up.

4. Click **Start Backup**.

5. On the **Backup Job Information** dialog box, click **Advanced**.

6. Set the advanced backup options you want, and then click **OK**. See the Notes section for a description of each option.

## Notes

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

| Item | Description |
|---|---|
| Back up data that is in Remote Storage | Backs up data that has been designated for Remote Storage. If you choose this option, Remote Storage reparse points (placeholder files) are backed up. If you do not select this option, Remote Storage reparse points are not backed up. You can restore Remote Storage data only to an NTFS volume. |
| Verify data after backup | Checks for disk errors that may have occurred while files were being copied to tape. This might substantially increase the time it takes to perform a backup. |
| If possible, compress the backup data to save space | Compresses the data you are backing up so that you can save more data on a tape. If this option is disabled, you do not have a tape drive on your computer or your tape drive cannot handle compressed data. |
| Automatically back up System protected Files with the System State | Backs up all of the system files that are in your systemroot directory in addition to the boot files that are included with the System State data. This option will substantially increase the size of your backup job, but select it if you have recently updated drivers or changed other operating system files. For example, if you choose this option on Windows XP Professional, it will add over 200 megabytes to the size of your backup job. |
| Backup Type | Determines how your data is backed up. Backup types include copy, daily, differential, incremental, and normal. |

#### Using a command line

1. Open Command prompt.

2. To set the advanced backup options, type:

   **ntbackup backup/V:{yes|no} /HC:{on|off}**

| Value | Description |
|---|---|
| **/V: {yes\|no}** | Specifies whether or not the backup data is verified after the backup is complete. |
| **/HC: {on\|off}** | Specifies whether or not hardware compression is used (if it is available on the backup media). Usually only tape drives have the ability to compress data. |

For other backup options, see information about the Ntbackup command.

For example, to create a backup job named "Backup Job 1" that backs up data on drive D:\ to the file C:\backup, type:

**ntbackup backup D:\ /J "Backup Job 1" /F "C:\backup.bkf"**

All other options will default to those specified in the Backup program.

### Notes

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **ntbackup /?**

- If you do not specify the other Backup options, **ntbackup** will use the default values of the Backup program for the backup type, verification setting, logging level, hardware compression, and any other settings.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set restore options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set restore options**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. Click the **Tools** menu, click **Options**.

4. On the **Restore** tab, do one of the following:

   - Click **Do not replace the file on my computer** if you do not want the restore operation to copy over files that are already on your disk.

   - Click **Replace the file on disk only if the file on disk is older** if you want the restore operation to replace older files on your disk with newer files from your backup.

   - Click **Always replace the file on my computer** if you want the restore operation to replace files on your disk regardless whether the backup files are newer or older.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set advanced restore options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set advanced restore options**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. Click the **Restore and Manage Media** menu and select the files to restore.

4. Click the **Start Restore** button.

5. On the **Confirm Restore** dialog box, click **Advanced**.

6. Set the advanced restore options you want, and then click **OK**. See the Notes section for a description of each option.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

| Item | Description |
|---|---|
| **Restore security** | Restores security settings for each file and folder. Security settings include permissions, audit entries, and ownership. This option is available only if you have backed up data from an NTFS volume used in the Windows Server 2003 family of operating systems, and you are restoring it to an NTFS volume used in Windows Server 2003 family operating systems. |
| **Restore junction points, and restore file and folder data under junction points to the original location** | Restores junction points on your hard disk as well as the data that the junction points point to. If you do not select this check box, the junction points will be restored as common directories and the data your junction points point to will not be accessible. Also, if you are restoring a mounted drive and you want to restore the data that is on the mounted drive, you must select this check box. If you do not select this check box, you will only restore the folder containing the mounted drive. |
| **When restoring replicated data sets, mark the restored data as the primary data for all replicas** | Performs a primary restore. Ensures that restored File Replication service (FRS) data is replicated to your other servers. Select this option only when restoring the *first* replica set to the network. Do not use this option if one or more replica sets have already been restored. |

| | |
|---|---|
| **Restore the Cluster Registry to the quorum disk and all other nodes** | Ensures that the cluster quorum database is restored and replicated on all nodes in a server cluster. If you select this option, Backup will stop the Cluster service on all other nodes of the server cluster after the node that was restored is rebooted. The entire server cluster will therefore be down during an authoritative restore of the data on the cluster quorum disk. For more information, see Related Topics. |
| **Preserve existing volume mount points** | Prevents the restore operation from writing over any volume mount points that you have created on the partition or volume you are restoring data to. This option is primarily applicable when you are restoring data to an entire drive or partition. For example, if you are restoring data to a replacement drive and you have partitioned, formatted the drive, and restored volume mount points, select this option so your volume mount points are not restored. If you are restoring data to a partition or drive that you have just reformatted and you want to restore the old volume mount points, do not select this option. |

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Maintain Media

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Maintain media**
Backup provides a way to perform some simple management of backup files and tapes. For advanced management of backup media, see Removable Storage.

- Format a tape
- Retension a tape
- Mark a tape as free
- Delete a catalog
- Update a catalog

# Format a tape

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To format a tape**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. On the **Restore and Manage Media** tab, right-click the tape you want to format in **Backup Identification Label**.

4. Click **Format**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- Not all drives support using Backup to format a tape.

- If you do not have a tape drive, this feature is not available.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Retension a tape

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To retension a tape**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. On the **Restore and Manage Media** tab, click the tape you want to retension.

4. On the **Tools** menu, click **Media Tools**, and then click **Retension**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- You can also access the **Retension** command by right-clicking a tape on the **Restore and Manage Media** tab.

- Not all drives require or support the retension option.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Maintain Media

# Mark a tape as free

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To mark a tape as free**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. On the **Restore and Manage Media** tab, click the tape you want to erase.

4. On the **Tools** menu, click **Media Tools**, and then click **Mark as free** .

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- Do not use this option if you need to erase tapes for legal reasons. **Mark as free** will not destroy the data on the tape. You must use another method to erase the tape.

- You can only mark a tape as free if it is in the tape drive or in a loader slot of a tape changer.

- Marking a tape as free moves the tape from the backup media pool to the free media pool.

- You can also use Removable Storage to manage tapes.

- You can also access the **Mark as free** command by right-clicking a tape on the **Restore and Manage Media** tab.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a catalog

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a catalog**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. On the **Restore and Manage Media** tab, right-click the backup set that contains the catalog you want to delete.

4. Click **Delete catalog** if the backup set has been saved to a file, or click **Delete from system** if the backup set has been saved to a tape.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- Use this procedure only if you have a damaged or lost tape or file and you want to delete it from the on-disk catalog.

- If you click **Delete catalog**, this procedure will delete the on-disk catalog for the selected backup set. It will not delete the backup file.

- If you click **Delete catalog from system**, this procedure will delete the on-disk catalog for the selected backup set, and it will delete the tape from the Removable Storage database if the tape is offline. It will not delete the on-media catalog that is on the tape.

- You can restore a catalog for a file or a tape by clicking the **Restore and Manage Media** tab, right-clicking **File** or the tape you want to catalog, and then clicking **Catalog file** or **Catalog**. For more information on creating a catalog, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Removable Storage
Format a tape

# Update a catalog

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To update a catalog**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. On the **Restore and Manage Media** tab, right-click the media containing the backup set you want to catalog.

4. Click **Catalog**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- This procedure creates an on-disk catalog. It does not create an on-media catalog.

- If you are creating a catalog of a backup set that is saved on a tape, do one of the following before you perform this procedure:

  - If you have all of the tapes in the backup set and the tapes are not damaged or corrupted, click the **Tools** menu, click **Options**, click the **General** tab, and then make sure the **Use the catalogs on the media to speed up building restore catalogs on disk** check box is checked.

  - If you are missing a tape in the backup set or a tape is damaged or corrupted, click the **Tools** menu, click **Options**, click the **General** tab, and then make sure the **Use the catalogs on the media to speed up building restore catalogs on disk** check box is cleared. This will ensure that the catalog is complete and accurate; however, it might take a long time to create the catalog.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Perform System Repair and Recovery

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Perform system repair and recovery**

- Create an Automated System Recovery set using Backup
- Recover from a system failure using Automated System Recovery
- Install the Recovery Console as a startup option
- Delete the Recovery Console
- Start the computer and use the Recovery Console

# Create an Automated System Recovery set using Backup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create an Automated System Recovery set using Backup**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled. You can use the Backup or Restore Wizard to create an Automated System Recovery (ASR) set by answering **All information on this computer** in the **What do you want to backup?** section. Otherwise, you can go to the next step to create an ASR set in **Advanced Mode**.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. On the **Tools** menu, click **ASR Wizard**.

4. Follow the instructions that appear on your screen.

### Important

- You will need a blank 1.44 MB floppy disk to save your system settings and media to contain the backup files. If your computer does not have a floppy drive, see Backup Troubleshooting.

### Notes

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- This procedure will only back up those system files that are necessary for starting your system. You will need to backup your data separately.

- After creating the ASR set, label this floppy disk and backup media carefully and keep them together. To use the backup media, you must have the floppy disk that you created with that set of media. You cannot use a floppy disk created at a different time or with a different set of media. You must also have your Setup CD available at the time you perform Automated System Recovery.

- Keep the ASR set in a secure location. The ASR set contains information about your systems configuration that could be used to do harm to your system.

- If you are backing up a server cluster, run the Automated System Recovery Preparation Wizard on all nodes of the cluster and make sure that the Cluster service is running when you start each Automated System Recovery backup. Make sure that one of the nodes on which you run the Automated System Recovery Preparation Wizard is listed as the owner of the quorum resource while the wizard is running.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Recover from a system failure using Automated System Recovery
Backing up and restoring server clusters

# Recover from a system failure using Automated System Recovery

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To recover from a system failure using Automated System Recovery**

1. Make sure you have the following available before you begin the recovery procedure:

   - Your previously created Automated System Recovery (ASR) floppy disk.
   - Your previously created backup media.
   - The original operating system installation CD.
   - If you have a mass storage controller and you are aware that the manufacturer has supplied a separate driver file for it (different from driver files available on the Setup CD), obtain the file (on a floppy disk) before you begin this procedure.

2. Insert the original operating system installation CD into your CD drive.
3. Restart your computer. If you are prompted to press a key to start the computer from CD, press the appropriate key.
4. If you have a separate driver file as described in step 1, use the driver as part of Setup by pressing F6 when prompted.
5. Press F2 when prompted at the beginning of the text-only mode section of Setup. You will be prompted to insert the ASR floppy disk you have previously created.
6. Follow the directions on the screen.
7. If you have a separate driver file as described in step 1, press F6 (a second time) when prompted after the system reboots.
8. Follow the directions on the screen.

## Notes

- Physical access to a server is a high security risk. To maintain a more secure environment, you must restrict physical access to all servers and network hardware.
- Automated System Recovery will not restore your data files. See Related Topics for more information on backing up and restoring your data files.
- If you are restoring a server cluster in which all nodes failed and the quorum disk cannot be restored from backup, use Automated System Recovery on each node in the original cluster to restore the disk signatures and the partition layout of the cluster disks (quorum and nonquorum). For more information about backing up and restoring server clusters, see the Related Topics link at the bottom of this page.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install the Recovery Console as a startup option

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install the Recovery Console as a startup option**

1. With Windows running, insert the Setup CD into your CD-ROM drive.
2. Click **Start** and select **Run**.
3. Type the following where *D*: is the CD-ROM drive letter:

   On 32-bit versions of Windows Server 2003: `D:\i386\winnt32.exe /cmdcons`

   - or -

   On x64-based versions of Windows Server 2003: `D:\amd64\winnt32.exe /cmdcons`
4. Follow the instructions on the screen.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- You can not install the Recovery Console on Itanium-based computers.
- To run the Recovery Console, you must restart your computer and select the Recovery Console option from the list of available operating systems.
- To see the commands available on the Recovery Console, type **help** at the console prompt.
- If your computer will not start or you are using an Itanium-based computer, you can run the Recovery Console from the Setup CD. See Start the computer and use the Recovery Console for information on running the Recovery Console when your computer will not start.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete the Recovery Console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete the Recovery Console**

1. Open My Computer.
2. Double-click the hard drive on which you installed the Recovery Console.
3. On the **Tools** menu, click **Folder Options**.
4. Click the **View** tab.
5. Click **Show hidden files and folders**, clear the **Hide protected operating system files** check box, and then click **OK**. If you receive a warning about displaying protected system files, click **Yes** to continue.
6. At the root directory, delete the \Cmdcons folder.
7. At the root directory, delete the file Cmldr.
8. Click **Start**, then **Control Panel**, then click **System**.
9. On the **Advanced** tab under **Startup and Recovery**, select **Settings**.
10. On the **Startup and Recovery** dialog box, under **System startup**, select **Edit** to edit the startup options file manually. Boot.ini will display in Notepad.
11. Remove the entry for the Recovery Console. It will look similar to this:

    C:\cmdcons\bootsect.dat="Microsoft Windows Recovery Console" /cmdcons

12. Save the file and close it.

### Caution

- Modifying the Boot.ini file incorrectly may prevent your computer from restarting. Be sure to delete only the entry for the Recovery Console.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- You can only install the Recovery Console feature on x86-based computers.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Repair overview

# Start the computer and use the Recovery Console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start the computer and use the Recovery Console**

1. Insert the Setup CD and restart the computer from the CD drive.
2. When the text-based part of Setup begins, follow the prompts; choose the repair or recover option by pressing **R**.
3. If you have a dual-boot or multiple-boot system, choose the installation that you need to access from the Recovery Console.
4. When prompted, type the password for the local administrator account.
5. At the system prompt, type the relevant Recovery Console commands; type **help** for a list of commands or **help***commandname* for help about a specific command.
6. To exit the Recovery Console and restart the computer, type **exit**.

**Important**

- Because the Recovery Console is quite powerful, it is recommended for use only by advanced users or administrators.
- In most cases, you will need the password for the built-in administrator account to use the Recovery Console.
- You can set the **Recovery console: Allow automatic administrative logon** setting in the Security Options section of Local Security Settings. Changing this setting will allow you to start the Recovery Console without having to provide the administrator password. For more information, see "Recovery console: Allow automatic administrative logon" and "Edit local security settings" in Related Topics at the bottom of this page.

  Be careful when enabling this option. This will allow anyone with physical access to a computer to boot into the Recovery Console and access the Recovery Console commands.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Backup Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about the Backup utility.

- Backup overview
- Understanding Backup
- Administering Backup

# Backup overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Backup overview**

The Backup utility helps you protect data from accidental loss if your system's hardware or storage media fails. For example, you can use Backup to create a duplicate copy of the data on your hard disk and then archive the data on another storage device. The backup storage medium can be a logical drive such as your hard disk, a separate storage device such as a removable disk, or an entire library of disks or tapes organized and controlled by a robotic changer. If the original data on your hard disk is accidentally erased or overwritten, or becomes inaccessible because of a hard disk malfunction, you can easily restore the data from the archived copy.

Backup creates a volume shadow copy of your data to create an accurate copy of the contents of your hard drive, including any open files or files that are being used by the system. Users can continue to access the system while the Backup utility is running without risking loss of data.

For more information on volume shadow copy, see Volume shadow copy overview.

Using Backup, you can:

- Archive selected files and folders on your hard disk.
- Restore the archived files and folders to your hard disk or any other disk you can access.
- Use Automated System Recovery to save and restore all the system files and configuration settings that you need to recover from a complete system failure.
- Make a copy of any Remote Storage data and any data stored in mounted drives.
- Make a copy of your computer's System State.
- Create a log of what files were backed up and when the backup was performed.
- Make a copy of your computer's system partition, boot partition, and the files needed to start up your system in case of computer or network failure.
- Schedule regular backups to keep your archived data up-to-date.
- Backup also performs simple media management functions, for example, formatting. More advanced management tasks such as mounting and dismounting a tape or disk are done by a service called Removable Storage. For more information on Removable Storage, see Removable Storage overview.

**Caution**

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.
- Physical access to a server is a high security risk. To maintain a more secure environment, you must restrict physical access to all servers and network hardware.

# Understanding Backup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Backup**
This section covers:

- Types of backup
- Volume shadow copy overview
- Permissions and user rights required to back up and restore
- System State data
- Authoritative, primary, and normal restores
- Repair overview
- Recovery Console overview
- Automated System Recovery (ASR) overview

# Types of backup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Types of backup**
The Backup utility supports five methods of backing up data on your computer or network.

**Copy backup**
A copy backup copies all the files you select, but does not mark each file as having been backed up (in other words, the archive attribute is not cleared). Copying is useful if you want to back up files between normal and incremental backups because copying does not affect these other backup operations.

**Daily backup**
A daily backup copies all the files that you select that have been modified on the day the daily backup is performed. The backed-up files are not marked as having been backed up (in other words, the archive attribute is not cleared).

**Differential backup**
A differential backup copies files that have been created or changed since the last normal or incremental backup. It does not mark files as having been backed up (in other words, the archive attribute is not cleared). If you are performing a combination of normal and differential backups, restoring files and folders requires that you have the last normal as well as the last differential backup.

**Incremental backup**
An incremental backup backs up only those files that have been created or changed since the last normal or incremental backup. It marks files as having been backed up (in other words, the archive attribute is cleared). If you use a combination of normal and incremental backups, you will need to have the last normal backup set as well as all incremental backup sets to restore your data.

**Normal backup**
A normal backup copies all the files you select and marks each file as having been backed up (in other words, the archive attribute is cleared). With normal backups, you only need the most recent copy of the backup file or tape to restore all of the files. You usually perform a normal backup the first time you create a backup set.

Backing up your data using a combination of normal backups and incremental backups requires the least amount of storage space and is the quickest backup method. However, recovering files can be time-consuming and difficult because the backup set might be stored on several disks or tapes.

Backing up your data using a combination of normal backups and differential backups is more time-consuming, especially if your data changes frequently, but it is easier to restore the data because the backup set is usually stored on only a few disks or tapes.

For more information, see Set the backup type.

# Volume shadow copy overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Volume shadow copy overview**

With Backup, you can create shadow copy backups of volumes and exact copies of files, including all open files. For example, databases that are held open exclusively and files that are open due to operator or system activity are backed up during a volume shadow copy backup. In this way, files that have changed during the backup process are copied correctly.

Shadow copy backups ensure that:

- Applications can continue to write data to the volume during a backup.
- Files that are open are no longer omitted during a backup.
- Backups can be performed at any time, without locking out users.

Some applications manage storage consistency differently while files are open, which can affect the consistency of the files in the backup. For critical applications, consult the application documentation or your provider for information about the recommended backup method. When in doubt, shutdown the application before performing a backup.

It is highly recommended that you perform backups when server usage is low. For example, perform backups late at night.

For more information, see Set advanced backup options.

# Permissions and user rights required to back up and restore

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Permissions and user rights required to back up and restore**
You must have certain permissions and user rights to back up files and folders. If you are an administrator or a backup operator in a local group, you can back up any file and folder on the local computer to which the local group applies. Likewise, if you are an administrator or backup operator on a domain controller you can back up any file and folder locally on any computer in the domain or any computer on a domain with which you have a two-way trust relationship. However, if you are not an administrator or a backup operator, and you want to back up files, then you must be the owner of the files and folders that you want to back up, or you must have one or more of the following permissions for the files and folders you want to back up: Read, Read and execute, Modify, or Full Control.

You must also be certain that there are no disk-quota restrictions that may restrict your access to a hard disk. These restrictions make it impossible for you to back up data. You can check whether you have any disk-quota restrictions by right-clicking the disk you want to save data to, clicking **Properties**, and then clicking the **Quota** tab.

You can also restrict access to a backup file by selecting **Allow only the owner and the Administrator access to the backup data** in the **Backup Job Information** dialog box. If you select this option, only an administrator or the person who created the backup file will be able to restore the files and folders.

**Notes**

- You can only use Backup locally; you cannot backup a remote computer.
- You can only back up and restore System State data on a local computer. You cannot back up and restore System State data on a remote computer even if you are an administrator on the remote computer.

For more information, see Identify members of a local group and Best practices for permissions and user rights.

# System State data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System State data**
With Backup, you can back up and restore the following system components to back up the System State:

| Component | When this component is included in System State? |
|---|---|
| Registry | Always |
| COM+ Class Registration database | Always |
| Boot files, including the system files | Always |
| Certificate Services database | If it is a Certificate Services server |
| Active Directory directory service | If it is a domain |
| SYSVOL directory | Only if it is a domain controller |
| Cluster service information | If it is within a cluster |
| IIS Metadirectory | If it is installed |
| System files that are under Windows File Protection | Always |

Backup refers to these system components as the System State data. The exact system components that make up your computer's System State data depend on the computer's operating system and configuration.

**Windows XP Professional**
The System State data includes only the registry, COM+ Class Registration database, files under Windows File Protection, and boot files.

**Windows Server 2003 family operating systems**
The System State data includes the registry, COM+ Class Registration database, files under Windows File Protection, and system boot files. Depending on the configuration of the server, other data may be included in the System State data. For example, if the server is a certificate server, the System State will also contain the Certificate Services database. If the server is a domain controller, Active Directory and the SYSVOL directory are also contained in the System State data.

**Backing up System State data**
When you choose to back up or restore the System State data, all of the System State data that is relevant to your computer is backed up or restored; you cannot choose to back up or restore individual components of the System State data. This is due to dependencies among the System State components. However, you can restore the System State data to an alternate location. If you do this, only the registry files, SYSVOL directory files, Cluster database information files, and system boot files are restored to the alternate location. The Active Directory directory services database, Certificate Services database, and COM+ Class Registration database are not restored if you designate an alternate location when you restore the System State data.

**Restoring Active Directory**
If you have more than one domain controller in your organization and the Active Directory directory service is replicated to any of these other servers, you may have to authoritatively restore any Active Directory data that you want to restore. To do this, run the Ntdsutil utility after you have restored the System State data, but before you restart the server on the network. Run this utility only while the server is in Directory Services Restore Mode. With the Ntdsutil utility, you can mark Active Directory objects for authoritative restore. This utility ensures that any replicated or distributed data that you restore is properly replicated or distributed throughout your organization.

For example, if you inadvertently delete or modify objects stored in the Active Directory directory service, and those objects are replicated or distributed to other servers, you will need to authoritatively restore those objects so they are replicated or distributed to the other servers. If you do not authoritatively restore the objects, they will never get replicated or distributed to your other servers because they will appear to be older than the objects currently on your other servers. Using the Ntdsutil utility to mark objects for authoritative restore ensures that the data you want to restore gets replicated or distributed throughout your organization. On the other hand, if your system disk has failed or the Active Directory database is corrupted,

then you can simply restore the data nonauthoritatively without using the Ntdsutil utility.

The Ntdsutil command line utility can be run from the command prompt. Help for the Ntdsutil utility can also be found at the command prompt by typing **ntdsutil /?**.

**Notes**

- System State data contains most elements of a system's configuration, but it might not include all of the information that you require to recover your system from a failure. Therefore, it is recommended that you back up all boot and system volumes, including the System State, when you back up your system.

- Although you cannot change which components of the System State are backed up, you can back up all of the protected system files with the System State data by setting advanced backup options.

- To restore the System State data on a domain controller, you must first start your computer in Directory Services Restore Mode. This will allow you to restore the SYSVOL directory and the Active Directory.

- You can only back up and restore the System State data on a local computer. You cannot back up and restore the System State data on a remote computer.

For more information, see Back up System State data.

# Authoritative, primary, and normal restores

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authoritative, primary, and normal restores**
In Backup, distributed services data that is part of the System State data, such as the Active Directory directory service data, can be restored using one of three restore methods:

- Primary restore
- Normal (nonauthoritative) restore
- Authoritative restore

To understand how each restore method works, it is important to understand how the Backup utility backs up data for distributed services. When you back up the System State data on a domain controller, you are backing up all Active Directory data that exists on that server (along with other system components such as the SYSVOL directory and the registry). To restore these distributed services to that server, you must restore the System State data. However, the number and configuration of domain controllers in your system will dictate the type of restore method you choose. For example, if you need to roll back replicated Active Directory changes, but have more than one domain controller in your organization, you will need to perform an authoritative restore to ensure that your restored data gets replicated to all of your servers. However, if you need to restore Active Directory data on a standalone domain controller or on the first of several domain controllers, you will need to perform a primary restore. If you need to restore Active Directory data on just one domain controller in a system where Active Directory data is replicated across several domain controllers, you can use a normal restore if your restored data does not have to be replicated to all your servers.

**Primary restore**
Use this type of restore when the server you are trying to restore is the only running server of a replicated data set (for example, the SYSVOL and FRS are replicated data sets). Select primary restore only when restoring the **first** replica set to the network. Do not use primary if one or more replica sets have already been restored. Typically, perform a primary restore only when all the domain controllers in the domain are lost, and you are trying to rebuild the domain from backup.

| Distributed Data | Reason for using Primary Restore of System State Data |
|---|---|
| Active Directory | Restoring a standalone domain controller.Restoring the first of several domain controllers. |
| SYSVOL | Restoring a standalone domain controller.Restoring the first of several domain controllers. |
| Replica Sets | Restoring the first replica set. |

To perform a primary restore, select **When restoring replicated data sets, mark the restored data as the primary data for all replicas** in the advanced options. For more information, see Set advanced restore options.

**Normal restore**
During a normal restore operation, Backup operates in nonauthoritative restore mode. That is, any data that you restore, including Active Directory objects, will have their original update sequence number. The Active Directory replication system uses this number to detect and propagate Active Directory changes among the servers in your organization. Because of this, any data that is restored nonauthoritatively will appear to the Active Directory replication system as though it is old, which means the data will never get replicated to your other servers. Instead, if newer data is available from your other servers, the Active Directory replication system will use this to update the restored data. To replicate the restored data to the other servers, you must use an authoritative restore.

| Distributed Data | Reason for using Normal Restore of System State Data |
|---|---|
| Active Directory | Restoring a single domain controller in a replicated environment. |
| SYSVOL | Restoring a single domain controller in a replicated environment. |
| Replica Sets | Restoring all but the first replica sets (that is, sets 2 through *n*, for *n* replica sets). |

**Authoritative restore**

To authoritatively restore Active Directory data, you need to run the Ntdsutil utility after you have restored the System State data but before you restart the server. The Ntdsutil utility lets you mark Active Directory objects for authoritative restore. When an object is marked for authoritative restore its update sequence number is changed so that it is higher than any other update sequence number in the Active Directory replication system. This will ensure that any replicated or distributed data that you restore is properly replicated or distributed throughout your organization.

For example, if you inadvertently delete or modify objects stored in the Active Directory directory service, and those objects are replicated or distributed to other servers, you will need to authoritatively restore those objects so they are replicated or distributed to the other servers. If you do not authoritatively restore the objects, they will never get replicated or distributed to your other servers because they will appear to be older than the objects currently on your other servers. Using the Ntdsutil utility to mark objects for authoritative restore ensures that the data you want to restore gets replicated or distributed throughout your organization. On the other hand, if your system disk has failed or the Active Directory database is corrupted, then you can simply restore the data nonauthoritatively without using the Ntdsutil utility.

You can run the Ntdsutil command-line utility from the command prompt. For more information about using ntsustil to perform an authoritative restore, see Ntdsutil. Help for the Ntdsutil utility is also available through the command prompt by typing **ntdsutil /?**.

| Distributed Data | Reason for using Authoritative Restore of System State Data |
|---|---|
| Active Directory | Rolling back or undoing changes. |
| SYSVOL | Resetting data. |
| Replica Sets | Rolling back or undoing changes. |

**Caution**

- When you restore the System State data, and you do not designate an alternate location for the data, Backup will erase the System State data that is currently on your computer and replace it with the System State data you are restoring.

**Notes**

- To restore the System State data on a domain controller, you must first start your computer in Directory Services Restore Mode. This will allow you to restore the SYSVOL directory and the Active Directory. For more information on starting your computer in Directory Services Restore Mode, see Startup options.

- You can only restore the System State data on a local computer. You cannot restore the System State data on a remote computer.

For more information, see Set advanced restore options.

# Repair overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Repair overview**
The Microsoft® Windows Server 2003 family includes several features to ensure that your computer and the applications and devices installed on it work correctly. These features help you solve the problems that can result from adding, deleting, or replacing files that your operating system, applications, and devices require to function.

**Important**

- Physical access to a server is a high security risk. To maintain a more secure environment, you must restrict physical access to all servers and network hardware.

The recovery feature or features that you use depend on the type of problem or failure you encounter. Use the following list to determine which features to use to address a specific problem.

- Your personal data files are missing or have been corrupted, or you want to revert to a previous version of a file.
- After updating a device driver, you can log on, but the system is unstable.
- After installing a new device, the system is unstable.
- After installing an application, the system is unstable or an application is not working properly.
- Operating system does not start (the logon screen does not appear).

**Your personal data files are missing or have been corrupted, or you want to revert to a previous version of a file.**
If you have saved a copy of the data file in another location, you can copy it from that location back to your hard disk. You can make a back-up copy at any time by copying the file to another location on your computer, to external storage such as a removable disk, or to a different computer.

**Feature: Backup Utility**

**When to use it:** When you need to restore a version of a data file that you saved using Backup.

**What it does:** Restores files from backups.

**For more information**, see Restore files from a file or a tape.

**After updating a device driver, you can log on, but the system is unstable.**

**Feature: Device Driver Roll Back**

**When to use it:** When the only change you want to undo is the updating of a device driver (other than a printer driver). You must be logged on as an administrator.

**What it does:** Reinstalls the driver you were using previously and restores any driver settings that were changed when you added the new driver. Affects no other files or settings. Printer drivers cannot be restored with Device Driver Roll Back.

**For more information**, see Roll back to the previous version of a driver.

**After installing a new device, the system is unstable.**

**Feature: Disable the Device**

**When to use it:** When you suspect that one or more specific hardware devices are causing the problem. You must be logged on as an administrator.

**What it does:** Disables the hardware device and its drivers.

**For more information**, see Disable a device.

**After installing an application, the system is unstable or an application is not working properly.**
Under some circumstances, the computer will prompt you to repair or reinstall an application from a network location or from

the original set-up media (for example, the program CD). If this happens, follow the directions on the screen to repair your program. If you are not prompted with this information, you can use one of the following features to repair your program:

**Feature: Add or Remove Programs**

**When to use it:** When you suspect that one or more specific programs are causing the problem.

**What it does:** Removes the programs you specify.

**For more information**, see Windows interface administrative tool reference A-Z: Add or Remove Programs.

**Operating system does not start (the logon screen does not appear).**

**Feature: Last Known Good Configuration startup option**

**When to use it:** When you suspect that a change you made to your computer before restarting might be causing the failure.

**What it does:** Restores the registry settings and drivers that were in effect the last time the computer started successfully.

**For more information**, see Start the computer using the last known good configuration.

**Feature: Recovery Console**

**When to use it:** If using the Last Known Good Configuration startup option is unsuccessful and you cannot start the computer in Safe Mode. This method is recommended only if you are an advanced user who can use basic commands to identify and locate problem drivers and files. To use the Recovery Console, restart the computer with the installation CD for the operating system in the CD drive. When prompted during text-mode setup, press R to start the Recovery Console.

**What it does:** From the Recovery Console, you can access the drives on your computer. You can then make any of the following changes so that you can start your computer:

- Enable or disable device drivers or services.
- Copy files from the installation CD for the operating system, or copy files from other removable media. For example, you can copy an essential file that had been deleted.
- Create a new boot sector and new master boot record (MBR). You might need to do this if there are problems starting from the existing boot sector.
-

**For more information**, see Recovery Console overview.

**Feature: Automated System Recovery**

**When to use it:** After all other attempts at recovery fail, or if you have replaced a damaged system hard drive. You must have previously used Backup to create an Automated System Recovery set.

**What it does:** Automated System Recovery restores all disk signatures, volumes, and partitions on the disks required to start the computer. Automated System Recovery then installs a simplified installation of Windows and automatically starts a restoration using the backup created by the Automated System Recovery Preparation Wizard.

**For more information**, see Automated System Recovery (ASR) overview.

**Feature: Windows installation CD**

**When to use it:** When you cannot start the computer in Safe Mode, you cannot use either the Last Known Good Configuration startup option or the Recovery Console successfully, and you have no backup to use with Automated System Recovery.

**What it does:** Reinstalls the operating system. You will then need to reinstall your applications and restore your data files from backups.

# Recovery Console overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Recovery Console overview**
If Safe Mode and other startup options do not work, consider using the Recovery Console. This method is recommended only if you are an advanced user who can use basic commands to identify and locate problem drivers and files. In addition, you will need the password for the built-in administrator account to use the Recovery Console.

Using the Recovery Console, you can enable and disable services, format drives, read and write data on a local drive (including drives formatted to use NTFS), and perform many other administrative tasks. The Recovery Console is particularly useful if you need to repair your system by copying a file from a floppy disk or CD-ROM to your hard drive, or if you need to reconfigure a service that is preventing your computer from starting properly.

**Important**

- Physical access to a server is a high security risk. To maintain a more secure environment, you must restrict physical access to all servers and network hardware.

There are two ways to start the Recovery Console:

- If you are unable to start your computer, you can run the Recovery Console from your Setup CD.
- As an alternative, you can install the Recovery Console on your computer to make it available in case you are unable to restart Windows. You can then select the Recovery Console option from the list of available operating systems on when you start your computer. You cannot install the Recovery Console on an Itanium-based computer.

After you start the Recovery Console, you will have to choose which installation you want to log on to (if you have a dual-boot or multiple-boot system), and you will have to log on with the password for the built in administrator account for that installation.

The console provides commands you can use to do simple operations such as changing to a different directory or viewing a directory, as well as more powerful operations such as fixing the boot sector. You can access Help for the commands in the Recovery Console by typing **help** at the Recovery Console command prompt.

For more information about securing your computer, see Best practices for security.

**Note**

- Installation of the Recovery Console provides an alternate method for logging on to the computer. This could potentially provide a method for an intruder to gain access to the computer by circumventing many of the built-in safeguards. Consider the potential security effects before installing the Recovery Console.

# Automated System Recovery (ASR) overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Automated System Recovery (ASR) overview**
With Automated System Recovery (ASR), you can create ASR sets on a regular basis as part of an overall plan for system recovery in case of system failure. Use ASR as a last resort in system recovery, only after you have exhausted other options such as the startup options Safe Mode and Last Known Good Configuration. For more information about these and other recovery options, see Startup options.

ASR is a recovery option that has two parts: ASR backup and ASR restore. You can access the backup portion through the Automated System Recovery Preparation Wizard located in Backup. The Automated System Recovery Preparation Wizard backs up the System State data, system services, and all disks associated with the operating system components. It also creates a floppy disk, which contains information about the backup, the disk configurations (including basic and dynamic volumes), and how to accomplish a restore.

You can access the restore part of ASR by pressing F2 when prompted in the text mode portion of setup. ASR reads the disk configurations from the floppy disk and restores all of the disk signatures, volumes and partitions on the disks required to start your computer (at a minimum). (It will attempt to restore all of the disk configurations, but under some circumstances, it may not be able to). ASR then installs a simple installation of Windows and automatically starts to restore from backup using the backup ASR set created by the Automated System Recovery Preparation Wizard.

**Notes**

- ASR does not include data files. Back up data files separately on a regular basis and restore them after the system is working.
- Using **All information on this computer** in the simple wizard also creates an ASR floppy disk and an ASR set.
- ASR supports FAT16 volumes up to 2.1 GB only. ASR does not support 4 GB FAT16 partitions that use a cluster size of 64K. If your system contains 4-GB FAT16 partitions, convert them from FAT16 to NTFS before using ASR.

# Administering Backup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administering Backup**
This section covers:

- Managing Backup from the command line
- Using batch files to back up data

# Managing Backup from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Backup from the command line**

In addition to using the Backup Wizard, you can use the following command line utility to manage Backup:

- Ntbackup

For information about other command-line utilities, see Command-line reference A-Z.

# Using batch files to back up data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using batch files to back up data**

You can perform backup operations from batch files using the **ntbackup** command followed by various command line parameters. However, there are two important limitations to using batch files to back up your data:

- Using the Ntbackup command, you can back up entire folders only. You cannot designate individual files for backup. However, you can designate a backup selection file (.bks file) from the command line, which contains a list of files you want to back up. You must use the GUI version of the Backup utility to create backup selection files.

- The **ntbackup** command does not support the use of wildcard characters. For example, typing ***.txt** will not back up files with a .txt extension.

For more information about using Backup, see "Backup and Restore" at the Microsoft Windows Resource Kits Web site.

# Backup Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
This section provides problem-solving guidelines for the Backup utility.

What problem are you having?

- Backup does not back up to a CD device.
- I cannot locate one of my old backup logs.
- I want to do an Automated System Recovery (ASR) backup, but my computer does not have a floppy drive.
- I want to do an Automated System Recovery (ASR) restore, but I do not have the original floppy disk created during the ASR backup.

**Backup does not back up to a CD device.**
**Cause:** Backup does not support the use of backup media such as CD-RW (compact disc rewritable), CD-R (compact disc recordable), and DVD-R (digital video disc recordable).

**Solution:** Back up to an alternate media type, such as a tape or hard disk. If you plan to use CD-RW, CD-R, or DVD-R disks as backup media, you must backup to a file and copy that file to the CD.

**Note**

- You can use Backup to restore from a CD-R, CD-RW, or DVD-R disk.

**I cannot locate one of my old backup logs.**
**Cause:** Backup saves only the last 10 backup reports (log files).

**Solution:** Copy the backup log files that you want to archive to another location. By default, Backup saves the backup log files in the Documents and Settings*user name*\Local Settings\Application Data\Microsoft\Windows NT\NTbackup\Data folder, where *user name* is the name of the user who performed the backup.

**I want to do an Automated System Recovery (ASR) backup, but my computer does not have a floppy drive.**
**Cause:** When you restore your system files in an ASR restore, Backup requires that you insert a floppy disk containing the ASR backup files.

**Solution:** Perform an ASR backup on the computer without the floppy drive. Copy the asr.sif and asrpnp.sif files located in the %systemroot%\repair directory to another computer with a floppy drive, then copy those files onto a floppy disk.

**Important**

- Before running the ASR restore, you must attach a floppy drive to your computer.

**I want to do an Automated System Recovery (ASR) restore, but I do not have the original floppy disk created during the ASR backup.**
**Cause:** When you restore your system files in an ASR restore, Backup requires that you insert a floppy disk containing the ASR backup files asr.sif and asrpnp.sif.

**Solution:** When you perform an ASR backup, the files asr.sif and asrpnp.sif are copied to a floppy disk and also to the ASR backup set (on tape or other backup media). If you lose the floppy disk, first use the Backup utility to locate and catalog the corresponding ASR backup set, then restore the asr.sif and asrpnp.sif files (located in the %systemroot%\repair directory on the backup media) to a floppy disk. You can use this newly created ASR floppy disk to perform the ASR restore.

# Shadow Copies for Shared Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shadow Copies of Shared Folders**
Shadow Copies of Shared Folders provides point-in-time copies of files that are located on shared resources, such as a file server. With Shadow Copies of Shared Folders, you can view shared files and folders as they existed at points of time in the past.

You can use shadow copies when you want to recover files that were accidentally deleted or overwritten, as well as to compare different versions of files.

- Before deploying Shadow Copies of Shared Folders, see Checklist: Deploying Shadow Copies of Shared Folders.
- For tips on using Shadow Copies of Shared Folders, see Best practices for Shadow Copies of Shared Folders.
- For help with specific tasks, see Shadow Copies for Shared Folders How To....
- For general background information, see Shadow Copies for Shared Folders Concepts.
- For problem-solving information, see Troubleshooting Shadow Copies for Shared Folders.

# Checklist: Deploying Shadow Copies of Shared Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Deploying Shadow Copies of Shared Folders**

| Step | Reference |
|---|---|
| Review key concepts. | Shadow Copies for Shared Folders overview |
| Create shared resources. | Share a folder or drive |
| Decide where to store the shadow copies. | Determining storage options for shadow copies |
| Determine the best schedule for taking shadow copies. | Defining a schedule for shadow copies |
| Enable Shadow Copies of Shared Folders on a volume. | Enable Shadow Copies for Shared Folders |
| Deploy the client software. | Deploying the client software for shadow copies |

# Best practices for Shadow Copies of Shared Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Select a separate volume on another disk as the storage area for shadow copies.**

- Select a storage area on a volume that is not being shadow copied. Using a separate volume on another disk provides two advantages. First, it eliminates the possibility that high I/O load will cause shadow copies to be deleted. Second, this configuration provides better performance. This is the recommended configuration for heavily used file servers.

  For more information, see Change the settings for Shadow Copies of Shared Folders.

**Consider how your clients will be using a shared resource before you enable Shadow Copies of Shared Folders and set scheduling options.**

- Adjust the shadow copy schedule to fit the work patterns of your clients.

  For more information about scheduling shadow copies, see Defining a schedule for shadow copies.

**Do not enable shadow copies on volumes that use mount points.**

- The mounted drive will not be included when shadow copies are taken. Enable shadow copies only on volumes without mount points or when you do not want the shared resources on the mounted volume to be shadow copied.

  For more information, see Using NTFS mounted drives.

**Do not enable shadow copies on dual-booting computers.**

- If you have enabled dual-booting into previous versions of Windows (such as Windows NT 4.0), the shadow copies which persist while restarting the older version might be corrupted and unusable when the computer is started again with Windows Server 2003 .

**Use Backup to perform regular backups of your file server.**

- Shadow Copies of Shared Folders is not a replacement for performing regular backups. Use a backup utility in coordination with Shadow Copies of Shared Folders as your best preparation for restoring.

  For more information, see Backup.

**Do not schedule copies to occur more often than once per hour.**

- The default schedule is 7:00 A.M. and 12:00 noon, Monday through Friday. If you decide that you need copies to be taken more often, verify that you have allotted enough storage space and that you do not take copies so often that server performance degrades. There is also an upper limit of 64 copies per volume that can be stored before the oldest copy is deleted. If shadow copies are taken too often, this limit might be reached very quickly, and older copies could be lost at a rapid rate.

  For more information, see Defining a schedule for shadow copies.

**Before deleting a volume that is being shadow copied, delete the scheduled task for creating shadow copies.**

- If the volume is deleted without deleting the shadow copy task, the scheduled task will fail and an Event ID: 7001 error will be written to the event log. Delete the task before deleting the volume to avoid filling the event log with these errors.

For more information, see Change the schedule for creating shadow copies.

**Use an allocation unit size of 16 kilobytes (KB) or larger when formatting a source volume on which Shadow Copies of Shared Folders will be enabled.**

- If you plan to defragment the source volume on which Shadow Copies of Shared Folders is enabled, it is recommended that you set the cluster allocation unit size to be 16 KB or larger when you initially format the source volume. If you do not, the number of changes caused by defragmentation can cause previous versions of files to be deleted.

- If you require NTFS file compression on the source volume, you cannot use an allocation unit size larger than 4 KB. In this case, when you defragment a volume that is very fragmented, you may lose older shadow copies faster than expected.

  For more information about formatting a volume, see Format a basic volume.

# Shadow Copies for Shared Folders How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Enable Shadow Copies for Shared Folders
- Change the settings for Shadow Copies of Shared Folders
- Change the schedule for creating shadow copies
- Delete a shadow copy
- Revert an entire volume shadow copy to a previous version
- Disable Shadow Copies for Shared Folders

# Enable Shadow Copies for Shared Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable Shadow Copies of Shared Folders**

1. Open Computer Management.
2. In the console tree, right-click **Shared Folders**, select **All Tasks**, and click **Configure Shadow Copies**.

   **Where?**

   - Computer Management/System Tools/Shared Folders

3. Click the volume where you want to enable Shadow Copies of Shared Folders, and then click **Enable**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- For information about enabling shadow copies in a server cluster, see Enable Shadow Copies for Shared Folders in a cluster. Do not use Cluster Administrator or cluster.exe to make changes to the settings or schedule for shadow copies of shared folders, use the shadow copies interface.
- You can also access Shadow Copies of Shared Folders by right-clicking a fixed NTFS volume in **My Computer** or in the Disk Management snap-in details pane (in **Computer Management**). Click **Properties**, and then click the **Shadow Copies** tab.
- You can use the Disk Management snap-in to manage Shadow Copies of Shared Folders on remote servers as well. In the **Computer Management** console tree, right-click **Disk Management**, point to **All Tasks**, and then click **Configure Shadow Copies**.
- By enabling Shadow Copies of Shared Folders, you also create a default schedule and settings for subsequent shadow copies. To make changes to these defaults, click **Settings**.
- You can only enable Shadow Copies of Shared Folders on a per-volume basis; that is, you cannot select specific shared folders and files on a volume to be copied or not copied.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Change the settings for Shadow Copies of Shared Folders

# Change the settings for Shadow Copies of Shared Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the settings for Shadow Copies of Shared Folders**

1. Open Computer Management.
2. In the console tree, right-click **Shared Folders**, select **All Tasks**, and click **Configure Shadow Copies**.

   **Where?**

   - Computer Management/System Tools/Shared Folders

3. Click the volume where you want to make changes, and then click **Settings**.
4. In the **Settings** dialog box, change the settings as appropriate.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- There is a limit of 64 shadow copies per volume that can be stored. When this limit is reached, the oldest shadow copy will be deleted and cannot be retrieved.
- The following table lists the settings that you can configure.

| Setting | Description |
|---|---|
| **Storage area** | Specifies the volume where the shadow copies are stored. The default setting is the volume that contains the source files. It is recommended that you use a separate volume on another disk to provide better performance for heavily-used file servers.<br><br>You can only change the storage volume when there are no shadow copies present. If you need to change the storage volume for a volume that has already been enabled, you must first delete all of the shadow copies on that volume. |
| **Maximum size** | Specifies the maximum amount of space that will be used to store shadow copies on a particular volume. The default size is 10% of the size of the volume that contains the source files that are being shadow copied. If the shadow copies are stored on a separate volume from the source files, change this default to reflect the amount of the storage volume that you want to dedicate to shadow copies.<br><br>The storage limit must be at least 300 megabytes (MB); with this limit, only a single shadow copy can be stored. If you set a restrictive storage limit, verify that the number of shadow copies that you have scheduled will fit within those restraints. If shadow copies are deleted prematurely due to storage limits, you may be defeating the purpose of enabling Shadow Copies of Shared Folders. Click **Details** to compare the amount of space used on your storage volume with the maximum storage limit. |

| | |
|---|---|
| **Schedule** | Specifies settings for creating a schedule to take shadow copies on a regular basis. Schedule shadow copies at a time of day that will work best for your users. The default schedule is 7:00 A.M. and 12:00 noon, Monday through Friday. For more information on creating a schedule for Shadow Copies of Shared Folders, see "Defining a schedule for shadow copies" in Related Topics. |

# Revert an entire volume shadow copy to a previous version

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To revert an entire volume shadow copy to a previous version**

1. Open Computer Management.
2. In the console tree, right-click **Shared Folders**, select **All Tasks**, and then click **Configure Shadow Copies**.

   **Where?**

   - Computer Management/System Tools/Shared Folders

3. In the **Shadow Copies** dialog box, click the shadow copy that you want to revert to and click **Revert**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- Shadow copies are not included in backups. Once they are deleted, they cannot be restored.
- You can use the **Revert** button to revert an entire volume back to an earlier point in time. Reverting the entire volume will undo any changes that were made to files and folders on the volume since the selected snapshot was taken. If you revert a volume, you cannot undo the action later. You should not use **Revert** on volumes that contain data stores like Active Directory or Exchange.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Shadow Copies for Shared Folders overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shadow Copies of Shared Folders overview**

Shadow Copies of Shared Folders provides point-in-time copies of files that are located on shared resources, such as a file server. With Shadow Copies of Shared Folders, you can view shared files and folders as they existed at points of time in the past. Accessing previous versions of your files, or shadow copies, is useful because you can:

- **Recover files that were accidentally deleted**. If you accidentally delete a file, you can open a previous version and copy it to a safe location.
- **Recover from accidentally overwriting a file**. If you accidentally overwrite a file, you can recover a previous version of the file.
- **Compare versions of file while working**. You can use previous versions when you want to check what has changed between two versions of a file.

You can access the server portion of Shadow Copies of Shared Folders through the **Shadow Copies** tab of the **Local Disk Properties** dialog box. For more information about how to use Shadow Copies of Shared Folders, see Shadow Copies for Shared Folders How To....

The client software for Shadow Copies of Shared Folders is located on the server and must be deployed to client computers. You can access the client view of shadow copies through the **Previous Versions** tab of the **Properties** dialog box of the shared file or folder. For more information about how to deploy Shadow Copies of Shared Folders, see Deploying Shadow Copies for Shared Folders.

**Notes**

- Physical access to a server is a high security risk. To maintain a more secure environment, you must restrict physical access to all servers and network hardware.
- When you restore a file, the file permissions will not be changed. Permissions will remain the same as they were before the restore. When you recover a file that was accidently deleted, the file permissions will be set to the default permissions for the directory.
- For information on enabling and using shadow copies of shared folders in a server cluster, see Using Shadow Copies of Shared Folders in a server cluster.
- Creating shadow copies is not a replacement for creating regular backups.
- When storage area limits are reached, the oldest shadow copy will be deleted and cannot be retrieved.
- There is a limit of 64 shadow copies per volume that can be stored. When this limit is reached, the oldest shadow copy will be deleted and cannot be retrieved.
- Shadow copies are read-only. You cannot edit the contents of a shadow copy.
- You can only enable Shadow Copies of Shared Folders on a per-volume basis; that is, you cannot select specific shared folders and files on a volume to be copied or not copied.

# Deploying Shadow Copies for Shared Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying Shadow Copies of Shared Folders**

This section provides general background information about Shadow Copies of Shared Folders:

- Determining storage options for shadow copies
- Defining a schedule for shadow copies
- Deploying the client software for shadow copies

# Determining storage options for shadow copies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Determining storage options for shadow copies**

Before deploying Shadow Copies of Shared Folders, it is recommended that you create a plan that specifies where the shadow copies will be stored and what the storage limits will be.

The minimum amount of storage space that you can specify is 300 megabytes (MB). The default storage size is 10% of the source volume (the volume being copied). If the shadow copies are stored on a separate volume, change the default to reflect the space available on the storage volume instead of the source volume. Remember that when the storage limit is reached, older versions of the shadow copies will be deleted and cannot be restored.

When determining the amount of space to allocate for storing shadow copies, you must consider both the number and size of files that are being copied, as well as the frequency of changes between copies. For example, 100 files that only change monthly require less storage space than 10 files that change daily.

Remember that to change the storage volume, you must delete the shadow copies. If you delete shadow copies, you lose the existing file change history that is kept on the original storage volume. To avoid this problem, verify that the storage volume that you initially select is large enough to handle your growing business needs.

**Caution**

- There is a limit of 64 shadow copies that can be stored on a volume. When this limit is reached, the oldest shadow copy is deleted and cannot be retrieved.

  For more information, see Change the settings for Shadow Copies of Shared Folders.

- If you are using a basic disk as a storage area for shadow copies and you intend to convert the disk into a dynamic disk, it is important to take the following precaution to avoid data loss. If the disk is a non-boot volume and is a different volume from where the original files reside, you must first dismount and take offline the volume containing the original files before you convert the disk containing shadow copies to a dynamic disk. You must bring the volume containing the original files back online within 20 minutes, otherwise, you will lose the data stored in the existing shadow copies. If the shadow copies are located on a boot volume, you can convert the disk to dynamic without losing shadow copies.

  You can use the **mountvol** command with the **/p** option to dismount the volume and take it offline. You can mount the volume and bring it online using the **mountvol** command or the Disk Management snap-in.

**Note**

- For information about enabling shadow copies in a server cluster, see Enable Shadow Copies for Shared Folders in a cluster. Do not use Cluster Administrator or cluster.exe to make changes to the settings or schedule for shadow copies of shared folders; use the shadow copies interface instead.

# Defining a schedule for shadow copies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Defining a schedule for shadow copies**

When you enable Shadow Copies of Shared Folders, a default schedule is also created. This schedule might work for your users, but it is important to consider the particular work habits of your users before defaulting to this schedule. You might want to consider the following questions:

- Do most of your users work from 9 A.M. to 5 P.M., Monday through Friday, in a single time zone?
- Are users spread out across time zones? Does this mean that you need more copies throughout the day to cover all of the work hours?
- How much work time can your users afford to lose? Will the default schedule of copies twice a day (7:00 A.M. and 12:00 noon, Monday through Friday) provide adequate coverage?
- How often can copies be taken without you needing to add additional storage?
- How many days of history can be retained before reaching the limit of 64 shadow copies?

You might want to create an initial schedule and deploy to a small group to test whether your scheduled shadow copies stay within the storage limits you set. Also, consider polling your users to find out their work habits and when they think that a shadow copy would be beneficial. This kind of information can help you determine the best schedule for your specific users.

**Note**

- It is recommended that you do not schedule copies to be taken more than once per hour.

For more information, see Change the schedule for creating shadow copies.

# Deploying the client software for shadow copies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying the client software for shadow copies**

The client software for Shadow Copies of Shared Folders is available from several locations:

- The Windows XP client is installed with Windows°XP Service Pack°2 (SP2).
- Windows 2000 (Service Pack 3 and later), Windows 98 Second Edition, and Windows XP clients are available at the Microsoft Web site.
- The client is also available on the server in the \\%systemroot%\system32\clients\twclient directory.

You can distribute the client software in a variety of ways. Consider the various options before deployment. There are several tools included in Windows Server 2003 operating systems, such as Group Policy, that can make deploying and maintaining the client software easier.

- We recommend that you place the client software on a shared resource and send an e-mail to users about what the client does and how to install it.

| **Example e-mail:** |
| --- |
| There is a new feature called Previous Versions that is available for employees who use shared folders for corporate documents. If you work with files that are located in shared folders on your network, you may be able to access previous versions of your files. Accessing previous versions of your files is useful because you can:<br>• **Recover files that were accidentally deleted.** If you accidentally delete a file, you can open a previous version and copy it to a safe location.<br>• **Recover from accidentally overwriting a file.** If you accidentally overwrite a file, you can recover a previous version of the file.<br>• **Compare versions of file while working.** You can use Previous Versions when you want to check what has changed between two versions of a file.<br>This feature has been enabled on the following file server: *server**sharedresource*. Copies are scheduled to be taken at 7:00 A.M. and 12:00 noon, Monday through Friday. Remember that these are copies of the files that were taken at these times. If you have worked on the file, you will lose all the work you did after the copy was taken. Saving your work frequently is still the best way to ensure your work is not lost.<br>To install the software for accessing previous versions on your desktop, go to: *server**sharedresource* and double-click twclient.msi. |

- Use Group Policy to assign the client to users within your network.

  For more information about deploying client software using Group Policy, see "Group Policy Software Deployment Background" at the Microsoft Windows Resource Kits Web site.

- Use Systems Management Server (SMS) or another software management application to deploy the client software. For more information about using Systems Management Server to deploy the client .msi package, see Deploying Windows Installer Setup Packages with SMS 2.0 at the Microsoft Web site.

**Note**

- The client software refers to shadow copies as "previous versions"; this was done to make the concept clearer for end

users.

For more information, see Accessing Previous Versions of Shared Files and Folders.

# Troubleshooting Shadow Copies for Shared Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
This section provides problem-solving guidelines for deploying Shadow Copies of Shared Folders.

What problem are you having?

- The Properties dialog box does not contain a Previous Versions tab (for example, on the shared resource or local volume). I cannot the list of previous versions that have been created.
- The Event Log is filled with Event ID: 7001.
- Shadow copies are being deleted, but I still have plenty of storage space available.

**The Properties dialog box does not contain a Previous Versions tab (for example, on the shared resource or local volume). I cannot the list of previous versions that have been created.**
**Cause:** You cannot view previous versions of files on a local shared resource. You must have a working network connection and be viewing the volume as a shared resource.

**Solution:** Verify that your network connection is available. Then, create a connection to the shared resource on your local computer as if it were in another location on the network. For example: To view previous versions of files in the shared folder \Documents on the local computer \\Server1, you would need to create a network connection to \\Server1\Documents and access the previous versions as if they were on a remote computer. Right-click this network connection and select **Properties** to see the **Previous Versions** tab.

**The Event Log is filled with Event ID: 7001.**
**Cause:** A volume that was scheduled for shadow copies has been removed or is unavailable. The task scheduler is attempting the task and every time the task fails, it writes an error to the event log.

**Solution:** Delete the scheduled task using the Task Scheduler. For more information, see Remove a scheduled task.

If you are removing a volume that is being shadow copied, delete the scheduled task before deleting the volume so the event log is not filled with errors.

**Shadow copies are being deleted, but I still have plenty of storage space available.**
**Cause:** There is an upper limit of 64 shadow copies per volume that can be stored.

**Solution:** Adjust the schedule for taking shadow copies to a rate which retains a long enough history of the files without reaching the limit of 64 shadow copies.

**See also:** Defining a schedule for shadow copies; Determining storage options for shadow copies

# Accessing Previous Versions of Shared Files and Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accessing previous versions of shared files and folders**

With Previous Versions, you can access previous versions of files and folders that are shared on your network.

- For general background information, see Accessing previous versions overview.
- For help with specific tasks, see Previous Versions How To....
- For problem-solving information, see Troubleshooting Previous Versions.

# Accessing previous versions overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accessing previous versions overview**

If you work with files that are located in shared folders on your network, you may be able to access previous versions of your files. Accessing previous versions of your files is useful because you can:

- **Recover files that were accidentally deleted**. If you accidentally delete a file, you can open a previous version and copy it to a safe location.
- **Recover from accidentally overwriting a file**. If you accidentally overwrite a file, you can recover a previous version of the file.
- **Compare versions of file while working**. You can use previous versions when you want to check what has changed between two versions of a file.

To access previous versions of files, your server administrator must enable Shadow Copies of Shared Folders on the file server. Shadow copies are copies of files that are located on the server and appear as previous versions. If you would like to have Shadow Copies of Shared Folders enabled, contact your administrator.

**Notes**

- For you to access previous versions of files, the shared files must be located on a computer running an operating system in the Microsoft® Windows Server 2003 family that has Shadow copies of Shared Folders enabled.
- Previous versions are read-only. You cannot make changes to a previous version of the file as it exists on the server.
- Previous versions are periodically deleted and can disappear at any time. If you think you might want a previous version of a file, it is recommended that you copy it to a safe place.
- Please contact your server administrator if you want to know when previous versions are created or deleted.

For more information, see Previous Versions How To....

# Previous Versions How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- View a previous version of a file
- Copy a previous version of a file to a new location
- Restore a previous version of a file
- Recover a file that was accidentally deleted

# View a previous version of a file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view a previous version of a file**

1. Locate the file that you want to view a previous version of (on the network), right-click the file, and click **Properties**. The **Properties** dialog box will appear.

2. On the **Previous Versions** tab, click the version you want to view and click **View**.

## Notes

- If the **Previous Versions** tab does not appear in the **Properties** dialog box, Shadow Copies of Shared Folders might not be enabled on the file server. Shadow copies are copies of files that are located on the server and appear as previous versions. Please contact your administrator for more information.

- If there are no previous versions listed, the file has not changed since the oldest copy was taken.

- Previous versions are read-only. You cannot make changes to the previous version of the file as it exists on the server.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Troubleshooting Previous Versions

# Copy a previous version of a file to a new location

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To copy a previous version of a file to a new location**

1. Locate the file that you want to copy (on the network), right-click the file, and click **Properties**. The **Properties** dialog box will appear.

2. On the **Previous Versions** tab, click the version of the file that you want to copy and click **Copy**.

3. In the **Copy Items** dialog box, click a new location to place the file and click **Copy**.

## Notes

- If the **Previous Versions** tab does not appear in the **Properties** dialog box, Shadow Copies of Shared Folders might not be enabled on the file server. Shadow copies are copies of files that are located on the server and appear as previous versions. Please contact your administrator for more information.

- If there are no previous versions listed, the file has not changed since the oldest copy was taken.

- When you use **Copy**, the file permissions will be set to the default permissions for the directory where the copy of the file is placed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Troubleshooting Previous Versions

# Restore a previous version of a file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To restore a previous version of a file**

1. Locate the file that you want to restore (on the network), right-click the file, and click **Properties**. The **Properties** dialog box will appear.

2. On the **Previous Versions** tab, click the version of the file that you want to restore and click **Restore**. A warning message about restoring a previous version will appear. Click **Yes** to complete the procedure.

## Caution

- Restoring a previous version will delete the current version. If you choose to restore a previous version of a folder, the folder will be restored to its state at the date and time of the version you selected. You will lose any changes that you have made to files in the folder since that time. If you do not want to delete the current version of a file or folder, use **Copy** to copy the previous version to a different location.

## Notes

- If the **Previous Versions** tab does not appear in the **Properties** dialog box, Shadow Copies of Shared Folders might not be enabled on the shared resource. Shadow copies are copies of files that are located on the server and appear as previous versions. Please contact your administrator for more information.

- If there are no previous versions listed, the file has not changed since the oldest copy was taken.

- When you restore a previous version of a folder, files in the current folder that were not contained in the previous version of the folder will not be erased.

- When you restore a file, the file permissions will not be changed; permissions will remain the same as they were before the restore. When you copy a previous version of a file, the permissions will be set to the default permissions for the directory where the copy of the file is placed.

- Restoring a large directory puts a heavy load on the file server and can result in previous versions being deleted. Try to restore individual files instead of entire directories whenever possible.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Troubleshooting Previous Versions

# Recover a file that was accidentally deleted

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To recover a file that was accidentally deleted**

1. Locate the folder where the deleted file was stored (on the network), right-click the folder, and click **Properties**. The **Properties** dialog box will appear.

2. On the **Previous Versions** tab, double-click the most recent version of the folder that contains the file that you want to recover. A list of files that are stored in that previous version will appear.

3. Right-click the file that was accidentally deleted and click **Copy**.

4. Right-click the location where you want to place the file and click **Paste**.

## Notes

- If the **Previous Versions** tab does not appear in the **Properties** dialog box, Shadow Copies of Shared Folders might not be enabled on the shared resource. Shadow copies are copies of files that are located on the file server and appear as previous versions. Please contact your administrator for more information.

- When you copy a file, file permissions will be set to the default permissions for the directory where the copy of the file is placed.

- When you recover a file that was accidentally deleted, you are copying a previous version. You will lose any changes made to the file after the last previous version was created.

- To recover a deleted folder, go to a previous version of the parent folder to view and select the folder to copy.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Troubleshooting Previous Versions

# Troubleshooting Previous Versions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
This section provides problem-solving guidelines for accessing previous versions of files and folders.

What problem are you having?

- I do not see a Previous Versions tab in the Properties dialog box.
- There are no files listed in the Previous Versions tab of the Properties dialog box.
- The previous version of the file I want to view is not listed anymore in the Previous Versions tab of the Properties dialog box.
- I am having problems viewing a previous version of a file.
- I cannot locate previous versions of files that are stored in my coworker's shared folder.

**I do not see a Previous Versions tab in the Properties dialog box.**
**Cause:** Shadow Copies of Shared Folders is not enabled on the file server.

**Solution:** Contact your administrator about enabling Shadow Copies of Shared Folders on the file server.

**There are no files listed in the Previous Versions tab of the Properties dialog box.**
**Cause:** The file has not changed.

**Solution:** The file must be changed to view a previous version.

**The previous version of the file I want to view is not listed anymore in the Previous Versions tab of the Properties dialog box.**
**Cause:** Previous versions are periodically deleted due to space limitations on the server.

**Solution:** Contact your administrator about providing space for more previous versions on the file server.

**I am having problems viewing a previous version of a file.**
**Cause:** Previous versions are read-only, and some applications do not work well with read-only files.

**Solution:** Use **Copy** instead to copy the file to another location and open it from there to view.

**I cannot locate previous versions of files that are stored in my coworker's shared folder.**
**Cause:** The shared folder must be located on a computer running an operating system in the Windows Server 2003 family that has shadow copies enabled.

**Solution:** Move the files you share with your coworker to a shared folder on a computer running an operating system in the Windows Server 2003 family that has shadow copies enabled.

# Disaster Recovery

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Disaster recovery**
Disaster recovery includes information about how to prepare for system problems, how to use options that can help start a system that otherwise would not start, and how to use the repair and recovery options.

- To safeguard your system, see Checklist: Safeguarding your system.
- To recover your system, see Checklist: Recovering a system that will not start.
- For tips about using disaster recovery, see Best practices for disaster recovery.
- For help with specific tasks, see Disaster Recovery How To....
- For general background information, see Disaster Recovery Concepts.
- For problem-solving instructions, see Troubleshooting Disaster Recovery.

# Checklist: Safeguarding your system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Safeguarding your system**

You can take a number of steps as precautions against the possibility of disk failure or other serious system problems.

| Step | Reference |
|---|---|
| Follow the best practices for security and keep your computer in a secure location. | Best practices for security |
| Specify what you want to do if the system stops unexpectedly. For example, you can specify that you want your computer to restart automatically. | Specify what happens when the system stops unexpectedly |
| Perform regular backups (including backups of your boot and system partitions and your System State). Keep your backup media in a safe place where it is not accessible to a malicious user. | Back up files to a file or a tape |
| Use the Automated System Recovery Preparation Wizard to create a backup of your system settings and your local system partition. Keep your Automated System Recovery (ASR) set in a safe place where it is not accessible to a malicious user. | Create an Automated System Recovery set using Backup |
| Keep the installation CD in a safe place where you can easily find it but it is not accessible to a malicious user. Then, if needed, you can start the computer from the CD and use the Recovery Console or Automated System Recovery. | Start the computer and use the Recovery Console<br><br>Recover from a system failure using Automated System Recovery |
| Install the Recovery Console as a startup option. | Install the Recovery Console as a startup option |

# Checklist: Recovering a system that will not start

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Recovering a system that will not start**

| Step | Reference |
|---|---|
| Try Safe Mode and related startup options, which you can use to start the system with only the minimal necessary services. | Startup options |
| If other startup options do not help, consider using the Recovery Console. This option is recommended only for advanced users or administrators. | Recovery Console overview<br><br>Start the computer and use the Recovery Console |
| If startup options and the Recovery Console do not work in your situation and if you made appropriate advance preparations, try using your original installation disk and an Automated System Recovery (ASR) set to restore your system. | Recover from a system failure using Automated System Recovery |

# Best practices for disaster recovery

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **Use Emergency Management Services if applicable.**

  To ensure access to the server regardless of the condition of the network drivers or operating system files, consider setting up Emergency Management Services, a new feature in the Windows Server 2003 family. With Emergency Management Services, you can remotely manage a server in emergency situations that would typically require a local keyboard, mouse, and monitor, such as when the network is unavailable or the server is not functioning properly. Emergency Management Services has specific hardware requirements, and is available only for products in the Windows Server 2003 family.

  For more information, see Emergency Management Services.

- **Create a plan for performing regular backup operations.**

  Review and incorporate the best practices for Backup into a plan for backing up all of your files on a regular basis.

  For more information, see Best practices for Backup.

- **Keep the installation CD where you can easily find it.**

  If needed, you can start the computer from the installation CD and use the Recovery Console or Automated System Recovery.

  For more information, see Start the computer and use the Recovery Console or Recover from a system failure using Automated System Recovery.

- **Install the Recovery Console as a startup option.**

  You can install the Recovery Console on your computer to make it available in case you are unable to restart Windows. You can then select the Recovery Console option from the list of available operating systems on startup. You cannot install the Recovery Console on an Itanium-based computer.

  For more information, see Install the Recovery Console as a startup option.

- **Specify startup and recovery options.**

  Specify what you want the operating system to do if the computer stops unexpectedly. For example, you can specify that you want your computer to restart automatically and you can control logging options.

  For information about these options, see Specify what happens when the system stops unexpectedly.

# Disaster Recovery How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Recover a System That Will Not Start
- Create an Automated System Recovery set using Backup
- Install the Recovery Console as a startup option
- Delete the Recovery Console

# Recover a System That Will Not Start

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Recover a system that will not start**

- Start the computer in Safe Mode
- Start the computer using the last known good configuration
- Start the computer at a command prompt
- Start the computer and use the Recovery Console
- Recover from a system failure using Automated System Recovery

# Start the computer in Safe Mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start the computer in Safe Mode**

1. Click **Start**, and then click **Shut Down**.

2. Select **Restart**, and then click **OK**.

3. Press F8 at the indicated time:

   - For an x86-based computer: When a screen of text appears and then disappears (the screen of text may include a memory test, lines about the BIOS, and other lines), press F8. There may be a prompt that tells you when to press F8.

   - For an Itanium architecture-based computer: After making your selection from the boot menu, press F8. There may be a prompt that tells you when to press F8.

   For information about configuring system settings that affect whether a prompt for F8 appears and how long it appears, see "To specify the default operating system for startup" in Related Topics at the bottom of this page.

4. Use the arrow keys to highlight the appropriate Safe Mode option, and then press ENTER.

   NUM LOCK must be off before the arrow keys on the numeric keypad will function.

5. Use the arrow keys to highlight an operating system, and then press ENTER.

## Notes

- In Safe Mode, Windows only uses basic files and drivers (that is, mouse, monitor, keyboard, mass storage, base video, default system services, and no network connections). You can choose the Safe Mode with Networking option, which loads all of the above files and drivers plus the essential services and drivers to start networking, or the Safe Mode with Command Prompt option, which is exactly the same as Safe Mode except that a command prompt is started instead of the user interface. You can also choose Last Known Good Configuration startup option, which starts your computer using registry information that was saved at the last shutdown.

- Safe Mode helps you diagnose problems. If a symptom does not reappear when you start in Safe Mode, you can eliminate the default settings and minimum device drivers as possible causes. If a newly added device or a changed driver is causing problems, you can use Safe Mode to remove the device or reverse the change.

- There are circumstances where Safe Mode will not be able to help you, such as when Windows system files required to start the system are corrupted or damaged. In this case, the Recovery Console may help you.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Repair overview

# Start the computer using the last known good configuration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start the computer using the last known good configuration**

1. Click **Start**, and then click **Shut Down**.

2. Select **Restart**, and then click **OK**.

3. Press F8 at the indicated time:

   - For an x86-based computer: When a screen of text appears and then disappears (the screen of text may include a memory test, lines about the BIOS, and other lines), press F8. There may be a prompt that tells you when to press F8.

   - For an Itanium architecture-based computer: After making your selection from the boot menu, press F8. There may be a prompt that tells you when to press F8.

   For information about configuring system settings that affect whether a prompt for F8 appears and how long it appears, see "To specify the default operating system for startup" in Related Topics at the bottom of this page.

4. Use the arrow keys to select **Last Known Good Configuration**, and then press ENTER.

   NUM LOCK must be off before the arrow keys on the numeric keypad will function.

5. Use the arrow keys to highlight an operating system, and then press ENTER.

## Notes

- Choosing the Last Known Good Configuration startup option provides a way to recover from problems such as a newly added driver that may be incorrect for your hardware. It does not solve problems caused by corrupted or missing drivers or files.

- When you choose Last Known Good Configuration, only the information in registry key HKLM\System\CurrentControlSet is restored. Any changes you have made in other registry keys remain.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Start the computer and use the Recovery Console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start the computer and use the Recovery Console**

1. Insert the Setup CD and restart the computer from the CD drive.
2. When the text-based part of Setup begins, follow the prompts; choose the repair or recover option by pressing **R**.
3. If you have a dual-boot or multiple-boot system, choose the installation that you need to access from the Recovery Console.
4. When prompted, type the password for the local administrator account.
5. At the system prompt, type the relevant Recovery Console commands; type **help** for a list of commands or **help***commandname* for help about a specific command.
6. To exit the Recovery Console and restart the computer, type **exit**.

**Important**

- Because the Recovery Console is quite powerful, it is recommended for use only by advanced users or administrators.
- In most cases, you will need the password for the built-in administrator account to use the Recovery Console.
- You can set the **Recovery console: Allow automatic administrative logon** setting in the Security Options section of Local Security Settings. Changing this setting will allow you to start the Recovery Console without having to provide the administrator password. For more information, see "Recovery console: Allow automatic administrative logon" and "Edit local security settings" in Related Topics at the bottom of this page.

  Be careful when enabling this option. This will allow anyone with physical access to a computer to boot into the Recovery Console and access the Recovery Console commands.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Recover from a system failure using Automated System Recovery

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To recover from a system failure using Automated System Recovery**

1. Make sure you have the following available before you begin the recovery procedure:

   - Your previously created Automated System Recovery (ASR) floppy disk.
   - Your previously created backup media.
   - The original operating system installation CD.
   - If you have a mass storage controller and you are aware that the manufacturer has supplied a separate driver file for it (different from driver files available on the Setup CD), obtain the file (on a floppy disk) before you begin this procedure.

2. Insert the original operating system installation CD into your CD drive.
3. Restart your computer. If you are prompted to press a key to start the computer from CD, press the appropriate key.
4. If you have a separate driver file as described in step 1, use the driver as part of Setup by pressing F6 when prompted.
5. Press F2 when prompted at the beginning of the text-only mode section of Setup. You will be prompted to insert the ASR floppy disk you have previously created.
6. Follow the directions on the screen.
7. If you have a separate driver file as described in step 1, press F6 (a second time) when prompted after the system reboots.
8. Follow the directions on the screen.

## Notes

- Physical access to a server is a high security risk. To maintain a more secure environment, you must restrict physical access to all servers and network hardware.
- Automated System Recovery will not restore your data files. See Related Topics for more information on backing up and restoring your data files.
- If you are restoring a server cluster in which all nodes failed and the quorum disk cannot be restored from backup, use Automated System Recovery on each node in the original cluster to restore the disk signatures and the partition layout of the cluster disks (quorum and nonquorum). For more information about backing up and restoring server clusters, see the Related Topics link at the bottom of this page.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**Concepts**

Create an Automated System Recovery set using Backup

Back Up and Restore Server Clusters

Backup overview

# Create an Automated System Recovery set using Backup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create an Automated System Recovery set using Backup**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled. You can use the Backup or Restore Wizard to create an Automated System Recovery (ASR) set by answering **All information on this computer** in the **What do you want to backup?** section. Otherwise, you can go to the next step to create an ASR set in **Advanced Mode**.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. On the **Tools** menu, click **ASR Wizard**.

4. Follow the instructions that appear on your screen.

### Important

- You will need a blank 1.44 MB floppy disk to save your system settings and media to contain the backup files. If your computer does not have a floppy drive, see Backup Troubleshooting.

### Notes

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- This procedure will only back up those system files that are necessary for starting your system. You will need to backup your data separately.

- After creating the ASR set, label this floppy disk and backup media carefully and keep them together. To use the backup media, you must have the floppy disk that you created with that set of media. You cannot use a floppy disk created at a different time or with a different set of media. You must also have your Setup CD available at the time you perform Automated System Recovery.

- Keep the ASR set in a secure location. The ASR set contains information about your systems configuration that could be used to do harm to your system.

- If you are backing up a server cluster, run the Automated System Recovery Preparation Wizard on all nodes of the cluster and make sure that the Cluster service is running when you start each Automated System Recovery backup. Make sure that one of the nodes on which you run the Automated System Recovery Preparation Wizard is listed as the owner of the quorum resource while the wizard is running.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Backing up and restoring server clusters

# Install the Recovery Console as a startup option

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install the Recovery Console as a startup option**

1. With Windows running, insert the Setup CD into your CD-ROM drive.
2. Click **Start** and select **Run**.
3. Type the following where *D*: is the CD-ROM drive letter:

   On 32-bit versions of Windows Server 2003: `D:\i386\winnt32.exe /cmdcons`

   - or -

   On x64-based versions of Windows Server 2003: `D:\amd64\winnt32.exe /cmdcons`
4. Follow the instructions on the screen.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- You can not install the Recovery Console on Itanium-based computers.
- To run the Recovery Console, you must restart your computer and select the Recovery Console option from the list of available operating systems.
- To see the commands available on the Recovery Console, type **help** at the console prompt.
- If your computer will not start or you are using an Itanium-based computer, you can run the Recovery Console from the Setup CD. See Start the computer and use the Recovery Console for information on running the Recovery Console when your computer will not start.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete the Recovery Console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete the Recovery Console**

1. Open My Computer.
2. Double-click the hard drive on which you installed the Recovery Console.
3. On the **Tools** menu, click **Folder Options**.
4. Click the **View** tab.
5. Click **Show hidden files and folders**, clear the **Hide protected operating system files** check box, and then click **OK**. If you receive a warning about displaying protected system files, click **Yes** to continue.
6. At the root directory, delete the \Cmdcons folder.
7. At the root directory, delete the file Cmldr.
8. Click **Start**, then **Control Panel**, then click **System**.
9. On the **Advanced** tab under **Startup and Recovery**, select **Settings**.
10. On the **Startup and Recovery** dialog box, under **System startup**, select **Edit** to edit the startup options file manually. Boot.ini will display in Notepad.
11. Remove the entry for the Recovery Console. It will look similar to this:

    C:\cmdcons\bootsect.dat="Microsoft Windows Recovery Console" /cmdcons

12. Save the file and close it.

### Caution

- Modifying the Boot.ini file incorrectly may prevent your computer from restarting. Be sure to delete only the entry for the Recovery Console.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- You can only install the Recovery Console feature on x86-based computers.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Repair overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Repair overview**
The Microsoft® Windows Server 2003 family includes several features to ensure that your computer and the applications and devices installed on it work correctly. These features help you solve the problems that can result from adding, deleting, or replacing files that your operating system, applications, and devices require to function.

**Important**

- Physical access to a server is a high security risk. To maintain a more secure environment, you must restrict physical access to all servers and network hardware.

The recovery feature or features that you use depend on the type of problem or failure you encounter. Use the following list to determine which features to use to address a specific problem.

- Your personal data files are missing or have been corrupted, or you want to revert to a previous version of a file.
- After updating a device driver, you can log on, but the system is unstable.
- After installing a new device, the system is unstable.
- After installing an application, the system is unstable or an application is not working properly.
- Operating system does not start (the logon screen does not appear).

**Your personal data files are missing or have been corrupted, or you want to revert to a previous version of a file.**
If you have saved a copy of the data file in another location, you can copy it from that location back to your hard disk. You can make a back-up copy at any time by copying the file to another location on your computer, to external storage such as a removable disk, or to a different computer.

**Feature: Backup Utility**

**When to use it:** When you need to restore a version of a data file that you saved using Backup.

**What it does:** Restores files from backups.

**For more information**, see Restore files from a file or a tape.

**After updating a device driver, you can log on, but the system is unstable.**

**Feature: Device Driver Roll Back**

**When to use it:** When the only change you want to undo is the updating of a device driver (other than a printer driver). You must be logged on as an administrator.

**What it does:** Reinstalls the driver you were using previously and restores any driver settings that were changed when you added the new driver. Affects no other files or settings. Printer drivers cannot be restored with Device Driver Roll Back.

**For more information**, see Roll back to the previous version of a driver.

**After installing a new device, the system is unstable.**

**Feature: Disable the Device**

**When to use it:** When you suspect that one or more specific hardware devices are causing the problem. You must be logged on as an administrator.

**What it does:** Disables the hardware device and its drivers.

**For more information**, see Disable a device.

**After installing an application, the system is unstable or an application is not working properly.**
Under some circumstances, the computer will prompt you to repair or reinstall an application from a network location or from

the original set-up media (for example, the program CD). If this happens, follow the directions on the screen to repair your program. If you are not prompted with this information, you can use one of the following features to repair your program:

**Feature: Add or Remove Programs**

**When to use it:** When you suspect that one or more specific programs are causing the problem.

**What it does:** Removes the programs you specify.

**For more information**, see Windows interface administrative tool reference A-Z: Add or Remove Programs.

**Operating system does not start (the logon screen does not appear).**

**Feature: Last Known Good Configuration startup option**

**When to use it:** When you suspect that a change you made to your computer before restarting might be causing the failure.

**What it does:** Restores the registry settings and drivers that were in effect the last time the computer started successfully.

**For more information**, see Start the computer using the last known good configuration.

**Feature: Recovery Console**

**When to use it:** If using the Last Known Good Configuration startup option is unsuccessful and you cannot start the computer in Safe Mode. This method is recommended only if you are an advanced user who can use basic commands to identify and locate problem drivers and files. To use the Recovery Console, restart the computer with the installation CD for the operating system in the CD drive. When prompted during text-mode setup, press R to start the Recovery Console.

**What it does:** From the Recovery Console, you can access the drives on your computer. You can then make any of the following changes so that you can start your computer:

- Enable or disable device drivers or services.
- Copy files from the installation CD for the operating system, or copy files from other removable media. For example, you can copy an essential file that had been deleted.
- Create a new boot sector and new master boot record (MBR). You might need to do this if there are problems starting from the existing boot sector.
-

**For more information**, see Recovery Console overview.

**Feature: Automated System Recovery**

**When to use it:** After all other attempts at recovery fail, or if you have replaced a damaged system hard drive. You must have previously used Backup to create an Automated System Recovery set.

**What it does:** Automated System Recovery restores all disk signatures, volumes, and partitions on the disks required to start the computer. Automated System Recovery then installs a simplified installation of Windows and automatically starts a restoration using the backup created by the Automated System Recovery Preparation Wizard.

**For more information**, see Automated System Recovery (ASR) overview.

**Feature: Windows installation CD**

**When to use it:** When you cannot start the computer in Safe Mode, you cannot use either the Last Known Good Configuration startup option or the Recovery Console successfully, and you have no backup to use with Automated System Recovery.

**What it does:** Reinstalls the operating system. You will then need to reinstall your applications and restore your data files from backups.

# Understanding Disaster Recovery

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding disaster recovery**
This section covers:

- Startup options
- Recovery Console overview
- Automated System Recovery (ASR) overview

# Startup options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Startup options**
If your computer will not start, you may be able to start it in Safe Mode. In Safe Mode, Windows uses default settings (VGA monitor, Microsoft mouse driver, no network connections, and the minimum device drivers required to start Windows).

For example, if your computer will not start after you install new software, you may be able to start it with minimal services in Safe Mode and then change your computer settings or remove the newly installed software that is causing the problem. You can reinstall the service pack or the entire operating system, if necessary.

If a symptom does not reappear when you start in Safe Mode, you can eliminate the default settings and minimum device drivers as possible causes.

**Caution**

- The startup options can potentially be used to perform malicious actions on your computer. To protect yourself from this kind of abuse, make sure your computer is in a secure location at all times.

The startup options are:

- Safe Mode
- Safe Mode with Networking
- Safe Mode with Command Prompt
- Enable Boot Logging
- Enable VGA Mode
- Last Known Good Configuration
- Directory Service Restore Mode
- Debugging Mode
- Disable Automatic Restart On System Failure

**Safe Mode**
Starts using only basic files and drivers (mouse, except serial mice; monitor; keyboard; mass storage; base video; default system services; and no network connections). If your computer does not start successfully using Safe Mode, you may need to use the Recovery Console feature to repair your system.

**Safe Mode with Networking**
Starts using only basic files and drivers, plus network connections.

**Safe Mode with Command Prompt**
Starts using only basic files and drivers. After logging on, the command prompt is displayed instead of the Windows desktop, **Start** menu, and Taskbar.

**Enable Boot Logging**
Starts while logging all the drivers and services that were loaded (or not loaded) by the system to a file. This file is called ntbtlog.txt and it is located in the %systemroot% directory. Safe Mode, Safe Mode with Networking, and Safe Mode with Command Prompt add to the boot log a list of all the drivers and services that are loaded. The boot log is useful in determining the exact cause of system startup problems.

**Enable VGA Mode**
Starts the computer using currently installed video driver at the lowest resolution. The basic video driver is always used when you start in Safe Mode (either Safe Mode, Safe Mode with Networking, or Safe Mode with Command Prompt).

**Last Known Good Configuration**
Starts using the registry information and drivers that Windows saved at the last logon. Any driver settings or other systems setting changes made since the last successful logon will be lost. Use only in cases of incorrect configuration.

**Directory Service Restore Mode**
This option is for the server operating systems and is only used in restoring the SYSVOL directory and the Active Directory directory service on a domain controller.

**Debugging Mode**
Starts while sending debugging information through a serial cable to another computer. The serial cable must be connected to the COM1 port with the baud rate set at 115,200.

If you are using, or have used, Remote Installation Services to install Windows on your computer, you may see additional options related to restoring or recovering your system using Remote Installation Services.

**Disable Automatic Restart on System Failure**
Specifies that the computer will not automatically restart whenever the system unexpectedly stops. Use this option to keep your system from restarting while you troubleshoot system failures. Starting with this option is the same as opening the **System** control panel, selecting the **Advanced** tab, clicking **Settings** under **Startup and Recovery Settings** and on the **Startup and Recovery** dialog box, clearing the **Automatically restart** check box under **System Failure**.

### Important

- Even if you disable the local administrator account, it will still be available when you use Safe Mode.
- Physical access to a server is a high security risk. To maintain a more secure environment, you must restrict physical access to all servers and network hardware.

# Recovery Console overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Recovery Console overview**
If Safe Mode and other startup options do not work, consider using the Recovery Console. This method is recommended only if you are an advanced user who can use basic commands to identify and locate problem drivers and files. In addition, you will need the password for the built-in administrator account to use the Recovery Console.

Using the Recovery Console, you can enable and disable services, format drives, read and write data on a local drive (including drives formatted to use NTFS), and perform many other administrative tasks. The Recovery Console is particularly useful if you need to repair your system by copying a file from a floppy disk or CD-ROM to your hard drive, or if you need to reconfigure a service that is preventing your computer from starting properly.

**Important**

- Physical access to a server is a high security risk. To maintain a more secure environment, you must restrict physical access to all servers and network hardware.

There are two ways to start the Recovery Console:

- If you are unable to start your computer, you can run the Recovery Console from your Setup CD.
- As an alternative, you can install the Recovery Console on your computer to make it available in case you are unable to restart Windows. You can then select the Recovery Console option from the list of available operating systems on when you start your computer. You cannot install the Recovery Console on an Itanium-based computer.

After you start the Recovery Console, you will have to choose which installation you want to log on to (if you have a dual-boot or multiple-boot system), and you will have to log on with the password for the built in administrator account for that installation.

The console provides commands you can use to do simple operations such as changing to a different directory or viewing a directory, as well as more powerful operations such as fixing the boot sector. You can access Help for the commands in the Recovery Console by typing **help** at the Recovery Console command prompt.

For more information about securing your computer, see Best practices for security.

**Note**

- Installation of the Recovery Console provides an alternate method for logging on to the computer. This could potentially provide a method for an intruder to gain access to the computer by circumventing many of the built-in safeguards. Consider the potential security effects before installing the Recovery Console.

# Automated System Recovery (ASR) overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Automated System Recovery (ASR) overview**
With Automated System Recovery (ASR), you can create ASR sets on a regular basis as part of an overall plan for system recovery in case of system failure. Use ASR as a last resort in system recovery, only after you have exhausted other options such as the startup options Safe Mode and Last Known Good Configuration. For more information about these and other recovery options, see Startup options.

ASR is a recovery option that has two parts: ASR backup and ASR restore. You can access the backup portion through the Automated System Recovery Preparation Wizard located in Backup. The Automated System Recovery Preparation Wizard backs up the System State data, system services, and all disks associated with the operating system components. It also creates a floppy disk, which contains information about the backup, the disk configurations (including basic and dynamic volumes), and how to accomplish a restore.

You can access the restore part of ASR by pressing F2 when prompted in the text mode portion of setup. ASR reads the disk configurations from the floppy disk and restores all of the disk signatures, volumes and partitions on the disks required to start your computer (at a minimum). (It will attempt to restore all of the disk configurations, but under some circumstances, it may not be able to). ASR then installs a simple installation of Windows and automatically starts to restore from backup using the backup ASR set created by the Automated System Recovery Preparation Wizard.

**Notes**

- ASR does not include data files. Back up data files separately on a regular basis and restore them after the system is working.
- Using **All information on this computer** in the simple wizard also creates an ASR floppy disk and an ASR set.
- ASR supports FAT16 volumes up to 2.1 GB only. ASR does not support 4 GB FAT16 partitions that use a cluster size of 64K. If your system contains 4-GB FAT16 partitions, convert them from FAT16 to NTFS before using ASR.

# Recovery Console commands

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Recovery Console commands**
The following commands can be used with the Recovery Console. For more information about each command, type the command name followed by **/?** in the Recovery Console.

For more information about the Recovery Console, see "Tools for Troubleshooting" at the Microsoft Windows Resource Kits Web site.

- **Attrib**

  Changes the attributes of a file or directory.

- **Batch**

  Executes the commands specified in the text file.

- **Bootcfg**

  Boot file (boot.ini) configuration and recovery.

- **ChDir (Cd)**

  Displays the name of the current directory or changes the current directory.

- **Chkdsk**

  Checks a disk and displays a status report.

- **Cls**

  Clears the screen.

- **Copy**

  Copies a single file to another location.

- **Delete (Del)**

  Deletes one or more files.

- **Dir**

  Displays a list of files and subdirectories in a directory.

- **Disable**

  Disables a system service or a device driver.

- **Diskpart**

  Manages partitions on your hard drives.

- **Enable**

Starts or enables a system service or a device driver.

- **Exit**

  Exits the Recovery Console and restarts your computer.

- **Expand**

  Extracts a file from a compressed file.

- **Fixboot**

  Writes a new partition boot sector onto the system partition.

- **Fixmbr**

  Repairs the master boot record of the partition boot sector.

- **Format**

  Formats a disk.

- **Help**

  Displays a list of the commands you can use in the Recovery Console.

- **Listsvc**

  Lists the services and drivers available on the computer.

- **Logon**

  Logs on to an Windows operating system installation.

- **Map**

  Displays the drive letter mappings.

- **Mkdir (Md)**

  Creates a directory.

- **More (Type)**

  Displays a text file.

- **Rename (Ren)**

  Renames a single file.

- **Rmdir (Rd)**

  Deletes a directory.

- **Set**

Displays and sets environment variables.

- **Systemroot**

  Sets the current directory to the systemroot directory of the system you are currently logged on to.

# Troubleshooting Disaster Recovery

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**

**Important**

- For more information about resolving computer issues, see Repair overview.

What problem are you having?

- My computer stops and displays a long message beginning with the word STOP.
- My computer supports starting directly from the CD-ROM drive. However, when I try to start from the setup compact disc, nothing happens.

**My computer stops and displays a long message beginning with the word STOP.**
**Cause:** Windows has encountered an error from which it cannot recover, and to prevent file damage, has stopped operating.

**Solution:** For general instructions on troubleshooting STOP messages, see Troubleshooting Stop messages: general strategies. For specific instructions on troubleshooting STOP messages, see Troubleshooting specific Stop messages.

**My computer supports starting directly from the CD-ROM drive. However, when I try to start from the setup compact disc, nothing happens.**
**Cause:** To start your computer directly from the setup compact disc, your computer's BIOS or EFI must support the El Torito Bootable CD-ROM (no emulation mode) format. Your BIOS or EFI may not support that format.

**Solution:** Check with your computer manufacturer if you are unsure whether your computer supports this feature. The BIOS or EFI specifies the boot order. Make sure that the CD-ROM is listed as the first boot device.

# Managing Data Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing data storage**
This section covers:

- Removable Storage
- Remote Storage

# Removable Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Removable Storage**
Removable Storage makes it easy for you to track your removable storage media (tapes and optical disks) and to manage the libraries, such as changers and jukeboxes, that contain them.

- Before you begin using Removable Storage, see the Checklist: Configure Removable Storage.
- For tips about using Removable Storage, see Best practices for Removable Storage.
- For step-by-step help with specific tasks, see Removable Storage How To....
- For background information about Removable Storage and how it works, see Removable Storage Concepts.
- For problem-solving guidelines, see Troubleshooting Removable Storage.

# Checklist: Configure Removable Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Configure Removable Storage**

| Step | Reference |
| --- | --- |
| Verify that you have a supported library. | See the hardware compatibility information in the Windows Catalog. You can access the Windows Catalog from Support resources. |
| Install and test the library. | Read the library's operation guide and follow the manufacturer's recommendations. Pay particular attention to slot numbering and supported media types, and note whether the drives require periodic cleaning. |
| Create new media pools to support applications, as needed. | Create a new media pool. |
| Move sufficient media to a free media pool. | Move media to another media pool. |
| Set user or group permissions for Removable Storage as needed. | Change user permissions for Removable Storage. |

# Best practices for Removable Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **Use Run as to run Removable Storage as an Administrator**.

  To maintain system security, log in as a member of the Users group and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking Run as, and choosing an account in the local Administrators group.

- **Keep tapes and disks secure**.

  A malicious user could use Removable Storage tapes and disks to gain access to sensitive data. To maintain security, keep tapes and disks in a secure location when not in use, and secure your libraries by assigning them sufficient permissions to prevent unauthorized users from tampering with or ejecting the tapes and disks.

- **Verify your library hardware is supported first before using Removable Storage**.

  Before adding a new library to a Removable Storage system, you should review the hardware compatibility information in the Windows Catalog. You can access the Windows Catalog from Support resources.

- **Use the Cleaner Management Wizard to clean tape drives**.

  If your library's drives support cleaning, inject cleaning tapes using the Cleaner Management Wizard.

- **Insert media into an automated library before use**.

  Before you create a new media pool, insert media into each automated library you want Removable Storage to control. If a library is empty, Removable Storage cannot detect the media type.

- **Keep your media count under 1,000 per system installation**.

  For performance reasons, do not manage more than 1,000 tapes or disks in a single Removable Storage system.

- **Turn on operator requests only when necessary**.

  Turning on operator requests enables programs on a remote computer to redirect and display operator requests on your computer. Turn off operator requests when it is not needed.

  You can turn on or turn off operator requests by selecting or clearing the **Display operator request and progress dialogs** and **Use notification area icon for pending operator requests** check boxes as described in Change how operator requests are displayed.

- **Give users the appropriate level of access**.

  The following table shows the media pool permissions applicable to specific types of users depending on their location. The Control permission on the Root pool enables users to create media pools. In addition, to create sub-pools, users must have the Control permission on the parent pool. Only those users who must have the ability of creating media pools should have Control permissions added to the Root pool.

| Location | User Type | Use | Control | Modify | View Permissions | Modify Permissions |
|---|---|---|---|---|---|---|
| Computer | User | X | | | | |

| | | | | | | |
|---|---|---|---|---|---|---|
| | Power User | X | X | | | |
| | Backup Operator | X | X | | | |
| | System | X | X | X | X | X |
| Media Library | User | X | | | | |
| | Power User | X | X | | | |
| | Backup Operator | X | X | | | |
| | System | X | X | X | X | X |
| Root Pool | User | | | | | |
| | Power User | | X | | | |
| | Backup Operator | | X | | | |
| | System | | X | | | |
| System Pool | User | X | | | | |
| | Power User | X | X | | | |
| | Backup Operator | X | X | | | |
| | System | X | X | X | X | X |

# Removable Storage How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- View or set Removable Storage properties
- Change the way Removable Storage displays
- Manage Libraries
- Manage Media Pools
- Manage Tapes and Disks
- Manage Operator Requests and Queued Work
- Manage Security for Removable Storage

# View or set Removable Storage properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view or set Removable Storage properties**

1. Open Removable Storage.
2. In the console tree, right-click **Removable Storage**, and then click **Properties**.
3. In the **Properties** dialog box, review the settings and make any changes.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- To view or set properties for specific media pools, library drives, media, or other items, click the applicable folder in the console tree, right-click the specific item in the details pane, and then click **Properties**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the way Removable Storage displays

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the way Removable Storage displays**

1. Open Removable Storage.
2. Verify that **Removable Storage** is selected in the console tree.
3. On the **View** menu, click **Full** (for the full view) or **Simple** (for a simplified view).

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- The Full view is the default view for the Windows Server 2003 family.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Working with MMC console files
Removable Storage How To...

# Manage Libraries

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage libraries**

- Enable or disable a library
- Enable or disable a drive
- Change the library media type
- Inventory a library
- Set the default inventory method
- Open a library door
- Set the library door and port time-out
- Clean a stand-alone drive
- Clean an automated library

# Enable or disable a library

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable a library**

1. Open Removable Storage.
2. In the console tree, double-click **Libraries**.
3. Right-click the library you want to enable or disable, and then click **Properties**.

   The library **Properties** dialog box appears.
4. On the **General** tab, verify that the **Enable library** check box is selected.

   Or, to disable the library, clear the **Enable library** check box.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- Disabling a library makes it unavailable for use.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable or disable a drive

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable a drive**

1. Open Removable Storage.
2. In the console tree, click **Drives**.

   **Where?**

   - Removable Storage *(computer name)*/Libraries/*applicable library*/Drives

3. In the details pane, right-click the applicable drive, and then click **Properties**.
4. On the **General** tab, verify that the **Enable drive** check box is selected.

   Or, to disable the drive, clear the **Enable drive** check box.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- Disabling a drive makes it unavailable for use.
- This procedure applies only to automated libraries. Since stand-alone drive libraries consist of a single drive, you enable or disable the entire library for such cases. For information on how to enable or disable a library, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the library media type

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the library media type**

1. Open Removable Storage.
2. In the console tree, double-click **Libraries**.
3. Right-click the library you want to change, and then click **Properties**.
4. In the *library***Properties** dialog box, click the **Media** tab, and then click **Change**.
5. In the **Change Media Types** dialog box, do the following:
   - To add a new media type, in **Available types**, click the entry you want to add, and then click **Add**.
   - To remove an existing media type, in **Selected types**, click the entry you want to remove, and then click **Remove**.
   - Repeat these steps as necessary.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Inventory a library

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To inventory a library**

1. Open Removable Storage.
2. In the console tree, double-click **Libraries**.
3. Right-click the library you want to inventory, and then click **Inventory**.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- This procedure applies only to automated libraries.
- The type of inventory performed will be the default for that library.
- An inventory is automatically performed each time a library door has been accessed.
- The inventory is performed according to the default inventory method: either Fast, Full, or None. For information on how to change the default inventory method, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Set the default inventory method
Working with MMC console files

# Set the default inventory method

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the default inventory method**

1. Open Removable Storage.
2. In the console tree, double-click **Libraries**.
3. Right-click the library you want to set an inventory method for, and then click **Properties**.
4. On the **General** tab, in **Inventory Method**, click the method you want to use: **None**, **Fast**, or **Full**.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- A fast inventory only checks for storage slots that have changed status between being occupied and unoccupied. A full inventory with bar-coded media will read bar-code information. Otherwise, the tape or disk is mounted and the on-media identifier is read.
- The selected inventory method is automatically performed each time a library door has been accessed.
- A full inventory is always performed when a mount operation fails, regardless of inventory method selected. To disable this feature, clear the **Perform full inventory on mount failure** check box.
- This procedure applies only to automated libraries.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Open a library door

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To open a library door**

1. Open Removable Storage.
2. In the console tree, double-click **Libraries**.
3. Right-click the applicable library, and then click **Door Access**.
4. When prompted, open the door.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- You can use the library door to insert or remove media. If the library has an inject/eject port, you can use that to prevent a re-inventory of the media. Make sure you use the correct slots in the library.
- If you exchange media in a library that are not bar-coded, you must perform a full inventory afterward. The media exchange is not detected during a fast inventory and a media ID mismatch will occur the next time the media in the applicable slot is mounted.
- This procedure applies only to automated libraries.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the library door and port time-out**

1. Open Removable Storage.
2. In the console tree, double-click **Libraries**.
3. Right-click the applicable library, and then click **Properties**.
4. In the **Properties** dialog box, click the **Components** tab.
5. Under **Doors**, in **Time-out**, enter a new value (if necessary) for the door time-out interval (in minutes).
6. Under **Ports**, in **Time-out**, enter a new value (if necessary) for the inject/eject port time-out interval (in minutes).

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- This procedure applies only to automated libraries.

# Clean a stand-alone drive

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To clean a stand-alone drive**

1. Open Removable Storage.
2. In the console tree, click **Drives**.

   **Where?**

   - Removable Storage/Libraries/*applicable library*/Drives

3. In the details pane, right-click the drive, and then click **Mark as Clean**.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- To clean a stand-alone drive, you manually insert a cleaning cartridge into the stand-alone drive. This procedure is performed only to notify Removable Storage that a stand-alone drive has been manually cleaned so that a record can be kept in the Removable Storage database.
- This procedure applies only to cleaning the drive in a stand-alone drive library. For information on how to clean drives in an automated library, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Clean an automated library

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To clean an automated library**

1. Open Removable Storage.
2. In the console tree, right-click the library you want to clean.

   **Where?**

   - Removable Storage *(computer name)*/Libraries/*applicable library*

3. Click **Cleaner Management**.
4. Follow the instructions in the Cleaner Management wizard.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- To complete this procedure, you must insert a cleaning cartridge into the library when prompted. Do not insert a cleaning cartridge using the same method used for inserting regular tapes (such as through the insert/eject port). Follow the instructions in the Cleaner Management wizard.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Media Pools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage media pools**

- Create a new media pool
- Delete an application media pool
- Automatically draw media from a free media pool
- Automatically return media to a free media pool
- Set the allocation limit for a media pool

# Create a new media pool

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a new media pool**

1. Open Removable Storage.

2. If Removable Storage is in Full view, in the console tree, right-click **Media Pools**, and then click **Create Media Pool**. Or, to create a new media pool within another media pool, right-click the applicable media pool and then click **Create Media Pool**.

   If Removable Storage is in Simple view, on the **View** menu, click **Full**, right-click **Media Pools**, and then click **Create Media Pool**. Or, to create a new media pool within another media pool, on the **View** menu, click **Full**, right-click the applicable media pool and then click **Create Media Pool**.

3. On the **General** tab, in **Name**, type a name for the new media pool; then, in **Description**, type a relevant description.

4. Under **Media Information**, click **Contains media of type**, and select the appropriate media type from the list.

5. Under **Allocation/Deallocation policy**, do one or more of the following:

   - To automatically draw unused media from a free media pool when needed, select the **Draw media from Free media pool** check box.

   - To automatically return media to a free media pool when no longer needed, select the **Return media to Free media pool** check box.

   - To set an allocation limit for media in this media pool, select the **Limit reallocations** check box, and then change the default value as necessary.

6. On the **Security** tab, if the user(s) is not listed in the **Group or user names** box, click **Add**, and then complete the **Select Users, Computers, or Groups** dialog box.

7. In the **Permissions for***user name* box, select the **Allow** check box for the Use, Control, and Modify permissions.

**Notes**

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.

- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.

- You can create media pools within application media pools only. You cannot create new media pools within free, unrecognized, or import media pools.

- To create a media pool or a sub-pool beneath the parent media pool, a user must have Control permissions on the Root pool. The Control permission enables users to create media pools.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete an application media pool

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete an application media pool**

1. Open Removable Storage.
2. If Removable Storage is in Full view, in the console tree, double-click **Media Pools**.

   If Removable Storage is in Simple view, on the **View** menu, click **Full**, and then double-click **Media Pools**.
3. Right-click the application media pool you want to delete, and then click **Delete**.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- You cannot delete free, import, or unrecognized media pools.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Automatically draw media from a free media pool

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To automatically draw media from a free media pool**

1. Open Removable Storage.
2. If Removable Storage is in Full view, in the console tree, double-click **Media Pools**.

   If Removable Storage is in Simple view, on the **View** menu, click **Full**, and then double-click **Media Pools**.
3. Right-click the applicable media pool, and then click **Properties**.
4. On the **General** tab, select the **Draw media from Free media pool** check box.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- If you do not select the **Draw media from Free media pool** check box, you must manually move tapes or disks from a free media pool whenever this media pool needs additional media. For information on how to manually move media to a free media pool, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Automatically return media to a free media pool

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To automatically return media to a free media pool**

1. Open Removable Storage.
2. If Removable Storage is in Full view, in the console tree, double-click **Media Pools**.
3. Right-click the applicable media pool, and then click **Properties**.

   If Removable Storage is in Simple view, on the **View** menu, click **Full**, and then double-click **Media Pools**.
4. On the **General** tab, select the **Return media to Free media pool** check box.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- If you do not select the **Return media to Free media pool** check box, you must manually move tapes or disks in this application media pool to a free media pool when no longer needed. After you do this, another application can use those tapes or disks. For information on how to manually move media to a free media pool, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Tapes and Disks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage tapes and disks**

- Move media to another media pool
- Enable or disable a tape or disk
- Insert a tape or disk into an automated library
- Eject a tape or disk from a stand-alone drive
- Eject a tape or disk from an automated library
- Mount a tape or disk
- Dismount a tape or disk from an automated library

# Move media to another media pool

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To move media to another media pool**

1. Open Removable Storage.
2. If Removable Storage is in Simple view, on the **View** menu, click **Full**.
3. In the console tree, click **Contents**.

   **Where?**

   - Removable Storage *(computer name)*/Libraries/*applicable library*/Contents

4. In the details pane, drag the applicable tape or disk from the details pane over to the applicable media pool in the console tree.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- When moving media to a free media pool, make sure the data on the tape or disk you are moving is no longer needed. Data will be automatically deleted when the tape or disk is moved to a free media pool. To manually delete data before moving media to a free media pool, right-click the tape or disk and then click **Free**.
- You cannot move read-only media, such as compact discs, to a free media pool.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Insert a tape or disk into an automated library

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To insert a tape or disk into an automated library**

1. Open Removable Storage.
2. In the console tree, double-click **Libraries**.
3. Right-click the applicable library, and then click **Inject**.
4. Follow the instructions in the Media Inject wizard.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- Use this procedure only with an automated library. For a stand-alone drive library, you must manually insert the tape or disk.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Eject a tape or disk from a stand-alone drive

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To eject a tape or disk from a stand-alone drive**

1. Open Removable Storage.
2. In the console tree, double-click **Libraries**.
3. Right-click the applicable library, and then click **Eject**.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- Use this procedure only with a stand-alone drive library. For information on how to eject a tape or disk from an automated library, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Eject a tape or disk from an automated library

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To eject a tape or disk from an automated library**

1. Open Removable Storage.
2. In the console tree, click **Contents**.

   **Where?**

   - Removable Storage *(computer name)*/Libraries/*applicable library*/Contents

3. In the details pane, right-click the applicable tape or disk, and then click **Eject**.
4. Follow the instructions in the Media Eject wizard.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Mount a tape or disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To mount a tape or disk**

1. Open Removable Storage.
2. In the console tree, click **Contents**.

   **Where?**

   - Removable Storage *(computer name)*/Libraries/*applicable library*/Contents

3. In the details pane, right-click the applicable tape or disk, and then click **Mount**.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.

# Dismount a tape or disk from an automated library

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To dismount a tape or disk from an automated library**

1. Open Removable Storage.
2. In the console tree, click **Drives**.

   **Where?**

   - Removable Storage *(computer name)*/Libraries/*applicable library*/Drives

3. In the details pane, right-click the drive from which you want to dismount the tape or disk, and then click **Dismount**.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.

# Manage Operator Requests and Queued Work

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage operator requests and queued work**

- Respond to an operator request
- Change how operator requests are displayed
- Delete operator requests
- Cancel pending operations in the work queue
- Change the mount order in the work queue

# Respond to an operator request

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To respond to an operator request**

1. Open Removable Storage.
2. On the **View** menu, click **Full**, and in the console tree, click **Operator Requests**.
3. In the details pane, right-click the applicable request, and then do one of the following:
   - To complete the request, click **Complete**, and then perform the action when prompted.
   - To cancel the request, click **Refuse**.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- Removable Storage stores operator requests for approximately 72 hours after they have been completed or cancelled.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change how operator requests are displayed

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change how operator requests are displayed**

1. Open Removable Storage.
2. In the console tree, right-click **Removable Storage** and then click **Properties**.
3. On the **General** tab, under **Options**, do the following:
   - To display operator requests in a pop-up window, select the **Display operator request dialogs** check box; otherwise, clear the check box (the default).
   - To display an icon on the Windows taskbar when there are operator requests waiting to be serviced, select the **Use notification area icon for pending operator requests** check box; otherwise, clear the check box (the default).

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.

# Delete operator requests

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete operator requests**

1. Open Removable Storage.
2. On the **View** menu, click **Full**, and in the console tree, right-click **Operator Requests**, and then click **Properties**.
3. To have all requests automatically deleted, in the **Operator Requests Properties** dialog box, verify that the **Automatically delete completed requests** check box is selected.
4. To automatically delete failed requests also, verify that **Delete failed requests** is selected.

   Or, to save failed requests, click **Keep failed requests**.
5. In **Delete after**, change the time interval as necessary for automatically deleting requests.
6. To restore default settings, click **Default**.
7. To delete all requests now, click **Delete All Now**.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- Restoring the default settings will automatically delete all requests, including failed requests, every 72 hours.
- To delete an individual operator request, right-click the applicable request in the details pane, and then click **Delete**.
- This procedure also applies for deleting items from the work queue. Right-click **Work Queue** in the console tree instead.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Cancel pending operations in the work queue

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To cancel pending operations in the work queue**

1. Open Removable Storage.
2. On the **View** menu, click **Full**, and in the console tree, click **Work Queue**.
3. In the details pane, right-click the applicable item in the work queue, and then click **Cancel Request**.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- You can also delete an item from the work queue by right-clicking the applicable item, and then clicking **Delete**.
- You cannot delete work items that are in progress, except for door opening requests.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the mount order in the work queue

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the mount order in the work queue**

1. Open Removable Storage.
2. On the **View** menu, click **Full**, and in the console tree, click **Work Queue**.
3. In the details pane, right-click the applicable mount operation, and then click **Re-order Mounts**.
4. In the **Change Mount Order** dialog box, do one of the following:
   - To make the selected mount operation the next to be completed, click **Move to the front of the queue**.
   - To make the selected mount operation the last to be completed, click **Move to the end of the queue**.
   - To move the selected mount operation to a specific position in the work queue, click **Make it number**, and then click the up or down arrow to move the item ahead or behind in the queue.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- You can re-order only queued mount operations. You cannot re-order mount operations that are completed or in progress.

# Add users for access to Removable Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add users for access to Removable Storage**

1. Open Removable Storage.
2. In the console tree, right-click the specific item you want to add user access to, and then click **Properties**.
3. On the **Security** tab, click **Add**.
4. In the **Select Users, Computers, or Groups** dialog box, in **Enter the object name to select**, type the name of the user or group, and click **Check Names** to verify the name against the user database. You can add users from a different domain by clicking **Locations** and choosing a domain from the list.
5. Click the name of the user or group that you just added, and then do one of the following:
   - To change specific permissions, select or clear the **Allow** and **Deny** check boxes for each of the three levels of permissions: **Use**, **Modify**, and **Control**, as applicable.
   - To deny all permissions, click **Remove**.

## Notes

- To complete this procedure, you need the appropriate administrative credentials for the affected Removable Storage item. To maintain system security, rather than logging in as an administrator, log in as a user without administrative credentials, and run Removable Storage as an administrator by right-clicking the Computer Management icon, clicking **Run As**, and choosing an account in the local Administrators group.
- To open Removable Storage, click **Start** and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Computer Management**. In the console tree, double-click **Storage** and then click **Removable Storage**.
- You can add user access to libraries, to media pools and their media, or to Removable Storage as a whole.

# Removable Storage overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Removable Storage overview**

Removable Storage makes it easy for you to track your removable storage media (tapes and optical disks) and to manage the hardware libraries, such as changers and jukeboxes, that contain them. Removable Storage labels, catalogs, and tracks media; controls library drives, slots, and doors; and provides drive-cleaning operations.

Removable Storage works in concert with your data-management programs, such as Backup. You use data-management programs to manage the actual data stored on the media. Removable Storage makes it possible for multiple programs to share the same storage media resources, which can reduce your costs.

Removable Storage organizes all the media in your libraries into different media pools. Removable Storage also moves media between media pools in order to provide the amount of data storage your applications require.

Removable Storage does not provide volume management, such as for media siding or striping. Also, Removable Storage does not provide file management, such as for data backup or disk-extender operations. These services are done by data-management applications such as Backup or Remote Storage. Remote Storage is not available on computers running Windows XP Professional, Windows Server 2003, Web Edition; or Windows Server 2003, Standard Edition.

You must run all your data-management programs on the same computer that connects to your library. Removable Storage does not support multiple data-management programs running on different computers that are connected to the same library.

# Understanding Removable Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Removable Storage**
This section covers:

- Removable Storage components
- Libraries
- Media pools
- Media identification
- Media states

# Removable Storage components

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Removable Storage components**
Removable Storage consists of an administrative interface implemented as a Microsoft Management Console (MMC) snap-in, a Windows service with an API, and a database. The Removable Storage service provides media services to data-management programs. The following figure illustrates the relationship between Removable Storage, data management programs, libraries, and Windows.

You can use the Removable Storage snap-in to perform the following tasks:

- Create media pools and set media pool properties.
- Insert and eject media in an automated library.
- Mount and dismount media.
- View the state of media and libraries.
- Clean tape drives.
- Perform library inventories.
- Set security permissions for users.

**Note**

- You do not use the Removable Storage API or database to perform administrative tasks. For more information on the Removable Storage API and database, including how to program to them, see "Managing Data with Removable and Remote Storage" at the Microsoft Windows Resource Kits Web site.

# Libraries

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Libraries**

In its simplest form, a library consists of data storage media and the device used to read from and write to the media. The group of libraries and associated media that are managed by a Removable Storage installation is called a *Removable Storage system*. There are two major types of libraries:

- **Automated libraries** are automated units that hold multiple tapes or disks, and some have multiple drives. These libraries are sometimes called *changers* or *jukeboxes*, and commonly use robotic subsystems to move media stored in the library's storage slots. Automated libraries can also consist of other hardware components that are managed by Removable Storage, such as doors, inject/eject ports, cleaner cartridges, and bar-code readers.

- **Stand-alone drive libraries**, or *stand-alone drives*, are single-drive, nonautomated units, such as tape or CD-ROM drives, that hold a single tape or disk. With these, you manually insert a tape or disk into the unit.

Not only can Removable Storage manage multiple libraries, but it can also track offline media that are not currently contained in a library. These media might be anywhere: on a shelf or in a drawer. Every tape or disk that is offline belongs to a library.

# Media pools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Media pools**

A media pool is a collection of tapes or disks to which the same management properties apply. All media in a Removable Storage system belong to a media pool, and each media pool holds only one type of media. Data management programs use media pools to gain access to specific tapes or disks within a library.

Using media pools, you can define properties that apply to a set of media. This is useful because Removable Storage allows multiple programs to share the same media within a single library. A library can include media from different media pools, each with different properties. A single media pool can span multiple libraries. You can also create hierarchies of media pools, or media pools that contain other media pools. For example, you can create a media pool for each specific media type required by a program, and then create another media pool that contains this collection of media pools. Media pools can contain either media or other media pools, but not both.

A Removable Storage system provides two classes of media pools: system and application.

System media pools include free media pools, unrecognized media pools, and import media pools. Removable Storage creates one free, one unrecognized, and one import media pool for each media type in your Removable Storage system. The system media pools are used to hold media that are not currently being used by an application.

Application media pools are created by data management programs such as Backup and Remote Storage, the latter for computers running Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; the 64-bit versions of Windows Server 2003, Enterprise Edition; or the 64-bit versions of Windows Server 2003, Datacenter Edition.

The different media pools are defined as follows:

- **Unrecognized media pools** contain blank (new) media and media that Removable Storage does not recognize. You should immediately move a new tape or disk from an unrecognized media pool to a free media pool so that the tape or disk can be used by applications, or remove it from the library.

  Unrecognized media are automatically deleted from the Removable Storage database when they are ejected from a library.

- **Import media pools** contain media that Removable Storage recognizes in the database but that have not been used before in a particular Removable Storage system. For example, media in an import media pool could be media from one office location that are introduced into a Removable Storage system at another office location.

  You can move media from import media pools to free media pools or application media pools so applications can use them.

- **Free media pools** contain media that are not currently in use by applications and do not contain useful data. Media in free media pools are available for use by applications.

  Application media pools can be configured to automatically draw media from free media pools when there are not sufficient media available in a particular application media pool. If this configuration is not implemented, you must manually move media from a free media pool when needed.

- **Application media pools**, created by data management applications (and by you), determine what media can be accessed by which applications.

  Media in an application media pool are controlled by that application or by an administrator. An application can use more than one media pool, and more than one application can share a single media pool. For example, Backup might use one media pool for full-backup and another media pool for incremental backup, each containing a different media type.

  There can be any number of application media pools in a Removable Storage system. Media that are currently reserved for use by an application, called *allocated media*, cannot be moved between media pools. Allocation controls how the media are used by applications.

The following illustration shows how media can move from one media pool to another.

# Media identification

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Media identification**
Removable Storage uses two identification methods to track media and perform inventories: on-media identifiers and bar codes.

**On-media identifiers**
On-media identifiers are electronically recorded on media the first time a tape or disk is inserted into a library. The next time the medium is inserted into the library, Removable Storage uses the on-media identifier to recognize and track the tape or disk.

An on-media identifier has two parts: a label type and a label ID. The label type identifies the specific format used to record information on the tape or disk, such as Microsoft Tape Format (MTF). The label ID is a unique identifier for the tape or disk in the Removable Storage system. If Removable Storage does not recognize the label type, it puts the medium in an unrecognized media pool. If Removable Storage recognizes the label type but does not recognize the label ID, it puts the media in an import media pool. If Removable Storage recognizes the label type and the label ID, it updates the Removable Storage database to reflect that the medium is online and available for use.

**Note**

- Removable Storage does not record on-media identifiers for read-only or write-once optical media, such as CD-ROM, DVD-ROM, CD-R, DVD-R, or WORM disks. Instead, Removable Storage uses the volume and serial number information that is already associated with the disk.

**Bar codes**
If your library supports bar codes, Removable Storage can use them to identify media. Media with bar codes also have on-media identifiers, and Removable Storage can use either one. Using bar codes to track media is generally much faster because each tape or disk does not have to be mounted to read the on-media identifier.

# Media states

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Media states**

Each tape or disk in a Removable Storage system has a state associated with it that determines what operations can be performed with the media. When media are inserted into a library, Removable Storage uses the on-media identifier or bar code to determine its state.

There are two sets of media states that govern media movement and usage by Removable Storage: physical states and side states.

**Physical states**

The physical states identify operations performed that involve media location or movement. There are five possible physical states:

| Physical state | Description |
|---|---|
| Idle | Tape or disk is currently in a storage slot in an automated library or is shelved offline. |
| In-use | Tape or disk is in the process of being moved. |
| Loaded | Tape or disk is mounted in a drive and data is available to be read or written. |
| Mounted | Tape or disk is mounted in a drive but data is not yet available to be read or written. |
| Unloaded | Tape or disk has been dismounted and is ready to be removed from a drive. |

**Side states**

A tape or disk side is where actual information is stored. Side states identify operations performed that involve media usage rather than location or movement. There are nine possible side states:

| Side state | Description |
|---|---|
| Allocated | Side is reserved for use by an application. The side is not available to any other application. |
| Available | Side is currently available for use by an application. |
| Completed | Side is in use but cannot be used for write operations. The side is full. |
| Decommissioned | Side is no longer available for use, as it has reached its allocation maximum. |
| Imported | Side's label type is recognized but its label ID is not recognized by Removable Storage. |
| Incompatible | The media type of the side is not compatible with the library. The tape or disk should be removed from the library. |
| Reserved | Side is unavailable for allocation except by a single application. This applies only to two-sided media where one side has already been allocated. |
| Unprepared | Side has been placed in a free media pool but does not yet have a free media label. This is a temporary state. |
| Unrecognized | Side's label type and label ID are not recognized by Removable Storage. |

There is a relationship between side states and media pools: Import media pools can only hold media sides in the imported state. Unrecognized media pools can only hold media sides that are in the unrecognized state. Free media pools can only hold media sides that are in the available (and transitional unprepared) state.

# Using Removable Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Removable Storage**
This section covers:

- Managing libraries
- Managing media pools
- Managing tapes and disks
- Managing operator requests and queued work
- Managing security for Removable Storage
- Managing Removable Storage from the command line

# Managing libraries

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing libraries**

Removable Storage attempts to automatically configure all libraries when you first start Removable Storage and when you add or remove a library from a computer that is running Removable Storage. Removable Storage can always automatically configure stand-alone drives.

You can use the automatic configuration feature of Removable Storage for automated libraries only if you connect all drives on the same SCSI bus as the associated media changer, or if all drives have unique serial numbers. Also, you must use automated libraries that support drive-element address reporting. For information on whether your library supports this feature, consult the library manufacturer.

**Note**

- Because not all library configurations support the automatic configuration feature, Removable Storage provides a method for manually configuring libraries. However, do not use this method unless it is absolutely necessary because manually configured libraries do not recognize system configuration changes. They also involve registry changes. For information on how to configure your libraries manually, see "Managing Data with Removable and Remote Storage" at the Microsoft Windows Resource Kits Web site.

Removable Storage provides comprehensive control and management of libraries. You can enable or disable entire libraries or only specific drives within a library. You can change the media type for a library. You can also open the door on an automated library and set various time-out values.

For information on how to perform a specific task, click:

- Enable or disable a library
- Enable or disable a drive
- Change the library media type
- Open a library door
- Set the library door and port time-out

**Inventorying libraries**

You can create an inventory of all media in a library. Removable Storage supports two inventory methods:

- **Fast inventory.** Removable Storage checks the storage slots and reads the on-media identifier on media in slots that were previously empty.
- **Full inventory.** Removable Storage mounts each tape or disk in your library and reads the on-media identifier.

For information on how to perform an inventory task, click:

- Inventory a library
- Set the default inventory method

**Cleaning drives**

Removable Storage can manage the cleaning of an entire automated library or the drive for a stand-alone drive. Each tape-based automated library can contain one cleaning cartridge. You can use Removable Storage to clean a drive, assign or release a cleaning cartridge slot, and insert or eject a cleaning cartridge. Removable Storage maintains a usage count for each cleaning

cartridge. When a cleaning cartridge reaches its maximum usage count, Removable Storage generates an operator request. If you eject a cleaning cartridge before it has reached its maximum usage count, Removable Storage deletes the usage count information.

For information on how to perform a specific task, click:

- Clean a stand-alone drive
- Clean an automated library

# Managing media pools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing media pools**
After configuring your libraries, you can configure your media pools. Before creating a new media pool, you should answer the following questions:

- What media types are available in your Removable Storage system?
- Should media be automatically drawn from a free media pool when there are not sufficient media in an application media pool? (It is recommended that you implement this configuration.)
- Should media be automatically returned to a free media pool when they are no longer needed by an application?

For information on how to perform a specific task, click:

- Create a new media pool
- Delete an application media pool
- Automatically draw media from a free media pool
- Automatically return media to a free media pool
- Set the allocation limit for a media pool

**Note**

- You cannot delete system media pools.

# Managing tapes and disks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing tapes and disks**

After you create and configure your media pools, you can move media to a specific media pool. It is important that you have a sufficient amount of media in a free media pool so that applications can use media in this pool when needed. For information on how to move media to a free media pool, see Move media to another media pool.

Next, you can use a data management application such as Backup to allocate media to the application media pool created for (or by) that application. Allocating media to an application media pool reserves all media in that media pool for exclusive use by that application. See the documentation for your particular data management application for information on how to reserve media for that application.

Removable Storage provides comprehensive control of tapes or disks in your library. You can enable or disable specific media in your library, insert and eject media, and mount and dismount media.

A tape or disk can be inserted in or ejected from an automated library using either a library door or an inject/eject port. A library door allows unrestricted access to the media inside. You can add or remove media directly from a storage slot using a door access. An inject/eject port allows controlled access to the media inside. You insert a tape or disk in the port and then the library uses the drive bay to move the media to a storage slot.

A tape or disk can be mounted in or dismounted from a particular drive in a library. You can use the same media many times before dismounting them. You can also mount and dismount the same media many times before deallocating them.

For information on how to perform a specific task, click:

- Enable or disable a tape or disk
- Insert a tape or disk into an automated library
- Eject a tape or disk from a stand-alone drive
- Eject a tape or disk from an automated library
- Mount a tape or disk
- Dismount a tape or disk from an automated library

**Notes**

- Removable Storage requires compact discs to be formatted with the CDFS file system, and rewritable optical media (such as MO disks) to be formatted with either the FAT, FAT32, or NTFS file system.
- Windows does not directly support the use of media that can be written to only once, such as WORM, CD-R, and DVD-R disks. If you plan to use these, you must acquire other software that supports these technologies.

# Managing operator requests and queued work

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing operator requests and queued work**

The work queue lists all library requests, or work items, whether initiated by an application or by Removable Storage. A request to mount a tape in a library, for example, results in a mount work item listed in the work queue.

The following table describes the states that a work item can have:

| Work state | Description |
|---|---|
| Completed | The work item has been completed successfully. |
| Failed | Removable Storage was unable to complete the work item. |
| In Process | Removable Storage is actively operating on the work item. |
| Queued | The work item is ready to be carried out, but Removable Storage has not yet begun to operate on it. |
| Waiting | One or more resources needed to satisfy the request are currently in use. |
| Cancelled | A user has cancelled the work item. |

An operator request is a message that asks you to perform a specific task. Operator requests can be issued by Removable Storage or by a program that is aware of Removable Storage, such as Backup. Removable Storage can generate an operator request when any of the following occur:

- An application initiates a mount request for a tape or disk that is offline.
- There are no available media online. That is, a program requires media, and none exist in the appropriate application media pool or in a free media pool.
- A library has failed and requires servicing.
- A drive needs cleaning and no usable cleaner cartridges are available in the library.

You can respond to operator requests by either completing or refusing the operator request. When you refuse an operator request, Removable Storage notifies the application that generated the request. By default, Removable Storage stores an operator request in the work queue for 72 hours after you respond to the request. For information on how to respond to an operator request, see Respond to an operator request.

The following table describes the states that an operator request can have:

| Operator request state | Description |
|---|---|
| Completed | You have indicated, or Removable Storage has detected, that the operator request was completed. |
| Refused | You have indicated that the operator request will not be performed. |
| Submitted | Removable Storage or an application has submitted an operator request for action. |

You can change how operator requests are displayed on your computer, delete operator requests, cancel any pending operation listed in the work queue, and change the order of mount requests in the work queue. For information on how to perform a specific task, click:

- Change how operator requests are displayed
- Delete operator requests

- Cancel pending operations in the work queue
- Change the mount order in the work queue

# Managing security for Removable Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing security for Removable Storage**
Removable Storage provides user-level security for media pools and libraries. Media pool security controls user access to media. Library security controls user access to library drives, slots, and inject/eject ports.

User permissions determine which users or groups of users can access media pools and libraries. Before assigning permissions for a particular media pool or library, it is a good idea to use Active Directory Users and Computers to create a user group containing the accounts of users who need access to a media pool or library. It is also a good idea to review the security tips listed in the Removable Storage Best practices for Removable Storage.

For information on how to perform a specific task, click:

- Change user permissions for Removable Storage
- Add users for access to Removable Storage

# Managing Removable Storage from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Removable Storage from the command line**

You can use the command-line utility for Removable Storage to manage media resources and to write batch scripts for applications that do not currently support the Removable Storage API (are not aware of Removable Storage). You can run the command-line utility from a command prompt by typing **rsm**.

For help using the Removable Storage command line utility, see Rsm.

For information about other command-line utilities, see Command-line reference A-Z.

# Removable Storage Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

The *Microsoft* Windows *Resource Kit* contains advanced information on how to configure, administer, optimize, and troubleshoot Removable Storage. For more information, see "Managing Data with Removable and Remote Storage" at the Microsoft Windows Resource Kits Web site.

# Troubleshooting Removable Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Windows cannot detect the library after you install it.
- Removable Storage has stopped the automatic configuration process for an automated library.
- Removable Storage was unable to automatically configure an automated library.
- The library is configured correctly but is malfunctioning.
- When configuring a media pool, Removable Storage cannot detect the media type.
- You cannot set or change security for Removable Storage.
- I cannot access the Computer Management extension snap-ins on a remote computer.

**Windows cannot detect the library after you install it.**
**Cause:** The library may not be supported by Windows.

**Solution:** Verify that the library is supported by Windows. For a comprehensive list of the libraries supported by Windows operating systems, see the hardware compatibility information in the Windows Catalog. You can access the Windows Catalog from Support resources. Make sure you have configured the library according to any guidelines listed for the applicable library.

**Cause:** The library may not be properly connected to your computer.

**Solution:** Verify that the library is properly connected to your computer. If an automated library is connected to a SCSI host adapter (by means of a SCSI cable), make sure there are no SCSI ID conflicts with other devices in your computer, such as your hard drive or CD-ROM drive. In addition, verify that all cables are installed and terminated properly in accordance with the guidelines for SCSI operation, especially that the maximum length for such cables is not exceeded.

**Removable Storage has stopped the automatic configuration process for an automated library.**
**Cause:** Occasionally, Windows will configure a drive inside an automated library before the library itself has been configured. In this situation, Removable Storage will complete the configuration process once Windows is done configuring the library.

**Solution:** Verify that Windows has recognized the library and associated drives and has configured the device drivers correctly.

**Removable Storage was unable to automatically configure an automated library.**
**Cause:** The library may not support drive-element address reporting. Consequently, Removable Storage cannot map each drive in the library to a particular drive bay.

**Solution:** Use only libraries that support drive-element address reporting, and connect all library drives on the same SCSI bus as the associated drive bay. For information on whether your library supports drive-element address reporting, consult the library manufacturer.

**Solution:** If Removable Storage still cannot automatically configure your library correctly, you will need to manually configure it. However, do not use this method unless it is absolutely necessary because manually configured libraries do not recognize system configuration changes and also involve registry changes. For information on how to configure your libraries manually, see "Managing Data with Removable and Remote Storage" at the Microsoft Windows Resource Kits Web site.

**The library is configured correctly but is malfunctioning.**
**Cause:** Many such problems can be caused by hardware device errors.

**Solution:** See the Windows system event log for details. You can use Event Viewer to view the error messages stored in the event log. Look for specific Removable Storage error messages as well as for device, drive, and controller error messages to

pinpoint the source of the problem. Contact the library manufacturer once you have ruled out Removable Storage as the source of the problem.

**When configuring a media pool, Removable Storage cannot detect the media type.**
**Cause:** The library may not contain any tapes or disks.

**Solution:** Before you create a new media pool, insert media into each automated library you want Removable Storage to control.

**You cannot set or change security for Removable Storage.**
**Cause:** Removable Storage requires that you have administrative credentials for these operations.

**Solution:** Verify that you are logged on with administrative credentials.

**I cannot access the Computer Management extension snap-ins on a remote computer.**
**Cause:** The Remote Registry service is not running on the remote computer.

**Solution:** Ensure that the Remote Registry service is started on the remote computer.

**See also:** Start, stop, pause, resume, or restart a service. You need appropriate credentials on the remote computer to start the service.

### Note

- You might also receive this error message if the remote computer is running Windows 95. Computer Management does not support remote access to computers that are running Windows 95.

# Remote Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Storage**
Remote Storage allows you to extend disk space on your server using a tape or magneto-optical disk library. Remote Storage manages the disk volumes on your server and automatically copies infrequently-used files to a tape or disk library. When the amount of free disk space falls below the defined level, Remote Storage then frees up the space on your disks.

Remote Storage is not included on Windows Server 2003, Standard Edition. If you are using Windows 2000 Server with Remote Storage, you cannot upgrade to Windows Server 2003, Standard Edition. You can upgrade to Windows Server 2003, Enterprise Edition, because Remote Storage is included in this product.

- Before you begin using Remote Storage, see Checklist: Setting up Remote Storage.
- For tips about using Removable Storage, see Best practices for Remote Storage.
- For help with specific tasks, see Remote Storage How To....
- For general background information see Remote Storage Concepts.
- For problem-solving instructions, see Troubleshooting Remote Storage.

# Checklist: Setting up Remote Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Setting up Remote Storage**

Remote Storage is not installed by default when you run Windows Server 2003, Enterprise Edition Setup, Windows Server 2003, Datacenter Edition Setup, or Setup for the 64-bit versions of Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition. You can select Remote Storage for installation during Setup, or you can manually install Remote Storage through **Add or Remove Programs** in **Control Panel**.

| Step | Reference |
|---|---|
| Log on to the local computer with administrative credentials. | Default local groups. |
| Verify that you have a supported tape or disk library and that Removable Storage can detect this library. Remote Storage can use any magneto-optical disk or 4mm, 8mm, or DLT tape library. | For more information about compatible hardware, see Support resources. |
| Using Removable Storage, verify that a sufficient number of tapes or magneto-optical disks for Remote Storage to use are assigned to either the Free or Remote Storage media pool. | View or set Removable Storage properties. |
| Verify that the volumes that will be managed have been formatted with the NTFS file system for Windows 2000 or the Windows Server 2003 family. | Convert command reference. |
| If you intend to use data compression, compress the volume data beforehand. | See the product documentation for your applicable software. |
| If you intend to use content indexing, index the volume data beforehand. | See the product documentation for your applicable software. |
| Install Remote Storage and start the Remote Storage Setup wizard. | Set up Remote Storage. |
| To maintain security, log out, log back in using an account in a different security group, and run Remote Storage as an administrator. To do this, right-click **Remote Storage**, click Run as, and choose an account in the Administrators group. | Access Control. |
| Select volumes for management. | Follow the Remote Storage Setup Wizard. |
| Set the free-space level for volumes that you choose to manage. | Follow the Remote Storage Setup Wizard. |
| Set the criteria for copying files to remote storage. | Follow the Remote Storage Setup Wizard. |
| Select the type of tape or disk to use for remote storage. | Follow the Remote Storage Setup Wizard. |
| Set the file-copy schedule. | Follow the Remote Storage Setup Wizard. |
| Set the number of media copies that you want to make. | Set the number of media copies. |

# Best practices for Remote Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

The following list represents some best practices for Remote Storage. You should implement this list whenever possible.

- **Backup files on managed volumes as well as the Remote Storage database files.** Remote Storage relies on backups to protect applicable files cached on your local volumes, in addition to the Remote Storage database and other program data files in the System32\RemoteStorage folder. You should keep track of when data backups occur and which tapes are used. For information on Backup, see Backup overview.

  For more information on protecting data managed by Remote Storage, see Protecting and recovering data from loss.

- **Backup files as an administrator when backing up Remote Storage database files.** Remote Storage requires that you run system state backups as a member of the Administrators group in order to backup the Remote Storage database files. If you run a system state backup as a member of the Backup Operators group, it will not include the Remote Storage database files.

- **Make copies of your remote storage data.** You should make multiple copies of the tapes or disks that Remote Storage uses and regularly update them. In this way, if you later encounter a problem with your original tape or optical disk (the *master media*), you can recreate it using a copy you have made. Doing this ensures no loss of data.

- **Keep full media copies off site**. If possible, keep full media copies off site or rotate media copies between your business sites for safekeeping. (Non-full media copies are required on site for synchronization.)

- **Do not use the Remote Storage command-line utility before you configure Remote Storage.** You must configure Remote Storage using the Remote Storage Setup wizard before you use the **rss.exe** command-line utility, or you will not be able to use the utility to successfully manage Remote Storage.

- **Do not create File Replication service (FRS) replica sets on a volume that is managed by Remote Storage.** In addition, do not add a volume that contains directories that are part of an FRS replica set to Remote Storage. Otherwise, you might severely impact system performance and possibly cause data loss within your media library.

  FRS might need to periodically read every file in the replica set to send the file contents to another computer. This causes FRS to recall all files that Remote Storage has sent to secondary storage, which might take a long time (hours or days). If you use tape for your secondary storage, remember FRS recalls files in directory order rather than media order, so the excessive number of tape seeks performed by FRS will likely ruin the tapes and cause data loss.

- **Validate your managed volumes regularly.** You should schedule validation of your managed volumes on a regular basis. Validation ensures that all files on managed volumes point to the correct data in remote storage.

- **Discontinue managing all volumes before uninstalling Remote Storage**. Before you uninstall Remote Storage, you should discontinue managing all volumes by selecting **Recall copied data from storage** in the Remove Volume Management wizard. Otherwise, you may lose your file data.

- **Think before you delete a file from a managed volume**. If you delete a file from a managed volume, the associated data can no longer be recalled from remote storage. Be careful not to delete such files if you might want to recall the data at a later time.

- **Do not use Remote Storage to manage excessively full volumes.** Remote Storage requires free space on each volume to store the metadata for each file it manages. If there is not enough space on the volume, Remote Storage will behave unpredictably or fail to work. There is no way to predict how much space you'll need for the metadata, so use your best judgment and clear space on excessively full volumes before attempting to manage them.

- **Do not format a managed volume**. When a managed volume is formatted, Remote Storage cannot locate the volume anymore, and does not know if the volume is temporarily unavailable or was permanently removed (which is the case when a volume is being formatted).

- **Load balance your scheduled tasks**. When managing several large-capacity volumes, you should schedule tasks to run on different days and at different times to spread out the workload on your server. For example, all tasks for volume A could be scheduled to run on Tuesdays and Thursdays at 2:00 am; all tasks for volume B could be scheduled to run on Mondays, Wednesdays, and Fridays at 2:00 am.

- **Avoid scheduling tasks at system restart**. To prevent excess workload on your server, you should not schedule any tasks to start at system restart.

- **Do not change the drive letter assigned to a managed volume.** If you must change a volume's drive letter, stop managing it with Remote Storage first.

- **Log in as a domain user when managing volumes**. Remote Storage only notifies you of file recalls when you are logged in as a domain user. If you log onto your local computer only, you will not receive these recall notifications.

- **Avoid deleting the USN journal, if it has been created.** If someone has created an update sequence number (USN) journal on the computer using the **fsutil** utility, deleting it will degrade the performance of Remote Storage.

# Remote Storage How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Set up Remote Storage
- View or set properties for Remote Storage
- Monitor tasks for Remote Storage
- View events for Remote Storage
- Manage Local Disk Volumes
- Manage Remote Storage Media

# Set up Remote Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set up Remote Storage**

1. If Remote Storage is not yet installed on your computer, do the following:

    - Open Add or Remove Programs in Control Panel.
    - Click **Add or Remove Windows Components**.
    - Select the **Remote Storage** check box, and then click **Next**.
    - When asked if you want to restart your computer now, click **Yes**.

2. Open Remote Storage.

3. Follow the instructions that appear in the **Remote Storage Setup wizard**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Add or Remove programs, click **Start**, click **Control Panel**, and then double-click **Add or Remove programs**.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**. Remote Storage will not be available until after you have installed it.
- The first time you open Remote Storage after it is installed, the Remote Storage Setup wizard guides you through the steps required to fully configure it for operation.
- Think carefully about the type of media you want to use for remote storage because this cannot be changed later.
- You should not install Remote Storage on a Windows server cluster. Remote Storage will not failover to the other computer node.
- Certain Windows components require configuration before they can be used. If you installed one or more of these components but did not configure them, when you click **Add/Remove Windows Components**, a list of components that need to be configured is displayed. To start the Windows Components Wizard, click **Components**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View or set properties for Remote Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view or set properties for Remote Storage**

1. Open Remote Storage.
2. In the console tree, click the applicable item. The objects are displayed in the details pane.
3. Right-click the object that you want to change, and then click **Properties**.
4. Review settings and make changes, as needed.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.

**Information about functional differences**

# Manage Local Disk Volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage local disk volumes**

- Add a volume for management
- Discontinue managing a volume
- Set the desired free space for a volume
- Specify basic file-selection criteria
- Add a file rule
- Change priority of file rules
- Set the runaway recall limit
- Set the maximum number of drives to use simultaneously
- Change the file-copy schedule
- Set advanced schedule options
- Copy files to remote storage
- Validate files
- Create free space immediately

# Add a volume for management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a volume for management**

1. Open Remote Storage.
2. In the console tree, double-click **Remote Storage**.
3. Right-click **Managed Volumes**, point to **New**, and then click **Managed Volume(s)**.
4. Follow the instructions that appear in the Add Volume Management wizard.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.
- You can use the Add Volume Management wizard any time after you run the Remote Storage Setup wizard.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Discontinue managing a volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To discontinue managing a volume**

1. Open Remote Storage.
2. In the console tree, double-click **Remote Storage**, and then click **Managed Volumes**.
3. In the details pane, right-click the applicable volume, and then click **Remove**.
4. Follow the instructions that appear in the Remove Volume Management wizard.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.
- If you have adequate disk space to recall all data from remote storage, but the **recall copied data from storage** option is not available, you may need to validate the files on the volume first. Validating the volume updates the statistics used by Remote Storage to determine if enough disk space is available to recall data from remote storage. For information on how to validate the files on a managed volume, see Related Topics.
- For information on how to monitor the status of this task, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set the desired free space for a volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the desired free space for a volume**

1. Open Remote Storage.
2. In the console tree, double-click **Remote Storage**, and then click **Managed Volumes**.
3. In the details pane, right-click the applicable volume, and then click **Settings**.
4. On the **Settings** tab, in **Desired free space**, click the UP or DOWN ARROW to increase or decrease the value.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.
- Using this procedure, you can define the free space for the volume. When the available space on the volume falls below this setting, Remote Storage frees up space on the volume by removing cached data from files that have been copied to remote storage.
- You use this procedure to configure Remote Storage to automatically free up space on your volume when the actual free space falls below the **Desired Free Space** setting. For information on how to override this setting and immediately free up space on your volume, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify basic file-selection criteria

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify basic file-selection criteria**

1. Open Remote Storage.
2. In the console tree, double-click **Remote Storage**, and then click **Managed Volumes**.
3. In the details pane, right-click the applicable volume, and then click **Settings**.
4. On the **Settings** tab, under **File criteria**, in **Larger than**, click the UP or DOWN ARROW to set the file size value.
5. Under **File criteria**, in **Not accessed in**, click the UP or DOWN ARROW to change the time value.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.
- If insufficient free space is created on your managed volume because not enough files are being copied to remote storage, you may need to decrease these values.
- For information on how to specify more complex criteria for copying files to remote storage based on file rules, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a file rule

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a file rule**

1. Open Remote Storage.
2. In the console tree, double-click **Remote Storage**, and then click **Managed Volumes**.
3. In the details pane, right-click the applicable volume, and then click **Include/Exclude Rules**.
4. On the **Include/Exclude Rules** tab, click **Add**.
5. In **Path**, type the folder path to the file (do not include the drive letter).
6. In **File type**, type the wildcard character and file extension (for example: *.jpg).
7. To exclude matching files when the rule is applied, click **Exclude matching files**.

   Or, to include matching files when the rule is applied, click **Include matching files**.
8. To apply the rule to any matching files stored in subordinate folders, select the **Apply rule to subfolders** check box.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.
- For information on how to copy files to remote storage based also on file size and last access date, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change priority of file rules

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change priority of file rules**

1. Open Remote Storage.
2. In the console tree, double-click **Remote Storage**, and then click **Managed Volumes**.
3. In the details pane, right-click the applicable volume, and then click **Include/Exclude Rules**.
4. On the **Include/Exclude Rules** tab, select the applicable rule.
5. Click the UP ARROW to give the rule a higher priority.

   Or click the DOWN ARROW to give the rule a lower priority.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.
- The position of a file rule on the list determines which rule is applied first. Remote Storage applies the first rule on the list that matches a file in a given folder.
- There are a number of predefined rules provided when Remote Storage is first set up. You cannot move some of these predefined rules up or down the list. You can however, move all rules that you define up or down the list.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set the runaway recall limit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the runaway recall limit**

1. Open Remote Storage.
2. In the console tree, right-click **Remote Storage**, and then click **Properties**.
3. On the **Limits** tab, change the value in **Maximum number of successive recalls** by clicking the UP or DOWN ARROWS.
4. To exclude all users with administrative credentials from this limit, select the **Limit does not apply to members of the Administrators group** check box.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.
- The runaway recall limit prohibits a user, or an application, from recalling files from remote storage more than the specified number of times in succession with less than 10 seconds between each recall. Virus checking, data backup, indexing, and search applications typically read all files on your computer and can cause excessive file recalls to occur otherwise.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set the maximum number of drives to use simultaneously

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the maximum number of drives to use simultaneously**

1. Open Remote Storage.
2. In the console tree, right-click **Remote Storage**, and then click **Properties**.
3. On the **Limits** tab, change the value in **Maximum number of removable media drives to use** by clicking the UP or DOWN ARROWS.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.
- This limit sets the maximum number of tape or magneto-optical drives in the selected device that Remote Storage can read from or write to simultaneously.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the file-copy schedule

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the file-copy schedule**

1. Open Remote Storage.
2. In the console tree, right-click **Remote Storage**, click **Properties**, and then click the **Schedule** tab. This displays the current schedule.
3. Click **Change Schedule**. This displays the **File Copy Schedule** dialog box.
4. In **Schedule Task**, click the arrow, and then select an interval.
5. In **Start time**, set the time by clicking the UP or DOWN ARROW.
6. Under **Schedule Task Daily**, in **Every**, change the value by clicking the UP or DOWN ARROW, if necessary.
7. To set multiple schedules, select the **Show multiple schedules** check box.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.
- You use this procedure to automatically copy files to remote storage based on a schedule. For information on how to immediately copy files from specific volumes to remote storage, see Related Topics.
- For information on how to monitor the status of this task, see Related Topics.

# Set advanced schedule options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set advanced schedule options**

1. Open Remote Storage.
2. In the console tree, right-click **Remote Storage**, and then click **Properties**.
3. On the **Schedule** tab, click **Change Schedule**.
4. In the **Remote Storage File Copy Schedule** dialog box, click **Advanced**.
5. In the **Advanced Schedule Options** dialog box, in **Start Date**, select a calendar date.
6. To set an end date, select the **End Date** check box, click the DOWN ARROW, and select a calendar date.
7. To repeat tasks, select the **Repeat task** check box and then do the following, as needed:
   - To change the time interval, in **Every**, click the UP or DOWN ARROW to set the value, and then click the DOWN ARROW and select the units.
   - To change the time, in **Until**, click **Time**, and click the UP or DOWN ARROW.
   - In **Until**, click **Duration**, and then change the settings in **hour(s)** and **minute(s)** by clicking the UP and DOWN ARROWS.
8. To stop a task if it is still running at the time previously specified, select the **If the task is still running, stop it at this time** check box.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

# Create free space immediately

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create free space immediately**

1. Open Remote Storage.
2. In the console tree, double-click **Remote Storage**, and then click **Managed Volumes**.
3. In the details pane, right-click the applicable volume, click **All Tasks**, and then click **Create Free Space**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.
- This procedure frees up space on your volume by removing cached data from files that have been copied to remote storage. If all cached data has already been removed, no additional free space can be created. In addition, recall activity will increase as data is no longer cached locally.
- You use this procedure to immediately free up space on your volume. For information on how to configure Remote Storage to automatically free up space on your volume when the available space falls below a specified amount, see Related Topics.
- For information on how to monitor the status of this task, see Related Topics.

**Information about functional differences**

# Manage Remote Storage Media

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage remote storage media**

- Set the number of media copies
- Synchronize media copies
- Delete media copies
- Recreate the media master

# Set the number of media copies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the number of media copies**

1. Open Remote Storage.
2. In the console tree, right-click **Remote Storage**, and then click **Properties**.
3. On the **Media Copies** tab, change the value in **Number of media copy sets** by clicking the UP or DOWN ARROW.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.
- Copies of remote storage media can be created only if two or more drives are available.
- You can make up to three copies of remote storage media. You should synchronize media copies with the original media (called the media master) on a regular basis to ensure no loss of data. For information on how to synchronize media copies, see Related Topics.
- Reducing the number of media copies does not cause any media to be deallocated, it only limits the copy sets that Remote Storage will display and access. To deallocate the media, select all the media and then delete the media copies. For information on how to delete media copies, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Synchronize media copies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To synchronize media copies**

1. Open Remote Storage.
2. In the console tree, right-click **Media** and then click **Synchronize Media Copies**.
3. Follow the instructions that appear in the Media Copy Synchronization wizard.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.
- Media copies can be created only if two or more drives are available.
- For information on how to monitor the status of this task, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete media copies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete media copies**

1. Open Remote Storage.
2. In the console tree, double-click **Remote Storage**, and then click **Media**.
3. In the details pane, right-click one or more of the media shown, and then click **Media Copies**.
4. On the **Media Copies** tab, do one or more of the following:
   - To delete the first copy of the media master, click **Delete Copy 1**.
   - To delete the second copy of the media master, click **Delete Copy 2**.
   - To delete the third copy of the media master, click **Delete Copy 3**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.
- Deleting a media copy removes it from the Remote Storage database, but it does not erase the data from the tape or disk on which it is stored. This data can still be read by a malicious user who has physical access to the tape or disk. To ensure the security of the data, keep tapes or disks in a secure location.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Recreate the media master

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To recreate the media master**

1. Open Remote Storage.
2. In the console tree, double-click **Remote Storage**, and then click **Media**.
3. In the details pane, right-click one of the media shown, and then click **Properties**.
4. Click the **Recovery** tab, and then click **Re-create Master**.
5. Follow the instructions that appear on-screen.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Remote Storage, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Storage**.
- You should recreate the media master only if you experience errors when you recall files from remote storage.
- Make sure the media copy you selected to use to recreate the media master is the most current version.
- Using Removable Storage (not to be confused with Remote Storage), you should verify that there are tapes or disks in a free media pool of equal or greater capacity to the media copy you are using to recreate the media master. For information on how to view Removable Storage properties, see Related Topics.

- Using Remote Storage
- Remote Storage Resources

# Remote Storage overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Storage overview**
Remote Storage makes it easy for you to extend disk space on your server computer without adding more hard disks. Remote Storage automatically copies eligible files on your local volumes to a library of magnetic tapes or magneto-optical disks. Remote Storage then monitors the amount of space available on your local volumes.

File data is cached locally so that it can be accessed quickly as needed. When the amount of available space on a managed volume dips below the level you need, Remote Storage automatically removes the content from the cached files, providing the disk space you need. When data is removed from a file, the disk space used by the file is reduced to zero. Data from cached files is not removed until more disk space is needed. When you need to open a file whose data has been removed, the data is automatically recalled from remote storage.

Since removable tapes or disks in a library are less expensive per megabyte (MB) than hard disks, this can be an economical way to provide both maximum data storage and optimal local disk performance.

**Levels of data storage**
Remote Storage data storage is hierarchical, with two defined levels. The upper level, called local storage, includes the NTFS disk volumes of the computer running Remote Storage. The lower level, called remote storage, is on the automated media library or stand-alone tape or disk drive that is connected to the server computer.

Remote Storage supports all SCSI class 4mm, 8mm, DLT, and magneto-optical devices that are supported by Removable Storage. Using Remote Storage with Exabyte 8200 tape libraries is not recommended. Remote Storage does not support QIC tape libraries or rewritable compact disc and DVD formats.

**Retrieval of stored files**
When you need to access a file on a volume managed by Remote Storage, you simply open the file as usual. If the data for the file is no longer cached on your local volume, Remote Storage recalls the data from a tape library. Because this can take more time than usual, Remote Storage removes the data only from those files on your local volumes that you are least likely to need, based on criteria that you set.

**Coordination with other tools**
Remote Storage uses Removable Storage to access the applicable tapes contained in libraries. Remote Storage also works with Backup for data recovery, and with Task Scheduler to schedule file copy operations. For information on Removable Storage, see Removable Storage. For information on Backup, see Backup overview. For information on Task Scheduler, see Task Scheduler.

Remote Storage also provides certain data-recovery features, including the ability to generate multiple copies of data in remote storage.

### Note

- Using Remote Storage to copy files to remote storage is not the same as backing up your files. You should follow a regular schedule of data backups, including backing up the contents of the local volumes that Remote Storage manages. You should also backup the Remote Storage database and other program files located in the System32\RemoteStorage folder.

### Caution

- Do not create File Replication service (FRS) replica sets on a volume that is managed by Remote Storage. In addition, do not add a volume that contains directories that are part of an FRS replica set to Remote Storage. Otherwise, you might severely impact system performance and possibly cause data loss within your media library.

  FRS might need to periodically read every file in the replica set to send the file contents to another computer. This causes FRS to recall all files that Remote Storage has sent to secondary storage, which might take a long time (hours or days). If you use tape for your secondary storage, remember FRS recalls files in directory order rather than media order, so the excessive number of tape seeks performed by FRS will likely ruin the tapes and cause data loss.

# Understanding Remote Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Remote Storage**
This section covers:

- Basic operation of Remote Storage
- How Remote Storage affects the operating system
- Managed volumes
- Remote Storage and Removable Storage

# Basic operation of Remote Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Basic operation of Remote Storage**

The following steps describe how to use Remote Storage to manage space on your local disk volumes.

Before Remote Storage can manage your volumes, you must verify that a sufficient number of tapes or disks have been moved to a free media pool using Removable Storage. For more information on managing tapes or disks using Removable Storage, see Managing tapes and disks.

- You determine which local disk volumes you want Remote Storage to manage. You then define the amount of free space you want maintained on the volumes, the file-selection criteria for copying files to remote storage, and the type of media to use for remote storage.

- Remote Storage then copies files to remote storage that meet the criteria, leaving the original data stored, or cached, on the local volumes.

- Remote Storage compares the amount of available space on a managed volume with the amount you defined above. If the actual free disk space is less than the amount that you defined, Remote Storage removes the data on your local volumes, reducing the disk space used by the files to zero. This step continues until the free space setting that you defined is met or when all data has been removed from cached files on your managed volumes.

- When you want to access a file, you simply open the file on your local volume in the usual way. Remote Storage automatically recalls the data from remote storage and copies the data back to your local volume. The type of library and media used determines how much time delay you experience.

Recalling a file does not erase it from the tape or disk on which it is stored. This data can still be read by a malicious user who has physical access to the tape or disk. To ensure the security of the data, keep tapes or disks in a secure location.

# How Remote Storage affects the operating system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How Remote Storage affects the operating system**

Remote Storage runs as a service and uses Removable Storage to access the applicable tapes or disks in a library that are used for remote storage. You administer Remote Storage from Microsoft Management Console (MMC), using the Remote Storage snap-in to perform all tasks, or from the command line using the Rss command. The following figure illustrates the relationship between Remote Storage and your server.

Remote Storage uses Windows security to grant or deny access for storage management. Only user accounts that have administrative credentials can administer Remote Storage; however, users with appropriate permissions can open the files on volumes that Remote Storage manages. To maintain system security, log in as a member of a different security group and run Remote Storage as an administrator. To do this, right-click **Remote Storage**, click Run as, and choose an account in the Administrators group.

Remote Storage adds a **Remote Storage** tab to the volume **Properties** dialog box of Windows Explorer and to the Disk Management snap-in on the local computer. This tab shows local and remote storage statistics and settings. While you can remotely manage volumes from other computers, the **Remote Storage** tab only appears on the computer that the Remote Storage services are running on.

Programs that use file size, such as Disk Quota, are not affected by Remote Storage operations. When Remote Storage frees up disk space by removing data from cached files that have been copied, the disk space used by file becomes zero. However, the *logical* size and the date and time (created, last modified, last accessed) attributes of the file remain unchanged.

When using Windows File Manager (Winfile.exe), files that Remote Storage manages are not displayed. This affects client computers running versions of Windows prior to Windows 2000.

Only one Remote Storage installation can exist on a server.

"You cannot remotely administer Remote Storage from a computer running Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, to a computer running Windows 2000."

**Important**

- Do not remotely administer Remote Storage on a computer running a different-language version of the operating system.

# Managed volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managed volumes**

The local disk volumes on your server computer that are under Remote Storage control are called managed volumes. For example, you can configure drive C as a managed volume. If you have supplementary hard disks on other drives, such as D, E, and so forth, you can also configure these as additional managed volumes.

Disk volumes managed by Remote Storage must be nonremovable and must be formatted with NTFS.

Remote Storage automatically copies data from managed volumes to remote storage according to a schedule and to rules that you specify. You configure the amount of free disk space you want to maintain on the managed volumes and the criteria used to copy specific files to remote storage.

The following figure illustrates how Remote Storage copies files from local storage to remote storage.

**Step 1** - Files copied to remote storage and cached locally

**Step 2** - Data removed from cached local files when actual free space is less than the desired free space setting

# Remote Storage and Removable Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Storage and Removable Storage**

Remote Storage uses Removable Storage to access the applicable media in a library that are used for remote storage.

Remote Storage can support a multiple-drive automated library, but only if all the drives within it are identical. Within such an automated library, Remote Storage can access two or more drives at the same time. If the automated library contains two or more drives, Remote Storage can simultaneously copy data to, and recall data from, two or more different tapes or disks.

All remote storage tapes or disks used by Remote Storage exist in a single application media pool that is automatically created during Remote Storage Setup. You use Removable Storage to verify that sufficient media have been moved to a free media pool, so that Remote Storage can use tapes or disks from that pool if needed. You cannot move tapes or disks from the Remote Storage application media pool to another application media pool.

Remote Storage can support only a single tape or disk type for use as remote storage. You specify which type is supported when you run the Remote Storage Setup wizard. You cannot change this type later.

Recalling data from remote storage may take more time than usual. The amount of this time delay depends on several factors:

- Whether or not a tape or disk is already mounted in a drive.
- The speed of a library in mounting a tape or disk.
- Availability of the tapes or disks and drives in a library.
- Whether or not other file recalls are pending.

The following figure illustrates how Remote Storage recalls data from remote storage to local storage. Note that when data is recalled, it is copied back to the original volume and the file again takes up disk space.

Remote Storage does not support the use of QIC tapes as remote storage media.

Media used by Remote Storage contain only data that has been copied from managed volumes. However, the library can contain additional media used by other applications, such as Backup.

Remote Storage does not support recalling data for a volume that has been managed at different times by two different Remote Storage installations.

# Using Remote Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Remote Storage**
This section covers:

- Setting up Remote Storage
- Managing local volumes
- Managing remote storage media
- Protecting and recovering data from loss
- Managing Remote Storage from the command line

# Setting up Remote Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting up Remote Storage**

Remote Storage is not installed by default when you install the operating system. You can set Remote Storage for installation when you set up your operating system, or afterwards using Add or Remove Programs in Control Panel. For information on how to set up Remote Storage after you have installed the operating system, see Set up Remote Storage.

You should not install Remote Storage on a Windows Server 2003, Enterprise Edition or Windows Server 2003, Datacenter Edition computer in a server cluster configuration. Remote Storage will not fail over to the other computer node.

Before you can use Remote Storage, you must satisfy three requirements:

- You must be logged on with administrative credentials.
- You must verify that a sufficient number of tapes or disks are in a free media pool. (Use Removable Storage to perform this task.)
- You must verify that volumes managed by Remote Storage are formatted with the version of NTFS used in Windows 2000 and the Windows Server 2003 family. For more information, see Convert.

If you intend to use data compression on managed volumes, compress the volumes beforehand. Also, if you intend to use content indexing, run your indexing software beforehand. See the product documentation for your particular software

You must open Remote Storage using an account in the Administrators group. To maintain system security, log in using an account in a different security group and run Remote Storage as an administrator. To do this, right-click **Remote Storage**, click Run as, and choose an account in the Administrators group.

Remote Storage is administered in Microsoft Management Console (MMC) using the Remote Storage snap-in. The first time you open the Remote Storage snap-in, the Remote Storage Setup wizard guides you through the steps required to fully configure Remote Storage for operation. After you have configured Remote Storage with the wizard, you can use either the Remote Storage snap-in or the Remote Storage command-line tool, Rss, to administer Remote Storage.

# Managing local volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing local volumes**

Remote Storage manages physical disk volumes on the local computer by copying selected files on those volumes to a tape or disk library according to the schedule and rules that you specify. The original files are left cached on your local volumes. You can use Remote Storage to automatically copy files, following a schedule that you specify, or you can immediately copy files to tape or disk.

Volumes managed by Remote Storage must be nonremovable (fixed) media. You initially select which volumes Remote Storage manages when you complete the Remote Storage Setup wizard. For information on how to add an additional volume for Remote Storage management, see Add a volume for management.

**Setting the desired free space**

You can specify the amount of free space that you want to maintain on each local volume. This setting establishes a threshold value.

Remote Storage continuously monitors the actual amount of free space on your local volumes. If the amount of actual free space falls below the Desired Free Space setting, Remote Storage removes the cached data from files on your local volumes that have been copied to tape or disk. The disk space used by files on your local volumes becomes zero.

You set the free space initially when you complete the Remote Storage Setup wizard. This value is used for each volume that Remote Storage manages. For information on how to change the Desired Free Space setting, or to set a different value for each volume, see Set the desired free space for a volume.

You can also free up disk space manually. Doing this immediately removes the cached data from files on your local volumes. For information on how to immediately free up disk space, see Create free space immediately.

**Specifying file-selection criteria and rules**

You can specify the criteria governing which files you want Remote Storage to copy to remote storage. All files that meet the criteria are eligible to be copied to tape or disk. You specify criteria based on minimum file size and time elapsed since the files were last accessed.

You initially specify file criteria when you complete the Remote Storage Setup wizard. These criteria are used for each volume that Remote Storage manages. For information on how to change the criteria, or to specify separate criteria for each volume, see Specify basic file-selection criteria.

You can also specify file inclusion and exclusion rules that affect file selection for copying to remote storage. These rules can include or exclude matching files based on:

- A specified folder, including all subfolders within it.
- A specified folder, excluding subfolders.
- File name extension.
- File name, including wildcard characters.

Remote Storage provides a predefined list of file inclusion and exclusion rules that you can use. You cannot edit or change the order of some of these predefined rules. You can, however, move and edit all rules that you create.

Remote Storage uses the first rule in the rule list that matches a file in a given folder. Changing the order of a rule in the list changes the priority of that rule.

For information on how to perform specific tasks, click:

- Add a file rule.
- Change priority of file rules.

### Note

- By default, all hidden, system, extended attribute, encrypted, and sparse files are excluded from the file rule list. These files cannot be copied to remote storage.

**Changing the file-copy schedule**

Remote Storage provides a default schedule used for file copying when you complete the Remote Storage Setup wizard. For information about how to change the file-copy schedule and about advanced schedule options, see Change the file-copy schedule.

You can also copy files to remote storage at any time, regardless of the schedule. For information on how to immediately copy eligible files, see Copy files to remote storage.

### Note

- Scheduled recalling of data in remote storage is not supported.

**Setting the maximum number of drives to access simultaneously**

You can specify how many drives in your multiple-drive device Remote Storage can access at the same time for file copy and file recall operations. The number you should specify depends on your individual needs. Increasing the limit can improve performance when you are managing multiple hard disks, and when several users at once try to access files that have been copied to different remote media. On the other hand, if you have another application (like Backup) that accesses removable storage, you may want to set the limit to less than the total number of drives in your device, so that Remote Storage cannot prevent the other application from running by using all of the available drives concurrently.

Setting the limit to a number greater than the total number of drives in your device has the same effect as setting it to the total number of drives.

**Setting the runaway recall limit**

Remote Storage provides a default value to the maximum number (called the runaway recall limit) of successive file-recalls that a user, or an application, can make on any managed volume in the same session. Once a file recall is completed, if the user or application requests another recall within 10 seconds, the count is increased. File-recalls copy the data back to local volumes, thereby decreasing the available free disk space on your computer. Virus checking, data backup, indexing, and search applications typically read all files on your computer and can also cause a large number of file-recalls. For information on how to change the runaway recall limit, see Set the runaway recall limit.

**Validating files**

Validation ensures that all the files on your managed volumes point to valid and correct data in remote storage. It also recalculates volume statistics. Validation is automatically performed two hours after a backup program is used to restore a remote storage file. Validation also detects files that have been moved from one local volume to another or that have been modified.

Validation should be performed on a regular basis to validate all files on a given volume and to correct any inconsistencies. Validation should also be performed after restoring files on a local volume or after disk errors have occurred on a volume. For information on how to validate the files on a managed volume, see Validate files.

The validation operation is integrated with and can be monitored using Scheduled Tasks. For more information on how to monitor Remote Storage tasks, see Monitor tasks for Remote Storage.

**Discontinuing volume management**

You can select one of the two following ways in which Remote Storage discontinues managing a volume:

- Remote Storage discontinues managing the local volume but leaves data in remote storage. Data that is already in remote storage can be recalled as before. No automatic freeing of disk space takes place.

- Remote Storage recalls data from remote storage and then discontinues managing the local volume. You should only select this option if your local volume has adequate disk space for the recalled data.

  If you have adequate disk space to recall data from remote storage, but the option of recalling all data is disabled, click the **Refresh** button in order to update volume statistics. After you have updated the volume statistics, the option should be enabled.

For information on how to discontinue managing a volume using the Remove Volume Management wizard, see Discontinue managing a volume.

These operations are integrated with and can be monitored using Scheduled Tasks. For more information on how to monitor Remote Storage tasks, see Monitor tasks for Remote Storage.

**Important**

- Before you uninstall Remote Storage, you should discontinue managing all volumes by clicking **Recall copied files from remote storage** in the Remove Volume Management wizard. Otherwise, you may lose your file data.

**Note**

- When a managed volume is formatted, the volume will still be displayed in the Remote Storage snap-in, but the only operation you can perform on it is to discontinue managing it. This occurs because Remote Storage cannot locate the volume anymore, and does not know if the volume is temporarily unavailable or was permanently removed (which is the case when a volume is formatted).

**Modifying files on managed volumes**

There are a number of considerations that must be taken into account before you modify or move a file on a managed volume. This section addresses those issues.

If a file on a managed volume is deleted, lost, or destroyed, you must retrieve a copy of the file from a backup tape or disk to gain access to the file. If you delete a file from a managed volume, the associated data can no longer be recalled from remote storage. Be careful not to delete such files if you might want to recall the data at a later time. You can protect such files using Backup. For information on Backup, see Backup overview.

Copying or moving a file between managed volumes causes the associated data in remote storage to be recalled. You must use a backup program to back up and then restore a file before you move the file between managed volumes to avoid causing a recall. All applicable volumes must be formatted using the version of NTFS used in Windows 2000 and the Windows Server 2003 family. The local volume on which the moved file now resides must be managed by Remote Storage for disk space to be automatically freed, and you should also validate the volume afterward.

**Note**

- Renaming a file on a managed volume does not recall the associated data from remote storage.

# Managing remote storage media

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing remote storage media**

Remote Storage supports all SCSI class optical disk or 4mm, 8mm, and DLT tape libraries. Using Remote Storage with Exabyte 8200 tape libraries is not recommended. Remote Storage does not support QIC tape libraries.

All tapes or magneto-optical disks used by Remote Storage exist in a single application media pool. This pool is automatically created at the completion of the Remote Storage Setup wizard. You must select the appropriate media type to be used for remote storage in the Remote Storage Setup wizard. The media type you specify cannot be changed later.

Verify that sufficient tapes or disks have been moved to a free media pool so that Remote Storage can use the tapes if needed. You cannot move media from the Remote Storage media pool to another application media pool.

Offline media are tapes or disks that are not currently inside a library and are therefore inaccessible by Remote Storage. Since these tapes or disks remain in the same media pool, Removable Storage is responsible for tracking their location. For information on Removable Storage, see Removable Storage.

If a file that has been copied to remote storage is currently on offline media, you will receive a message from Removable Storage to manually insert the applicable tape or disk. If you do not do so within a couple of minutes or so, the recall will fail.

### Note

- Remote Storage is optimized for copying large files. If a managed volume has many small files that are eligible for copying to remote storage, the data transfer rate may not match the rating given for the tape library.

**Creating media copies**

Remote Storage can back up the data on tapes or disks that it uses. The original tape or disk collection used to hold all files copied from local storage is called the media master set. Remote Storage can automatically create copies from the media master. The collection of copies for a media master is called a media copy set. You can specify up to three media copy sets. For information on how to set the number of media copy sets, see Set the number of media copies.

### Notes

- Files that are copied to remote storage are not protected by mirroring or striping. The only way to obtain redundancy for data in remote storage is to create copies of your media masters.

- Media copies can be created only if two drives are available for use in a tape library.

Remote Storage will first use available tapes or disks in the Remote Storage media pool, then use tapes or disks from a free media pool, for media copies. The free media pool is a collection of unused media that can be used when there is not enough storage space available in the Remote Storage media pool.

**Synchronizing media copies**

You should update, or *synchronize*, media copies on a regular basis. This ensures that data on a media copy matches that on the media master. Synchronization updates media copies for all the media masters; however, you can only synchronize one media copy set at a time. Files cannot be managed or recalled while a media copy set is being synchronized, even if additional drives are available. For information on how to synchronize media copies, see Synchronize media copies.

Media copies can be synchronized later as needed if they are removed from a library.

**Recreating the media master**

When data on a media master becomes corrupted or is lost, Remote Storage can recreate the media master using data from a media copy. For information on how to recreate the media master, see Recreate the media master.

# Protecting and recovering data from loss

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Protecting and recovering data from loss**
Keep the following points in mind if you are restoring files on a managed volume using Backup or other data backup application:

- You cannot restore Remote Storage files to a different computer.
- You cannot restore Remote Storage files to a volume that is not formatted with the version of NTFS used by Windows 2000 and the Windows Server 2003 family.
- You should not restore Remote Storage files to other NTFS volumes on the same computer unless you are sure that those volumes are also managed by Remote Storage.
- Remote Storage uses the same data format as Backup. In an emergency you can use Backup to restore files. For more information, see Backup.

For advanced information on how to protect and recover data that is managed or needed by Remote Storage, see "Managing Data with Removable and Remote Storage" at the Microsoft Windows Resource Kits Web site.

# Managing Remote Storage from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Remote Storage from the command line**

You can use the command-line utility for Remote Storage to copy and recall files, to configure and manage Remote Storage, and to write batch scripts for applications that will allow them to access Remote Storage directly. You can run the command-line utility from a command prompt by typing **Rss**.

For help using the Remote Storage command line utility, see Rss.

For information about other command-line utilities, see Command-line reference A-Z.

# Remote Storage Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

**Windows Server 2003 Family Resource Kit**
The *Microsoft* Windows Server 2003 *Family Resource Kit* contains advanced information on how to configure, administer, optimize, and troubleshoot Remote Storage. For more information, see "Managing Data with Removable and Remote Storage" at the Microsoft Windows Resource Kits Web site.

# Troubleshooting Remote Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
Keep in mind that Remote Storage is used to move data between your local computer and tape libraries, and depends on Removable Storage to access specific tapes within these libraries. Consequently, Removable Storage must be properly configured beforehand and must be running for Remote Storage to function correctly.

What problem are you having?

- You cannot install or run Remote Storage.
- You cannot find the Remote Storage snap-in.
- Remote Storage could not find any valid media type to use.
- Remote Storage cannot manage a particular volume or find a volume that you want to manage.
- You have set a file-copying schedule but no files have been copied to remote storage.
- You can no longer recall files from remote storage.
- File recalls are slow.
- There are excessive file recalls occurring.

**You cannot install or run Remote Storage.**
**Cause:** Remote Storage requires that you have administrative credentials.

**Solution:** Verify that you are running Remote Storage with administrative credentials. To maintain system security, log in using an account in a different security group and run Remote Storage as an administrator. To do this, right-click **Remote Storage**, click Run as, and choose an account in the Administrators group.

**You cannot find the Remote Storage snap-in.**
**Cause:** Remote Storage is not installed by default when the operating system is installed.

**Solution:** Install Remote Storage on your computer using **Add or Remove Programs**.

**Remote Storage could not find any valid media type to use.**
**Cause:** Removable Storage has not detected the media type yet.

**Solution:** Wait until the Removable Storage snap-in displays the available media that can be used.

**Cause:** You do not have a supported tape or disk library.

**Solution:** Verify that you have a supported tape or disk library. Remote Storage supports all SCSI class magneto-optical disk or 4mm, 8mm, and DLT tape libraries. Remote Storage does not support QIC tape libraries. For tape and disk libraries supported by Removable Storage, see the information about compatible hardware at the Support resources page.

**Remote Storage cannot manage a particular volume or find a volume that you want to manage.**
**Cause:** Remote Storage can only manage nonremovable (fixed), local NTFS volumes; other file systems or volumes will not be displayed in the Remote Storage Setup wizard.

**Solution:** Format all volumes that will be managed with the version of the NTFS file system used in Windows 2000 or the Windows Server 2003 family. For help converting volumes to NTFS, see Convert.

**You have set a file-copying schedule but no files have been copied to remote storage.**
**Cause:** There may be no files that meet the specified criteria.

**Solution:** Change the file rules and other file-copy criteria as necessary.

**You can no longer recall files from remote storage.**
**Cause:** Remote Storage uses the runaway recall limit to prohibit a user, or an application, from recalling files from remote storage more than a specified number of times in succession. Virus checking, data backup, indexing, and search applications typically read all files on your computer, and can cause the runaway recall limit to be quickly reached.

**Solution:** Increase this setting as necessary or close the application causing the excessive recalls.

**File recalls are slow.**
**Cause:** Remote Storage may take five minutes or longer to recall a file from a tape-based library.

**Solution:** Set the free space value lower so data in cached files are not removed as often. In this way, data will not have to be recalled from remote storage as often.

**There are excessive file recalls occurring.**
**Cause:** Virus checking, data backup, indexing, and search applications typically read all files on your computer.

In particular, if you use Find (on the Edit menu) in Microsoft Office 95 or later to search for content on a managed volume, all files in remote storage are automatically recalled.

**Solution:** Take into account use of applications that cause excessive files recalls on your managed volumes when planning your activities.

**Cause:** If Microsoft Word (.doc), Microsoft PowerPoint (.ppt), or HTML files have been copied to remote storage, all files in remote storage are recalled if you install Microsoft Office 97 on the computer running Remote Storage. This occurs at the end of the Office 97 installation.

**Solution:** To stop the recalls, you must use Windows Task Manager (press CTRL-ALT-DEL) to end the Findfast.exe task.

# Managing Files and Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing files and folders**
This section covers:

- Shared Folders
- Distributed File System (DFS)
- Encrypting File System
- File compression overview
- Using Indexing Service
- Offline Files
- Synchronization Manager

# Shared Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shared Folders**
You can use the Shared Folders snap-in to manage shared resources over a network. With Shared Folders you can control user access permissions, session activity, and shared resource properties.

- For tips about using Shared Folders, see Best practices for Shared Folders.
- For help with specific tasks, see Shared Folders How To....
- For general background information, see Shared Folders Concepts.
- For problem-solving instructions, see Troubleshooting Shared Folders.

# Best practices for Shared Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Assign permissions to groups, not user accounts.**

- Assigning permissions to groups simplifies management of shared resources, because you can then add users to or remove them from the groups without having to reassign permissions. To deny all access to a shared resource, deny the Full Control permission.

**Assign the most restrictive permissions that still allow users to perform required tasks.**

- For example, if users need only to read information in a folder, and they will never delete, create, or change files, assign the Read permission.

**If users log on locally to access shared resources, such as on a terminal server, set permissions by using NTFS file system permissions or access control.**

- Share permissions apply only to users who access shared resources over the network; they do not apply to users who log on locally. For this situation, use NTFS and access control. For more information, see Set, view, change, or remove permissions on files and folders.

**Organize resources so that objects with the same security requirements are located in the same folder.**

- For example, if users require the Read permission for several application folders, store the application folders in the same parent folder. Then, share the parent folder, rather than sharing each individual application folder. Note that if you need to change the location of an application, you may need to reinstall it.

**When you share applications, organize all shared applications in one folder.**

- Organizing all applications in one shared folder simplifies administration, because there is only one location for installing and upgrading software.

**To prevent problems with accessing network resources, do not deny permissions to the Everyone group.**

- The Everyone group includes anyone who has access to network resources, including the Guest account, with the exception of the Anonymous Logon group. For more information, see Default security settings for groups and Differences in default security settings.

**Avoid explicitly denying permissions to a shared resource.**

- It is usually necessary to explicitly deny permissions only when you want to override specific permissions that are already assigned.

**Limit membership in, and assign the Full Control permission to, the Administrators group.**

- This enables administrators to manage application software and to control user rights.

**In most cases, do not change the default permission (Read) for the Everyone group.**

- The Everyone group includes anyone who has access to network resources, including the Guest account. In most cases, do not change this default unless you want users to be able to make changes to the files and objects in the shared

resource. For more information about share permissions, see Share permissions.

**Grant access to users by using domain user accounts.**

- On computers running Windows XP Professional that are connected to a domain, grant access to shared resources through domain user accounts, rather than through local user accounts. This centralizes the administration of share permissions.

**Use centralized data folders.**

- With centralized data folders, you can manage resources and back up data easily.

**Use intuitive, short labels for shared resources.**

- This ensures that the shared resources can be easily recognized and accessed by users and all client operating systems.

**Use a firewall.**

- A firewall protects shared resources from access through the Internet. In Windows XP and in the Windows Server 2003 family, you can take advantage of new firewall capabilities. For more information, see Internet Connection Firewall. Instead of Internet Connection Firewall, computers running Windows XP with Service Pack 2 (SP2) and computers running Windows Server 2003 with Service Pack 1 (SP1), use Windows Firewall. For more information, see Help: Windows Firewall.

# Shared Folders How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Share a folder or drive
- Set permissions on a shared resource
- View information about shared resources
- Manage properties of a shared resource
- Disconnect a user or users
- Close an open file or resource
- Stop sharing a resource
- Limit the number of users of a shared resource
- Configure offline settings for a shared resource

# Share a folder or drive

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To share a folder or drive**

- Using Shared Folders
- Using Windows Explorer
- Using a command line

**Using Shared Folders**

1. Open Computer Management.
2. In the console tree, click **Shares**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Shares

3. On the **Action** menu, click **New Share**.
4. Follow the steps in the Share a Folder Wizard, and then click **Finish**.

**Note**

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Using Windows Explorer**

1. Open Windows Explorer.
2. Right-click the folder or drive to be shared, and then click **Sharing and Security**.
3. Click **Share this folder**.
4. Set any other options that you want, and then click **OK**.

**Note**

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **net share***sharename=drive:path*

| Value | Description |
| --- | --- |
| **net share** | Creates, deletes, or displays shared resources. |
| *sharename=drive:path* | The network name of the shared resource and the absolute path of its location. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To view the complete syntax for this command, at the command prompt, type:

  **net help share**

**Important**

- When you create a shared resource, determine how to secure that resource. There are several methods that you can use to secure shared resources. For more information, see Related Topics.

**Notes**

- You must be logged on as a member of the Administrators group, Server Operators group, or Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- You can use Shared Folders to manage shared resources on both local and remote computers. For information about how to connect to another computer, see Related Topics. With Windows Explorer and the command line, you can manage shared resources on your local computer only.
- You can hide the shared resource from users by typing **$** as the last character of the shared resource name (the **$** then becomes part of the resource name). Users can map a drive to this shared resource, but they cannot see the shared resource when they browse to it in Windows Explorer, or in My Computer on the remote computer, or when they use the **net view** command on the remote computer. For more information about this command, see Related Topics.
- File sharing options may be limited if simple file sharing is enabled. For more information about simple file sharing, see article Q304040, "Description of File Sharing and Permissions in Windows XP," in the Microsoft Knowledge Base.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set permissions on a shared resource

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set permissions on a shared resource**

- Using Shared Folders
- Using Windows Explorer

**Using Shared Folders**

1. To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
2. In the console tree, click **Shares**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Shares

3. In the details pane, right-click the shared resource that you want to set permissions for, and then click **Properties**.
4. On the **Share Permissions** tab, make any of the following changes, and then click **OK**:

   - To assign permissions to a user or group for a shared resource, click **Add**. In the **Select Users, Computers, or Groups** dialog box, look for or type the user or group name, and then click **OK**.
   - To revoke access to the shared resource, click **Remove**.
   - To set individual permissions for the user or group, in the **Permissions for***group or user* box, select the **Allow** or **Deny** check boxes.

**Note**

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Using Windows Explorer**

1. Open Windows Explorer.
2. Right-click the shared folder or drive that you want to set permissions for, and then click **Sharing and Security**.
3. On the **Sharing** tab, click **Permissions**, make any of the following changes, and then click **OK**:

   - To assign permissions to a user or group for a shared resource, click **Add**. In the **Select Users, Computers, or Groups** dialog box, look for or type the user or group name, and then click **OK**.
   - To revoke access to a shared resource, click **Remove**.
   - To set individual permissions for the user or group, in the **Permissions for** *group or user* box, select the **Allow** or **Deny** check boxes.

### Note

- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

### Important

- Share permissions apply only to users who gain access to the resource over the network. They do not apply to users who log on locally, such as on a terminal server. In these cases, use access control on the NTFS file system to set permissions. For more information, see Related Topics.

### Notes

- You must be logged on as a member of the Administrators group, Server Operators group, or Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

- You can use Shared Folders to manage shared resources on both local and remote computers. For information about how to connect to another computer, see Related Topics. With Windows Explorer and the command line, you can manage shared resources on your local computer only.

- When permissions have been assigned both to the shared resource and at the file system level, the more restrictive permission always applies.

- It is usually easier to assign permissions to groups and then add users to groups, rather than assigning identical permissions to individual users.

- If you change permissions on special shared resources, such as ADMIN$, the default settings may be restored when the Server service is stopped and restarted or when the computer is restarted. Note that this does not apply to user-created shared resources whose share name ends in $. For more information about special shared resources, see Related Topics.

- File sharing options may be limited if simple file sharing is enabled. For more information about simple file sharing, see article Q304040, "How to configure file sharing in Windows XP," in the Microsoft Knowledge Base.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View information about shared resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view information about shared resources**

- Using Shared Folders
- Using a command line

**Using Shared Folders**

1. Open Computer Management.
2. In the console tree, click one of the following folders:
   - To view information about the shared resources on the selected computer, click **Shares**.
   - To view information about open sessions, click **Sessions**.
   - To view information about open files, click **Open Files**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Shares, Sessions, Open Files

**Note**

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Using a command line**

1. Open Command Prompt.
2. Type one of the following:

   **net share**

   **net session**

   **net file**

| Value | Description |
|---|---|
| **net share** | Displays information about all shared resources on the local computer. |
| **net session** | Displays information about all open sessions between the local computer and other computers on the network. |
| **net file** | Displays information about all open files on shared resources. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for these commands, at the command prompt, type one of the following:

  **net help share**

  **net help session**

  **net help file**

## Notes

- You must be logged on as a member of the Administrators group, Server Operators group, or Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

- When you administer another computer remotely, your connection appears as an open named pipe. It cannot be closed.

- Only files that are open on the selected computer are visible.

- For information about how to connect to another computer, see Related Topics.

- File sharing options may be limited if simple file sharing is enabled. For more information about simple file sharing, see article Q304040, "Description of File Sharing and Permissions in Windows XP," in the Microsoft Knowledge Base.

# Manage properties of a shared resource

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manage properties of a shared resource**

- Using Shared Folders
- Using Windows Explorer

**Using Shared Folders**

1. Open Computer Management.
2. In the console tree, click **Shares**.

   **Where?**

   - Computer Management\System Tools\Shared Folders\Shares

3. In the details pane, right-click the shared resource that you want to manage, and then click **Properties**.
4. Make the changes that you want, and then click **OK**.

### Note

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Using Windows Explorer**

1. Open Windows Explorer.
2. Right-click the shared folder or drive that you want to manage, and then click **Sharing and Security**.
3. Make the changes that you want, and then click **OK**.

### Notes

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- You must be logged on as a member of the Administrators group, Server Operators group, or Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- You can use Shared Folders to manage shared resources on both local and remote computers. For information about how to connect to another computer, see Related Topics. With Windows Explorer and the command line, you can manage shared resources on your local computer only.

# Disconnect a user or users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disconnect a user or users**

- Using Shared Folders
- Using a command line

**Using Shared Folders**

1. Open Computer Management.
2. In the console tree, click **Sessions**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Sessions

3. Do one of the following:

   - To disconnect all users, on the **Action** menu, click **Disconnect All Sessions**.
   - To disconnect one user, in the details pane, right-click the user name, and then click **Close Session**.
   - To disconnect multiple users, press the CTRL key while clicking the user names, right-click any user name, and then click **Close Session**.

## Notes

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- When you administer another computer remotely, your connection appears as an open named pipe. It cannot be closed.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **net session***computername***/delete**

| Value | Description |
|---|---|
| **net session** | Lists or disconnects inbound sessions on the local computer. |
| *computername* | Identifies the computer for which you want to list or disconnect sessions. |
| **/delete** | Ends sessions that are originated by *computername*, and closes all open files that are opened from *computername*. If *computername* is omitted, all inbound sessions and associated files are closed. |

### Notes

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at the command prompt, type:

  **net help session**

### Caution

- If you disconnect users who are accessing shared resources, they might lose data. You may want to warn connected users before you disconnect them.

### Notes

- You must be logged on as a member of the Administrators group, Server Operators group, or Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

- For information about how to connect to another computer, see Related Topics.

- File sharing options may be limited if simple file sharing is enabled. For more information about simple file sharing, see article Q304040, "Description of File Sharing and Permissions in Windows XP," in the Microsoft Knowledge Base.

# Close an open file or resource

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To close an open file or resource**

- Using Shared Folders
- Using a command line

**Using Shared Folders**

1. Open Computer Management.
2. In the console tree, click **Open Files**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Open Files

3. Do one of the following:

   - To disconnect all open resources, on the **Action** menu, click **Disconnect All Open Files**.
   - To disconnect one open file or resource, in the details pane, right-click the file name, and then click **Close Open File**.
   - To disconnect multiple open files or resources, press the CTRL key while clicking the file names, right-click any selected file name, and then click **Close Open File**.

**Note**

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Using a command line**

- Open Command Prompt.
- Type:

  **net file***ID***/close**

| Value | Description |
|---|---|
| **net file** | Displays the names of all open shared files on a server and the number of file locks, if any, on each file. |
| *ID* | The dynamically assigned ID of the shared resource. |
| **/close** | Closes the shared resource and removes file locks. Type this command from the server where the file is shared. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You can use the **openfiles** command to determine the file ID of the shared resource. For more information, see Related Topics.

- To view the complete syntax for this command, at the command prompt, type:

  **net help file**

### Caution

- If you close open files or resources, users might lose data. You may want to warn connected users before you close an open file or resource. For more information, see Related Topics.

### Notes

- You must be logged on as a member of the Administrators group, Server Operators group, or Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

- You can use Shared Folders to manage shared resources on both local and remote computers. For information about how to connect to another computer, see Related Topics. With Windows Explorer and the command line, you can manage shared resources on your local computer only.

- When you administer another computer remotely, your connection appears as an open named pipe. It cannot be closed.

- File sharing options may be limited if simple file sharing is enabled. For more information about simple file sharing, see article Q304040, "Description of File Sharing and Permissions in Windows XP," in the Microsoft Knowledge Base.

# Stop sharing a resource

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To stop sharing a resource**

- Using Shared Folders
- Using Windows Explorer
- Using a command line

**Using Shared Folders**

1. Open Computer Management.
2. In the console tree, click **Shares**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Shares

3. In the details pane, right-click the folder that you want to stop sharing, and then click **Stop Sharing**.

   To stop sharing multiple instances of a folder or drive, press the CTRL key while you click the instances, right-click any instance of the folder or drive, and then click **Stop Sharing**.

**Note**

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Using Windows Explorer**

1. Open Windows Explorer.
2. Right-click the shared folder or drive that you want to stop sharing, and then click **Sharing and Security**.
3. On the **Sharing** tab, do one of the following, and then click **OK**:

   - To stop sharing all instances of the shared resource, click **Do not share this folder**.
   - To stop sharing only one instance of a folder or drive that is shared multiple times, in **Share name**, click the folder or drive that you want to remove, and then click **Remove Share**.

**Note**

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.

**Using a command line**

1. Open Command Prompt.

2. Type:

   **net share***sharename***/delete**

| Value | Description |
|---|---|
| **net share** | Creates, deletes, or displays shared resources. |
| *sharename* | The network name of the shared resource. |
| **/delete** | Stops sharing the resource. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To view the complete syntax for this command, at the command prompt, type:

  **net help share**

**Caution**

- If you stop sharing open resources, users might lose data. You may want to warn connected users before you close an open file or resource. For more information, see Related Topics.
- In most cases, it is recommended that you not stop sharing the special shared resources that are created by the system, such as ADMIN$. These special shared resources are automatically recreated with their original settings when the computer is restarted.
- The special shared resources NETLOGON and SYSVOL are required on domain controllers. Removing them causes a loss of functionality on all clients that the domain controller serves.
- The IPC$ special shared resource is required for the Server service to operate, and it cannot be deleted.

**Notes**

- You must be logged on as a member of the Administrators group, Server Operators group, or Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- You can use Shared Folders to manage shared resources on both local and remote computers. For information about how to connect to another computer, see Related Topics. With Windows Explorer and the command line, you can manage shared resources on your local computer only.
- File sharing options may be limited if simple file sharing is enabled. For more information about simple file sharing, see article Q304040, "Description of File Sharing and Permissions in Windows XP," in the Microsoft Knowledge Base.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Limit the number of users of a shared resource

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To limit the number of users of a shared resource**

- Using Shared Folders
- Using Windows Explorer
- Using a command line

**Using Shared Folders**

1. Open Computer Management.
2. In the console tree, click **Shares**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Shares

3. In the details pane, right-click the shared folder or drive that you want to limit the number of users for, and then click **Properties**.
4. Under **User limit**, click **Maximum allowed**, and then click **OK**, or click **Allow this number of users**.

   If you click **Allow this number of users**, type or click a maximum number of users, and then click **OK**.

**Note**

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Using Windows Explorer**

1. Open Windows Explorer.
2. Right-click the shared folder or drive that you want to limit the number of users for, and then click **Sharing and Security**.
3. Under **User limit**, click **Maximum allowed**, and then click **OK**, or click **Allow this number of users**.

   If you click **Allow this number of users**, type or click a maximum number of users, and then click **OK**.

**Note**

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.

**Using a command line**

1. Open Command Prompt.

2. Type:

   **net share***sharename***/users:***number*

| Value | Description |
|---|---|
| **net share** | Creates, deletes, or displays shared resources. |
| *sharename* | The network name of the shared resource and its absolute path. |
| **/users:** *number* | Sets the maximum number of users who can simultaneously access the shared resource. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To view the complete syntax for this command, at the command prompt, type:

  **net help share**

**Notes**

- You must be logged on as a member of the Administrators group, Server Operators group, or Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- You can use Shared Folders to manage shared resources on both local and remote computers. For information about how to connect to another computer, see Related Topics. With Windows Explorer and the command line, you can manage shared resources on your local computer only.
- The maximum number of users allowed is limited by software licensing limits. Software licensing limits preempt any limits that can be set in Shared Folders.
- File sharing options may be limited if simple file sharing is enabled. For more information about simple file sharing, see article Q304040, "Description of File Sharing and Permissions in Windows XP," in the Microsoft Knowledge Base.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure offline settings for a shared resource

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure offline settings for a shared resource**

- Using Shared Folders
- Using Windows Explorer
- Using a command line

**Using Shared Folders**

1. Open Computer Management.
2. In the console tree, click **Shares**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Shares

3. In the details pane, right-click the shared resource that you want to configure offline settings for, and then click **Properties**.
4. On the **General** tab, click **Offline Settings**.
5. In the **Offline Settings** dialog box, click the option that you want, and then click **OK**.

### Note

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Using Windows Explorer**

1. Open Windows Explorer.
2. Right-click the shared folder or drive that you want to configure offline access for, and then click **Sharing and Security**.
3. On the **Sharing** tab, click **Offline Settings**.
4. In the **Offline Settings** dialog box, click the option that you want, and then click **OK**.

### Note

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.

**Using a command line**

1. Open Command Prompt.
2. Type:

**net share***sharename***/cache:manual**

or

**net share***sharename***/cache:documents**

or

**net share***sharename***/cache:programs**

or

**net share***sharename***/cache:none**

| Value | Description |
|---|---|
| **net share** | Manages shared resources. |
| *sharename* | The network name of the shared resource in *drive:path* format. To display information about a shared folder, type **net share** with only the share name. |
| **/cache:manual** | Allows users to manually select which documents and programs are stored offline. |
| **/cache:documents** | Automatically stores documents offline. |
| **/cache:programs** | Automatically stores documents and programs offline. |
| **/cache:none** | Prevents users from storing any files offline. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To view the complete syntax for this command, at the command prompt, type:

  **net help share**

**Important**

- When you create a new shared resource, offline access is allowed by default, which means that secure shared resources can be stored offline on potentially insecure computers. For best security, do not allow users to store files offline. If you do, be sure to set permissions appropriately by using either share permissions or access control on the NTFS file system. For more information, see "Set permissions on a shared resource" and "Set, view, change, or remove permissions on files and folders" in Related Topics.

**Notes**

- You must be logged on as a member of the Administrators group, Server Operators group, or Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- For more information about offline files, see Related Topics.
- For information about how to connect to another computer, see Related Topics.
- File sharing options and offline access may be limited if simple file sharing is enabled. For more information about simple file sharing, see article Q304040, "Description of File Sharing and Permissions in Windows XP," in the Microsoft

Knowledge Base.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Shared Folders overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shared Folders overview**
You can use Shared Folders to view a summary of connections and resource use for local and remote computers. Shared Folders replaces resource-related components in Control Panel in Microsoft Windows NT® 4.0 Server.

With Shared Folders, you can:

- Create, view, and set permissions for shared resources.
- View a list of all users who are connected over a network to the computer and disconnect one or all of them.
- View a list of files that are opened by remote users and close one or all of the open files.

You must be logged on as a member of the Administrators group, Server Operators group, or the Power Users group to use Shared Folders. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure. File sharing options may be limited if simple file sharing is enabled. For more information about simple file sharing, see article Q304040, "Description of File Sharing and Permissions in Windows XP," in the Microsoft Knowledge Base.

For information about publishing a shared folder in Active Directory, see Publish a shared folder.

The subfolders in Shared Folders contain information, arranged in columns, about all the shared resources, sessions, and open files on the computer. If Services for Macintosh is installed, information about resources that are managed by that service may appear as well. The column headings in these folders are defined as follows:

**Shares**
The following table shows the information that the Shares folder contains about the shared resources that are available on the computer.

| Column | Description |
|---|---|
| **Share Name** | Lists the shared resources that are available on the computer. In some cases, a connection to a printer is monitored here as a connection to a named pipe. A shared resource can be a shared directory, a named pipe, a shared printer, or a resource of an unrecognized type. |
| **Folder Path** | Displays the path to the shared resource. |
| **Type** | Displays the type of network connection: Windows, NetWare, or Macintosh. |
| **# Client Connections** | Displays the number of users who are connected to the shared resource. |
| **Description** | Describes the shared resource. |

**Sessions**
The following table shows the information that the Sessions folder contains about all the network users who are connected to the computer.

| Column | Description |
|---|---|
| **User** | Lists the network users who are connected to the computer. |
| **Computer** | Displays the computer name of the connected user's computer. |
| **Type** | Displays the type of network connection: Windows, NetWare, or Macintosh. |
| **# Open Files** | Displays the number of resources that have been opened on this computer by this user. |

| | |
|---|---|
| **Connected Time** | Displays the hours and minutes that have elapsed since this session was established. |
| **Idle Time** | Displays the hours and minutes that have elapsed since this user last initiated an action. |
| **Guest** | Specifies whether this user is connected to this computer as a guest (displayed as Yes or No). |

**Open Files**

The following table shows the information that the Open Files subfolder contains about all the open files on the computer.

| Column | Description |
|---|---|
| **Open File** | Lists the names of open files. An open file could be a file, a named pipe, a print job in a print spooler, or a resource of an unrecognized type. In some cases, a print job is shown here as an open named pipe. |
| **Accessed By** | The name of the user who has opened the file or accessed the resource. |
| **Type** | The type of network connection: Windows, NetWare, or Macintosh. |
| **# Locks** | Displays the number of application-initiated file locks on the resource. |
| **Open Mode** | Displays the permission that was granted when the resource was opened. |

# Understanding Shared Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Shared Folders**
This section covers:

- Share permissions
- Offline settings for shared resources
- Special shared resources

# Share permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Share permissions**
A shared resource provides access to applications, data, or a user's personal data. You can assign or deny permissions for each shared resource.

You can control access to shared resources with a variety of methods. You can use share permissions, which are simple to apply and manage. Or, you can use access control on the NTFS file system, which provides more detailed control of the shared resource and its contents. You can also use a combination of these methods. If you use a combination of these methods, the more restrictive permission always applies. For example, if the share permission is set to Everyone = Read (which is the default), and the NTFS permission allows users to make changes to a shared file, the share permission applies, and the user is not allowed to change the file.

It is not always necessary to explicitly deny a permission to a shared resource. Denying permission is usually necessary only when you want to override specific permissions that are already assigned.

For information about how to set NTFS file permissions, see Set, view, change, or remove permissions on files and folders. For information about best practices for working with Shared Folders, including assigning permissions, see Best practices for Shared Folders.

**Important**

- In the Windows Server 2003 family, when you create a new shared resource, the Everyone group is automatically assigned the Read permission, which is the most restrictive.

Share permissions:

- Apply only to users who gain access to the resource over the network. They do not apply to users who log on locally, such as on a terminal server. In these cases, use access control on NTFS to set permissions.
- Apply to all files and folders in the shared resource. If you want to provide a more detailed level of security to the subfolders or objects in a shared folder, use access control on NTFS.
- Are the only way to secure network resources on FAT and FAT32 volumes, because NTFS permissions are not available on FAT or FAT32 volumes.
- Specify the maximum number of users who are allowed to access the shared resource over the network. This is in addition to the security provided by NTFS.

You can assign the following types of access permissions to shared folders or drives:

**Read**
Read is the default permission that is assigned to the Everyone group. Read allows:

- Viewing file names and subfolder names
- Viewing data in files
- Running program files

**Change**
Change is not a default permission for any group. The Change permission allows all Read permissions, plus:

- Adding files and subfolders

- Changing data in files
- Deleting subfolders and files

**Full Control**

Full Control is the default permission that is assigned to the Administrators group on the local computer. Full Control allows all Read and Change permissions, plus:

- Changing permissions (NTFS files and folders only)

# Offline settings for shared resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Offline settings for shared resources**

You can use Offline Files to work with shared resources even when you are not connected to the network. When you create a shared resource, you can specify if and how files in the shared resource are cached (stored) locally on client computers when other users access the files.

To make shared network resources available offline, Offline Files stores a version of the shared resources in a reserved portion of disk space on the client computer, which is called a file system cache. The client computer can access this cache whether or not the client computer is connected to the network.

You can choose one of the following caching options for each shared resource:

**Only the files and programs that users specify will be available offline.**
This option gives users control over which files are available offline.

**All files and programs that users open from the share will be automatically available offline.**
This option allows all the files that users open from the shared folder to be automatically available offline.

If you select the **Optimized for performance** check box, all programs will be automatically cached so that they can be run locally. This option is especially useful for file servers that host applications, because it reduces network traffic and improves server scalability.

**Files or programs from the share will not be available offline.**
This option prevents users from storing files offline.

**Important**

- When you create a new shared resource, offline access is allowed by default, which means that secure shared resources can be stored offline on potentially insecure computers. For best security, do not allow users to store files offline. If you do, be sure to set permissions appropriately using either share permissions or access control on the NTFS file system. For more information, see Set permissions on a shared resource and Set, view, change, or remove permissions on files and folders.

Offline access may be limited if simple file sharing is enabled. For more information about simple file sharing, see article Q304040, "Description of File Sharing and Permissions in Windows XP," in the Microsoft Knowledge Base.

For more information about Offline Files, see Offline Files overview. For more information about how to configure offline access for shared resources, see Configure offline settings for a shared resource.

# Special shared resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Special shared resources**

Depending on the configuration of your computer, some or all of the following special shared resources are created for administrative and system use. These shared resources are not visible from My Computer, but you can view them by using Shared Folders. In most cases, it is recommended that you not delete or modify special shared resources.

You can hide other shared resources from users by typing **$** as the last character of the shared resource name (the **$** then becomes part of the resource name). These shared folders are hidden from Windows Explorer like special shared resources, but otherwise they are not special. For more information about how to share a resource, see Share a folder or drive.

If you change permissions on special shared resources, such as ADMIN$, the default settings may be restored when the Server service is stopped and restarted or when the computer is restarted. Note that this does not apply to user-created shared resources whose share name ends in $.

You may see some or all of the following administrative shared resources in the Shares folder in Shared Folders. Other applications may create additional special shared resources. To view special shared resources in the Shares folder, see View information about shared resources.

***drive letter*$**
A shared resource that enables administrators to connect to the root directory of a drive.

**ADMIN$**
A resource that is used during remote administration of a computer. The path of this resource is always the path to the system root (the directory in which the operating system is installed, for example, C:\Windows).

**IPC$**
A resource that shares the named pipes that are essential for communication between programs. You use IPC$ during remote administration of a computer and when you view a computer's shared resources. You cannot delete this resource.

**NETLOGON**
A required resource that is used on domain controllers. Removing this shared resource causes a loss of functionality on all client computers that the domain controller serves.

**SYSVOL**
A required resource that is used on domain controllers. Removing this shared resource causes a loss of functionality on all client computers that the domain controller serves.

**PRINT$**
A resource that is used during remote administration of printers.

**FAX$**
A shared folder on a server that is used by fax clients in the process of sending a fax. The shared folder is used to temporarily cache files and to access cover pages that are stored on the server.

# Administering Shared Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administering Shared Folders**
This section covers:

- Securing shared resources
- Managing shared folders from the command line

# Securing shared resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Securing shared resources**

You can control access to shared resources with a variety of methods. You can use share permissions, which are simple to apply and manage. You can use access control on the NTFS file system, which provides more detailed control of a shared resource and its contents. You can also use a combination of these methods. If you use a combination of these methods, the more restrictive permission always applies. For example, if the share permission is set to Everyone = Read (which is the default), and the NTFS permission allows users to make changes to a shared file, the share permission applies, and the user is not allowed to change the file.

For more information about how to set NTFS file permissions, see Set, view, change, or remove permissions on files and folders. For more information about how to set share permissions, see Set permissions on a shared resource. For more information about best practices for working with Shared Folders, see Best practices for Shared Folders.

Fixed disks on your computer, such as drive C or drive D, are automatically shared using the syntax *drive letter$*, such as C$ or D$. These drives do not appear with the hand icon that indicates sharing in My Computer or Windows Explorer, and they are also hidden when users connect to your computer remotely.

If your computer is not protected by a firewall, and someone knows the user name and password of any member of the Administrators group, Backup Operators group, or Server Operators group, that person has the same access to your computer as an administrator.

**Important**

- To keep your drives secure, use a strong password for all accounts. For more information, see Strong passwords.
- For best security, you can also rename the Administrator account. For more information about how to do this, see Accounts: Rename administrator account.
- If you change permissions on special shared resources, such as ADMIN$, the default settings may be restored when the Server service is stopped and restarted or when the computer is restarted. Note that this does not apply to user-created shared resources whose share name ends in $. For more information about special shared resources, see Special shared resources.

# Managing shared folders from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing shared folders from the command line**

In addition to Shared Folders and Windows Explorer, you can use the command-line utilities in the following table to manage shared resources.

| Name | Use to |
|---|---|
| net file | View and control resources that are shared on the network. The Server service must be running for you to use this command. |
| net config | View the maximum number of users who can access a shared resource and the maximum open files per session. |
| Net use | Connect a computer to or disconnect a computer from a shared resource. |
| net session | Manage server connections. |
| net share | Create, delete, manage, and display shared resources. |
| net view | Display information about the domains, computers, or resources that are shared by the specified computer, including the offline client caching settings. |
| Net help | View help for network commands. |

For information about other command-line utilities, see Command-line reference A-Z. For more information about manageability, see Management Strategies and Tools.

# Troubleshooting Shared Folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- I cannot access shared resources.
- I cannot view shared resource information in Shared Folders.

**I cannot access shared resources.**
**Cause:** The network connection was lost.

**Solution:** Verify network settings.

**See also:** Troubleshooting network and dial-up connections

**Cause:** Share permissions or file system permissions prevent access.

**Solution:** Verify that the share permissions and file system permissions on the computer to which you are connecting allow access to network resources and that you have access to these resources. If you can access Shared Folders on the remote computer, check the Sessions folder to determine the user rights with which you are logged on to the remote computer. You may be connected as Guest.

You can also verify that the Full Control permission is not denied to the Everyone group. If the Full Control permission is denied to the Everyone group, no one is able to access the shared resource, even if you grant Full Control to the Administrators group.

**See also:** View information about shared resources; Set, view, change, or remove permissions on files and folders

**I cannot view shared resource information in Shared Folders.**
**Cause:** You are not logged on to the specified computer as a member of the Administrators group, Server Operators group, or Power Users group.

**Solution:** Log on to the specified computer with the appropriate user rights.

**Note**

- File sharing options may be limited if simple file sharing is enabled. For more information about simple file sharing, see article Q304040, "Description of File Sharing and Permissions in Windows XP," in the Microsoft Knowledge Base.

# Distributed File System (DFS)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Distributed File System**

This topic describes Distributed File System (DFS) and how to administer it.

- Before creating a distributed file system, see Checklist: Creating a distributed file system.
- For recommendations on implementing DFS, see Best practices for Distributed File System (DFS).
- For help with specific tasks, see Distributed File System (DFS) How To....
- For general background information, see Distributed File System (DFS) Concepts.

# Checklist: Creating a distributed file system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Creating a distributed file system**

| Step | Reference |
|---|---|
| Review distributed file system concepts | Distributed File System (DFS) Concepts |
| Create a DFS root for a distributed file system | Create a DFS root |
| (Optional) If using a domain DFS root, add a root target | Add a DFS root target |
| Add a DFS link to a distributed file system | Add a DFS link |
| Add targets to a DFS link | Add a target |
| (Optional) Configure replication for targets | Configure DFS Replication |
| Manage security on shared folders used by DFS | Securing shared resources |

# Best practices for Distributed File System (DFS)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **Use DFS with the NTFS file system only.**

  Do not install DFS on a FAT file system. DFS on the Windows Server 2003 family can only be used with the NTFS file system. For information on converting a volume to NTFS, see Convert.

- **Set the** replication policy**.**

  To maintain a balanced load on your server, you should consider the schedule of synchronization. This requires that you understand the following:

  - The topology between the participating servers.
  - How network performance may be impacted, based on available bandwidth.
  - The quantity of replication traffic likely to occur.
  - Replication schedules for the distributed file system, as well as the replication schedules for any other distributed file systems in the same site.

    Automatic file replication through the File Replication service (FRS) is only available with domain DFS.

- **Do not create FRS replica sets on a volume that is managed by** Remote Storage**.**

  Doing so might severely impact system performance and possibly cause data loss within your media library.

  FRS might need to periodically read every file in the replica set to send the file contents to another computer. This causes FRS to recall all files that Remote Storage has sent to secondary storage, which might take a long time (hours or days). If you use tape for your secondary storage, remember FRS recalls files in directory order rather than media order, so the excessive number of tape seeks performed by FRS will likely ruin the tapes and cause data loss.

- **Perform regular administration as follows:**

  After you have created a DFS console for the DFS roots that you administer, save the console file for future use.

  Periodically, perform a status check on common targets to ensure that the targets are still accessible.

- **Ensure that file system permissions are set correctly.**

  In order for a user to access files in a DFS target folder, the user must be allowed access to the target and to all parent folders. In addition, the user must be allowed access to the server hosting the DFS root, and to the link and the link's parent folders. For more information on setting permissions, see Access control overview.

- **Monitor anti-virus or defragmentation software carefully.**

  Anti-virus and defragmentation software can interfere with successful file replication. If you are running anti-virus or defragmentation software on any of the computers that host your domain DFS root or targets, disable it or monitor it carefully until initial file replication is complete.

- **Consider the needs of your users.**

Include commonly-used network shares in your DFS namespace.

For links that point to targets with content that frequently changes,use a shorter cache time-out value to ensure that clients maintain an updated list of targets.

# Distributed File System (DFS) How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Create a DFS root
- Add a DFS root target
- Show a DFS root
- Add a DFS link
- Filter the DFS link display
- Enable or disable DFS referral
- Add a target
- Check status of a DFS root, DFS link, or target
- Hide a DFS root
- Delete a DFS root, root target, link, or target
- Configure DFS Replication

# Create a DFS root

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a DFS root**

1. Open Distributed File System.
2. On the **Action** menu, click **New Root**.
3. Follow the instructions that appear in the New Root wizard.

## Notes

- In order to make changes to an existing DFS namespace, you must be a member of the Administrators group on the server hosting the namespace. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- If the folder that you specify to correspond to the root does not exist, or has not been shared, you will be prompted to create a new shared folder. You can then type the name of a new folder, or type the name of an existing folder that has not yet been shared. DFS will create the folder (if necessary), then share the folder.
- You can host multiple DFS roots on a single computer when using Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition.
- On server clusters, the name you give a non-clustered DFS root on a node's local storage must be different from the name you give a clustered DFS root on the cluster storage.
- To remove a root, select the root, open the **Action** menu, and click **Delete Root**.
- Any member server or domain controller can host a DFS root. You must have be a member of the Administrators group on a server to create a DFS root on that server. In addition, you need domain administrator credentials to create a domain root.
- If your DFS namespace includes roots and root targets which exist on both computers running one of the Windows Server 2003 family of products and computers running Windows 2000, you must administer those roots from a computer running a product in the Windows Server 2003 family, or from a computer running the Windows Server 2003 Administration Tools Pack. You can not administer the DFS namespace from a computer running Windows 2000.
- Only NTFS volumes can host DFS roots. You cannot host a DFS root on a FAT or FAT32 partition.
- When working with shared folders, use NTFS and file sharing permissions to secure the folder and any subfolders so that only authorized users can access them.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

**Concepts**

Creating a DFS root
Delete a DFS root, root target, link, or target
Add a DFS root target
Securing shared resources
Set permissions on a shared resource
Set, view, change, or remove permissions on files and folders

# Add a DFS root target

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a DFS root target**

1. Open Distributed File System.
2. Select the domain root for which you want to add a root target.
3. On the **Action** menu, click **New Root Target**.
4. Follow the instructions that appear in the New Root wizard.

## Notes

- In order to make changes to an existing DFS namespace, you must be a member of the Administrators group on the server hosting the namespace. As a security best practice, consider using Run as to perform this procedure. You must be a member of the Administrators group on a server to create a root target on that server. For more information, see Default local groups, Default groups, and Using Run as.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- To remove a root target, select the root target, open the **Action** menu, and click **Remove Target**.
- You can only add root targets to domain DFS roots.
- If the folder that you specify to correspond to the root target does not exist or has not been shared, you will be prompted to create a new shared file. You can then type the name of a new folder, or type the name of an existing folder that has not yet been shared. DFS will create the folder (if necessary), then share the folder. Be aware that although the name of the folder itself does not have to be the same as the root, the folder will automatically be shared with the same name as the root.
- If you add a shared folder on a Windows 2000 computer as a root target, it may not display in the list of root targets immediately.
- If your DFS namespace includes roots and root targets which exist on both computers running one of the Windows Server 2003 family of products and computers running Windows 2000, you must administer those roots from a computer running a product in the Windows Server 2003 family, or from a computer running the Windows Server 2003 Administration Tools Pack. You can not administer the DFS namespace from a computer running Windows 2000.
- When working with shared folders, use NTFS and file sharing permissions to secure the folder and any subfolders so that only authorized users can access them.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Create a DFS root
Delete a DFS root, root target, link, or target

Securing shared resources
Set permissions on a shared resource
Set, view, change, or remove permissions on files and folders

# Show a DFS root

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To show a DFS root**

1. Open Distributed File System.
2. Click **Distributed File System**.
3. On the **Action** menu, click **Show Root**.
4. In the **Root or host server** field, type in the UNC name for an existing DFS root, or expand the list of trusting domains and click the DFS root, then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- To specify the DFS root, you can type either *HostDomain**DFSRootName* or *HostServer**DFSRootName*, where *HostDomain* is the name of the domain on which the root resides (for domain DFS), *HostServer* is the name of the server on which the root resides (for stand-alone DFS), and *DFSRootName* is the name of the root.
- You can also show a root by typing the name of the host server alone. If the host server has a single root, DFS will show the root. If the host server has multiple roots, DFS will display a list of all the roots on the server and allow you to pick the root or roots to display. You can select more than one root by holding down the SHIFT or CTRL keys as you click.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a DFS link

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a DFS link**

1. Open Distributed File System.
2. In the console tree, click the DFS root.
3. On the **Action** menu, click **New Link**.
4. Type a name for the new link.
5. Type a path for the new link or click **Browse** to select from the list of available shared folders.
6. Type a comment, if you would like to use it to further identify or describe the link.
7. Type the duration for which a reference to this link will be cached on a DFS client, then click **OK**.

## Notes

- In order to make changes to an existing DFS namespace, you must be a member of the Administrators group on the server hosting the namespace. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- The folder that you specify as the target must be an existing shared folder.
- To delete a link, select the link, open the **Action** menu, and click **Delete Link**.
- If you later delete a target from this link using **dfscmd /remove** on the command line, you must specify the same name you used to create the link. For example, if you create the link using its DNS name, you must specify the DNS name when using **dfscmd**, rather than the NetBIOS name. Consider using a consistent naming standard when adding links, so it will be easier to remember later.
- When working with shared folders, use NTFS and file sharing permissions to secure the folder and any subfolders so that only authorized users can access them.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Add a target
Delete a DFS root, root target, link, or target

# Filter the DFS link display

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To filter the DFS link display**

1. Open Distributed File System.
2. In the console tree, click the DFS root.
3. On the **Action** menu, click **Filter Links**.
4. In the **Type the maximum number of links** box, type the maximum number of links to display in the console tree.
5. Select **Filter links by name**, and then do one of the following:
   - To display all links with names starting with a certain text string, select **Starts with** in the list box, and then type the text string on which you would like to filter.
   - To display all links with names containing a certain text string, select **Contains** in the list box, and then type the text string on which you want to filter.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- To display all DFS links, type a number greater than or equal to the total number of existing links in the **Type the maximum number of links** box, and select **Do not filter links by name**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable or disable DFS referral

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable DFS referral**

1. Open Distributed File System.
2. In the console tree, click the DFS link that points to the target for which you would like to change the referral status.
3. Click the desired target. On the **Action** menu, select **Enable or Disable Referral**.

## Notes

- In order to make changes to an existing DFS namespace, you must be a member of the Administrators group on the server hosting the namespace. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- When you disable DFS referral for a target, DFS will not direct users to the target folder until DFS referral is enabled.
- If DFS referral is enabled for a target, selecting **Enable or Disable Referral** will disable it. If DFS referral is disabled, the action will enable it.
- The **DFS Referral** column and **Status** column in the details pane provide information about the referral status of each target. The **DFS Referral** column indicates if DFS referral is enabled and the **Status** column indicates if a particular target is available. If a target can not accessed, the **Status** column will read **Offline**. To see the current status for a target, click it and select **Check Status** from the **Action** menu.
- When working with shared folders, use NTFS and file sharing permissions to secure the folder and any subfolders so that only authorized users can access them.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a target

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a target**

1. Open Distributed File System.
2. In the console tree, click the DFS link to which you want to assign a target.
3. On the **Action** menu, click **New Target**.
4. Under **Path to target (shared folder)**, enter the name of a shared folder, or click **Browse** to select from the list of available shared folders.
5. If you are adding the target to a domain root, click **Add this target to the replication set** to enable automatic file replication for the target.
6. If you are not enabling automatic file replication, you must manually copy files to the new target from other targets.

## Notes

- In order to make changes to an existing DFS namespace, you must be a member of the Administrators group on the server hosting the namespace. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- The folder that you specify as the target must be an existing shared folder.
- To remove a target, select the target, open the **Action** menu, and click **Remove Target**.
- This procedure for adding a target should not be used for adding the first target. The first target is added when you create the DFS link.
- If a link points to another domain DFS, it cannot point to any other targets. To add a target in this case, you must add it to the targeted DFS and not to the link itself.
- Automatic file replication through the File Replication service is only available with domain DFS.
- When working with shared folders, use NTFS and file sharing permissions to secure the folder and any subfolders so that only authorized users can access them.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Check status of a DFS root, DFS link, or target

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To check status of a DFS root, DFS link, or target**

1. Open Distributed File System.
2. In the DFS administration tool, click the DFS root, DFS link, or target whose status you want to check.
3. On the **Action** menu, click **Check Status**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Hide a DFS root

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To hide a DFS root

1. Open Distributed File System.
2. In the console tree, click the DFS root.
3. On the **Action** menu, click **Hide Root**.
4. A dialog box will appear, asking if you want to hide the root. Click **Yes**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- The root is removed from the DFS administration tool. The distributed file system itself is not affected. User access to the root is not affected by this procedure.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a DFS root, root target, link, or target

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a DFS root, root target, link, or target**

1. Open Distributed File System.
2. Click the DFS root, root target, link, or target that you want to delete. You might have to navigate through the console tree to reveal the object you would like to delete.
3. On the **Action** menu, click **Delete Root**, **Delete Link**, or **Remove Target**, depending on the nature of the object you would like to delete.
4. A dialog box will appear asking you for confirmation. Click **Yes**.

### Important

- Deleting a root is not a recoverable operation. Deleting a root removes the root from the administration tool and removes the entire DFS structure associated with the root, but does not delete any data. If it is a stand-alone root, the procedure removes the DFS configuration data from the host computer. If it is a domain root, the procedure removes the configuration data from each host computer and from Active Directory.
- Deleting a root, root target, link, or target does not delete any associated shared folders from the file system, and it does not change any permissions associated with files or folders. If you no longer want users to have access to data in these shared folders, use NTFS or file sharing permissions to restrict access.

### Notes

- In order to make changes to an existing DFS namespace, you must be a member of the Administrators group on the server hosting the namespace. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- If you remove the only target of a link, the link will be deleted.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

# Configure DFS Replication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure replication**

- View replication properties
- Initiate file replication
- Show or hide replication information for a list of targets
- Enable or disable replication for a target
- Modify replication topology
- Set the replication schedule
- Exclude files or subfolders from replication
- Remove files or subfolders from the exclusion list

# View replication properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view replication properties**

1. Open Distributed File System.
2. Click the domain DFS root or link for which replication has been configured.
3. On the **Action** menu, click **Properties**.
4. Click the **Replication** tab.

## Caution

- Do not create File Replication service (FRS) replica sets on a volume that is managed by Remote Storage. Otherwise you might severely impact system performance and possibly cause data loss within your media library.

  FRS might need to periodically read every file in the replica set to send the file contents to another computer. This causes FRS to recall all files that Remote Storage has sent to secondary storage, which might take a long time (hours or days). If you use tape for your secondary storage, remember FRS recalls files in directory order rather than media order, so the excessive number of tape seeks performed by FRS will likely ruin the tapes and cause data loss.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- This procedure is applicable only after you have initiated replication.
- Automatic file replication through the File Replication service is only available with domain DFS.
- From here, you can view and change the replication topology, view and change the replication schedule, and exclude files and subfolders from replication.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Initiate file replication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To initiate file replication**

1. Open Distributed File System.
2. Click the domain root or link for which you would like to initiate replication.
3. On the **Action** menu, select **Configure Replication**.
4. Follow the instructions that appear in the Configure Replication wizard.

## Caution

- Do not create File Replication service (FRS) replica sets on a volume that is managed by Remote Storage. Otherwise you might severely impact system performance and possibly cause data loss within your media library.

  FRS might need to periodically read every file in the replica set to send the file contents to another computer. This causes FRS to recall all files that Remote Storage has sent to secondary storage, which might take a long time (hours or days). If you use tape for your secondary storage, remember FRS recalls files in directory order rather than media order, so the excessive number of tape seeks performed by FRS will likely ruin the tapes and cause data loss.

- Do not enable replication on Distributed File System (DFS) roots.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- Automatic file replication through the File Replication service is only available with domain DFS.
- A domain DFS root or link must have at least two targets before you can begin replication.
- To stop replication on a link, click the link, click the **Action** menu, and then click **Stop Replication**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Show or hide replication information for a list of targets

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To show or hide replication information for a list of targets**

1. Open Distributed File System.
2. Click the DFS link for which you want to display or hide replication information.
3. On the **Action** menu, click **Show Replication Information** (if the "File Replication" column is currently hidden and you want to display it) or **Hide Replication Information** (if the "File Replication" column is currently visible and you want to hide it).

### Caution

- Do not create File Replication service (FRS) replica sets on a volume that is managed by Remote Storage. Otherwise you might severely impact system performance and possibly cause data loss within your media library.

  FRS might need to periodically read every file in the replica set to send the file contents to another computer. This causes FRS to recall all files that Remote Storage has sent to secondary storage, which might take a long time (hours or days). If you use tape for your secondary storage, remember FRS recalls files in directory order rather than media order, so the excessive number of tape seeks performed by FRS will likely ruin the tapes and cause data loss.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- Automatic file replication through the File Replication service is only available with domain DFS.
- The "File Replication" column shows whether each individual target participates in replication.

# Enable or disable replication for a target

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable replication for a target**

1. Open Distributed File System.
2. Click the DFS link for which you want to manage replication.
3. If the "File Replication" column is not visible in the list of targets, display it by clicking the **Action** menu and clicking **Show Replication Information.**
4. Click the target for which you would like to change the replication status.
5. On the **Action** menu, click **Enable Replication** (if replication is currently disabled and you want to enable it) or **Disable Replication** (if replication is currently enabled and you want to disable it).

   If you are enabling replication for the target, you will be prompted to designate a staging folder.

## Caution

- Do not create File Replication service (FRS) replica sets on a volume that is managed by Remote Storage. Otherwise you might severely impact system performance and possibly cause data loss within your media library.

  FRS might need to periodically read every file in the replica set to send the file contents to another computer. This causes FRS to recall all files that Remote Storage has sent to secondary storage, which might take a long time (hours or days). If you use tape for your secondary storage, remember FRS recalls files in directory order rather than media order, so the excessive number of tape seeks performed by FRS will likely ruin the tapes and cause data loss.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- Automatic file replication through the File Replication service is only available with domain DFS.
- You cannot disable replication on a target that is serving as the hub in a hub-and-spoke replication system without first designating a different target as a hub.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Modify replication topology

# Modify replication topology

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To modify replication topology**

1. Open Distributed File System.
2. Click the root or link for which you want to manage replication.
3. On the **Action** menu, click **Properties**.
4. On the **Replication** tab, click the **Customize** button.
5. In the **Topology** drop-down list, click the type of replication topology you want to use. A list of server connections will appear under **Connections**.
6. Under **Connections**, select or clear the check boxes to enable or disable replication connections between servers.
7. If you choose a custom topology, you must add and delete connections manually. To add a connection, click the **New** button, or, to delete an existing connection, click **Delete**.
8. To change the synchronization priority for initial synchronization or restores, click the **Priorities** button.

## Caution

- Do not create File Replication service (FRS) replica sets on a volume that is managed by Remote Storage. Otherwise you might severely impact system performance and possibly cause data loss within your media library.

  FRS might need to periodically read every file in the replica set to send the file contents to another computer. This causes FRS to recall all files that Remote Storage has sent to secondary storage, which might take a long time (hours or days). If you use tape for your secondary storage, remember FRS recalls files in directory order rather than media order, so the excessive number of tape seeks performed by FRS will likely ruin the tapes and cause data loss.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- Automatic file replication through the File Replication service is only available with domain DFS.
- The **Replication** tab is only available for domain DFS roots or links for which you have already configured replication.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Set the replication schedule

# Set the replication schedule

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the replication schedule**

1. Open Distributed File System.
2. Click the domain DFS root or link for which you want to manage replication. On the **Action** menu, click **Properties**.
3. On the **Replication** tab, click **Schedule**. The replication schedule appears, with blue representing the times when replication is available, and white representing the times when replication is not available.
4. On the replication schedule, click to select an hour or drag to select a range of hours.
5. Enable or disable replication for the selected time period or periods as follows:
   - To enable replication, click **Replication Available**.
   - To disable replication, click **Replication Not Available**
6. Repeat the previous two steps as necessary, then click **OK**.

### Caution

- Do not create File Replication service (FRS) replica sets on a volume that is managed by Remote Storage. Otherwise you might severely impact system performance and possibly cause data loss within your media library.

  FRS might need to periodically read every file in the replica set to send the file contents to another computer. This causes FRS to recall all files that Remote Storage has sent to secondary storage, which might take a long time (hours or days). If you use tape for your secondary storage, remember FRS recalls files in directory order rather than media order, so the excessive number of tape seeks performed by FRS will likely ruin the tapes and cause data loss.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- Automatic file replication through the File Replication service is only available with domain DFS.
- Clicking on the name of a day of the week will select the entire day. Clicking directly underneath an hour label will select that hour every day. Clicking **All** will select the entire schedule.
- This method allows you to set the schedule for all existing connections. To set the schedule for individual connections, on the **Replication** tab, click **Customize**, select the connection or connections for which you would like to change the schedule, and click **Schedule**.
- Modifying the schedule for all existing connections will override any changes you have made to the schedule for individual connections.

- To override the replication schedule for the initial synchronization of inbound connections and during file restoration operations, on the **Replication** tab, click **Customize**, click **Priorities** and then check the **Override Schedule** check box for the appropriate inbound connection.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Setting the initial synchronization priorities for inbound connections

# Exclude files or subfolders from replication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To exclude files or subfolders from replication**

1. Open Distributed File System.
2. Click the domain DFS root or link for which you want to manage replication. On the **Action** menu, click **Properties**.
3. On the **Replication** tab, next to **File filter** (for files) or **Subfolder filter** (for subfolders), click **Edit**.
4. Type the name of a file or subfolder you want to exclude from replication.
5. Click **Add** to add the file or folder name to the exclusion list, and then click **OK**.

### Caution

- Do not create File Replication service (FRS) replica sets on a volume that is managed by Remote Storage. Otherwise you might severely impact system performance and possibly cause data loss within your media library.

  FRS might need to periodically read every file in the replica set to send the file contents to another computer. This causes FRS to recall all files that Remote Storage has sent to secondary storage, which might take a long time (hours or days). If you use tape for your secondary storage, remember FRS recalls files in directory order rather than media order, so the excessive number of tape seeks performed by FRS will likely ruin the tapes and cause data loss.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open DFS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Distributed File System**.
- Automatic file replication through the File Replication service is only available with domain DFS.
- When typing the file or folder name to exclude from replication, you can use the asterisk (*) or the question mark (?) as wildcard characters. For example, **.tmp* matches all files with the .tmp extension.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Remove files or subfolders from the exclusion list

# Remove files or subfolders from the exclusion list

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove files or subfolders from the exclusion list**

1. Open Distributed File System.
2. Click the domain DFS root or link for which you want to manage replication. On the **Action** menu, click **Properties**.
3. On the **Replication** tab, next to **File filter** or **Subfolder filter**, click **Edit**.
4. Click the file or folder name or specification you would like to remove from the list.
5. Click **Remove** to remove the item from the exclusion list, and then click **OK**.

### Caution

- Do not create File Replication service (FRS) replica sets on a volume that is managed by Remote Storage. Otherwise you might severely impact system performance and possibly cause data loss within your media library.

  FRS might need to periodically read every file in the replica set to send the file contents to another computer. This causes FRS to recall all files that Remote Storage has sent to secondary storage, which might take a long time (hours or days). If you use tape for your secondary storage, remember FRS recalls files in directory order rather than media order, so the excessive number of tape seeks performed by FRS will likely ruin the tapes and cause data loss.

# Distributed File System (DFS) Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section covers:

- Distributed File System overview
- Understanding Distributed File System
- Using Distributed File System

# Distributed File System overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Distributed File System overview**
With Distributed File System (DFS), system administrators can make it easy for users to access and manage files that are physically distributed across a network. With DFS, you can make files distributed across multiple servers appear to users as if they reside in one place on the network. Users no longer need to know and specify the actual physical location of files in order to access them.

For example, if you have marketing material scattered across multiple servers in a domain, you can use DFS to make it appear as though all of the material resides on a single server. This eliminates the need for users to go to multiple locations on the network to find the information they need.

**Reasons for using DFS**
You should consider implementing DFS if:

- You expect to add file servers or modify file locations.
- Users who access targets are distributed across a site or sites.
- Most users require access to multiple targets.
- Server load balancing could be improved by redistributing targets.
- Users require uninterrupted access to targets.
- Your organization has Web sites for either internal or external use.

**DFS types**
You can implement a distributed file system in either of two ways, either as a stand-alone root distributed file system, or as a domain distributed file system.

**Accessing DFS targets from other computers**
In addition to the server-based DFS component of the Windows Server 2003 family, there is a client-based DFS component. The DFS client caches a referral to a DFS root or a DFS link for a specific length of time, defined by the administrator.

The DFS client component runs on a number of different Windows platforms. For information on DFS client versions and their associated platforms, see Platform compatibility.

For more information, see Understanding Distributed File System and Using Distributed File System.

# Understanding Distributed File System

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Distributed File System**
This section covers:

- Distributed File System features
- Distributed File System mapping
- Distributed File System and security
- Platform compatibility

# Distributed File System features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Distributed File System features**
The Distributed File System (DFS) provides several important features, described in the following sections.

**Easy access to files**
A distributed file system makes it easier for users to access files. Users need only go to one location on the network to access files, even though the files may be physically spread across multiple servers.

Also, when you change the physical location of a target, user access to the folder is not impacted. They still access the folder in the same way as before, because the location of the file looks the same.

Users no longer need multiple drive mappings to access their files.

Finally, scheduled file server maintenance, software upgrades and other tasks that normally require taking the server offline can be accomplished without disrupting user access. This is particularly useful for Web servers. By selecting the root for the Web site as a DFS root, you can move resources within the distributed file system without breaking any HTML links.

**Availability**
Domain DFS ensures that users retain access to their files, in two ways:

First, the Windows Server 2003 operating system automatically publishes the DFS mapping to Active Directory. This ensures that the DFS namespace is always visible to users on all servers in the domain.

Second, as an administrator, you can replicate your DFS roots and your targets. Replication means that you can duplicate DFS roots and targets on multiple servers in the domain. In this way, users can still access their files, even if one of the physical servers on which those files reside becomes unavailable.

**Server load balancing**
A DFS root can support multiple targets that are physically distributed across a network. This is useful, for example, if you have a file that you know will be accessed heavily by your users. Rather than all users physically accessing this file on a single server, and thus taxing the server, DFS ensures that user access to the file is distributed to multiple servers. To users, however, the file resides in one location on the network.

**File and folder security**
Because the shared resources DFS manages use standard NTFS and file sharing permissions, you can use preexisting security groups and user accounts to ensure that only authorized users have access to sensitive data.

# Distributed File System mapping

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Distributed File System mapping**

A Distributed File System (DFS) mapping consists of a DFS root, one or more DFS links, and referrals to one or more targets.

The domain server on which a DFS root resides is known as a host server. You can replicate a DFS root by creating root targets on other servers in the domain. This provides file availability when the host server becomes unavailable.

To users, a DFS mapping provides unified and transparent access to the network resources they need. To system administrators, a DFS mapping is a single DNS namespace: With domain DFS, the DNS names for the DFS root targets resolve to the host servers for the DFS root.

Because the host server for a domain distributed file system is a member server within a domain, the DFS mapping is automatically published to Active Directory by default, thus providing synchronization of DFS topologies across host servers. This, in turn, provides fault tolerance for the DFS root and supports optional replication of targets.

You can expand a DFS mapping by adding a DFS link to the DFS root. The only constraint on the number of hierarchical levels in a DFS mapping is imposed by the Windows Server 2003 family limit of 260 characters for any file path. A new DFS link can refer to a target with or without subfolders, or to an entire Windows Server 2003 family volume. If you have adequate permissions, you can also access any local subfolders that exist in or are added to a target.

# Distributed File System and security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Distributed File System and security**

Aside from granting the necessary permissions, Distributed File System (DFS) service does not implement any additional security measures, beyond what the Windows Server 2003 family system provides. The permissions assigned to a DFS root or DFS link determine who can add a new DFS link.

Permissions to a target are not related to the DFS topology. For example, suppose there is a DFS link named MarketingDocs and you have appropriate permissions to access a particular target to which MarketingDocs points. In this case, you can then access all other targets in the set of targets, regardless of whether or not you have permissions to access those other targets. However, having permission to access these targets does determine whether or not you have access to any of the information within the targets. Such access is determined by standard Windows Server 2003 family security controls.

In summary, security is enforced by the underlying file system when a user tries to access a target and its contents. Thus, a FAT volume provides share-level security on files, while an NTFS volume provides full Windows Server 2003 family security. To maintain security, you should use NTFS and file sharing permissions to secure any shared folders used by DFS so that only authorized users can access them.

For more information on setting permissions, see Securing shared resources. For security recommendations for DFS, see Best practices for Distributed File System (DFS).

# Platform compatibility

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Platform compatibility**

The Windows Server 2003 family supports targets on the following platforms.

| Platform | Host DFS Client | Host DFS Root |
|---|---|---|
| MS-DOS, Windows 3.x, Windows for Workgroups, and NetWare servers | No | No |
| Windows 95 | Yes, download client | No |
| Windows 98 | Yes, stand-alone client included; download client for domain | No |
| Windows NT 4.0 and Service Pack 3 | Yes, stand-alone client included | Yes, stand-alone root DFS only |
| Windows 2000 and the Windows Server 2003 family | Yes, client included | Yes, stand-alone and domain DFS |

**Note**

- To support synchronization of targets, the referenced resource for a target must be located on a Windows Server 2003 family NTFS partition.

# Using Distributed File System

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Distributed File System**

This section covers:

- Creating a DFS root
- Adding a DFS root target
- Adding a DFS link
- Adding a target
- Using File Replication Service
- Checking target status
- Managing Distributed File System from the command line

# Creating a DFS root

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating a DFS root**
You can create a DFS root on an NTFS partition residing on a computer in the Windows Server 2003 family. When creating a DFS root, you have the option of establishing either a stand-alone DFS root or a domain DFS root.

A stand-alone DFS root:

- Does not use Active Directory.
- Cannot have more than one root-level target.
- Does not support automatic file replication using the File Replication service.
- Supports fault tolerance through Server Clusters.

A domain DFS root:

- Must be hosted on a domain member server.
- Has its DFS namespace automatically published to Active Directory.
- Can have more than one root-level target.
- Supports automatic file replication through FRS.
- Supports fault tolerance through FRS.

Using the DFS administration tool, you specify a target to assign as the DFS root. In addition to accessing this target, users can access any subfolders of this target.

You can host multiple DFS roots on a single computer when using Windows Server 2003, Enterprise Edition or Windows Server 2003, Datacenter Edition.

On server clusters, the name you give a non-clustered DFS root on a node's local storage must be different from the name you give a clustered DFS root on the cluster storage.

Large domain-based DFS namespaces might cause significantly increased network traffic due to the size of the DFS Active Directory object. As a result, it is recommended that you use fewer than 5,000 DFS links for a domain root. The largest recommended namespace size for a stand-alone root is 50,000 links on servers running Windows Server 2003.

If your DFS namespace includes roots and root targets which exist on both computers running one of the Windows Server 2003 family of products and computers running Windows 2000, you must administer those roots from a computer running a product in the Windows Server 2003 family, or from a computer running the Windows Server 2003 Administration Tools Pack. You can not administer the DFS namespace from a computer running Windows 2000.

For more information, see Create a DFS root.

# Adding a DFS root target

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Adding a DFS root target**

Having more than one root target for a domain root helps ensure that if the host server becomes unavailable for any reason, the distributed file system associated with that DFS root is still available to domain users.

To add a root target, click the root and select **New Root Target** from the **Action** menu. This invokes the New Root Wizard.

**Note**

- You can also delete a root target.

# Adding a DFS link

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Adding a DFS link**

A Distributed File System (DFS) link is an element in the DFS namespace that lies below the root and maps to one or more targets. Instead of seeing the target's actual name and physical location, users accessing a DFS namespace see the link name listed as a folder under the root. Because link names are not constrained by the target's name or location, you can create link names that are meaningful to the user. For example, you could create a link named "Marketing" that points to one or more targets that contain marketing information regardless of the actual name and location of those targets.

Large domain-based DFS namespaces might cause significantly increased network traffic due to the size of the DFS Active Directory object. As a result, it is recommended that you use fewer than 5,000 DFS links for a domain root. The largest recommended namespace size for a stand-alone root is 50,000 links on servers running Windows Server 2003.

For more information, see Add a DFS link.

# Adding a target

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Adding a target**

For each DFS link, you can create a set of targets to which the DFS link points. Within a set of targets, you add the first folder to the set when you create the DFS link. Subsequent targets are added using the DFS administration tool's **New Target** dialog box.

Within a set of targets, you can choose which folders will participate in replication. If you add targets for domain DFS roots, you also need to do the following:

- Set the replication policy among the targets.
- Check the replication status.

For information on setting replication policy, see Using File Replication Service.

For information on checking replication status, see Checking target status.

# Using File Replication Service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using the File Replication service**
This section covers:

- Configuring replication topology
- Configuring the replication schedule
- Excluding files and folders from replication
- Setting the initial synchronization priorities for inbound connections

# Configuring replication topology

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring replication topology**

The word "topology" typically refers to the relationship between components in a network. The replication topology describes the logical connections that FRS uses to replicate files between computers.

For each DFS root or DFS link, you can specify one of four basic topology types:

- In a ring topology, files replicate from one computer to another in a circular configuration, with each computer connected to the computers on either side of it in the ring.
- In a hub and spoke topology, one computer is designated as the hub and is connected to each of the other computers, called spokes. Files replicate from the hub computer to the spoke computers and vice versa, but files do not replicate directly between two spoke computers. You must choose which computer will serve as the hub.
- In a full mesh topology, every computer is connected to every other computer. A file created on one computer replicates directly to all the others.
- In a custom topology, you create the connections between computers yourself.

**Ring Topology**

**Hub and Spoke Topology**

**Full Mesh Topology**

When you select a topology, you can further customize it by selectively enabling or disabling the connections between computers. You can completely disable the relationship between two computers to prevent files from replicating between them at all, or you can make it one-way by disabling the connection from the first computer to the second while leaving the opposite connection available.

Many factors can affect the type of topology that is appropriate for your network, including bandwidth, security, geographic, and organizational considerations.

### Note

- Automatic file replication is available only for domain roots.

# Configuring the replication schedule

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring the replication schedule**

When you first configure a /DFS root or a DFS link for replication, the File Replication service (FRS) schedules replication to take place around the clock. Whenever you copy a file to a target that participates in replication, FRS replicates the file to the other targets using the connections specified in the replication topology.

You might not want replication to take place automatically at certain times. For example, if certain servers are taken off the network every Friday evening from 9 to 11 for maintenance and restarting, you might want to halt replication to and from those servers at 9 on Friday and resume it two hours later. When a connection returns to replication, FRS immediately reconciles any differences between the two shares.

FRS lets you schedule the times when replication will or will not be available. You can modify the schedule for individual connections or for all connections at once. The **Schedule** dialog box displays the schedule for every hour in the week and lets you select blocks of time during which replication will or will not take place. Clicking the name of a weekday will select the entire day. Clicking a box at the top of the schedule to the right of the word **All** will select the same hour on every day throughout the week. Clicking **All** will select the entire schedule.

You can access the schedule in two ways. Clicking the **Schedule** button on the Replication tab of a root's or link's **Properties** sheet lets you view and change the schedule for all of the connections belonging to that root or link. If you select one or more connections in the **Customize Topology** dialog box and click the **Schedule** button, you can change the schedule for the selected connections only.

### Notes

- Automatic file replication through the File Replication service is only available with domain DFS.
- Changing the schedule for all connections will overwrite any changes you have made to the schedule for individual connections.

# Excluding files and folders from replication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Excluding files and folders from replication**
Sometimes you may not want to replicate every file or subfolder contained within a DFS root or DFS link. For example, if a shared folder used as a target contains several temporary files created by applications for caching or record-keeping purposes, you might not want to replicate those files to all of the targets that participate in replication.

For each root and link, you can use the File Replication service to specify files and subfolders to exclude from replication. The exclusion rules apply to every target or root target designated as belonging to the selected root or link, and also apply to subfolders beneath the shared folders themselves.

You can use * and ? as wildcard characters when entering file or folder names. For example, *.tmp matches all files with the .tmp extension.

For specific instructions on excluding files and folders from replication, see:

- Exclude files or subfolders from replication
- Remove files or subfolders from the exclusion list

**Note**

- Automatic file replication is only available for domain roots.

# Setting the initial synchronization priorities for inbound connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting the initial synchronization priority for inbound connections**

It is often advantageous to control the sequence of synchronization during replication. Using Distributed File System (DFS) snap-in and the File Replication Service (FRS), you can configure synchronization priorities. You can determine which inbound connection will go first in the initial synchronization that occurs when you add a new member to a replica set or when you restore one of your replica set members. For example, you can adjust synchronization priorities to ensure that computers across a high-bandwidth network connection synchronize first, followed by synchronization with computers that are communicating through a lower-bandwidth connection. By adjusting the synchronization priorities, you can often reduce the time needed to perform the synchronization process.

Using FRS, you can choose from three synchronization priorities:

- High: All connections marked High must successfully synchronize before a synchronization is attempted on Medium-priority connections.
- Medium: At least one Medium priority connection must successfully complete an initial synchronization before any synchronization is attempted on Low-priority connections. FRS attempts to synchronize all connections in the Medium priority level, but only one must be successful before FRS attempts to synchronize Low priority connections.
- Low: FRS attempts to synchronize with each computer on a Low priority connection one time, but any failure will not delay other synchronization attempts.

Low is the default synchronization priority for all connections. Typically, you should configure high-bandwidth or local connections to have a higher synchronization priority than low-bandwidth connections. Therefore, depending on the scenario, a priority of either Medium or High is appropriate for your local connections. However, be aware that if you have a High priority connection that fails, no other synchronization will take place.

The following two scenarios describe how you might use synchronization priorities:

In the first example, you are using a hub and spoke topology. Computer X at a branch site fails and needs to be restored. Computer X has inbound connections from Computers A and B, which are located at a hub site. Computer X also has an inbound connection from Computer Y, which is located at the same branch site as Computer X. You should set the synchronization priority from Computer Y to Computer X to High. Set synchronization priorities from Computers A and B at the hub site to Computer X at the branch site to Low.

The reason for these settings is that under normal conditions, you would not want to do a full synchronization over the slow link between Computer X and Computer A or Computer B. A synchronization from the hub site would take too long and consume all of the bandwidth of the slow link. Instead, the recovery of Computer X must occur first from the local Computer Y. Computer X can then try to synchronize from either Computer A or Computer B, but if communication problems prevent the synchronization, Computer X can still come online with the same content as Computer Y.

For the second example, you are using a custom topology that consists of a two-level hub and spoke architecture. Computer A is at the hub site. The second level consists of Computers J, K, L, and M at the regional offices. At the bottom level are several departmental computers in branch offices.

Computer A at the hub site has high bandwidth bi-directional connections to Computers J, K, L and M. At the regional offices, Computers J, K, L and M are connected in a medium bandwidth bi-directional ring. The branch office computers are each connected to two of the regional computers (J, K, L and M) by a low-bandwidth connection.

Computers J, K, L and M are all expected to be up to date. Therefore, for Computer A, you should set the inbound connections from Computers J, K, L and M to Medium priority. You should also set the priority for the ring of connections between the regional office computers to Medium. The priority from the branch office computers to Computers J, K, L and M should be set to Low.

Consider Computer K. Its inbound connections from A, J and L should all be set to Medium priority because a synchronization with any one of them would be sufficient for Computer K to come online. If the hub site (Computer A) is unavailable, Computers J, K, L and M can still complete a recovery without first synchronizing with Computer A. The justification for the Low priority from the branch office computers is the same as described in the first example.

**Overriding the schedule for initial synchronization**

Typically, synchronization will only take place at times defined in the synchronization schedule that you configure. However, you can override the schedule for initial synchronization or the initial creation of replica set member. By selecting the Override Schedule check box in the Priorities dialog box, you can cause the initial replication to occur immediately.

For more information on setting the priority, see Modify replication topology. For more information on setting the replication schedule, see Set the replication schedule.

# Checking target status

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checking target status**

You can check whether the targets that you have assigned are being referenced properly by DFS. The status check indicates one of the following conditions:

Checking status on a DFS root or DFS link will reveal one of the following icons:

- A blue check mark on the root or link indicates that the root or link can be reached, and all of its targets can be reached.
- A yellow exclamation point on the root or link indicates that the root or link can be reached, but not all of its targets can be reached, either because DFS referral is disabled on that target, or some other problem is preventing access to the target.
- A red cross on the root or link indicates that the root or link cannot be reached.

Checking status on a target will result in the **Status** column in the details pane indicating **Online** or **Offline**. If the status of a target is **Offline**, that indicates that the target cannot be reached.

# Managing Distributed File System from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing DFS from the command line**

You can use the **dfscmd** command-line utility to manage and configure DFS and DFS roots, links, and targets, and to write batch scripts so that other applications can interact with DFS. You can run the command-line utility from a command prompt by typing **dfscmd**.

For help using the DFS command line utility, see Dfscmd.

For information about other command-line utilities, see Command-line reference A-Z.

# Synchronization Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Synchronization Manager**

Using Synchronization Manager, you can control when your offline files are synchronized with files on the network.

- For general background information, see Synchronization Manager overview.
- For help with synchronizing offline items, see Synchronizing offline items.
- For help with scheduling synchronization, see Scheduling offline items to synchronize.
- For help with synchronizing items when users log on or log off, see Synchronizing offline items when you log on to or log off from a computer.
- For help with synchronizing items while your computer is idle, see Synchronizing offline items while your computer is idle.

# Synchronization Manager overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Synchronization Manager overview**
Using Synchronization Manager, you can control when your offline files are synchronized with files on the network. This ensures that you have the latest information from your network or from the Internet when you need it, while minimizing the disruption to work on your system.

You can use Synchronization Manager to automatically synchronize the information that is available to you offline in the following ways:

- Every time you log on or log off your computer
- At specific intervals while your computer is idle
- At scheduled times

You can apply these options in various combinations to offline files for each shared resource.

Synchronization Manager compares items on the network to those that you opened or updated while working offline, and then makes the most current version available to both the computer and the network. Items that you can synchronize include individual files, folders and their contents, and offline Web pages. Synchronization Manager provides a single location where you can go to synchronize shared files that are available offline, regardless of the type of file or program that was used to make the file available offline.

For more information about using offline items, see Offline Files and Synchronization Manager.

**Note**

- You must share files before you can use them with Offline Files. Once shared, the files appear in the list of items that are available for synchronization.

# Synchronizing offline items

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To synchronize offline items**

1. Open Synchronization Manager.
2. Under **Select the check box for any items you want to synchronize**, select the check box for each offline item that you want to synchronize, such as a folder on a mapped network drive or an Internet Explorer offline Web page.
3. Click **Synchronize**.

## Notes

- To open Synchronization Manager from the command line, click **Start**, click **Run**, type **mobsync**, and then click **OK**.
- You must share files before you can use them with Offline Files. Once shared, the files appear in the list of items that are available for synchronization. For more information about working with Offline Files, see Related Topics.
- To synchronize individual files, folders, or Web pages in Microsoft Windows Explorer, My Computer, or Microsoft Internet Explorer, click the item that you want to synchronize, and then, on the **Tools** menu, click **Synchronize**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Synchronizing offline items when you log on to or log off from a computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To synchronize offline items when you log on to or log off from a computer**

1. Open Synchronization Manager.
2. Click **Setup**, and then click the **Logon/Logoff** tab.
3. In **When I am using this network connection**, click the network connection that you want to use.
4. In **Synchronize the following checked items**, select the check box for the offline items that you want to synchronize, such as a folder on a mapped network drive or an Internet Explorer offline Web page.
5. Under **Automatically synchronize the selected items**, do any of the following:
   - To synchronize items when you log on to your computer, select the **When I log on to my computer** check box.
   - To synchronize items when you log off of your computer, select the **When I log off my computer** check box.
   - To request permission before synchronizing your offline items, select the **Ask me before synchronizing the items** check box.

## Notes

- To open Synchronization Manager from the command line, click **Start**, click **Run**, type **mobsync**, and then click **OK**.
- To synchronize individual files, folders, or Web pages in Windows Explorer, My Computer, or Internet Explorer, select the item that you want to synchronize, and then, on the **Tools** menu, click **Synchronize**.
- By choosing when offline items are synchronized, you can better manage the work on your computer and on the network. For example, when connected to the network by modem, synchronization time is minimized by clearing all automatic synchronization options and manually synchronizing individual files.
- When using offline files, it is recommended that you always synchronize when you log on to your computer. This ensures that changes that were made on your computer are synchronized with changes that were made on the network while you were disconnected.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Synchronizing offline items while your computer is idle

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To synchronize offline items while your computer is idle**

1. Open Synchronization Manager.
2. Click **Setup**, and then click the **On Idle** tab.
3. In **When I am using this network connection**, click the network connection that you want to use.
4. In **Synchronize the following checked items**, select the check box for the offline items that you want to synchronize, such as a folder on a mapped network drive or an Internet Explorer offline Web page.
5. Select the **Synchronize the selected items while my computer is idle** check box.

## Notes

- To open Synchronization Manager from the command line, click **Start**, click **Run**, type **mobsync**, and then click **OK**.
- To synchronize individual files, folders, or Web pages in Windows Explorer, My Computer, or Internet Explorer, click the item that you want to synchronize, and then, on the **Tools** menu, click **Synchronize**.
- You can create a different synchronization setup for each of your network connections.
- To specify whether to synchronize offline items while your computer is running on batteries, open Synchronization Manager, click **Setup**, and then click the **On Idle** tab. In **When I am using this network connection**, click the network connection that you want to use, click **Advanced**, and then select the items that you want to synchronize and for which you want to prevent synchronization when the computer is on battery power.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Managing Disks and Volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing disks and volumes**

- Disk Management
- Disk Defragmenter
- Disk Quotas

# Disk Management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Disk Management**
You use Disk Management in Windows XP Professional and Windows Server 2003 operating systems to perform disk-related tasks, such as creating and formatting partitions and volumes, and assigning drive letters. On computers running Windows Server 2003 operating systems, you can also use Disk Management to perform advanced tasks, such as creating and repairing fault tolerant volumes. In addition, you can use the **DiskPart** command, along with other command-line utilities, to perform Disk Management tasks. For information about Disk Management-related command-line utilities, see Managing disks and volumes from the command line.

- Checklist: Adding a new disk.
- To find features that have been moved from where they were located in previous versions of Windows, see New ways to do familiar tasks for Disk Management.
- For tips about using Disk Management, see Best practices for Disk Management.
- For help with specific tasks, see Disk Managment How To....
- For general background information, see Disk Management Concepts.
- For problem-solving instructions, see Troubleshooting Disk Management.

# Checklist: Adding a new disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Adding a new disk**

| Step | Reference |
|---|---|
| Review key concepts. | Disk Management overview; Best practices for Disk Management |
| Confirm that you are a member of the Backup Operators group or the Administrators group.<br><br>If you have access to the administrator account and password, it is a security best practice to log on as a user that is not a member of the Administrators group and run Disk Management by right-clicking the Computer Management snap-in icon, and then clicking Run as. | Default local groups; Why you should not run your computer as an administrator; Run a program with administrative credentials |
| Add the new disk. | Adding a disk |

| Format volumes on the disk. | Choosing a file system: NTFS, FAT, or FAT32;Format a basic volume;Format a dynamic volume |

# New ways to do familiar tasks for Disk Management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

The following table lists common tasks for administering disks and volumes. The user interface for performing these tasks is different in this version of Windows from the way it was in Windows NT version 4.0.

### Note

- There are no significant user interface differences between Windows 2000, Windows XP, and Windows Server 2003 operating systems for this component.

| If you want to | In Windows NT 4.0 use | In this version of Windows use |
|---|---|---|
| Format a volume | **Disk Administrator** in Administrative tools. | Computer Management (Local).<br><br>For more information, see Format a dynamic volume. |
| Add a new disk | **Disk Administrator** in Administrative tools. | Computer Management (Local).<br><br>For more information, see Adding a disk |
| Create a volume set | **Disk Administrator** in Administrative tools. | Computer Management (Local). For more information, see Create a spanned volume. |
| Create a stripe set | **Disk Administrator** in Administrative tools. | Computer Management (Local).<br><br>For more information, see Create a striped volume. |
| Create a mirror set | **Disk Administrator** in Administrative tools. | Computer Management (Local).<br><br>For more information, see Create a mirrored volume. |
| Create a stripe set with parity | **Disk Administrator** in Administrative tools. | Computer Management (Local).<br><br>For more information, see Create a RAID-5 volume. |

# Best practices for Disk Management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

### Best practices

#### Use the appropriate credentials

- When using Disk Management, confirm that you are a member of the Backup Operators group or the Administrators group.

  If you have access to the administrator account and password, it is a security best practice to log on as a user that is not a member of the Administrators group and run Disk Management by right-clicking the Computer Management snap-in icon, and then clicking Run as.

  For more information about why you should not run your computer as an administrator, see Why you should not run your computer as an administrator.

#### Back up data

- Because deleting or creating partitions or volumes destroys any existing data, be sure to back up the disk contents beforehand. As with any major change to disk contents, you should back up the entire contents of the hard disk before working with partitions or volumes, even if you do not plan to make any changes to one or more of your partitions or volumes.

  For more information on how to back up and restore data, see Backup.

#### Format volumes using the NTFS file system

- Many features in Windows 2000 and Windows Server 2003 operating systems, such as file and folder permissions, encryption, large volume support, and sparse file management, require the NTFS file system format.

  For more information about file system compatibility and limitations, see Choosing a file system: NTFS, FAT, or FAT32.

#### Use dynamic disks

- Several Disk Management tasks, including creating fault-tolerant disks, can be performed only with dynamic disks. You can use dynamic disks to create and delete simple, spanned, striped, mirrored, and RAID-5 volumes. Dynamic disks cannot be directly accessed by computers running MS-DOS, Windows 95, Windows 98, Windows Millennium Edition, Windows NT, or Windows XP Home Edition. As a result, you cannot start these operating systems on dynamic disks. Shared folders on dynamic disks are available across a network to computers running all of these operating systems, however.

  For more information about dynamic disks, see Dynamic disks and volumes.

#### Use disks and disk controllers that are the same model and size, and from the same manufacturer

- When creating or repairing mirrored or RAID-5 volumes, it is best to use disks that are the same model and size and from the same manufacturer. This ensures that the disk geometries are the same and simplifies the processes of creating a new mirrored or RAID-5 volume or replacing a failed disk. It is also recommended that you have spare disks and disk controllers available so that if a disk or disk controller fails, you can quickly replace the faulty disk or disk controller with one of the same type.

#### Use Event Viewer to check the system log when mirrored or RAID-5 volumes fail

- When a mirrored or RAID-5 volume fails, it is sometimes due to a faulty disk controller. Changing one of the disks that make up a mirrored or RAID-5 volume will not fix the volume if the problem is being caused by a faulty disk controller. Always use Event Viewer to check the system log to determine the true nature of the disk-related problem before changing a disk or disk controller.

  For more information on how to use Event Viewer to check the system log, see Event Viewer.

# Disk Managment How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Manage Disks
- Manage Basic Volumes
- Manage Dynamic Volumes

# Manage Disks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage disks**

- Initialize new disks
- Move disks to another computer
- View disk properties
- Update disk information
- Refresh drive letter, file system, and volume information
- Reactivate a missing or offline dynamic disk
- Change a basic disk into a dynamic disk
- Change a dynamic disk back to a basic disk
- Change a master boot record disk into a GUID partition table disk
- Change a GUID partition table disk into a master boot record disk
- Manage disks on a remote computer
- Remove a missing dynamic disk

# Initialize new disks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To initialize new disks**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the disk you want to initialize, and then click **Initialize Disk**.
4. In the **Initialize Disk** dialog box, select the disk(s) to initialize.

   On x86-based computers running Windows Server 2003 with Service Pack 1 (SP1), Itanium-based computers, or x64-based computers, you can select whether to use the master boot record (MBR) or GUID partition table (GPT) partition style.

   The disk is initialized as a basic disk.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- New disks appear as **Not Initialized**. Before you can use a disk, you must first initialize it. If you start Disk Management after adding a disk, the Initialize Disk Wizard appears so you can initialize the disk.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Update disk information
Disk status descriptions
Working with MMC console files

# Move disks to another computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To move disks to another computer**

1. Print this procedure or write down the steps before attempting to move disks from one computer to another.

2. Use Disk Management to make sure the status of the volumes on the disks is **Healthy**. If the status is not **Healthy**, you should repair the volumes before you move the disks. For more information about repairing disks, see Related Topics.

   **How?**

   a. Open Computer Management (Local).

   b. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.

      Volume status is displayed in the **Volume List** and **Graphical View**:

      In the **Volume List** view, volume status is displayed in the **Status** column.

      In the **Graphical View**, volume status is displayed under the volume size and file system information.

3. Uninstall the disks you want to move using Device Manager.

   **How?**

   a. Open Computer Management (Local).

   b. In the console tree, click **Computer Management**, click **System Tools**, and then click **Device Manager**.

   c. In the device list, double-click **Disk drives**.

   d. Right-click the disks you want to uninstall, and then click **Uninstall**.

   e. In the **Confirm Device Removal** dialog box, click **OK**.

4. For basic disks, skip to step 5. For dynamic disks, use Disk Management to remove the disks you want to move.

   **How?**

   a. Open Computer Management (Local).

   b. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.

   c. Right-click the disks that you want to move, and then click **Remove Disk**.

   d. If the disks are external, unplug them from the computer. If the disks are internal, turn off the computer and then physically remove the disks.

5. If the disks are external, plug them into the computer. If the disks are internal, make sure the computer is turned off and then physically install the disks in that computer.

6. Start the computer that contains the disks you moved.

7. Follow the instructions in the **Found New Hardware** dialog box.

   If the **Found New Hardware** dialog box does not appear, click **Start**, point to **Settings**, click **Control Panel**, and then click **Add Hardware** to start the Add Hardware Wizard.

8. Use Disk Management to detect the new disks.

   **How?**

   a. Open Computer Management (Local).

   b. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.

   c. Click **Action**, and then click **Rescan Disks**.

   d. Right-click any disk marked **Foreign**, click **Import Foreign Disks**, and then follow the instructions on your screen.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- When moved to another computer, basic volumes receive the next available drive letter on that computer. Dynamic volumes retain the drive letter they had on the previous computer. If a dynamic volume did not have a drive letter on the previous computer, it does not receive a drive letter when moved to another computer. If the drive letter is already used on the computer where they are moved, the volume receives the next available drive letter. If an administrator has used the **mountvol /n** or the **diskpart automount** commands to prevent new volumes from being added to the system, volumes moved from another computer are prevented from being mounted and from receiving a drive letter. To use the volume, you must manually mount the volume and assign it a drive letter using Disk Management or the **DiskPart** and **mountvol** commands.

- If you are moving spanned, striped, mirrored, or RAID-5 volumes, it is highly recommended that you move all disks containing the volume together. Otherwise, the volumes on the disks cannot be brought online and will not be accessible except to delete them.

- Do not move multidisk volumes from computers running Windows NT 4.0 to computers running Windows XP Professional or Windows Server 2003 operating systems. These operating systems do not support mirror sets, stripe sets, stripe sets with parity, or volume sets. Instead, you must back up and then delete these volumes before you move the disks, and then create new dynamic volumes and restore the data to the new volumes.

- Every time you remove or import disks to a computer, you must click **Action**, click **Rescan Disks**, and then verify that the disk information is correct.

- You can move multiple disks from different computers to a computer by installing the disks, opening Disk Management, right-clicking any of the new disks, and then clicking **Import Foreign Disks**. When importing multiple disks from different computers, always import all of the disks from one computer at a time. For example, if you want to move disks from two computers, import disks from the first computer and then import disks from the second computer.

- Disk Management describes the condition of the volumes on the disks before they are imported. Review this information carefully. If there are any problems, this will tell you what will happen to each volume on these disks once the disks have been imported. For more information, see Related Topics.

- You can only move GUID partition table (GPT) disks that are used for data storage among x86-based computers running Windows Server 2003 with Service Pack 1 (SP1), Itanium-based computers, or x64-based computers. If you move a GPT disk containing the Windows operating system from an Itanium-based computer to an x86-based or x64-based computer, you can access the data, but you cannot boot from that operating system.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View disk properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view disk properties**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. In the graphical view or disk list, right-click a disk and then click **Properties**.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- The **Properties** dialog box lists information about the physical disk and the volumes it contains. If you want to view the properties of one of the volumes listed, click the volume and then click **Properties**.
- You can view the disk's partitioning style on the **Volumes** tab in the **Properties** dialog box. Disks with the MBR partitioning style are displayed as Master Boot Record (MBR) disks, and disks with the GPT partitioning style are displayed as GUID Partition Table (GPT) disks.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list disk**

4. At the **DISKPART** prompt, type:

   **select disk** *n*

   Select the disk *n* that you want to display additional details about.

5. At the **DISKPART** prompt, type:

   **detail disk**

   **DiskPart** displays information about the disk, such as the disk's type, volumes on the disk, drive letter, file system, size, and status.

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select disk** *n* | Selects the specified disk *n*, and gives it focus. |
| **detail disk** | Displays the properties of the selected disk and the volumes on that disk. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- For more information about **DiskPart**, see related topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Manage Disks

# Update disk information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To update disk information**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Click **Action**, and then click **Rescan Disks**.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- Use Device Manager to scan your computer's hardware for changes. Then, use the **Rescan Disks** command if your disk configuration has changed but the changes do not appear in Disk Management. For more information about Device Manager, see Related Topics.
- When Disk Management rescans disks, it scans all attached disks for disk configuration changes. It also updates information on removable media, CD-ROM drives, basic volumes, file systems, and drive letters.
- Rescanning disks can take several minutes, depending on the number of hardware devices installed.
- If you add a new disk to your computer and Disk Management does not detect it after you click **Rescan Disks**, you might need to restart your computer. New disks appear as **Not Initialized**. Before you can use a disk, you must first initialize it. For instructions describing how to initialize a disk, see Related Topics. If you start Disk Management after adding a disk, the Initialize Disk Wizard appears so you can initialize the disk.
- If you create partitions using another program or utility and Disk Management does not detect the changes, you must close and then restart Disk Management.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **rescan**

| Value | Description |
|---|---|
| **rescan** | Locates new disks that may have been added to the computer. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- Use Device Manager to scan your computer's hardware for changes. Then, use the **DiskPart rescan** command if your disk configuration has changed but the changes do not appear in DiskPart. For more information about Device Manager, see Related Topics.

- When DiskPart rescans disks, it scans all attached disks for disk configuration changes. It also updates information on removable media, CD-ROM drives, basic volumes, file systems, and drive letters.

- Rescanning disks can take several minutes, depending on the number of hardware devices installed.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Refresh drive letter, file system, and volume information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To refresh drive letter, file system, and volume information**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Click **Action**, and then click **Refresh**.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- When you click the **Refresh** command, Disk Management refreshes drive letter, file system, volume, and removable media information, and also checks to see if unreadable volumes are now readable. However, it does not scan hardware. To update hardware information, click **Rescan Disks** instead.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reactivate a missing or offline dynamic disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To reactivate a missing or offline dynamic disk

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the disk marked **Missing** or **Offline**, and then click **Reactivate Disk**.

   The disk should be marked **Online** after the disk is reactivated.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- A dynamic disk may become **Missing** when it is corrupted, powered down, or disconnected.
- A dynamic disk may become **Offline** if it is corrupted or intermittently unavailable. A dynamic disk may also become **Offline** if you attempt to import a foreign (dynamic) disk and the import fails. An error icon appears on the **Offline** disk. Only dynamic disks display the **Missing** or **Offline** status.
- Only dynamic disks can be reactivated.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk number of the missing or offline disk that you want to bring online. Missing disks are numbered M0, M1, M2, etc. and offline disks are numbered 0, 1, 2, etc.

4. At the **DISKPART** prompt, type:

   **select disk***n*

5. At the **DISKPART** prompt, type:

   **online**

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select disk** *n* | Sets the focus to the specified disk, where *n* is the disk number. |
| **online** | Brings an offline disk or volume with focus online. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- A dynamic disk may become **Missing** when it is corrupted, powered down, or disconnected.

- A dynamic disk may become **Offline** if it is corrupted or intermittently unavailable. A dynamic disk may also become **Offline** if you attempt to import a foreign (dynamic) disk and the import fails. Only dynamic disks display the **Offline** status.

- Only dynamic disks can be reactivated.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change a basic disk into a dynamic disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change a basic disk into a dynamic disk**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the basic disk you want to convert, click **Convert to Dynamic Disk**, and then follow the instructions on your screen.

   If you do not see this menu item, you might be right-clicking a volume instead of a disk, the disk might have been previously converted to a dynamic disk, or the computer is a portable computer. (Dynamic disks are not supported on portable computers, removable disks, detachable disks that use Universal Serial Bus (USB) or IEEE 1394 (also called FireWire) interfaces, or on disks connected to shared SCSI buses.) In addition, you cannot convert cluster disks connected to shared SCSI or Fibre Channel buses to dynamic. The Cluster service supports basic disks only.)

### Caution

- If you are using a basic disk as a storage area for shadow copies and you intend to convert the disk into a dynamic disk, it is important to take the following precaution to avoid data loss. If the disk is a non-boot volume and is a different volume from where the original files reside, you must first dismount and take offline the volume containing the original files before you convert the disk containing shadow copies to a dynamic disk. You must bring the volume containing the original files back online within 20 minutes, otherwise, you will lose the data stored in the existing shadow copies. If the shadow copies are located on a boot volume, you can convert the disk to dynamic without losing shadow copies.

  You can use the **mountvol** command with the **/p** option to dismount the volume and take it offline. You can mount the volume and bring it online using the **mountvol** command or the Disk Management snap-in.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- For additional information about converting basic disks to dynamic disks, see Related Topics.
- After you convert a basic disk to a dynamic disk, you cannot change the dynamic volumes back to partitions. Instead, you must delete all dynamic volumes on the disk and then use the **Convert To Basic Disk** command. If you want to keep your data, you must first back it up or move it to another volume. For more information about the **Convert To Basic Disk** command, see Related Topics.

- Before you convert disks, close any programs that are running on those disks.

- Once converted, a dynamic disk will not contain basic volumes (primary partitions or logical drives), nor can it be accessed by MS-DOS, Windows 95, Windows 98, Windows Millennium Edition, Windows NT, or Windows XP Home Edition operating systems. Dynamic disks can only be accessed with Windows 2000, Windows XP Professional, or Windows Server 2003 operating systems.

- When you convert a basic disk to a dynamic disk, any existing partitions or logical drives on the basic disk become simple volumes on the dynamic disk.

- Do not convert disks to dynamic that contain multiple installations of Windows 2000, Windows XP Professional, or Windows Server 2003 operating systems. It is likely that you will no longer be able to start the second installation.

- For the conversion to succeed, any master boot record (MBR) disks to be converted must contain at least 1 MB of space for the dynamic disk database. Windows 2000, Windows XP Professional, and Windows Server 2003 operating systems, automatically reserves this space when creating partitions or volumes on a disk, but disks with partitions or volumes created by other operating systems may not have this space available. (This space may exist even if it is not visible in Disk Management.)

**Using a command line**

1. Open Command prompt.

2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk number of the disk you want to convert to dynamic.

4. At the **DISKPART** prompt, type:

   **select disk***n*

5. At the **DISKPART** prompt, type:

   **convert dynamic**

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select disk** | Selects the specified disk, where *n* is the disk number, and gives it focus. |
| **convert dynamic** | Converts a basic disk into a dynamic disk. Any existing partitions on the disk become simple volumes. |

**Caution**

- If you are using a basic disk as a storage area for shadow copies and you intend to convert the disk into a dynamic disk, it is important to take the following precaution to avoid data loss. If the disk is a non-boot volume and is a different volume

from where the original files reside, you must first dismount and take offline the volume containing the original files before you convert the disk containing shadow copies to a dynamic disk. You must bring the volume containing the original files back online within 20 minutes, otherwise, you will lose the data stored in the existing shadow copies. If the shadow copies are located on a boot volume, you can convert the disk to dynamic without losing shadow copies.

You can use the **mountvol** command with the **/p** option to dismount the volume and take it offline. You can mount the volume and bring it online using the **mountvol** command or the Disk Management snap-in.

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- For additional information about converting basic disks to dynamic disks, see Related Topics.

- After you convert a basic disk to a dynamic disk, you cannot change the dynamic volumes back to partitions. Instead, you must delete all dynamic volumes on the disk and then use the **DiskPart convert basic** command. If you want to keep your data, you must first back it up or move it to another volume. For more information about **DiskPart**, see Related Topics.

- Before you convert disks, close any programs that are running on those disks.

- Once converted, a dynamic disk will not contain partitions or logical drives, nor can it be accessed by MS-DOS, Windows 95, Windows 98, Windows Millennium Edition, Windows NT, or Windows XP Home Edition operating systems. Dynamic disks can be accessed only with Windows 2000, Windows XP Professional, or Windows Server 2003 operating systems.

- When you convert a basic disk to a dynamic disk, any existing partitions or logical drives on the basic disk become simple volumes on the dynamic disk.

- Do not convert disks to dynamic that contain multiple installations of Windows 2000, Windows XP Professional, or Windows Server 2003 operating systems. It is likely that you will no longer be able to start the second installation.

- For the conversion to succeed, any master boot record (MBR) disks to be converted must contain at least 1 MB of space for the dynamic disk database. Windows 2000, Windows XP Professional, and Windows Server 2003 operating systems, automatically reserves this space when creating partitions or volumes on a disk, but disks with partitions or volumes created by other operating systems may not have this space available. (This space may exist even if it is not visible in Disk Management.)

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change a dynamic disk back to a basic disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change a dynamic disk back to a basic disk**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Back up all volumes on the disk you want to convert from dynamic to basic.

   For more information about backing up volumes, see Related Topics.

2. Open Computer Management (Local).

3. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.

4. Right-click each volume on the dynamic disk you want to convert to a basic disk, and then click **Delete Volume** for each volume on the disk.

5. When all volumes on the disk have been deleted, right-click the disk, and then click **Convert To Basic Disk**.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- The disk must not have any volumes nor contain any data before you can change it back to a basic disk. If you want to keep your data, back it up or move it to another volume before you convert the disk to a basic disk.

- Once you change a dynamic disk back to a basic disk, you can create only partitions and logical drives on that disk.

**Using a command line**

1. Back up all volumes on the disk you want to convert from dynamic to basic.

   For more information about backing up volumes, see Related Topics.

2. Open Command Prompt.

3. Type:

   **diskpart**

4. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the dynamic disk you want to convert to a basic disk.

5. At the **DISKPART** prompt, type:

   **select disk***n*

6. At the **DISKPART** prompt, type:

   **detail disk***n*

7. For each volume on the disk, at the **DISKPART** prompt, type:

   **select volume=***n*

   and then type:

   **delete volume**

8. At the **DISKPART** prompt, type:

   **select disk***n*

   Specify the disk number of the disk that you want to convert to a basic disk.

9. At the **DISKPART** prompt, type:

   **convert basic**

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select disk** | Selects the specified disk, where *n* is the disk number, and gives it focus. |
| **detail disk** | Displays the properties of the selected disk and the volumes on that disk. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |
| **delete volume** | Deletes the selected volume. You cannot delete the system volume, boot volume, or any volume that contains the active paging file or crash dump (memory dump). |
| **convert basic** | Converts an empty dynamic disk into a basic disk. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- The disk must not have any volumes nor contain any data before you can change it back to a basic disk. If you want to keep your data, back it up or move it to another volume before you convert the disk to a basic disk.
- Once you change a dynamic disk back to a basic disk, you can create only partitions and logical drives on that disk.
- For more information about **DiskPart**, see Related Topics.

# Change a master boot record disk into a GUID partition table disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change a master boot record disk into a GUID partition table disk**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Back up or move the data on the basic master boot record (MBR) disk you want to convert into a GUID partition table (GPT) disk. If the disk does not contain any partitions or volumes, skip to step 2.

   For more information about backing up volumes, see Related Topics.

2. Open Computer Management (Local).

3. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.

4. If the disk does not contain any partitions or volumes, skip to step 5. Otherwise, right-click any volumes on the disk and then click **Delete Partition** or **Delete Volume**.

5. Right-click the MBR disk that you want to change into a GPT disk, and then click **Convert to GPT Disk**.

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- You can change a disk from MBR to GPT as long as the disk does not contain any partitions or volumes.

- You cannot use the GPT partitioning style on removable media, or on cluster disks that are connected to shared SCSI or Fibre Channel buses used by Cluster service.

- Itanium-based computers, x86-based computers running Windows Server 2003 with Service Pack 1 (SP1), and x64-based computers support both MBR and GPT disks.

**Using a command line**

1. Back up or move all data on the basic master boot record (MBR) disk you want to convert into a GUID partition table (GPT) disk. If the disk does not contain any partitions or volumes, skip to step 2.

   For more information about backing up volumes, see Related Topics.

2. Open Command Prompt.

3. Type:

   **diskpart**

   If the disk does not contain any partitions or volumes, skip to step 7.

4. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the number of the volume that you want to delete.

5. At the **DISKPART** prompt, type:

   **select volume** *n*

6. At the **DISKPART** prompt, type:

   **delete volume**

7. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk number of the disk that you want to convert to a GUID partition table (GPT) disk.

8. At the **DISKPART** prompt, type:

   **select disk** *n*

9. At the **DISKPART** prompt, type:

   **convert gpt**

**Important**

- You can only convert basic MBR disks without any partitions or volumes into a GPT disk. Back up your data and then delete all partitions or volumes before converting the disk.

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |
| **delete volume** | Deletes the selected volume. You cannot delete the system volume, boot volume, or any volume that contains the active paging file or crash dump (memory dump). |
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |

| | |
|---|---|
| **select disk** *n* | Selects the specified disk, where *n* is the disk number, and gives it focus. |
| **convert gpt** | Converts an empty basic disk with the master boot record (MBR) partition style into a basic disk with the GUID partition table (GPT) partition style. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You can change a disk from MBR to GPT as long as the disk does not contain any partitions or volumes.

- You cannot use the GPT partitioning style on removable media, or on cluster disks that are connected to shared SCSI or Fibre Channel buses used by Cluster service.

- Itanium-based computers, x86-based computers running Windows Server 2003 with Service Pack 1 (SP1), and x64-based computers support both MBR and GPT disks.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change a GUID partition table disk into a master boot record disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change a GUID partition table disk into a master boot record disk**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Back up or move all volumes on the basic GUID partition table (GPT) disk you want to convert into a master boot record (MBR) disk. If the disk does not contain any partitions or volumes, skip to step 2.

   For more information about backing up volumes, see Related Topics.

2. Open Computer Management (Local).

3. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.

4. If the disk does not contain any partitions or volumes, skip to step 5. Otherwise, right-click the any volumes on the disk and then click **Delete Volume**.

5. Right-click the GPT disk that you want to change into an MBR disk, and then click **Convert to MBR disk**.

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- You can change a disk from GPT to MBR as long as the disk is empty.

- Itanium-based computers, x86-based computers running Windows Server 2003 with Service Pack 1 (SP1), and x64-based computers support both MBR and GPT disks.

**Using a command line**

1. Back up or move all volumes on the basic GUID partition table (GPT) disk you want to convert into a master boot record (MBR) disk. If the disk does not contain any partitions or volumes, skip to step 2.

   For more information about backing up volumes, see Related Topics.

2. Open Command Prompt.

3. Type:

**diskpart**

If the disk does not contain any partitions or volumes, skip to step 7.

4. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the number of the volume that you want to delete.

5. At the **DISKPART** prompt, type:

   **select volume** *n*

6. At the **DISKPART** prompt, type:

   **delete volume**

7. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk number of the disk that you want to convert to an MBR disk.

8. At the **DISKPART** prompt, type:

   **select disk** *n*

9. At the **DISKPART** prompt, type:

   **convert mbr**

**Important**

- The disk must be empty to convert it to an MBR disk. Back up your data and then delete all partitions or volumes before converting the disk.

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |
| **delete volume** | Deletes the selected volume. You cannot delete the system volume, boot volume, or any volume that contains the active paging file or crash dump (memory dump). |
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select disk** | Selects the specified disk, where *n* is the disk number, and gives it focus. |

| | |
|---|---|
| **convert mbr** | Converts an empty basic disk with the GUID Partition Table (GPT) partition style to a basic disk with the master boot record (MBR) partition style. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You can change a disk from GPT to MBR as long as the disk is empty.

- Itanium-based computers, x86-based computers running Windows Server 2003 with Service Pack 1 (SP 1), and x64-based computers support both MBR and GPT disks.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage disks on a remote computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manage disks on a remote computer**

1. Open Computer Management (Local).
2. In the console tree, right-click **Computer Management (Local)**, and then click **Connect to another computer**.
3. In **Another computer**, type the name of the computer that you want to manage remotely.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

  The user of the client computer must also be a member of the Backup Operators group or Administrators group on the remote computer.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- If Windows Firewall (included in Windows XP Service Pack 2 (SP2) and in Windows Server 2003 Service Pack 1 (SP1)) is enabled on either the local or remote computer, you must add the following settings to the **Exceptions** tab in Windows Firewall on the appropriate computer to perform this procedure:

| | **Windows XP SP2** | **Windows Server 2003 SP1** |
|---|---|---|
| Client computer (local) | Dmremote.exe<br>TCP 135 | Dmremote.exe<br>Vdsldr.exe<br>TCP 135 |
| Server computer (remote) | Dmadmin.exe<br>TCP 135 | Dmadmin.exe<br>Vds.exe<br>TCP 135 |

- Mirrored volumes, RAID-5 volumes, and GUID partition table (GPT) disks are not available on all versions of Windows. The types of volumes and disks you can create depend on the version of Windows running on the remote computer, not the local computer. For example, you can use a local computer running Windows XP Professional to create mirrored and RAID-5 volumes on a remote computer that is running Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, or Windows Server 2003 operating systems.

- You can use a computer running Windows XP Professional to manage disks on a remote computer running Windows 2000 or Windows Server 2003 operating systems and vice versa.

- You can use an x86-based or x64-based computer to manage an Itanium-based computer and vice versa.

- If you use a computer running Windows XP Professional or Windows Server 2003 of operating systems to manage a

remote computer running Windows 2000, the property pages for IEEE 1394 and universal serial bus (USB) detachable disks do not show all of the information.

- If you use a computer running Windows 2000 to manage a remote x86-based computer running Windows Server 2003 with Service Pack 1 (SP 1), an x64-based computer, or an Itanium-based computer, you cannot manage GUID partition table (GPT) disks or dynamic disks in the remote computer if one of the disks in the disk group is a GPT disk.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove a missing dynamic disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To remove a missing dynamic disk

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click each volume on the dynamic disk marked **Missing**, and then click **Delete Volume** to remove all volumes on the **Missing** disk.
4. Right-click the dynamic disk marked **Missing**, and then click **Remove Disk**.

### Important

- Do not delete the volumes from a **Missing** dynamic disk unless you are certain that the disk will not be powered up, reconnected, repaired or otherwise returned to the computer. Otherwise, you will not be able to access those volumes when the disk is returned to the computer.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- A dynamic disk may become **Missing** when it is corrupted, powered down, or disconnected.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk number of the missing disk that you want to remove from the disk list. Missing disks are

numbered M0, M1, M2, etc.

4. At the **DISKPART** prompt, type:

   **select disk***n*

5. At the **DISKPART** prompt, type:

   **delete disk**

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select disk** *n* | Selects the specified disk, where *n* is the disk number, and gives it focus. |
| **delete disk** | Deletes a missing dynamic disk from the disk list. |

**Important**

- Do not delete the volumes from a **Missing** dynamic disk unless you are certain that the disk will not be powered up, reconnected, repaired or otherwise returned to the computer. Otherwise, you will not be able to access those volumes when the disk is returned to the computer.

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- A dynamic disk may become **Missing** when it is corrupted, powered down, or disconnected.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Basic Volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage basic volumes**

- View the properties of a volume
- Assign, change, or remove a drive letter
- Create a mounted drive
- Mark a partition as active (32-bit only)
- Format a basic volume
- Create a partition or logical drive
- Delete a partition or logical drive
- Extend a basic volume

# View the properties of a volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view the properties of a volume**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the partition, logical drive, or other volume, and then click **Properties**.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can only view the properties for local volumes.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list volume**

   **DiskPart** displays a list of volumes in the computer and information about them, such as their drive letter, file system, size, and status.

4. At the **DISKPART** prompt, type:

   **select volume***n*

   Select the volume *n* that you want to display additional details about.

5. At the **DISKPART** prompt, type:

**detail volume**

**DiskPart** displays information about the disk on which the volume is located, such as the disk's size, status, free space, and whether the disk is dynamic or whether it uses the GUID Partition Table (GPT) partitioning scheme.

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** *n* | Selects the specified volume *n*, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. You can view the numbers of all volumes on the computer by using the **list volume** command. |
| **detail volume** | Displays the disks on which the current volume resides. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- For more information about **DiskPart**, see related topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign, change, or remove a drive letter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign, change, or remove a drive letter**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click a partition, logical drive, or volume, and then click **Change Drive Letter and Paths**.
4. Do one of the following:
    - To assign a drive letter, click **Add**, click the drive letter you want to use, and then click **OK**.
    - To modify a drive letter, click it, click **Change**, click the drive letter you want to use, and then click **OK**.
    - To remove a drive letter, click it, and then click **Remove**.

### Important

- Be careful when making drive-letter assignments because many MS-DOS and Windows programs make references to a specific drive letter. For example, the path environment variable shows specific drive letters in conjunction with program names.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- A computer can use up to 26 drive letters. Drive letters A and B are typically reserved for a floppy disk drives. If the computer does not have a floppy disk drive, you can assign drive letters A and B to removable drives, hard disk drives, or mapped network drives. Hard disk drives are typically assigned drive letters C through Z, while mapped network drives are assigned drive letters in reverse order (Z through C).
- You cannot change the drive letter of the system volume or boot volume.
- An error message may appear when you attempt to assign a letter to a volume, CD-ROM drive, or other removable media device, possibly because it is in use by a program in the system. If this happens, close the program accessing the volume or drive, and then click the **Change Drive Letter and Paths** command again.

- You can also mount a local drive at an empty folder on an NTFS volume using a drive path instead of a drive letter. For more information, see Related Topics.

**Using a command line**

1. Open Command Prompt.

2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the number of the simple volume whose drive letter you want to assign, change, or remove.

4. At the **DISKPART** prompt, type:

   **select volume** *n*

   Select the volume, where *n* is the volume's number, whose drive letter you want to assign, change, or remove.

5. At the **DISKPART** prompt, type one of the following:

   - **assign letter=***L*

     Where *L* is the drive letter you want to assign or change.

   - **remove letter=***L*

     Where *L* is the drive letter you want to remove.

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |
| **assign letter=** *L* | Assigns a drive letter, *L*, to the volume with focus. If no drive letter is specified, then the next available drive letter is assigned. If the drive letter is already in use, an error is generated. |
| **remove letter=** *L* | Removes the drive letter, *L*, from the volume with focus. If no drive letter or mount point is specified, then **DiskPart** removes the first drive letter or mount point it encounters.<br><br>The **remove** command can be used to change the drive letter associated with a removable drive. You cannot remove the drive letters on system, boot, or paging volumes. In addition, you cannot remove the drive letter for an OEM partition, any GPT partition with an unrecognized GUID, or any of the special, non-data, GPT partitions such as the EFI system partition. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of

the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- A computer can use up to 26 drive letters. Drive letters A and B are typically reserved for a floppy disk drives. If the computer does not have a floppy disk drive, you can assign drive letters A and B to removable drives, hard disk drives, or mapped network drives. Hard disk drives are typically assigned drive letters C through Z, while mapped network drives are assigned drive letters in reverse order (Z through C).

- You cannot change the drive letter of the system volume or boot volume.

- An error message may appear when you attempt to assign a letter to a volume, CD-ROM drive, or other removable media device, possibly because it is in use by a program in the system. If this happens, close the program accessing the volume or drive, and then click the **Change Drive Letter and Paths** command again.

- You can also mount a local drive at an empty folder on an NTFS volume using a drive path instead of a drive letter. For more information, see Related Topics.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a mounted drive

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a mounted drive**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the partition or volume you want to mount, and then click **Change Drive Letter and Paths**.
4. Do one of the following:
    - To mount a volume, click **Add**. Click **Mount in the following empty NTFS folder**, type the path to an empty folder on an NTFS volume, or click **Browse** to locate it.
    - To unmount a volume, click it and then click **Remove**.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- When you mount a local drive at an empty folder on an NTFS volume, Disk Management assigns a drive path to the drive rather than a drive letter. Drive paths are available only on empty folders on basic or dynamic NTFS volumes.
- If you are administering a local or remote computer, you can browse NTFS folders on that computer.
- When using server clusters, make sure that you create unique mounted drives so that they do not conflict with existing local drives on any node in the cluster.
- When using server clusters, do not create mounted drives between disks on the cluster storage device (cluster disks) and local disks.
- When using server clusters, do not create mounted drives from the cluster disk that contains the quorum resource (the quorum disk). You can, however, create a mounted drive from the quorum disk to a clustered disk.
- When using server clusters, mounted drives from one cluster disk to another must be in the same cluster resource group, and must be dependent on the root disk.

For more information on server clusters, see Server clusters overview.

- When creating mounted drives, use Event Viewer to check the system log for any Cluster service errors or warnings indicating mount point failures. These errors would be listed as ClusSvc in the Source column and Physical Disk Resource in the Category column.

  For more information on how to use Event Viewer to check the system log, see Event Viewer.

  For more information on how to resolve errors with mounted drives on server clusters, see Cluster disk and drive connection problems.

**Using a command line**

1. Open Command Prompt.

2. From the NTFS drive\folder that you want to mount elsewhere, type:

   **diskpart**.

3. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the number of the simple volume that you want to mount elsewhere.

4. At the **DISKPART** prompt, type:

   **select volume** *n*

   Select the simple volume, *n*, that you want to mount elsewhere.

5. At the **DISKPART** prompt, type:

   **assign** [**mount=***path*]

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |
| **assign** | Assigns a drive letter or mount point to the volume with focus. If no drive letter or mount point is specified, then the next available drive letter is assigned. If the drive letter or mount point is already in use, an error is generated.<br><br>Using the **assign** command, you can change the drive letter associated with a removable drive.<br><br>You cannot assign drive letters to system volumes, boot volumes, or volumes that contain the paging file. In addition, you cannot assign a drive letter to an Original Equipment Manufacturer (OEM) partition, EFI system partition, or any GPT partition other than a basic data partition. |
| **mount=** *path* | Specifies an empty, existing NTFS folder where the mounted drive will reside. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of

the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- Drive paths are available only on empty folders on basic or dynamic NTFS volumes.
- To modify a drive path, remove it and then create a new drive path using the new location. You cannot modify the drive path directly.
- When using server clusters, make sure that you create unique mounted drives so that they do not conflict with existing local drives on any node in the cluster.
- When using server clusters, do not create mounted drives between disks on the cluster storage device (cluster disks) and local disks.
- When using server clusters, do not create mounted drives from the cluster disk that contains the quorum resource (the quorum disk). You can, however, create a mounted drive from the quorum disk to a clustered disk.
- When using server clusters, mounted drives from one cluster disk to another must be in the same cluster resource group, and must be dependent on the root disk.

  For more information on server clusters, see Server clusters overview.
- When creating mounted drives, use Event Viewer to check the system log for any Cluster service errors or warnings indicating mount point failures. These errors would be listed as ClusSvc in the Source column and Physical Disk Resource in the Category column.

  For more information on how to use Event Viewer to check the system log, see Event Viewer.

  For more information on how to resolve errors with mounted drives on server clusters, see Cluster disk and drive connection problems.
- For more information about **DiskPart**, see Related Topics.
- You can also create a mounted drive using the **mountvol** command. For more information about **mountvol**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Mark a partition as active (32-bit only)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To mark a partition as active (32-bit only)**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the primary partition you want to mark as active, and then click **Mark Partition as Active**.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- Changing or deleting an active partition might cause your computer not to start.
- You cannot mark a logical drive as active.
- You can only mark a partition as active on a master boot record (MBR) disk.
- A computer can only have one active partition per disk.
- In the list and graphical views, the system, active, and boot partitions are marked as **System**, **Active**, or **Boot**, respectively.
- The names commonly used for partitions containing the startup and operating system files are system and boot partitions, respectively.
- The system partition must be a primary partition that has been marked as active for startup purposes and must be located on the disk that the computer accesses when starting up the system. There can be only one active system partition on a disk at a time. You can have multiple basic disks and each can have one active partition. However the computer will only start from one specific disk. If you want to use another operating system, you must first mark its system partition as active before restarting the computer.
- The system partition can never be part of a striped volume, spanned volume, or RAID-5 volume.
- You cannot mark an existing dynamic volume as active. However, you can convert a basic disk containing the active partition to a dynamic disk. Once the disk is converted, the partition becomes a simple volume that is active. If the active

partition is not the current system or boot partition it becomes a simple volume and loses its entry in the partition table, so it can no longer be active.

#### Using a command line

1. Open Command Prompt.

2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list partition**

   Make note of the number of the partition that you want to mark as active.

4. At the **DISKPART** prompt, type:

   **select partition***n*

   Select the partition, *n*, you want to mark as active.

5. At the **DISKPART** prompt, type:

   **active**

### Important

- **DiskPart** verifies only that the partition is capable of containing an operating system's startup files. **DiskPart** does not check the contents of the partition. If you mistakenly mark a partition as "active" and it does not contain the operating system's startup files, your computer might not start.

| Value | Description |
|---|---|
| **list partition** | Displays the partitions listed in the partition table of the current disk. |
| **select partition** | Selects the specified partition and gives it focus. If no partition is specified, the **select** command lists the current partition with focus. |
| **active** | On basic disks, marks the partition with focus as active. This informs the basic input/output system (BIOS) or Extensible Firmware Interface (EFI) that the partition or volume is a valid system partition or system volume. Only partitions can be marked as active. |

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- Changing or deleting an active partition might cause your computer not to start.

- You cannot mark a logical drive as active.

- You can only mark a partition as active on a master boot record (MBR) disk.
- A computer can only have one active partition per disk.
- The names commonly used for partitions containing the startup and operating system files are system and boot partitions, respectively.
- The system partition must be a primary partition that has been marked as active for startup purposes and must be located on the disk that the computer accesses when starting up the system. There can be only one active system partition on a disk at a time. You can have multiple basic disks and each can have one active partition. However the computer will only start from one specific disk. If you want to use another operating system, you must first mark its system partition as active before restarting the computer.
- The system partition can never be part of a striped volume, spanned volume, or RAID-5 volume.
- You cannot mark an existing dynamic volume as active. However, you can convert a basic disk containing the active partition to a dynamic disk. Once the disk is converted, the partition becomes a simple volume that is active. If the active partition is not the current system or boot partition it becomes a simple volume and loses its entry in the partition table, so it can no longer be active.
- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Format a basic volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To format a basic volume**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the partition, logical drive, or basic volume you want to format (or reformat), and then click **Format**.
4. Select the options you want, and then click **OK**.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You cannot format system, boot, OEM, or unknown partitions.
- Before you enable shadow copies on a volume, we recommend that you select a cluster size of 16 KB or larger. If you do not, the number of changes caused by defragmenting the volume might cause previous versions of files to be deleted.
- File compression is supported only on NTFS volumes with cluster sizes 4 KB and smaller.
- If you select the **Perform a quick format** check box, the files are removed from the disk but the disk is not scanned for bad sectors. Use this option only if this disk has been previously formatted and you are sure the disk is not damaged.

**Using a command line**

1. Open Command prompt.
2. Type:

   **format***volume*[**/fs:***filesystem*] [**/v:***label*] [**/q**] [**/a:***unitsize*] [**/c**]

| Value | Description |
|---|---|

| | |
|---|---|
| *Volume* | Specifies the mount point, volume name, or drive letter (followed by a colon), of the drive you want to format. If you do not specify any of the following command-line options, **format** uses the volume type to determine the default format for the disk. |
| **/fs:** *filesystem* | Specifies the file system to use FAT, FAT32, or NTFS. Floppy disks can use only the FAT file system. |
| **/v:** *label* | Specifies the volume label. If you omit the **/v** command-line option or use it without specifying a volume label, **format** prompts you for the volume label after the formatting is completed. Use the syntax **/v:** to prevent the prompt for a volume label. If you format more than one disk by using one **format** command, all of the disks will be given the same volume label. |
| **/q** | Performs a quick format. Deletes the file table and the root directory of a previously formatted volume but does not perform a sector by sector scan for bad areas. You should use the **/q** command-line option to format only previously formatted volumes that you know are in good condition. |
| **/a:** *unitsize* | Specifies the cluster size, also known as allocation unit size, to use on FAT, FAT32, or NTFS volumes. Use one of the following values for *unitsize*. If *unitsize* is not specified, it will be chosen based on volume size.<br><br>**512** - Creates 512 bytes per cluster.<br><br>**1024** - Creates 1024 bytes per cluster.<br><br>**2048** - Creates 2048 bytes per cluster.<br><br>**4096** - Creates 4096 bytes per cluster.<br><br>**8192** - Creates 8192 bytes per cluster.<br><br>**16K** - Creates 16 kilobytes per cluster.<br><br>**32K** - Creates 32 kilobytes per cluster.<br><br>**64K** - Creates 64 kilobytes per cluster. |
| **/c** | NTFS only. Files created on the new volume will be compressed by default. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You cannot format system, boot, OEM, or unknown partitions.

- Compression is supported only on NTFS volumes.

- Quick format removes files from the disk but does not scan the disk for bad sectors. Use this option only if this disk has been previously formatted and you are sure the disk is not damaged.

- Before you enable shadow copies on a volume, we recommend that you select a cluster size of 16 KB or larger. If you do not, the number of changes caused by defragmenting the volume might cause previous versions of files to be deleted.

- File compression is supported only on NTFS volumes with cluster sizes 4 KB and smaller.

- For Windows NT 4.0, Windows 2000, Windows XP Professional, and Windows Server 2003 operating systems, the cluster size of FAT16 volumes from 2 GB through 4 GB is 64 KB, which can create compatibility issues with some applications. For example, setup programs do not compute free space properly on a volume with 64 KB clusters and

cannot run because of a perceived lack of free space. For this reason, either FAT32 or NTFS must be used on volumes larger than 2 GB. **Format** displays a warning and asks for a confirmation before formatting a volume that has 64 KB clusters using FAT16.

- For more information about **format**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a partition or logical drive

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a partition or logical drive**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click an unallocated region of a basic disk, and then click **New Partition**, or right-click free space in an extended partition, and then click **New Logical Drive**.
4. In the New Partition wizard, click **Next**, click **Primary partition**, **Extended partition**, or **Logical drive**, and then follow the instructions on your screen.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can create primary partitions, extended partitions, and logical drives only on basic disks. You should create basic volumes instead of dynamic volumes if this computer also runs MS-DOS, Windows 95, Windows 98, Windows Millennium Edition, Windows NT 4.0, or Windows XP Home Edition.
- On a master boot record (MBR) disk, you can create up to four primary partitions, or three primary partitions, one extended partition, and unlimited logical drives.
- On a GUID partition table (GPT) disk, you can create up to 128 primary partitions.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list disk**

Make note of the disk number of the disk on which you want to create a primary or extended partition.

4. At the **DISKPART** prompt, type:

   **select disk***n*

   Select the disk *n* where you want to create the primary or extended partition.

5. At the **DISKPART** prompt, type one of the following:

   **create partition primary** [**size=***n*] [**offset=***n*] [**ID=***byte* | *GUID*] [**noerr**]

   or

   **create partition extended** [**size=***n*] [**offset=***n*] [**noerr**]

   or

   **create partition logical** [**size=***n*] [**offset=***n*] [**noerr**]

6. At the **DISKPART** prompt, type:

   **assign letter**=*D*

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select disk** | Selects the specified disk, where *n* is the disk number, and gives it focus. |
| **create partition primary** | Creates a primary partition on the current basic disk. After you create the partition, the focus automatically shifts to the new partition. The partition does not receive a drive letter; you must use the **assign** command to assign a drive letter to the partition. |
| **create partition extended** | Creates an extended partition on the current drive. After the partition has been created, the focus automatically shifts to the new partition. Only one extended partition can be created per disk. This command fails if you attempt to create an extended partition within another extended partition. You must create an extended partition before you can create logical drives. |
| **create partition logical** | Creates a logical drive in the extended partition. After the partition has been created, the focus automatically shifts to the new logical drive. |
| **size=** *n* | The size of the partition in megabytes (MB). If no size is given, the partition continues until there is no more unallocated space in the current region. The size is cylinder snapped; the size is rounded to the closest cylinder boundary. For example, if you specify a size of 500 MB, the partition would be rounded up to 504 MB. |
| **offset=** *n* | The byte offset at which to create the partition. If no offset is given, the partition will start at the beginning of the first free space on the disk. For master boot record (MBR) disks, the offset is cylinder snapped; the offset is rounded to the closest cylinder boundary. For example, if you specify an offset that is 27 MB and the cylinder size is 8 MB, the offset is rounded to the 24 MB boundary. |

| | |
|---|---|
| **ID=** *byte* \| *GUID* | Intended for Original Equipment Manufacturer (OEM) use only.<br><br>**Caution**<br><br>• Creating partitions with this parameter might cause your computer to crash or be unable to start up. Unless you are an OEM or an IT professional experienced with GPT disks, do not create partitions on GPT disks using the **ID=***byte* \| *GUID* parameter. Instead, always use the **create partition efi** command to create EFI System partitions, the **create partition msr** command to create Microsoft Reserved partitions, and the **create partition primary** command (without the **ID=***byte* \| *GUID* parameter) to create primary partitions on GPT disks.<br><br>For MBR disks, you can specify a partition type byte for the partition. If no partition type byte is specified on an MBR disk, the **create partition primary** command creates a partition of type 0x6. Any partition type byte can be specified with the **ID=***byte* \| *GUID* parameter. **DiskPart** does not check the partition type byte for validity, nor does it perform any other checking of the ID parameter.<br><br>For GPT disks you can specify a partition type GUID for the partition you want to create:<br><br>• EFI System partition: c12a7328-f81f-11d2-ba4b-00a0c93ec93b<br><br>• Microsoft reserved partition: e3c9e316-0b5c-4db8-817d-f92df00215ae<br><br>• Basic data partition: ebd0a0a2-b9e5-4433-87c0-68b6b72699c7<br><br>• LDM Metadata partition on a dynamic disk: 5808c8aa-7e8f-42e0-85d2-e1e90434cfb3<br><br>• LDM Data partition on a dynamic disk: af9b60a0-1431-4f62-bc68-3311714a69ad<br><br>If no partition type GUID is specified, the **create partition primary** command creates a basic data partition. Any partition type can be specified with the **ID=***byte* \| *GUID* parameter. **DiskPart** does not check the partition GUID for validity, nor does it perform any other checking of the ID parameter. |
| **noerr** | For scripting only. When an error is encountered, specifies that **DiskPart** continues to process commands as if the error did not occur. Without the **noerr** parameter, an error causes **DiskPart** to exit with an error code. |
| **assign letter**=*D* | Assigns a drive letter, *D*, to the volume with focus. If no drive letter or mount point is specified, the next available drive letter is assigned. If the drive letter or mount point is already in use, an error is generated. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You can create primary partitions, extended partitions, and logical drives only on basic disks. You should create basic volumes instead of dynamic volumes if this computer also runs MS-DOS, Windows 95, Windows 98, Windows Millennium Edition, Windows NT 4.0, or Windows XP Home Edition.

- On a master boot record (MBR) disk, you can create up to four primary partitions, or three primary partitions, one extended partition, and unlimited logical drives.

- On a GUID partition table (GPT) disk, you can create up to 128 primary partitions, but no extended partitions or logical drives.

- You cannot create partitions on removable media using **DiskPart**.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a partition or logical drive

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a partition or logical drive**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the partition, logical drive, or basic volume you want to delete, and then click **Delete Partition**.

   If the menu item reads **Delete Volume** instead of **Delete Partition**, the volume is a dynamic volume. For instructions on how to delete a dynamic volume, see Related Topics.

### Caution

- When you delete a partition, all data on that deleted partition or logical drive is lost.
- You cannot recover deleted partitions or logical drives.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You cannot delete the system volume, boot volume, or any volume that contains the active paging file or crash dump (memory dump), or OEM partition.
- You cannot delete an extended partition unless the extended partition is empty.

  All the logical drives in an extended partition be deleted before you can delete the extended partition.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk number of the disk from which you want to delete the partition.

4. At the **DISKPART** prompt, type:

   **select disk***n*

   Select the disk *n* from which you want to delete the partition.

5. At the **DISKPART** prompt, type:

   **list partition**

   Make note of the number of the partition that you want to delete.

6. At the **DISKPART** prompt, type:

   **select partition***n*

   Select the partition *n* that you want to delete.

7. At the **DISKPART** prompt, type:

   **delete partition**

**Caution**

- Deleting a partition on a dynamic disk can delete all dynamic volumes on the disk, thus leaving the disk in a corrupt state. To delete a dynamic volume, use the **delete volume** command instead. For instructions on how to delete a dynamic volume, see Related Topics.

- When you delete a partition, all data on that deleted partition or logical drive is lost.

- You cannot recover deleted partitions or logical drives.

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select disk** | Selects the specified disk, where *n* is the disk number, and gives it focus. |
| **list partition** | Displays the partitions listed in the partition table of the current disk. |
| **select partition** *n* | Selects the specified partition and gives it focus. If no partition is specified, the **select** command lists the current partition with focus. |
| **delete partition** | On a basic disk, deletes the partition with focus. You cannot delete the system partition, boot partition, or any partition that contains the active paging file or crash dump (memory dump). |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You cannot delete the system volume, boot volume, or any volume that contains the active paging file or crash dump (memory dump), or OEM partition.

- You cannot delete an extended partition unless the extended partition is empty.

  All the logical drives in an extended partition be deleted before you can delete the extended partition.

- You cannot delete partitions on removable media using **DiskPart**.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Delete a dynamic volume

# Extend a basic volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To extend a basic volume**

1. Open Command Prompt.
2. Type:

   **diskpart**
3. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the number of the basic volume you want to extend.
4. At the **DISKPART** prompt, type:

   **select volume***n*

   Selects the basic volume, *n*, you want to extend into contiguous, empty space on the same disk.
5. At the **DISKPART** prompt, type:

   **extend** [**size=***n*]

   Extends the selected volume by size=*n* megabytes (MB).

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |
| **extend** | Extends the volume with focus into next contiguous unallocated space. For basic volumes, the unallocated space must be on the same disk as, and must follow (be of higher sector offset than) the partition with focus. A dynamic simple or spanned volume can be extended to any empty space on any dynamic disk. Using this command, you can extend an existing volume into newly created space.<br><br>If the partition was previously formatted with the NTFS file system, the file system is automatically extended to occupy the larger partition. No data loss occurs. If the partition was previously formatted with any file system format other than NTFS, the command fails with no change to the partition.<br><br>You cannot extend the current system or boot partitions. |
| **size=** *n* | The amount of space, in megabytes (MB), to add to the current partition. If you do not specify a size, the disk is extended to take up all of the next contiguous unallocated space. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the

computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To extend a basic volume, it must either not be formatted with a file system or it must be formatted with the NTFS file system.
- You can only extend a basic volume onto the same disk.
- You can only extend a basic volume if it is followed by contiguous unallocated space.
- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Dynamic Volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage dynamic volumes**

- View the properties of a volume
- Assign, change, or remove a drive letter
- Create a mounted drive
- Format a dynamic volume
- Delete a dynamic volume
- Reactivate a dynamic volume
- Manage Simple Volumes
- Manage Spanned Volumes
- Create a striped volume
- Manage Mirrored Volumes
- Manage RAID-5 Volumes

# View the properties of a volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view the properties of a volume**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the partition, logical drive, or other volume, and then click **Properties**.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can only view the properties for local volumes.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list volume**

   **DiskPart** displays a list of volumes in the computer and information about them, such as their drive letter, file system, size, and status.

4. At the **DISKPART** prompt, type:

   **select volume***n*

   Select the volume *n* that you want to display additional details about.

5. At the **DISKPART** prompt, type:

**detail volume**

**DiskPart** displays information about the disk on which the volume is located, such as the disk's size, status, free space, and whether the disk is dynamic or whether it uses the GUID Partition Table (GPT) partitioning scheme.

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** *n* | Selects the specified volume *n*, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. You can view the numbers of all volumes on the computer by using the **list volume** command. |
| **detail volume** | Displays the disks on which the current volume resides. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- For more information about **DiskPart**, see related topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign, change, or remove a drive letter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign, change, or remove a drive letter**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click a partition, logical drive, or volume, and then click **Change Drive Letter and Paths**.
4. Do one of the following:
    - To assign a drive letter, click **Add**, click the drive letter you want to use, and then click **OK**.
    - To modify a drive letter, click it, click **Change**, click the drive letter you want to use, and then click **OK**.
    - To remove a drive letter, click it, and then click **Remove**.

### Important

- Be careful when making drive-letter assignments because many MS-DOS and Windows programs make references to a specific drive letter. For example, the path environment variable shows specific drive letters in conjunction with program names.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- A computer can use up to 26 drive letters. Drive letters A and B are typically reserved for a floppy disk drives. If the computer does not have a floppy disk drive, you can assign drive letters A and B to removable drives, hard disk drives, or mapped network drives. Hard disk drives are typically assigned drive letters C through Z, while mapped network drives are assigned drive letters in reverse order (Z through C).
- You cannot change the drive letter of the system volume or boot volume.
- An error message may appear when you attempt to assign a letter to a volume, CD-ROM drive, or other removable media device, possibly because it is in use by a program in the system. If this happens, close the program accessing the volume or drive, and then click the **Change Drive Letter and Paths** command again.

- You can also mount a local drive at an empty folder on an NTFS volume using a drive path instead of a drive letter. For more information, see Related Topics.

**Using a command line**

1. Open Command Prompt.

2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the number of the simple volume whose drive letter you want to assign, change, or remove.

4. At the **DISKPART** prompt, type:

   **select volume** *n*

   Select the volume, where *n* is the volume's number, whose drive letter you want to assign, change, or remove.

5. At the **DISKPART** prompt, type one of the following:

   - **assign letter=***L*

     Where *L* is the drive letter you want to assign or change.

   - **remove letter=***L*

     Where *L* is the drive letter you want to remove.

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |
| **assign letter=** *L* | Assigns a drive letter, *L*, to the volume with focus. If no drive letter is specified, then the next available drive letter is assigned. If the drive letter is already in use, an error is generated. |
| **remove letter=** *L* | Removes the drive letter, *L*, from the volume with focus. If no drive letter or mount point is specified, then **DiskPart** removes the first drive letter or mount point it encounters.<br><br>The **remove** command can be used to change the drive letter associated with a removable drive. You cannot remove the drive letters on system, boot, or paging volumes. In addition, you cannot remove the drive letter for an OEM partition, any GPT partition with an unrecognized GUID, or any of the special, non-data, GPT partitions such as the EFI system partition. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of

the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- A computer can use up to 26 drive letters. Drive letters A and B are typically reserved for a floppy disk drives. If the computer does not have a floppy disk drive, you can assign drive letters A and B to removable drives, hard disk drives, or mapped network drives. Hard disk drives are typically assigned drive letters C through Z, while mapped network drives are assigned drive letters in reverse order (Z through C).

- You cannot change the drive letter of the system volume or boot volume.

- An error message may appear when you attempt to assign a letter to a volume, CD-ROM drive, or other removable media device, possibly because it is in use by a program in the system. If this happens, close the program accessing the volume or drive, and then click the **Change Drive Letter and Paths** command again.

- You can also mount a local drive at an empty folder on an NTFS volume using a drive path instead of a drive letter. For more information, see Related Topics.

- For more information about **DiskPart**, see Related Topics.

DiskPart

# Create a mounted drive

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a mounted drive**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the partition or volume you want to mount, and then click **Change Drive Letter and Paths**.
4. Do one of the following:
    - To mount a volume, click **Add**. Click **Mount in the following empty NTFS folder**, type the path to an empty folder on an NTFS volume, or click **Browse** to locate it.
    - To unmount a volume, click it and then click **Remove**.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- When you mount a local drive at an empty folder on an NTFS volume, Disk Management assigns a drive path to the drive rather than a drive letter. Drive paths are available only on empty folders on basic or dynamic NTFS volumes.
- If you are administering a local or remote computer, you can browse NTFS folders on that computer.
- When using server clusters, make sure that you create unique mounted drives so that they do not conflict with existing local drives on any node in the cluster.
- When using server clusters, do not create mounted drives between disks on the cluster storage device (cluster disks) and local disks.
- When using server clusters, do not create mounted drives from the cluster disk that contains the quorum resource (the quorum disk). You can, however, create a mounted drive from the quorum disk to a clustered disk.
- When using server clusters, mounted drives from one cluster disk to another must be in the same cluster resource group, and must be dependent on the root disk.

For more information on server clusters, see Server clusters overview.

- When creating mounted drives, use Event Viewer to check the system log for any Cluster service errors or warnings indicating mount point failures. These errors would be listed as ClusSvc in the Source column and Physical Disk Resource in the Category column.

  For more information on how to use Event Viewer to check the system log, see Event Viewer.

  For more information on how to resolve errors with mounted drives on server clusters, see Cluster disk and drive connection problems.

**Using a command line**

1. Open Command Prompt.

2. From the NTFS drive\folder that you want to mount elsewhere, type:

   **diskpart**.

3. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the number of the simple volume that you want to mount elsewhere.

4. At the **DISKPART** prompt, type:

   **select volume** *n*

   Select the simple volume, *n*, that you want to mount elsewhere.

5. At the **DISKPART** prompt, type:

   **assign** [**mount=***path*]

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |
| **assign** | Assigns a drive letter or mount point to the volume with focus. If no drive letter or mount point is specified, then the next available drive letter is assigned. If the drive letter or mount point is already in use, an error is generated.<br><br>Using the **assign** command, you can change the drive letter associated with a removable drive.<br><br>You cannot assign drive letters to system volumes, boot volumes, or volumes that contain the paging file. In addition, you cannot assign a drive letter to an Original Equipment Manufacturer (OEM) partition, EFI system partition, or any GPT partition other than a basic data partition. |
| **mount=** *path* | Specifies an empty, existing NTFS folder where the mounted drive will reside. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of

the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- Drive paths are available only on empty folders on basic or dynamic NTFS volumes.
- To modify a drive path, remove it and then create a new drive path using the new location. You cannot modify the drive path directly.
- When using server clusters, make sure that you create unique mounted drives so that they do not conflict with existing local drives on any node in the cluster.
- When using server clusters, do not create mounted drives between disks on the cluster storage device (cluster disks) and local disks.
- When using server clusters, do not create mounted drives from the cluster disk that contains the quorum resource (the quorum disk). You can, however, create a mounted drive from the quorum disk to a clustered disk.
- When using server clusters, mounted drives from one cluster disk to another must be in the same cluster resource group, and must be dependent on the root disk.

  For more information on server clusters, see Server clusters overview.
- When creating mounted drives, use Event Viewer to check the system log for any Cluster service errors or warnings indicating mount point failures. These errors would be listed as ClusSvc in the Source column and Physical Disk Resource in the Category column.

  For more information on how to use Event Viewer to check the system log, see Event Viewer.

  For more information on how to resolve errors with mounted drives on server clusters, see Cluster disk and drive connection problems.
- For more information about **DiskPart**, see Related Topics.
- You can also create a mounted drive using the **mountvol** command. For more information about **mountvol**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Format a dynamic volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To format a dynamic volume**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the volume you want to format (or reformat), and then click **Format**.
4. Select the options you want, and then click **OK**.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You cannot format the system or boot volume.
- Before you enable shadow copies on a volume, we recommend that you select a cluster size of 16 KB or larger. If you do not, the number of changes caused by defragmenting the volume might cause previous versions of files to be deleted.
- File compression is supported only on NTFS volumes with cluster sizes 4 KB and smaller.
- If you select the **Perform a quick format** check box, the files are removed from the disk but the disk is not scanned for bad sectors. Use this option only if this disk has been previously formatted and you are sure the disk is not damaged.
- Only the NTFS file system is available for dynamic volumes in Disk Management. However, you can format dynamic volumes with either the FAT or FAT32 file systems using the **format** command.

**Using a command line**

1. Open Command prompt.
2. Type:

   **format***volume*[**/fs:***filesystem*] [**/v:***label*] [**/q**] [**/a:***unitsize*] [**/c**]

| Value | Description |
| --- | --- |
| *Volume* | Specifies the mount point, volume name, or drive letter of the drive you want to format. If you do not specify any of the following command-line options, **format** uses the volume type to determine the default format for the disk. |
| **/fs:** *filesystem* | Specifies the file system to use FAT, FAT32, or NTFS. Floppy disks can use only the FAT file system. |
| **/v:** *label* | Specifies the volume label. If you omit the **/v** command-line option or use it without specifying a volume label, **format** prompts you for the volume label after the formatting is completed. Use the syntax **/v:** to prevent the prompt for a volume label. If you format more than one disk by using one **format** command, all of the disks will be given the same volume label. |
| **/q** | Performs a quick format. Deletes the file table and the root directory of a previously formatted volume but does not perform a sector by sector scan for bad areas. You should use the **/q** command-line option to format only previously formatted volumes that you know are in good condition. |
| **/a:** *unitsize* | Specifies the cluster size, also known as allocation unit size, to use on FAT, FAT32, or NTFS volumes. Use one of the following values for *unitsize*. If *unitsize* is not specified, it will be chosen based on volume size.<br><br>**512** - Creates 512 bytes per cluster.<br><br>**1024** - Creates 1024 bytes per cluster.<br><br>**2048** - Creates 2048 bytes per cluster.<br><br>**4096** - Creates 4096 bytes per cluster.<br><br>**8192** - Creates 8192 bytes per cluster.<br><br>**16K** - Creates 16 kilobytes per cluster.<br><br>**32K** - Creates 32 kilobytes per cluster.<br><br>**64K** - Creates 64 kilobytes per cluster. |
| **/c** | NTFS only. Files created on the new volume will be compressed by default. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You cannot format the system or boot volume.

- Quick format removes files from the disk but does not scan the disk for bad sectors. Use this option only if this disk has been previously formatted and you are sure the disk is not damaged.

- Before you enable shadow copies on a volume, we recommend that you select a cluster size of 16 KB or larger. If you do not, the number of changes caused by defragmenting the volume might cause previous versions of files to be deleted.

- File compression is supported only on NTFS volumes with cluster sizes 4 KB and smaller.

- For Windows NT 4.0, Windows 2000, Windows XP Professional, and Windows Server 2003 operating systems, the cluster size of FAT16 volumes from 2 GB through 4 GB is 64 KB, which can create compatibility issues with some applications. For example, setup programs do not compute free space properly on a volume with 64 KB clusters and cannot run because of a perceived lack of free space. For this reason, either FAT32 or NTFS must be used on volumes larger than 2 GB. **Format** displays a warning and asks for a confirmation before formatting a volume that has 64 KB clusters using FAT16.

- For more information about **format**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a dynamic volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To delete a dynamic volume

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the dynamic volume you want to delete, and then click **Delete Volume.**

   If the menu item reads **Delete Partition** instead of **Delete Volume**, the volume is a partition or logical drive. For instructions on how to delete a partition or logical drive, see Related Topics.

### Caution

- Use caution when deleting a volume. Deleting a simple volume, spanned volume, striped volume, mirrored volume, or RAID-5 volume deletes all the data on the volume as well the volume itself.
- You cannot recover deleted volumes.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You cannot delete the system volume, boot volume, or any volume that contains the active paging file or crash dump (memory dump).
- Dynamic simple, spanned, striped, mirrored, and RAID-5 volumes are not available on Windows XP Home Edition. Dynamic mirrored and RAID-5 volumes are not available on Windows XP Professional or Windows XP 64-bit Edition (Itanium).

#### Using a command line

1. Open Command prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the number of the dynamic volume you want to delete.

4. At the **DISKPART** prompt, type:

   **select volume***n*

   Select the dynamic volume, where *n* is the volume's number, that you want to delete.

5. At the **DISKPART** prompt, type:

   **delete volume**

   Deletes the selected dynamic volume.

**Caution**

- Use caution when deleting a volume. Deleting a simple volume, spanned volume, striped volume, mirrored volume, or RAID-5 volume deletes all the data on the volume as well the volume itself.

- You cannot recover deleted volumes.

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |
| **delete volume** | Deletes the selected volume. You cannot delete the system volume, boot volume, or any volume that contains the active paging file or crash dump (memory dump). |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You cannot delete the system volume, boot volume, or any volume that contains the active paging file or crash dump (memory dump).

- Dynamic simple, spanned, striped, mirrored, and RAID-5 volumes are not available on Windows XP Home Edition. Dynamic mirrored and RAID-5 volumes are not available on Windows XP Professional or Windows XP 64-bit Edition (Itanium).

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reactivate a dynamic volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To reactivate a dynamic volume

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. If the disk that contains the volume does not display the **Online** status, right-click the disk and then click **Reactivate Disk**.
4. Right-click the dynamic volume with **Failed** status, and then click **Reactivate Volume**.

   The volume should return to **Healthy** status.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- A dynamic disk may become **Missing** when it is corrupted, powered down, or disconnected.
- A dynamic disk may become **Offline** if it is corrupted or intermittently unavailable. A dynamic disk may also become **Offline** if you attempt to import a foreign (dynamic) disk and the import fails. Only dynamic disks display the **Offline** status.
- Only dynamic disks can be reactivated.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list disk**

Make note of the disk number of the missing or offline dynamic disk that you want to bring online. Missing disks are numbered M0, M1, M2, etc. and offline disks are numbered 0, 1, 2, etc.

4. At the **DISKPART** prompt, type:

   **select disk***n*

5. At the **DISKPART** prompt, type:

   **online**

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select disk** *n* | Sets the focus to the specified disk, where *n* is the disk number. |
| **online** | Brings an offline disk or volume with focus online. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- If the disk does not return to **Online** status, select the volume and then try the **online** command again.

- A dynamic disk may become **Missing** when it is corrupted, powered down, or disconnected.

- A dynamic disk may become **Offline** if it is corrupted or intermittently unavailable. A dynamic disk may also become **Offline** if you attempt to import a foreign (dynamic) disk and the import fails. Only dynamic disks display the **Offline** status.

- Only dynamic disks can be reactivated.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Simple Volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage simple volumes**

- Create a simple volume
- Extend a simple or spanned volume

# Create a simple volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a simple volume**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the unallocated space on the dynamic disk on which you want to create the simple volume, and then click **New Volume**.
4. In the New Volume Wizard, click **Next**, click **Simple**, and then follow the instructions on your screen.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can create simple volumes on dynamic disks only.
- You can extend a volume only if it does not have a file system or if it is formatted using the NTFS file system. You cannot extend volumes formatted using FAT or FAT32.
- You cannot extend a system volume, boot volume, striped volume, mirrored volume, or RAID-5 volume.
- You can extend simple or extended volumes that are not system or boot volumes, as long as there is available disk space. This includes volumes created as dynamic volumes or created as basic volumes and then converted to dynamic on Windows XP Professional or on Windows Server 2003 operating systems.
- If you upgraded from Windows 2000 to Windows XP Professional or Windows Server 2003 operating systems, you cannot extend a simple or spanned volume that was originally created as a basic volume and converted to a dynamic volume on Windows 2000.
- You can extend a simple volume onto additional dynamic disks to create a spanned volume. Spanned volumes cannot be mirrored.
- If you extend a spanned volume, you cannot delete any portion of it without deleting the entire spanned volume.
- Simple volumes are not fault tolerant.

- Simple volumes can only be accessed by Windows 2000, Windows XP Professional, and Windows Server 2003 operating systems. You should create basic volumes on basic disks if the computer also runs MS-DOS, Windows 95, Windows 98, Windows Millennium Edition, Windows NT 4.0, or Windows XP Home Edition because these operating systems cannot access dynamic volumes.

**Using a command line**

1. Open Command prompt.

2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk number of the disk where you want to create a simple volume.

4. At the **DISKPART** prompt, type:

   **create volume simple** [**size=***n*] [**disk=***n*]

5. At the **DISKPART** prompt, type:

   **assign letter**=*D*

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **create volume simple** | Creates a simple volume. After you create the volume, the focus automatically shifts to the new volume. |
| **size=** *n* | The size of the volume in megabytes (MB). If no size is given, the new volume takes up the remaining free space on the disk. |
| **disk=** *n* | The dynamic disk on which to create the volume. If no disk is given, the current disk is used. |
| **assign letter**=*D* | Assigns a drive letter, *D*, to the volume with focus. If no drive letter or mount point is specified, the next available drive letter is assigned. If the drive letter or mount point is already in use, an error is generated. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You can create simple volumes on dynamic disks only.

- You can extend a volume only if it does not have a file system or if it is formatted using the NTFS file system. You cannot

extend volumes formatted using FAT or FAT32.

- You cannot extend a system volume, boot volume, striped volume, mirrored volume, or RAID-5 volume.
- You can extend simple or extended volumes that are not system or boot volumes, as long as there is available disk space. This includes volumes created as dynamic volumes or created as basic volumes and then converted to dynamic on Windows XP Professional or on Windows Server 2003 operating systems.
- If you upgraded from Windows 2000 to Windows XP Professional or Windows Server 2003 operating systems, you cannot extend a simple or spanned volume that was originally created as a basic volume and converted to a dynamic volume on Windows 2000.
- You can extend a simple volume onto additional dynamic disks to create a spanned volume. Spanned volumes cannot be mirrored.
- If you extend a spanned volume, you cannot delete any portion of it without deleting the entire spanned volume.
- Simple volumes are not fault tolerant.
- Simple volumes can only be accessed by Windows 2000, Windows XP Professional, and Windows Server 2003 operating systems. You should create basic volumes on basic disks if the computer also runs MS-DOS, Windows 95, Windows 98, Windows Millennium Edition, Windows NT 4.0, or Windows XP Home Edition because these operating systems cannot access dynamic volumes.
- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Extend a simple or spanned volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To extend a simple or spanned volume**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the simple or spanned volume you want to extend, click **Extend Volume**, and then follow the instructions on your screen.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can extend a volume only if it does not have a file system or if it is formatted using the NTFS file system. You cannot extend volumes formatted using FAT or FAT32.
- You cannot extend a system volume, boot volume, striped volume, mirrored volume, or RAID-5 volume.
- You can extend simple or extended volumes that are not system or boot volumes, as long as there is available disk space. This includes volumes created as dynamic volumes or created as basic volumes and then converted to dynamic on Windows XP Professional or Windows Server 2003 operating systems.
- If you upgraded from Windows 2000 to Windows XP Professional or Windows Server 2003 operating systems, you cannot extend a simple or spanned volume that was originally created as a basic volume and converted to a dynamic volume on Windows 2000.
- You can extend a simple volume onto additional dynamic disks to create a spanned volume. Spanned volumes cannot be mirrored.
- If you extend a spanned volume, you cannot delete any portion of it without deleting the entire spanned volume.

**Using a command line**

1. Open Command prompt.
2. Type:

**diskpart**

3. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the number of the simple volume you want to extend onto another disk.

4. At the **DISKPART** prompt, type:

   **select volume***n*

   Selects the simple volume, *n*, you want to extend onto another disk.

5. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the number of the disk that you want to extend the simple volume onto.

6. At the **DISKPART** prompt, type:

   **extend** [**size=***n*] [**disk=***n*]

   Extends the selected volume onto disk *n*, and make the extension size=*n* megabytes (MB) in size.

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **extend** | Extends the volume with focus into next contiguous unallocated space. For basic volumes, the unallocated space must be on the same disk as, and must follow (be of higher sector offset than) the partition with focus. A dynamic simple or spanned volume can be extended to any empty space on any dynamic disk. Using this command, you can extend an existing volume into newly created space.<br><br>If the partition was previously formatted with the NTFS file system, the file system is automatically extended to occupy the larger partition. No data loss occurs. If the partition was previously formatted with any file system format other than NTFS, the command fails with no change to the partition.<br><br>You cannot extend the current system or boot partitions. |
| **disk=** *n* | The dynamic disk on which to extend the volume. An amount of space equal to **size=***n* is allocated on the disk. If no disk is specified, the volume is extended on the current disk. |
| **size=** *n* | The amount of space, in megabytes (MB), to add to the current partition. If you do not specify a size, the disk is extended to take up all of the next contiguous unallocated space. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of

the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- You can extend a volume only if it does not have a file system or if it is formatted using the NTFS file system. You cannot extend volumes formatted using FAT or FAT32.
- You cannot extend a system volume, boot volume, striped volume, mirrored volume, or RAID-5 volume.
- You can extend simple or extended volumes that are not system or boot volumes, as long as there is available disk space. This includes volumes created as dynamic volumes or created as basic volumes and then converted to dynamic on Windows XP Professional or Windows Server 2003 operating systems.
- If you upgraded from Windows 2000 to Windows XP Professional or Windows Server 2003 operating systems, you cannot extend a simple or spanned volume that was originally created as a basic volume and converted to a dynamic volume on Windows 2000.
- You can extend a simple volume onto additional dynamic disks to create a spanned volume. Spanned volumes cannot be mirrored.
- If you extend a spanned volume, you cannot delete any portion of it without deleting the entire spanned volume.
- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Spanned Volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage spanned volumes**

- Create a spanned volume
- Extend a simple or spanned volume

# Create a spanned volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To create a spanned volume

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the unallocated space on one of the dynamic disks where you want to create the spanned volume, and then click **New Volume**.
4. In the New Volume Wizard, click **Next**, click **Spanned**, and then follow the instructions on your screen.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can create spanned volumes on dynamic disks only.
- You need at least two dynamic disks to create a spanned volume.
- You can extend a spanned volume onto a maximum of 32 dynamic disks.
- Spanned volumes cannot be mirrored.
- Spanned volumes are not fault tolerant.

#### Using a command line

1. Open Command prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list disk**

Make note of the disk number of the disk where you want to create a simple volume.

4. At the **DISKPART** prompt, type:

   **create volume simple** [**size=***n*] [**disk=***n*]

5. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the number of the simple volume you want to extend onto another disk.

6. At the **DISKPART** prompt, type:

   **select volume***n*

   Selects the simple volume, *n*, you want to extend onto another disk.

7. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the number of the disk that you want to extend the simple volume onto.

8. At the **DISKPART** prompt, type:

   **extend** [**size=***n*] [**disk=***n*]

   Extends the selected volume onto disk *n*, and make the extension size=*n* megabytes (MB) in size.

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **create volume simple** | Creates a simple volume. After you create the volume, the focus automatically shifts to the new volume. |
| **size=** *n* | The size of the volume in megabytes (MB). If no size is given, the new volume takes up the remaining free space on the disk. |
| **disk=** *n* | The dynamic disk on which to create the volume. If no disk is given, the current disk is used. |
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |

| | |
|---|---|
| **extend** | Extends the volume with focus into next contiguous unallocated space. For basic volumes, the unallocated space must be on the same disk as, and must follow (be of higher sector offset than) the partition with focus. A dynamic simple or spanned volume can be extended to any empty space on any dynamic disk. Using this command, you can extend an existing volume into newly created space.<br><br>If the partition was previously formatted with the NTFS file system, the file system is automatically extended to occupy the larger partition. No data loss occurs. If the partition was previously formatted with any file system format other than NTFS, the command fails with no change to the partition.<br><br>You cannot extend the current system or boot partitions. |
| **disk=** *n* | The dynamic disk on which to extend the volume. An amount of space equal to **size=***n* is allocated on the disk. If no disk is specified, the volume is extended on the current disk. |
| **size=** *n* | The amount of space, in megabytes (MB), to add to the current partition. If you do not specify a size, the disk is extended to take up all of the next contiguous unallocated space. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You can create simple volumes on dynamic disks only.

- You can extend a volume only if it does not have a file system or if it is formatted using the NTFS file system. You cannot extend volumes formatted using FAT or FAT32.

- You cannot extend a system volume, boot volume, striped volume, mirrored volume, or RAID-5 volume.

- You can extend simple or extended volumes that are not system or boot volumes, as long as there is available disk space. This includes volumes created as dynamic volumes or created as basic volumes and then converted to dynamic on Windows XP Professional or Windows Server 2003 operating systems.

- If you upgraded from Windows 2000 to Windows XP Professional or Windows Server 2003 operating systems, you cannot extend a simple or spanned volume that was originally created as a basic volume and converted to a dynamic volume on Windows 2000.

- You can extend a simple volume onto additional dynamic disks to create a spanned volume. Spanned volumes cannot be mirrored.

- If you extend a spanned volume, you cannot delete any portion of it without deleting the entire spanned volume.

- Simple volumes are not fault tolerant.

- Simple volumes can only be accessed by Windows 2000, Windows XP Professional, and Windows Server 2003 operating systems. You should create basic volumes on basic disks if the computer also runs MS-DOS, Windows 95, Windows 98, Windows Millennium Edition, Windows NT 4.0, or Windows XP Home Edition because these operating systems cannot access dynamic volumes.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Extend a simple or spanned volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To extend a simple or spanned volume**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the simple or spanned volume you want to extend, click **Extend Volume**, and then follow the instructions on your screen.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can extend a volume only if it does not have a file system or if it is formatted using the NTFS file system. You cannot extend volumes formatted using FAT or FAT32.
- You cannot extend a system volume, boot volume, striped volume, mirrored volume, or RAID-5 volume.
- You can extend simple or extended volumes that are not system or boot volumes, as long as there is available disk space. This includes volumes created as dynamic volumes or created as basic volumes and then converted to dynamic on Windows XP Professional or Windows Server 2003 operating systems.
- If you upgraded from Windows 2000 to Windows XP Professional or Windows Server 2003 operating systems, you cannot extend a simple or spanned volume that was originally created as a basic volume and converted to a dynamic volume on Windows 2000.
- You can extend a simple volume onto additional dynamic disks to create a spanned volume. Spanned volumes cannot be mirrored.
- If you extend a spanned volume, you cannot delete any portion of it without deleting the entire spanned volume.

**Using a command line**

1. Open Command prompt.
2. Type:

**diskpart**

3. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the number of the simple volume you want to extend onto another disk.

4. At the **DISKPART** prompt, type:

   **select volume***n*

   Selects the simple volume, *n*, you want to extend onto another disk.

5. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the number of the disk that you want to extend the simple volume onto.

6. At the **DISKPART** prompt, type:

   **extend** [**size=***n*] [**disk=***n*]

   Extends the selected volume onto disk *n*, and make the extension size=*n* megabytes (MB) in size.

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **extend** | Extends the volume with focus into next contiguous unallocated space. For basic volumes, the unallocated space must be on the same disk as, and must follow (be of higher sector offset than) the partition with focus. A dynamic simple or spanned volume can be extended to any empty space on any dynamic disk. Using this command, you can extend an existing volume into newly created space.<br><br>If the partition was previously formatted with the NTFS file system, the file system is automatically extended to occupy the larger partition. No data loss occurs. # Create a striped volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a striped volume**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click unallocated space on one of the dynamic disks on which you want to create the striped volume, and then click **New Volume**.
4. In the New Volume Wizard, click **Next**, click **Striped**, and then follow the instructions on your screen.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You need at least two dynamic disks to create a striped volume. You can create a striped volume onto a maximum of 32 disks.
- Striped volumes are not fault tolerant and cannot be extended or mirrored.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk number of the disk on which you want to create a striped volume.

4. At the **DISKPART** prompt, type:

**create volume stripe** [**size=***n*] [**disk=***n*[,[*n*,...]]

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **create volume stripe** | Creates a striped volume on the specified disks. After you create the volume, the focus automatically shifts to the new volume. |
| **size=** *n* | The amount of disk space, in megabytes (MB), that the volume will occupy on each disk. If no size is given, the new volume takes up the remaining free space on the smallest disk and an equal amount of space on each subsequent disk. |
| **disk=** *n* | The dynamic disks on which to create the volume. An amount of space equal to **size=***n* is allocated on each disk. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You need at least two dynamic disks to create a striped volume. You can create a striped volume onto a maximum of 32 disks.

- Striped volumes are not fault tolerant and cannot be extended or mirrored.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Mirrored Volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage mirrored volumes**

- Create a mirrored volume
- Create and test a mirrored system or boot volume
- Add a mirror to an existing simple volume
- Break a mirrored volume into two volumes
- Remove a mirror from a mirrored volume
- Reconnect the disk and repair the mirrored volume
- Reactivate a mirrored volume
- Replace a failed mirror with a new mirror on another disk

# Create a mirrored volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a mirrored volume**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the unallocated space on one of the dynamic disks on which you want to create the mirrored volume, and then click **New Volume**.
4. In the New Volume Wizard, click **Next**, click **Mirrored**, and then follow the instructions on your screen.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can create mirrored volumes only on computers running Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, or Windows Server 2003 operating systems.
- You need two dynamic disks to create a mirrored volume.
- You can mirror an existing simple volume.
- Mirrored volumes are fault tolerant and use RAID-1, which provides redundancy by creating two identical copies of a volume.
- Mirrored volumes cannot be extended.
- Both copies (mirrors) of the mirrored volume share the same drive letter.
- You can create mirrored, striped, spanned and RAID-5 volumes using a combination of MBR and GPT disks, but the MBR cylinder-alignment restriction may cause some difficulties in creating mirrored volumes. Always mirror the MBR disk to the GPT disk to avoid cylinder-alignment difficulties.

**Using a command line**

1. Open Command Prompt.

2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk numbers for the dynamic disks that will make up the mirrored volume.

4. At the **DISKPART** prompt, type:

   **select disk** *n*

5. At the **DISKPART** prompt, type:

   **create volume simple** [**size=***n*] [**disk=***n*]

6. At the **DISKPART** prompt, type:

   **add disk** *n*

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select disk** | Selects the specified disk, where *n* is the disk number, and gives it focus. |
| **create volume simple** | Creates a simple volume. After you create the volume, the focus automatically shifts to the new volume. |
| **size=** *n* | The size of the volume in megabytes (MB). If no size is given, the new volume takes up the remaining free space on the disk. |
| **disk=** *n* | The dynamic disk on which to create the volume. If no disk is given, the current disk is used. |
| **add disk=** *n* | Mirrors the simple volume with focus to the specified disk, where *n* is the disk number. The specified disk must have unallocated space at least as large as the size of the simple volume you want to mirror. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You can create mirrored volumes only on computers running Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, or Windows Server 2003 operating systems.

- You need at least two dynamic disks to create a mirrored volume.

- Mirrored volumes are fault tolerant and use RAID-1, which provides redundancy by creating two identical copies of a volume.

- Mirrored volumes cannot be extended.

- Both copies (mirrors) of the mirrored volume share the same drive letter.

- You can create mirrored, striped, spanned and RAID-5 volumes using a combination of MBR and GPT disks, but the MBR cylinder alignment-restriction may cause some difficulties in creating mirrored volumes. Always mirror the MBR disk to the GPT disk to avoid cylinder-alignment difficulties.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create and test a mirrored system or boot volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create and test a mirrored system or boot volume (32-bit only)**
To ensure that your x86-based computer can load Windows if one of the disks or controllers fails, you can mirror the system volume. This makes an exact copy of the volume that contains the hardware-specific files needed to load Windows. You can also mirror the boot volume. This makes an exact copy of the volume that contains the Windows operating system.

- To create a mirrored system or boot volume
- To test a mirrored system or boot volume

**To create a mirrored system or boot volume**

1. Print this procedure or write down the steps before attempting to create a mirrored system or boot volume.
2. Read and understand all of the information in the **Important** and **Notes** sections.
3. Open Computer Management (Local).
4. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
5. If the system or boot volume already resides on a dynamic disk, skip to step 6. Otherwise, you must convert the disk to a dynamic disk before you can mirror it.

   **How?**

   a. Right-click the disk that contains the system or boot volume and click **Convert to Dynamic Disk**.

      **Caution**

      Do not convert basic disks to dynamic disks if they contain multiple operating systems (for example, the disk is set up to dual boot with another operating system). After the disk is converted to dynamic you can start the operating system that you used to convert the disk, but you will not be able to start the other operating system(s) on the disk.

   b. In the **Convert to Dynamic Disk** dialog box, select the basic disk you want to convert to dynamic and then click **OK**.

   c. In the **Disks to Convert** dialog box, click **Convert**.

   d. In the **Disk Management** dialog, click **Yes**.

   e. In the **Convert Disk to Dynamic** dialog box, click **Yes**.

   f. In the **Confirm** dialog box, click **OK** to restart your computer.

   g. After your computer restarts, log on. On the **System Settings Change** dialog box, click **Yes** to restart your computer again.

   h. After your computer restarts, log on.

   i. Open Computer Management (Local).

   j. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.

Continue to step 6.

6. Right-click the system or boot volume and click **Add Mirror**.

7. In the **Add Mirror** dialog box, select an unallocated dynamic disk with enough free space to mirror the system or boot volume and click **Add Mirror**.

   Disk Management resynchronizes both disks. When resynchronization is complete, the system or boot volume is a fault-tolerant mirrored volume.

**Important**

- Because a problem might go undetected until you try to restart the computer from the second disk, you must create a Windows startup floppy disk that you can use to start Windows on the remaining mirror. In addition, you should recreate your startup floppy disk after you add or remove volumes on the disk that contains the boot volume, after you convert the disk to dynamic, or after you install a Windows service pack.

- Consider creating an Automated System Recovery (ASR) set that you can use to restore the computer in case both halves of the mirrored system or boot volume become damaged. For more information about how to create an Automated System Recovery set, see Related Topics.

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- For additional information about converting basic disks to dynamic disks, see Related Topics.

- After you convert a basic disk to a dynamic disk, you cannot change the dynamic volumes back to partitions. Instead, you must delete all dynamic volumes on the disk and then use the **Convert To Basic Disk** command. If you want to keep your data, you must first back it up or move it to another volume. For more information about the **Convert To Basic Disk** command, see Related Topics.

- Before you convert disks, close any programs that are running on those disks.

- Once converted, a dynamic disk will not contain basic volumes (primary partitions or logical drives), nor can it be accessed by MS-DOS, Windows 95, Windows 98, Windows Millennium Edition, Windows NT, or Windows XP Home Edition operating systems. You can access dynamic disks only with computers running Windows 2000, Windows XP Professional, or Windows Server 2003 operating systems.

- When you convert a basic disk to a dynamic disk, any existing partitions or logical drives on the basic disk become simple volumes on the dynamic disk.

- Do not convert basic disks to dynamic disks if they contain multiple operating systems (for example, the disk is set up to dual boot with another operating system). After the disk is converted to dynamic you will be able to start the operating system that you used to convert the disk, but you will not be able to start the other operating system(s) on the disk.

- For the conversion to succeed, any master boot record (MBR) disks to be converted must contain at least 1 MB of free space at the end of the disk for the dynamic disk database. Windows 2000, Windows XP Professional, and Windows Server 2003 operating systems automatically reserve this space when creating partitions or volumes on a disk, but disks with partitions or volumes created by other operating systems might not have this space available. (This space might

exist even if it is not visible in Disk Management.)

- You can create mirrored volumes only on computers running Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, or Windows Server 2003 operating systems.
- You need two dynamic disks to create a mirrored volume.
- Mirrored volumes are fault tolerant and use RAID-1, which provides redundancy by creating two identical copies of a volume.
- Mirrored volumes cannot be extended.
- Both copies (mirrors) of the mirrored volume share the same drive letter and mount points.
- You can mirror the system and boot volumes to a different disk on the same controller or to a different disk on a different controller. Using one controller per disk is referred to as duplexing.
- Before you mirror the system or boot volume in an x86-based computer, you must note the following guidelines:
    - Using Advanced Technology Attachment (ATA) disks for a mirrored system volume is supported, but the recovery procedure is more complicated when the master disk on the primary integrated device electronics (IDE) channel fails. In this case, you must move the disk with the remaining mirror to the primary IDE channel and set its jumper to master position.
    - Do not mirror the system volume by using an ATA disk with a SCSI disk because startup problems can occur if one of the disks fails.
    - If you use duplexed SCSI controllers, use identical controllers from the same manufacturer.
    - To ensure that the computer can start from the remaining mirror, you must test the mirrored system volume before a failure.
- For more information about how to mirror the system or boot volume, see "Disk Management" at the Microsoft Resource Kits Web site.

**To test a mirrored system or boot volume**

1. Print this procedure or write down the steps before testing a mirrored system or boot volume.
2. Read and understand all of the information in the **Notes** section.
3. Shut down the computer, and then disconnect or turn off one of the disks to simulate the failure of a disk.
4. Restart the computer by using the remaining mirror.
5. After you verify that Windows starts correctly, shut down the computer and reconnect the disk.
6. Restart the computer. When the boot menu appears, select the mirror on the disk that remained connected.
7. Open Computer Management (Local).
8. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
9. Right-click the disk that has any of the volumes marked **Failed Redundancy**, and then click **Reactivate Disk**.
10. After the mirrors are resynchronized, shut down the computer and repeat steps 1 through 9 using the other disk.

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- In Steps 4 and 6, the Windows can start from the remaining mirror if all of the following conditions are met:

    - In SCSI systems, the remaining disk must be the first disk specified by the SCSI controller. If other disks are present and the remaining mirror is on the same SCSI controller as the failed disk, the BIOS for that controller must support specifying the boot device from any disk on the controller. If other disks are present and the remaining mirror is on a different controller, the original controller must support turning off the BIOS, and the mirror's controller must support specifying the boot device from any disk on the controller.

    - In SCSI systems, both SCSI controllers must have translation options set identically, either both enabled or both disabled.

    - In IDE systems, the disk that contains the remaining mirror must be the master disk on the primary IDE controller. You can move the remaining disk to this position if the master disk on the primary controller fails. Set the jumper to the master position, if necessary.

    - The disk remaining after a failure must contain a valid system volume that is marked active and must contain a valid Boot.ini file along with Ntldr and Ntdetect.com.

- When you mirror the boot volume, operating systems in the Windows Server 2003 family usually automatically update Boot.ini. If Windows cannot update Boot.ini, as when the BIOS for the second SCSI controller is disabled, you see a message instructing you to update Boot.ini manually. Therefore, to ensure that the computer can start from the remaining mirror, you need to verify that the information in Boot.ini is correct before a failure occurs, especially if you manually make changes to Boot.ini.

  For example, if you use the Signature syntax to specify the disk that contains the boot volume and that disk fails, the computer does not start because the system is looking for the disk with this particular signature. For this reason, you need to use Multi syntax to specify the disk that contains the boot volume. For more information about Boot.ini, Signature syntax, and Multi syntax, see "Troubleshooting Startup" at the Microsoft Resource Kits Web site.

- When you break a mirrored system or boot volume using the Disk Management snap-in, you must select the disk in the mirrored volume that was used to start the computer. Disk Management retains the volume on the selected disk, which keeps its drive letter and becomes a simple volume. The other disk in the mirrored system or boot volume receives the next available drive letter and becomes a new simple volume.

  When breaking a mirrored system or boot volume using the DiskPart command, however, you must specify the disk in the mirrored system or boot volume that was not used to start the computer. The disk used to start the computer keeps the mirrored volume's drive letter and becomes a simple volume, while the specified disk receives the next available drive letter and becomes a simple volume.

- For more information about how to test a mirrored the system or boot volume, see "Disk Management" at the Microsoft Resource Kits Web site.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create or break a mirrored boot volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create or break a mirrored boot volume (Itanium-based computers only)**
To ensure that your Itanium-based computer can load Windows if one of the disks or controllers fails, you can add a mirror to the boot volume, which makes an exact copy of the volume that contains the Windows operating system.

- To create a mirrored boot volume
- To break a mirrored boot volume

**To create a mirrored boot volume**

1. Print this procedure or write down the steps before attempting to create a mirrored system or boot volume.
2. Read and understand all of the information in the **Important** and **Notes** sections. In this procedure, disk 0 is the boot disk and disk 1 is the disk that you will mirror to the boot disk.
3. Before performing this procedure, make sure that the boot entries in NVRAM are in the following order:
   - EFI
   - OEM (optional)
   - MSR
   - Unknown OEM (platform flag is not set)
4. Open **Command Prompt** (click **Start**, click **Run**, and then type **cmd**).
5. Type:

   **diskpart**
6. At the DISKPART prompt, type:

   **list disk**

   Make note of the disk numbers for the dynamic disks that will make up the mirrored volume.
7. At the DISKPART prompt, type:

   **select disk 1**

   Disk 1 is an empty disk that you will mirror to the boot disk.
8. At the DISKPART prompt, type:

   **clean**
9. At the DISKPART prompt, type:

**convert gpt**

10. Delete the Microsoft Reserved (MSR) partition. At the DISKPART prompt, type:

    **select partition 1**

11. At the DISKPART prompt, type:

    **delete partition override**

12. Determine the size of the Extensible Firmware Interface (EFI) partition and the MSR partition on the boot disk. At the DISKPART prompt, type:

    **select disk 0**

13. List the partitions on disk 0. At the DISKPART prompt, type:

    **list partition**

14. Switch to disk 1. At the DISKPART prompt, type:

    **select disk 1**

15. Create an EFI partition of the same size as that on disk 0. At the DISKPART prompt, type:

    **create partition efi size=**

16. Create an MSR partition of the same size as that on disk 0. At the DISKPART prompt, type:

    **create partition msr size=**

17. Mount the EFI partition on disk 0. At the DISKPART prompt, type:

    **select disk 0**

18. At the DISKPART prompt, type:

    **select partition 1**

19. At the DISKPART prompt, type:

    **assign letter=m**

20. Mount the EFI partition on disk 1. At the DISKPART prompt, type:

    **select disk 1**

21. At the DISKPART prompt, type:

    **select partition 1**

22. At the DISKPART prompt, type:

    **assign letter=n**

23. At the DISKPART prompt, type:

**exit**

24. Format the EFI on disk 1. At the command prompt, type:

    **format n:/fs:FAT /q /y**

25. Copy all contents from the EFI on disk 0 to the EFI on disk 1. Use the **/h** option to copy the hidden files. At the command prompt, type:

    **xcopym:*.* n:\ /s /h**

26. Convert disk 0 and disk 1 to dynamic disks. At the command prompt, type:

    **diskpart**

27. At the DISKPART prompt, type:

    **select disk=1**

28. At the DISKPART prompt, type:

    **convert dynamic**

29. At the DISKPART prompt, type:

    **select disk=0**

30. At the DISKPART prompt, type:

    **convert dynamic**

    DiskPart displays the following message:

    **You must reboot your computer to complete this operation.**

31. At the DISKPART prompt, type:

    **exit**

32. Restart the computer. Wait for Windows to load and to prompt you to restart the computer a second time to complete the conversion of the boot disk to dynamic.

33. Add a mirror to the boot volume. At the command prompt, type:

    **diskpart**

34. At the DISKPART prompt, type:

    **select volume=c**

    Drive letter C is the boot volume, which is mirrored to disk 1 in the next step.

35. At the DISKPART prompt, type:

    **add disk=1**

Wait for the volume to synchronize.

36. At the DISKPART prompt, type:

    **exit**

37. Verify that there are 2 boot entries. At the command prompt, type:

    **bootcfg**

    The first entry is to boot to the first disk with the original EFI on disk 0. The second entry is to boot to the second disk with the original EFI on disk 0.

38. Clone the EFI partition. At the command prompt, type:

    **bootcfg /list**

    Write down the first EFI partition's globally unique identifier (GUID). You will need this in step 40.

39. Clone the EFI partition. At the command prompt, type:

    **bootcfg /list 1**

    Write down the second EFI partition's GUID. You will need this in step 40.

40. At the command prompt, type:

    **bootcfg /clone /sg** *GUID 1***/tg** *GUID 2***/d+ clone_entry**

    Use double quotes if the description (**/d** argument) has spaces.

41. Verify that the **bootcfg /clone** command created two entries in NVRAM. At the command prompt, type:

    **bootcfg**

    There should be 2 new entries, 4 total: two entries that use the EFI on disk 0, and two entries that use the EFI on disk 1.

**Important**

- Consider creating an Automated System Recovery (ASR) set that you can use to restore the computer in case both halves of the mirrored system or boot volume become damaged. For more information about how to create an Automated System Recovery set, see Related Topics.

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- For additional information about converting basic disks to dynamic disks, see Related Topics.

- After you convert a basic disk to a dynamic disk, you cannot change the dynamic volumes back to partitions. Instead, you must delete all dynamic volumes on the disk and then use the **Convert To Basic Disk** command. If you want to keep

your data, you must first back it up or move it to another volume. For more information about the **Convert To Basic Disk** command, see Related Topics.

- Before you convert disks, close any programs that are running on those disks.

- Once converted, a dynamic disk will not contain basic volumes (primary partitions or logical drives), nor can it be accessed by MS-DOS, Windows 95, Windows 98, Windows Millennium Edition, Windows NT, or Windows XP Home Edition operating systems. You can access dynamic disks only with computers running Windows 2000, Windows XP Professional, or Windows Server 2003 operating systems.

- When you convert a basic disk to a dynamic disk, any existing partitions or logical drives on the basic disk become simple volumes on the dynamic disk.

- Do not convert basic disks to dynamic disks if they contain multiple operating systems (for example, if the disk is set up to dual boot with another operating system). After the disk is converted to dynamic, you will be able to start the operating system that you used to convert the disk, but you will not be able to start the other operating system(s) on the disk.

- For the conversion to succeed, any master boot record (MBR) disks to be converted must contain at least 1 MB of free space at the end of the disk for the dynamic disk database. Windows 2000, Windows XP Professional, and Windows Server 2003 operating systems automatically reserve this space when creating partitions or volumes on a disk, but disks with partitions or volumes created by other operating systems might not have this space available. (This space might exist even if it is not visible in Disk Management.)

- If there are any known original equipment manufacturer (OEM) partitions on the disk, they remain as basic partitions when you convert the disk to dynamic.

- You can create mirrored volumes only on computers running Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, or Windows Server 2003 operating systems.

- You need two dynamic disks to create a mirrored volume.

- Mirrored volumes are fault tolerant and use RAID-1, which provides redundancy by creating two identical copies of a volume.

- Mirrored volumes cannot be extended.

- Both copies (mirrors) of the mirrored volume share the same drive letter and mount points.

- You can mirror the system and boot volumes to a different disk on the same controller or to a different disk on a different controller. Using one controller per disk is referred to as duplexing.

- Before you mirror the system or boot volume in an x86-based computer, you must note the following guidelines:

    - Using Advanced Technology Attachment (ATA) disks for a mirrored system volume is supported, but the recovery procedure is more complicated when the master disk on the primary integrated device electronics (IDE) channel fails. In this case, you must move the disk with the remaining mirror to the primary IDE channel and set its jumper to master position.

    - Do not mirror the system volume by using an ATA disk with a SCSI disk because startup problems can occur if one of the disks fails.

    - If you use duplexed SCSI controllers, use identical controllers from the same manufacturer.

    - To ensure that the computer can start from the remaining mirror, you must test the mirrored system volume before a failure.

**To break a mirrored boot volume**

When you no longer require a mirrored boot volume or when a disk failure occurs, you can use this procedure to break the mirrored boot volume.

1. Remove the disk that is no longer on the system. At the command prompt, type:

   **diskpart**

2. At the DISKPART prompt, type:

   **list disk**

   Note the disk number of the disk that is missing. You will need this disk number in step 4.

3. At the DISKPART prompt, type:

   **select volume=c**

4. At the DISKPART prompt, type:

   **break disk=***disk number* **nokeep**

5. At the DISKPART prompt, type:

   **list volume**

6. Verify that disk 0 is removed from the mirror and the existing disk is now a simple volume.

7. At the DISKPART prompt, type:

   **exit**

8. Clean up the boot configuration entries from the deleted disk. At the command prompt, type:

   **bootcfg**

   Note the entries in the boot list that are no longer valid (for example, ID 1) These are the entries that boot from the original EFI partition, not the new EFI partition.

# Add a mirror to an existing simple volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a mirror to an existing simple volume**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the simple volume you want to mirror, click **Add Mirror**, and then follow the instructions on your screen.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can mirror volumes only on computers running Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, or Windows Server 2003 operating systems.
- Any existing simple volume can be mirrored onto another dynamic disk, as long as there is sufficient unallocated space on that disk. If you do not have a dynamic disk with enough unallocated space, the **Add Mirror** menu item is unavailable. (To verify you have enough space, right-click the disk, click **Properties**, and then check the size in **Unallocated Space**. This size may be slightly smaller than shown in the graphical and list views.)
- You need at least two dynamic disks to create a mirrored volume.
- Mirrored volumes are fault tolerant and use RAID-1, which provides redundancy by creating two identical copies of a volume.
- Mirrored volumes cannot be extended.
- Both copies (mirrors) of the mirrored volume share the same drive letter.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the number of the simple volume that you want to mirror onto another disk.

4. At the **DISKPART** prompt, type:

   **select volume***n*

   Select the simple volume, *n*, you want to mirror onto another disk.

5. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk number of the disk on which you want to mirror the volume.

6. At the **DISKPART** prompt, type:

   **add disk***n*

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **add disk** *n* | Mirrors the simple volume with focus to the specified disk. The specified disk must have unallocated space at least as large as the size of the simple volume you want to mirror. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You can mirror volumes only on computers running Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, or Windows Server 2003 operating systems.

- You need at least two dynamic disks to create a mirrored volume.

- Mirrored volumes are fault tolerant and use RAID-1, which provides redundancy by creating two identical copies of a volume.

- Mirrored volumes cannot be extended.

- Both copies (mirrors) of the mirrored volume share the same drive letter.
- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Break a mirrored volume into two volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To break a mirrored volume into two volumes**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click one of the volume copies in the mirrored volume, and then click **Break Mirrored Volume**.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- When you break a mirrored volume, the two volume copies that made up the mirrored volume become two independent simple volumes. These volumes are no longer fault tolerant. One of the volumes retains the drive letter or mount point, while the other volume is assigned the next available drive letter.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the number of the mirrored volume.

4. At the **DISKPART** prompt, type:

   **select volume** *n*

   Select the mirrored volume you want to break into two separate volumes.

5. At the **DISKPART** prompt, type:

**detail volume**

Make note of the disk number of the mirrored volume you want to break into two separate volumes.

6. At the **DISKPART** prompt, type:

   **break disk** *n*

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |
| **detail volume** | Displays the disks on which the current volume resides. |
| **break disk** *n* | Applies to dynamic disks only. Breaks a mirrored volume into two simple volumes. These volumes are no longer fault tolerant. The disk specified by *n* receives the focus so you can assign it a drive letter. If the specified disk is the current system or boot disk, the command fails. The other disk retains the drive letter and any mount points that belonged to the mirrored volume. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove a mirror from a mirrored volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To remove a mirror from a mirrored volume

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the mirror you want to remove, click **Remove Mirror**, and then follow the instructions on your screen.

### Important

- Once you remove a mirror from a mirrored volume, the removed mirror becomes unallocated space and the remaining mirror becomes a simple volume that is no longer fault tolerant. All of the data on the removed mirror is deleted.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can only regenerate mirrored volumes with **Failed Redundancy** status. If the mirrored volume has **Failed** status, try to return it to **Failed Redundancy** status by using the **Reactivate Disk** command on the remaining disks.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the volume number of the mirrored volume.

4. At the **DISKPART** prompt, type:

**select volume** *n*

5. At the **DISKPART** prompt, type:

   **detail volume**

   Make note of the disk number that specifies the half of the mirrored volume you want to remove and convert to free space.

6. At the **DISKPART** prompt, type:

   **break disk** *n* [**nokeep**]

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** *n* | Selects the specified volume and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. You can view the numbers of all volumes on the computer by using the **list volume** command. |
| **detail volume** | Displays the disks on which the current volume resides. |
| **break disk** *n* | Applies to dynamic disks only. Breaks a mirrored volume into two simple volumes. These volumes are no longer fault tolerant. The disk specified by *n* receives the focus so you can assign it a drive letter. If the specified disk is the current system or boot disk, the command fails. The other disk retains the drive letter and any mount points that belonged to the mirrored volume.<br><br>Using the **nokeep** parameter, the specified disk, *n*, is deleted and converted to free space, while the other half of the mirror is retained as a simple volume. Neither volume receives focus. |
| **Nokeep** | Specifies that only one of the mirrored volumes retained; the other simple volume is deleted and converted to free space. Neither volume receives the focus. |

**Important**

- Once you remove a mirror from a mirrored volume, the removed mirror becomes unallocated space and the remaining mirror becomes a simple volume that is no longer fault tolerant. All of the data on the removed mirror is deleted.

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You can only regenerate mirrored volumes with **Failed Redundancy** status. If the mirrored volume has **Failed** status, try to return it to **Failed Redundancy** status by using the **DiskPart online** command on the remaining disks.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reconnect the disk and repair the mirrored volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reconnect the disk and repair the mirrored volume**

A disk containing part of a mirrored volume has been disconnected. Try to reconnect and reactivate the disk.

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Make sure that the physical disk is turned on, plugged in, and attached to the computer. If necessary, turn on or reattach the physical disk.
2. Open Computer Management (Local).
3. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
4. Right-click the Missing or Offline disk, and then click **Reactivate Disk**.

   If the disk does not return to **Online** status or if the volume does not return to **Healthy** status, see Replace a failed mirror with a new mirror on another disk.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Using a command line**

1. Make sure that the physical disk is turned on, plugged in, and attached to the computer. If necessary, turn on or reattach the physical disk.
2. Open Command Prompt.
3. Type:

   **diskpart**

4. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk number for the disk with **Offline** status.

5. At the **DISKPART** prompt, type:

**select disk***n*

Select the disk with **Offline** status.

6. At the **DISKPART** prompt, type:

   **online**

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select disk** | Selects the specified disk, where *n* is the disk number, and gives it focus. |
| **online** | Brings an offline disk or volume with focus online. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reactivate a mirrored volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reactivate a mirrored volume**

If the I/O errors are transient, you can try to reactivate the disk.

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the partially failed disk, and then click **Reactivate Disk**.

   The mirrored volume's status should change to **Regenerating**, then **Healthy**.

   If the disk containing part of the mirrored volume does not return to **Healthy** status, see Replace a failed mirror with a new mirror on another disk.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk number for the disk with **Offline** status.

4. At the **DISKPART** prompt, type:

   **select disk***n*

   Select the disk with **Offline** status.

5. At the **DISKPART** prompt, type:

   **online**

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select disk** | Selects the specified disk, where *n* is the disk number, and gives it focus. |
| **online** | Brings an offline disk or volume with focus online. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- For more information about **DiskPart**, see Related Topics.

# Replace a failed mirror with a new mirror on another disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To replace the failed mirror with a new mirror on another disk**
If the disk containing part of the mirrored volume is missing and the volume does not return to **Healthy** status, you should replace the failed mirror with a new mirror on another disk.

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the mirror on the **Missing** or **Offline** disk, and then click **Remove Mirror**. Follow the instructions on your screen.
4. Right-click the volume to be re-mirrored, and then click **Add Mirror**. Follow the instructions on your screen.

### Important

- Before installing a new disk, break the mirror and then examine the system log to see if the disk or the disk controller is failing. If the failing mirror is on a controller that is failing, installing a new disk on the failing controller will not solve the problem. For instructions describing how to open Event Viewer to examine the system log, see Related Topics.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- To replace a mirror in the mirrored volume, you must have a dynamic disk with unallocated space that is at least as large as the region to repair. If you do not have a dynamic disk with enough unallocated space, the **Add Mirror** command is unavailable. (To verify you have enough space, right-click the disk, click **Properties**, and then check the size in **Unallocated space**. This size may be slightly smaller than shown in the graphical and list views.)
- If you are replacing one of the disks in a mirrored system volume, be sure to use an identical disk to the one you are replacing. Otherwise, startup problems might occur if the disks use different geometries or if the system volumes are at different offsets on the disks. Always test your configuration by attempting to start the operating system from each volume to ensure that the operating system can actually start if one of the disks fails. For more information about mirroring the system volume, see "Disk Management" at the Microsoft Windows Resource Kits Web site.

**Using a command line**

1. Open Command Prompt.

2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the volume number of the mirrored volume.

4. At the **DISKPART** prompt, type:

   **select volume** *n*

5. At the **DISKPART** prompt, type:

   **detail volume**

   Make note of the disk number that specifies the half of the mirrored volume you want to remove and convert to free space.

6. At the **DISKPART** prompt, type:

   **break disk** *n* **[nokeep]**

7. At the **DISKPART** prompt, type:

   **select volume** *n*

   Select the volume that contains the volume you want to mirror.

8. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk number of the dynamic disk on which you want to mirror the volume.

9. At the **DISKPART** prompt, type:

   **add disk** *n*

**Important**

- Before installing a new disk, break the mirror and then examine the system log to see if the disk or the disk controller is failing. If the failing mirror is on a controller that is failing, installing a new disk on the failing controller will not solve the problem. For instructions describing how to open Event Viewer to examine the system log, see Related Topics.

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **select volume** *n* | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |

| | |
|---|---|
| **detail volume** | Displays the disks on which the current volume resides. |
| **break disk** *n* | Applies to dynamic disks only. Breaks a mirrored volume into two simple volumes. These volumes are no longer fault tolerant. The disk specified by *n* receives the focus so you can assign it a drive letter. If the specified disk is the current system or boot disk, the command fails. The other disk retains the drive letter and any mount points that belonged to the mirrored volume.<br><br>Using the **nokeep** parameter, the specified disk, *n*, is deleted and converted to free space, while the other half of the mirror is retained as a simple volume. Neither volume receives focus. |
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **add disk** *n* | Mirrors the simple volume with focus to the specified disk. The specified disk must have unallocated space at least as large as the size of the simple volume you want to mirror. |
| **Nokeep** | Specifies that only one of the mirrored volumes retained; the other simple volume is deleted and converted to free space. Neither volume receives the focus. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To replace a mirror in the mirrored volume, you must have a dynamic disk with unallocated space that is at least as large as the region to repair.

- If you are replacing one of the disks in a mirrored system volume, be sure to use an identical disk to the one you are replacing. Otherwise, startup problems might occur if the disks use different geometries or if the system volumes are at different offsets on the disks. Always test your configuration by attempting to start the operating system from each volume to ensure that the operating system can actually start if one of the disks fails. For more information about mirroring the system volume, see "Disk Management" at the Microsoft Windows Resource Kits Web site.

- For more information about **DiskPart**, see Related Topics.

# Manage RAID-5 Volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage RAID-5 volumes**

- Create a RAID-5 volume
- Reconnect the disk and repair the RAID-5 volume
- Replace a disk region in the RAID-5 volume
- Reactivate a RAID-5 disk

# Create a RAID-5 volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a RAID-5 volume**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the unallocated space on one of the dynamic disks where you want to create the RAID-5 volume, and then click **New Volume**.
4. In the New Volume Wizard, click **Next**, click **RAID-5**, and then follow the instructions on your screen.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can create RAID-5 volumes only on computers running Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, or Windows Server 2003 operating systems.
- You need at least three (but no more than 32) dynamic disks to create a RAID-5 volume.
- RAID-5 volumes provide fault tolerance at a cost of only one additional disk for the volume. For example, if you use three 10-GB disks to create a RAID-5 volume, the volume will have a 20-GB capacity. The remaining 10-GB is used for parity.
- RAID-5 volumes cannot be extended or mirrored.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list disk**

Make note of the disk number of the disks where you want to create a RAID-5 volume.

4. At the **DISKPART** prompt, type:

   **create volume raid** [size=*n*] disk=*n*,*n*,*n*

   Creates a RAID-5 volume of *n* MB on the selected disks.

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **create volume raid** | Creates a RAID-5 volume using three or more specified dynamic disks. After you create the volume, the focus automatically shifts to the new volume. |
| **size=** *n* | The amount of disk space, in megabytes (MB), that the volume will occupy on each disk. If no size is given, the largest possible RAID-5 volume will be created. The disk with the smallest available contiguous free space determines the size for the RAID-5 volume and the same amount of space is allocated from each disk. The actual amount of usable disk space in the RAID-5 volume is less than the combined amount of disk space because some of the disk space is required for parity. |
| **disk=** *n* | The dynamic disks on which to create the volume. An amount of space equal to **size=***n* is allocated on each disk. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You can create RAID-5 volumes only on computers running Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, or Windows Server 2003 operating systems.

- You need at least three (but no more than 32) dynamic disks to create a RAID-5 volume.

- RAID-5 volumes provide fault tolerance at a cost of only one additional disk for the volume. For example, if you use three 10-GB disks to create a RAID-5 volume, the volume will have a 20-GB capacity. The remaining 10-GB is used for parity.

- RAID-5 volumes cannot be extended or mirrored.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reconnect the disk and repair the RAID-5 volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reconnect the disk and repair the RAID-5 volume**

A disk containing part of a RAID-5 volume has been disconnected. Try to reconnect and reactivate the disk.

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Make sure that the physical disk is turned on, plugged in, and attached to the computer. If necessary, turn on or reattach the physical disk.
2. Open Computer Management (Local).
3. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
4. Right-click the Missing or Offline disk, and then click **Reactivate Disk**.

   If the disk containing part of the RAID-5 volume cannot be reactivated and the volume does not return to the **Healthy** status, you should replace the failed disk region in the RAID-5 volume, see Replace a disk region in the RAID-5 volume

### Important

- Examine the system log to see if the disk or the disk controller is failing. If the failing disk is on a controller that is failing, installing a new disk on the failing controller will not solve the problem. For instructions describing how to open Event Viewer to examine the system log, see Related Topics.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Using a command line**

1. Make sure that the physical disk is turned on, plugged in, and attached to the computer. If necessary, turn on or reattach the physical disk.
2. Open Command Prompt.
3. Type:

   **diskpart**

4. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk number for the disk with **Offline** status.

5. At the **DISKPART** prompt, type:

   **select disk***n*

   Select the disk with **Offline** status.

6. At the **DISKPART** prompt, type:

   **online**

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select disk** | Selects the specified disk, where *n* is the disk number, and gives it focus. |
| **online** | Brings an offline disk or volume with focus online. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- For more information about **DiskPart**, see Related Topics.

# Replace a disk region in the RAID-5 volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To replace a disk region in the RAID-5 volume**
If the disk containing part of the RAID-5 volume cannot be reactivated and the volume does not return to the **Healthy** status, you should replace the failed disk region in the RAID-5 volume.

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the portion of the RAID-5 volume on the failed disk, click **Repair Volume**, and then follow the instructions on your screen.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- To replace a disk region in the RAID-5 volume, you must have a dynamic disk with unallocated space that is at least as large as the region to repair. If you do not have a dynamic disk with enough unallocated space, the **Repair Volume** command is unavailable. (To verify that you have enough space, right-click the disk, click **Properties**, and then check the size in **Unallocated Space**. This size may be slightly smaller than shown in the graphical and list views.)
- When a member of a RAID-5 volume fails in a severe manner (such as a loss of power or a complete hard disk failure), computers running Windows Server 2003 operating systems can regenerate the data from the remaining members of the RAID-5 volume.
- If the RAID-5 failure is due to a power or cabling failure on a single device, you can regenerate the data within the failed member of the RAID-5 volume once the hardware state is restored.
- The RAID-5 volume will not display **Healthy** status in Disk Management until regeneration is complete.
- You can only regenerate RAID-5 volumes with **Failed Redundancy** status. If the RAID-5 volume has **Failed** status, try to return it to **Failed Redundancy** status by using the **Reactivate Disk** command on the remaining disks.

**Using a command line**

1. Make sure that the physical disk is turned on, plugged in, and attached to the computer. If necessary, turn on or reattach the physical disk.

2. Open Command Prompt.

3. Type:

   **diskpart**

4. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the volume number of the RAID-5 volume with **Failed Rd** status.

5. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the number of the dynamic disk you want to use to repair the RAID-5 volume.

6. At the **DISKPART** prompt, type:

   **select volume** *n*

7. At the **DISKPART** prompt, type:

   **repair disk=***N*

   Using the **list volume** command, you can check the status of the RAID-5 volume while it is being regenerated. During regeneration, the volume status is **Rebuild**, and after regeneration, the volume status is **Healthy**.

| Value | Description |
|---|---|
| **list volume** | Displays a list of basic and dynamic volumes on all disks. |
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select volume** | Selects the specified volume, where *n* is the volume number, and gives it focus. If no volume is specified, the **select** command lists the current volume with focus. You can specify the volume by number, drive letter, or mount point path. On a basic disk, selecting a volume also gives the corresponding partition focus. |
| **repair disk=** *N* | Repairs the RAID-5 volume with focus by replacing the failed RAID-5 member with the specified dynamic disk, *N*. The specified dynamic disk must have free space greater than or equal to the total size of the failed RAID-5 member. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To replace a disk region in the RAID-5 volume, you must have a dynamic disk with unallocated space that is at least as large as the region to repair. If you do not have a dynamic disk with enough unallocated space, the **Repair Volume** command is unavailable. (To verify that you have enough space, right-click the disk, click **Properties**, and then check the size in **Unallocated Space**. This size may be slightly smaller than shown in the graphical and list views.)

- When a member of a RAID-5 volume fails in a severe manner (such as a loss of power or a complete hard disk failure), computers running Windows Server 2003 operating systems can regenerate the data from the remaining members of the RAID-5 volume.

- If the RAID-5 failure is due to a power or cabling failure on a single device, you can regenerate the data within the failed member of the RAID-5 volume once the hardware state is restored.

- The RAID-5 volume will not display **Healthy** status in Disk Management until regeneration is complete.

- You can only regenerate RAID-5 volumes with **Failed Redundancy** status. If the RAID-5 volume has **Failed** status, try to return it to **Failed Redundancy** status by using the **Reactivate Disk** command on the remaining disks.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reactivate a RAID-5 disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reactivate a RAID-5 disk**

If the I/O errors are transient, you can try to reactivate the disk.

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management (Local).
2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.
3. Right-click the partially failed disk, and then click **Reactivate Disk**.

   The RAID-5 volume's status should change to **Regenerating**, then **Healthy**.

   If the disk containing part of the RAID-5 volume does not return to **Healthy** status, see Replace a disk region in the RAID-5 volume.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list disk**

   Make note of the disk number of the missing or offline disk that you want to bring online. Missing disks are numbered M0, M1, M2, etc. and offline disks are numbered 0, 1, 2, etc.

4. At the **DISKPART** prompt, type:

   **select disk***n*

5. At the **DISKPART** prompt, type:

   **online**

| Value | Description |
|---|---|
| **list disk** | Displays a list of disks and information about them, such as their size, amount of available free space, whether the disk is a basic or dynamic disk, and whether the disk uses the master boot record (MBR) or GUID partition table (GPT) partition style. The disk marked with an asterisk (*) has focus. |
| **select disk** *n* | Sets the focus to the specified disk, where *n* is the disk number. |
| **online** | Brings an offline disk or volume with focus online. |

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- A dynamic disk may become **Missing** when it is corrupted, powered down, or disconnected.

- A dynamic disk may become **Offline** if it is corrupted or intermittently unavailable. A dynamic disk may also become **Offline** if you attempt to import a foreign (dynamic) disk and the import fails. Only dynamic disks display the **Offline** status.

- Only dynamic disks can be reactivated.

- For more information about **DiskPart**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disk Management overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 8 Beta

**Disk Management overview**

Disk Management is a system utility for managing hard disks and the volumes or partitions that they contain. With Disk Management, you can initialize disks, create volumes, format volumes with the FAT, FAT32, or NTFS file systems, and create fault-tolerant disk systems. Disk Management enables you to perform most disk-related tasks without restarting the system or interrupting users; most configuration changes take effect immediately.

Disk Management, which replaces the Disk Administrator utility used in Microsoft® Windows® NT 4.0, offers many features, including:

- **Simplified tasks and intuitive user interface.** Disk Management is easy to use. Menus that are accessible from the right mouse button display the tasks you can perform on the selected object, and wizards guide you through creating partitions or volumes and initializing or converting disks. For more information, see The Disk Management window.

- **Basic and dynamic disk storage.** Basic disks contain basic volumes, such as primary partitions and logical drives in extended partitions. Use basic disks on portable computers or when you plan to install multiple operating systems in different partitions on the same disk. For more information, see Basic disks and volumes.

  Dynamic disks contain dynamic volumes that offer more features than basic disks, such as the ability to create fault-tolerant volumes on the Microsoft® Windows® 2000 Server family or Microsoft® Windows Server 2003 family of operating systems. You can extend dynamic volumes (except system or boot volumes), mirror dynamic volumes, and add new dynamic disks without restarting the computer. For more information, see Dynamic disks and volumes.

- **Local and remote disk management.** By using Disk Management, you can manage any remote computer running Windows 2000, Microsoft® Windows® XP Professional, or Windows Server 2003 operating systems on which you are a member of the Backup Operators group or Administrators group. For more information about managing disks and volumes remotely, see Remote disk management.

- **Mounted drives.** You can use Disk Management to connect, or mount, a local drive at any empty folder on a local NTFS-formatted volume. Mounted drives make data more accessible and give you the flexibility to manage data storage based on your work environment and system usage. Mounted drives are not subject to the 26-drive limit imposed by drive letters, so you can use mounted drives to access more than 26 drives on your computer. For more information, see Using NTFS mounted drives.

- **Support for MBR and GPT disks.** Disk Management offers support for master boot record (MBR) disks in x86-based computers running Windows Server 2003 with Service Pack 1 (SP 1), x64-based computers, and Itanium-based computers. You can create mirrored, striped, spanned and RAID-5 volumes using a combination of MBR and GPT disks, but the MBR cylinder-alignment restriction may cause some difficulties in creating mirrored volumes. Always mirror the MBR disk to the GPT disk to avoid cylinder-alignment difficulties. For more information, see Partition styles.

- **Support for storage area networks (SANs).** For better interoperability in storage area network (SAN) environments, on Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition, volumes on new basic disks are not automatically mounted and assigned drive letters by default when added to the system. You must manually mount basic volumes and assign the drive letters using Disk Management or the **DiskPart** and **mountvol** commands. Dynamic disks, removable media devices (such as Zip or Jaz drives), and optical discs (such as CD-ROM or DVD-RAM) are always automatically mounted by the system when they are detected.

- **Manage disks at the command line.** Use the command-line tool **DiskPart** to perform disk-related tasks at the command line as an alternative to using Disk Management. With **DiskPart**, you can create scripts to automate tasks, such as creating volumes or converting disks to dynamic. For more information, see Managing disks and volumes from the command line.

# Understanding Disk Management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Disk Management**
This section covers:

- The Disk Management window
- Partition styles
- Basic disks and volumes
- Dynamic disks and volumes
- Remote disk management

# The Disk Management window

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The Disk Management window**

The Disk Management window displays disks and volumes in a list view and in a graphical view. The following figure depicts the disk and volume status columns in Disk Management's graphical view:

In the **Status** column of the list view, you can view the status of a disk or volume. The status also appears in the graphical view of each disk or volume. If a disk or volume status indicates an error condition, it is important to repair the disk or volume as quickly as possible to avoid data loss. If the status is not **Healthy** for volumes or **Online** for disks, see Troubleshooting Disk Management.

You can customize the list or graphical views by changing the type of information that is displayed in the top and bottom panes and by selecting the colors and patterns used to display volumes and disk regions. To change the way objects are displayed in the Disk Management window, click **View** and then select the options you want.

For more information about disk and volume statuses, see:

- Disk status descriptions
- Volume status descriptions

# Disk status descriptions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Disk status descriptions**
One of the following disk status descriptions will always appear in the graphical view of the disk and in the **Status** column of the disk in list view.

Audio CD

Foreign

Initializing

Missing

No Media

Not Initialized

Online

Online (Errors)

Offline

Unreadable

**Audio CD**
The **Audio CD** status occurs when you have an audio CD in your CD-ROM or DVD-ROM drive.

**Foreign**
The **Foreign** status occurs when you move a dynamic disk to the local computer from another computer running Windows 2000, Windows XP Professional, Windows XP 64-bit Edition (Itanium), or the Windows Server 2003 family of operating systems. **Foreign** status can also occur on computers running Windows XP Home Edition that are configured to dual-boot with another operating system that uses dynamic disks (such as Windows 2000 Professional or Windows XP Professional). Dynamic disks are not supported on Windows XP Home Edition or on portable computers. A warning icon appears on disks that display the **Foreign** status.

To access data on the disk, you must add the disk to your computer's system configuration. To add a disk to your computer's system configuration, import the foreign disk (right-click the disk and then click **Import Foreign Disks**). Any existing volumes on the foreign disk become visible and accessible when you import the disk. For instructions describing how to move and import disks, see Move disks to another computer.

However, you cannot access data on the disk if you are running Windows XP Home Edition. To use the disk on Windows XP Home Edition, you must convert it to a basic disk, which destroys all data on the disk.

**Caution**

- Do not convert a dynamic disk to a basic disk unless you are certain that you no longer need the data on that disk. Converting a dynamic disk to a basic disk destroys all data on the disk.

To convert the disk to an empty basic disk, see Change a dynamic disk back to a basic disk.

In some cases, a disk that was previously connected to the system can display the **Foreign** status. Configuration data for dynamic disks is stored on all dynamic disks, so the information about which disks are owned by the system is lost when all dynamic disks fail.

For instructions describing how to fix disks with **Foreign** status, see Troubleshooting Disk Management.

**Initializing**
The **Initializing** status is a temporary status that occurs when you convert a basic disk into a dynamic disk. When initialization is complete, the disk's status changes to **Online**.

**Missing**
The **Missing** status occurs when a dynamic disk is corrupted, turned off, or disconnected. Instead of appearing in the status column, the **Missing** status is displayed as the disk name. After you reconnect or turn on the missing disk, open Disk Management, right-click the missing disk, and then click **Reactivate Disk**. If there is more than one missing disk in the disk group, Disk Management will attempt to reactivate all of them.

For instructions describing how to fix disks with **Missing** status, see Troubleshooting Disk Management.

**No Media**
The **No media** status occurs when the CD-ROM, DVD-ROM, or removable drive is empty. The status changes to **Online** or **Audio CD** when you insert the appropriate media into the drive. Only CD-ROM, DVD-ROM, or removable disk types display the **No Media** status.

**Not Initialized**
The **Not Initialized** status occurs when a disk does not contain a valid signature. After you install a new disk, Windows XP Professional or the Windows Server 2003 family of operating systems must write a master boot record (MBR) or GUID partition table (GPT) before you can create partitions on the disk. When you first start Disk Management after installing a new disk, a wizard appears that provides a list of the new disks detected. If you cancel the wizard before the disk signature is written, the disk status remains **Not Initialized** until you right-click the disk and then click **Initialize Disk**. The disk status briefly changes to **Initializing** and then **Online** status.

For instructions describing how to fix disks with **Not Initialized** status, see Troubleshooting Disk Management.

**Online**
The **Online** status occurs when a basic or dynamic disk is accessible and has no known problems. This is the normal disk status. No user action is required.

**Online (Errors)**
The **Online (Errors)** status occurs when I/O errors are detected on a region of a dynamic disk. A warning icon appears on the dynamic disk with errors.

If the I/O errors were temporary, (e.g., due to a loose cable that is no longer loose) the disk returns to the **Online** status when you reactivate it.

For instructions describing how to fix disks with **Online (Errors)** status, see Troubleshooting Disk Management.

**Offline**
The **Offline** status occurs when a dynamic disk is not accessible. The dynamic disk may be corrupted or intermittently unavailable. An error icon appears on the offline dynamic disk.

If the disk status is **Offline** and the disk's name changes to **Missing**, the disk was recently available on the system but can no longer be located or identified. The missing disk may be corrupted, powered down, or disconnected.

**To bring a disk that is Offline and Missing back online**
Repair any disk, controller, or cable problems and make sure that the physical disk is turned on, plugged in, and attached to the computer. In Disk Management, right-click the disk and then click **Reactivate Disk** to bring the disk back online.

If the disk status remains **Offline** and the disk name remains **Missing**, and you determine that the disk has a problem that cannot be repaired, you can remove the disk from the system (using the **Remove Disk** command). However, before you can remove the disk, you must delete all volumes (or mirrors) on the disk. You can save any mirrored volumes on the disk by removing the mirror instead of the entire volume. Deleting a volume destroys the data in the volume, so you should remove a disk only if you are absolutely certain that the disk is permanently damaged and unusable.

**To bring a disk that is Offline and is still named Disk # (not Missing) back online**
In Disk Management, right-click the disk and then click **Reactivate Disk** to bring the disk back online. If the disk status remains **Offline**, check the cables and disk controller, and make sure that the physical disk is healthy. Correct any problems and try to reactivate the disk again. If the disk reactivation succeeds, any volumes on the disk should automatically return to the **Healthy** status.

For instructions describing how to fix disks with **Offline** status, see Troubleshooting Disk Management.

**Unreadable**
The **Unreadable** status occurs when either a basic or dynamic disk is not accessible. The disk may have experienced hardware failure, corruption, or I/O errors. The disk's copy of the system's disk configuration database may be corrupted. An error icon appears on disks that display the **Unreadable** status.

Disks may display the **Unreadable** status while they are spinning up or when Disk Management is rescanning all of the disks

on the system. In some cases, an unreadable disk has failed and is not recoverable. For dynamic disks, the **Unreadable** status usually results from corruption or I/O errors on part of the disk, rather than failure of the entire disk. You can rescan the disks (click **Action** and then click **Rescan Disks**) or restart the computer to see if the disk status changes.

For instructions describing how to fix disks with **Unreadable** status, see Troubleshooting Disk Management.

# Volume status descriptions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Volume status descriptions**

In Disk Management, one of the following volume status descriptions will always appear in the graphical view of the volume and in the **Status** column of the volume in list view.

- Failed
- Failed Redundancy
- Formatting
- Healthy
- Regenerating
- Resynching
- Unknown

**Failed**

The **Failed** status occurs when a basic or dynamic volume cannot be started automatically, or the disk is damaged. This status also occurs after importing a volume with **Data Incomplete** status. An error icon appears on the failed volume. Unless the disk or file system can be repaired, the **Failed** status indicates data loss.

If the volume is a basic volume, make sure that the underlying physical disk is turned on, plugged in, and attached to the computer. No other user action is possible for basic volumes.

If the volume is a dynamic volume, make sure the underlying dynamic disks are online. If the disks are not online, you should reactivate them. If this succeeds, the volume automatically restarts and returns to the **Healthy** status. For instructions describing how to bring a disk online, see Reactivate a missing or offline dynamic disk.

If the underlying dynamic disk returns to the **Online** status, but the dynamic volume does not return to the **Healthy** status, you can reactivate the volume manually. For instructions describing how to reactivate a volume, see Reactivate a dynamic volume.

If the volume is a mirrored or RAID-5 volume with old data, bringing the underlying disk online automatically reactivates the volume. If the disks that contain current data are disconnected, you should bring those disks online first (to allow the data to become synchronized). Otherwise, reactivate the mirrored or RAID-5 volume manually, and then run Chkdsk.exe.

For instructions describing how to reactivate a volume, see Reactivate a dynamic volume. To run Chkdsk.exe, click **Start**, click **Run**, type **chkdsk**, and then click **OK**.

For instructions describing how to fix volumes with **Failed** status, see Troubleshooting Disk Management.

**Failed Redundancy**

The **Failed Redundancy** status occurs when the data on a mirrored or RAID-5 volume is no longer fault tolerant because one of the underlying disks is not online. A warning icon appears on the volume with failed redundancy.

Volumes with the **Failed Redundancy** status often display an associated substatus (in parentheses). A volume may only display one substatus at a time. The substatus is displayed according to the order in which they appear in the table below. For example, if you have only one volume that serves as the boot volume, system volume, active volume, page file, and crash dump, its status is displayed as **Failed Redundancy (System)**. However, if an error occurs on a mirrored or RAID-5 volume, the **(At Risk)** substatus takes precedence.

| Failed Redundancy (substatuses) | Description |
|---|---|
| System | Indicates that the volume is the system volume. |
| Boot | Indicates that the volume is the boot volume. |
| Page File | Indicates that the volume holds the paging file. For more information about the paging file, see System Properties overview. |
| Crash Dump | Indicates that the volume holds the crash dump, also known as a memory dump. The memory dump is used to record the contents of the system memory when Windows XP Professional or Windows Server 2003 operating systems stop unexpectedly. For more information about the different types of memory dumps available, see Specify what happens when the system stops unexpectedly. |
| At Risk | Indicates that the data on a mirrored or RAID-5 volume is no longer fault tolerant because one of the disks has failed and I/O errors have been detected on the remaining dynamic disks. If an I/O error is detected on any part of a disk, a warning icon appears on all dynamic volumes on the disk. Dynamic volumes that are not fault tolerant display the **Healthy (At Risk)** status.<br><br>When the volume status is **Failed Redundancy (At Risk)**, the underlying disk's status is usually **Online (Errors)**. You should reactivate the disk to return it to **Online** status, and then the volume status should change to **Failed Redundancy**. |

You can continue to access the volume using the remaining online disks, but if another disk that contains the volume fails, you will lose the volume and its data. To avoid such loss, you should attempt to repair the volume as soon as possible:

- If an underlying disk is not online, reactivate the disk (right-click the disk and then click **Reactivate Disk**). If disk reactivation succeeds, the volume automatically repairs itself and returns to the **Healthy** status. A mirrored volume repairs itself by resynchronizing the data in its mirrors. A RAID-5 volume repairs itself by regenerating its parity and data.

- If the disk returns to the **Online** status, but the volume does not return to the **Healthy** status, you can reactivate the volume manually (right-click the volume and then click **Reactivate Volume**).

- If the disk does not return to the **Online** status and the volume does not return to the **Healthy** status, there may be something wrong with the disk. You should replace the failed mirror or RAID-5 disk region. To replace the failed mirror in a mirrored volume, right-click the failed mirror and then click **Remove Mirror**, and then right-click the other volume and click **Add Mirror** to create a new mirror on another disk. To replace the failed disk region in a RAID-5 volume, right-click the RAID-5 volume and then click **Repair Volume**.

For more information about how to fix mirrored or RAID-5 volumes with **Failed Redundancy** status, see Troubleshooting Disk Management.

**Formatting**

The **Formatting** status is a temporary status that occurs only while a volume is being formatted with a file system. As the volume is being formatted, the amount of the volume formatted is shown as a percentage. When formatting is complete, the volume status changes to **Healthy**.

**Healthy**

The **Healthy** status is the normal volume status on both basic and dynamic volumes when the volume is accessible and has no known problems. No user action is required.

Volumes with the **Healthy** status often display an associated substatus (in parentheses). A volume can display only one substatus at a time. The substatus is displayed according to the order in which they appear in the table below. For example, if you have only one volume which serves as the boot volume, system volume, active volume, page file, and crash dump, its status is displayed as **Healthy (System)**. However, if an error occurs on a dynamic volume, the **(At Risk)** substatus takes precedence.

| Healthy (substatuses) | Description |
|---|---|
| System | Indicates that the volume is the system volume. |

| | |
|---|---|
| Boot | Indicates that the volume is the boot volume. |
| Page File | Indicates that the volume holds the paging file. For more information about the paging file, see System Properties overview. |
| Active | Indicates that the volume is an active volume on a basic disk. For more information about making a volume the active volume, see Mark a partition as active (32-bit only). |
| Crash Dump | Indicates that the volume holds the crash dump, also known as a memory dump. The memory dump is used to record the contents of the system memory when Windows XP Professional or Windows Server 2003 operating systems stop unexpectedly. For more information about the different types of memory dumps available, see Specify what happens when the system stops unexpectedly. |
| Hibernation Partition | Indicates that the volume is an original equipment manufacturer (OEM) hibernation partition, which is used on some laptops to save the current state of the system during hibernation. |
| GPT protective Partition | Indicates that the volume is a GUID partition table (GPT) disk. The GPT protective partition contains the protective MBR to prevent disk utilities that are not compatible with GPT disks from accidentally destroying GPT partitions. |
| EFI System Partition | Indicates that the volume is the Extensible Firmware Interface (EFI) system partition on a GPT disk. |
| EISA Configuration | Indicates that the volume is an original equipment manufacturer (OEM) partition. |
| Unknown Partition | Indicates that the partition is not recognized.<br><br>Partitions on master boot record (MBR) or GUID partition table (GPT) disks with **Healthy (Unknown Partition)** status might be an unrecognized original equipment manufacturer (OEM) partition, or non-Windows operating system partition. You cannot format, assign drive letters or mount points to, or access data on partitions with **Healthy (Unknown Partition)** status. You can, however, delete these partitions using Disk Management or the DiskPart command. For instructions describing how to delete partitions, see Delete a partition or logical drive. |
| At Risk | Indicates that the dynamic volume is currently accessible, but I/O errors have been detected on the underlying dynamic disk. If an I/O error is detected on any part of a dynamic disk, all volumes on the disk display the **Healthy (At Risk)** status and a warning icon appears on the volume.<br><br>When the volume status is **Healthy (At Risk)**, an underlying disk's status is usually **Online (Errors)**. You should reactivate the underlying disk to return it to **Online** status, and then the volume should return to the **Healthy** status. If the **Healthy (At Risk)** status persists, the disk might be failing. Back up the data and replace the disk as soon as possible.<br><br>For instructions describing how to fix volumes with **Healthy (At Risk)** status, see Troubleshooting Disk Management. |

**Regenerating**

The **Regenerating** status occurs when a missing disk in a RAID-5 volume is reactivated, when an offline disk in a RAID-5 volume is reactivated, when a failed RAID-5 volume is reactivated, when disks in a RAID-5 volume are imported, and when data and parity are being regenerated for a RAID-5 volume. No user action is required. When regeneration is complete, the volume's status returns to **Healthy**. You can access a RAID-5 volume while data and parity regeneration is in progress.

**Resynching**

The **Resynching** status occurs when creating a mirror or restarting a computer with a mirrored volume, when an offline disk in a mirrored volume is reactivated, when disks in a mirrored volume are imported, and when a mirrored volume is being resynchronized so that both mirrors contain identical data. No user action is required. When resynchronization is complete, the mirrored volume's status returns to **Healthy**. Resynchronization might take some time, depending on the size of the mirrored volume. Although you can access a mirrored volume while resynchronization is in progress, you should avoid making configuration changes (such as breaking a mirror) during resynchronization.

Volumes with the **Resynching** status often display an associated substatus (in parentheses). The table below lists the possible substatuses displayed by volumes with **Resynching** status:

| Resynching (substatuses) | Description |
| --- | --- |
| System | Indicates that the volume is the system volume. |
| Boot | Indicates that the volume is the boot volume. |
| Page File | Indicates that the volume holds the paging file. For more information about the paging file, see System Properties overview. |
| Crash Dump | Indicates that the volume holds the crash dump, also known as a memory dump. The memory dump is used to record the contents of the system memory when Windows XP Professional or Windows Server 2003 operating systems stop unexpectedly. For more information about the different types of memory dumps available, see Specify what happens when the system stops unexpectedly. |

**Unknown**

The **Unknown** status occurs when the boot sector for the volume is corrupted (possibly due to a virus) and you can no longer access data on the volume.

For instructions describing how to fix volumes with **Unknown** status, see Troubleshooting Disk Management.

When importing disks, all volumes on those disks display the **OK** condition in the **Foreign Disk Volumes** dialog box unless there are problems with the volumes. When importing mirrored or RAID-5 volumes, these problems might be **Data Incomplete**, **Data Not Redundant**, or **Stale Data**.

**Data Incomplete**

The **Data Incomplete** status is displayed in the **Foreign Disk Volumes** dialog box, and occurs when data spans multiple disks, but not all of the disks were moved. Data on this volume will be destroyed unless you move the remaining disks that contain this volume, and then import all of the disks together. You cannot import the missing disks at a later time to restore the data.

For instructions describing how to fix volumes with **Data Incomplete** status, see Troubleshooting Disk Management.

**Data Not Redundant**

The **Data Not Redundant** status is displayed in the **Foreign Disk Volumes** dialog box when you import all but one of the disks in a mirrored or RAID-5 volume. In Disk Management, the imported half of the mirrored volume receives **Failed Redundancy** status, while the disk that holds the half of the mirror that was not imported receives **Missing** status. RAID-5 volumes receive **Failed Redundancy** status.

To prevent the **Data Not Redundant** status from occurring, connect all disks that belong to the mirrored or RAID-5 volume to the computer at the same time, and then import all of the disks together. For mirrored volumes, you can import the **Missing** disk at a later time to restore redundancy.

For instructions describing how to fix volumes with **Data Not Redundant** status, see Troubleshooting Disk Management.

**Stale Data**

The **Stale Data** status is displayed in the **Foreign Disk Volumes** dialog box, and occurs when a mirrored or RAID-5 volume has stale mirror information, stale parity information, or I/O errors.

For instructions describing how to fix mirrored or RAID-5 volumes with **Stale Data** status, see Troubleshooting Disk Management.

# Partition styles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Partition styles**

Partition style refers to the method that Windows XP Professional and Windows Server 2003 operating systems use to organize partitions on the disk. All x86-based and x64-based computers use the partition style known as master boot record (MBR). MBR contains a partition table that describes where the partitions are located on the disk. Because MBR is the only partition style available on x86-based computers without Windows Server 2003 with Service Pack 1 (SP1), you do not need to choose this style. It is used automatically.

Itanium-based computers, x86-based computers running Windows Server 2003 with Service Pack 1 (SP 1), and x64-based computers can use either the MBR partition style or the GUID partition table (GPT) partition style. There are some differences between MBR and GPT partition styles, but most disk-related tasks remain the same. Basic disks and dynamic disks work the same way as in Windows 2000, and these storage types are available on disks that use either partition style. For more information about basic disks and volumes, see Basic disks and volumes. For more information about dynamic disks and volumes, see Dynamic disks and volumes. For more information about GPT disks, see GUID partition table.

In order to start, x86-based and x64-based computers must have an MBR disk with an active partition. You can also install GPT disks on x86-based computers with Windows Server 2003 with Service Pack 1 (SP1), and on x64-based computers, but you cannot start an operating system from them. Itanium-based computers require a GPT disk that contains an Extensible Firmware Interface (EFI) system partition and the files necessary to start the computer. You can also install MBR disks on Itanium-based systems, but you cannot start an operating system from them. For more information about EFI and EFI System partitions, see Extensible Firmware Interface.

In order to more easily differentiate between disks that use the MBR and GPT partition styles, Disk Management labels disks that use the master boot record partition style as MBR disks, while disks that use the GUID partition table partition style are labeled GPT disks.

The following table depicts storage types and partition styles in Windows XP Professional and Windows Server 2003 operating systems:

| Operating system | Basic volumes | Dynamic simple, spanned, and striped volumes | Dynamic mirrored and RAID-5 volumes | MBR boot volume | MBR data volume | GPT boot volume | GPT data volume |
|---|---|---|---|---|---|---|---|
| Windows XP Home Edition | X | | | X | X | | |
| Windows XP Professional | X | X | | X | X | | |
| Windows Server 2003, Standard Edition | X | X | X | X | X | | |
| Windows Server 2003, Enterprise Edition | X | X | X | X | X | | |
| Windows Server 2003, Datacenter Edition | X | X | X | X | X | | |
| Windows Server 2003, Standard Edition with Service Pack 1 (SP1) | X | X | X | X | X | | X |
| Windows Server 2003, Enterprise Edition with Service Pack 1 (SP1) | X | X | X | X | X | | X |
| Windows Server 2003, Datacenter Edition with Service Pack 1 (SP1) | X | X | X | X | X | | X |

| | | | | | | | |
|---|---|---|---|---|---|---|---|
| Windows XP 64-bit Edition (Itanium) | X | X | | | X | X | X |
| Windows Server 2003, Enterprise Edition for Itanium-based Systems | X | X | X | | X | X | X |
| Windows Server 2003, Datacenter Edition for Itanium-based Systems | X | X | X | | X | X | X |
| Windows XP Professional x64 Edition | X | X | | X | X | | X |
| Windows Server 2003, Standard x64 Edition | X | X | X | X | X | | X |
| Windows Server 2003, Enterprise x64 Edition | X | X | X | X | X | | X |
| Windows Server 2003, Datacenter x64 Edition | X | X | X | X | X | | X |

Disk Management requires NTFS on all dynamic disks and GUID partition table (GPT) disks. You can, however, use the **format** command to format these disks using FAT or FAT32. For more information about the **format** command, see Format.

For more information about file system compatibility and limitations, see Choosing a file system: NTFS, FAT, or FAT32.

# Basic disks and volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Basic disks and volumes**

A basic disk is a physical disk that contains primary partitions, extended partitions, or logical drives. Partitions and logical drives on basic disks are known as basic volumes. You can only create basic volumes on basic disks.

The number of partitions you can create on a basic disk depends on the disk's partition style:

- On master boot record (MBR) disks, you can create up to four primary partitions per disk, or you can create up to three primary partitions and one extended partition. Within the extended partition, you can create unlimited logical drives.

- On GUID partition table (GPT) disks, you can create up to 128 primary partitions. Because GPT disks do not limit you to four partitions, you do not need to create extended partitions or logical drives.

You can add more space to existing primary partitions and logical drives by extending them into adjacent, contiguous unallocated space on the same disk. To extend a basic volume, it must be formatted with the NTFS file system. You can extend a logical drive within contiguous free space in the extended partition that contains it. If you extend a logical drive beyond the free space available in the extended partition, the extended partition grows to contain the logical drive as long as the extended partition is followed by contiguous unallocated space. For instructions describing how to extend a basic volume, see Extend a basic volume.

Always use basic volumes, instead of dynamic volumes, on computers running MS-DOS, Windows 95, Windows 98, Windows Millinnium Edition, Windows NT 4.0, or Windows XP Home Edition that are configured to dual-boot with Windows XP Professional or Windows Server 2003 operating systems. These operating systems cannot access the data stored on dynamic volumes.

Windows XP Professional and the Windows Server 2003 operating systems do not support multidisk basic volumes created using Windows NT 4.0 or earlier, such as volume sets, mirror sets, stripe sets, or stripe sets with parity. For information about using Windows NT 4.0 multidisk basic volumes, see Using Windows NT 4.0 multidisk storage.

For more information about dynamic volumes, see Dynamic disks and volumes.

# Dynamic disks and volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Dynamic disks and volumes**

Dynamic disks provide features that basic disks do not, such as the ability to create volumes that span multiple disks (spanned and striped volumes), and the ability to create fault tolerant volumes (mirrored and RAID-5 volumes). All volumes on dynamic disks are known as dynamic volumes.

There are five types of dynamic volumes: simple, spanned, striped, mirrored, and RAID-5. Mirrored and RAID-5 volumes are fault tolerant and are available only on computers running Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, or Windows Server 2003 operating systems. You can, however, use a computer running Windows XP Professional to remotely create mirrored and RAID-5 volumes on these operating systems.

Regardless of whether the dynamic disk uses the master boot record (MBR) or GUID partition table (GPT) partition style, you can create up to 2,000 dynamic volumes, although the recommended number of dynamic volumes is 32 or less.

For information about how to manage dynamic volumes, see Manage Dynamic Volumes.

**Considerations when using dynamic disks and dynamic volumes**

When using dynamic volumes, the following considerations apply:

- **Installing Windows Server 2003 operating systems**. You can perform a fresh installation of Windows Server 2003 operating systems on a dynamic volume only if that volume was converted from a basic boot volume or basic system volume. If the dynamic volume was created from unallocated space on a dynamic disk, you cannot install Windows Server 2003 operating systems on that volume. This setup limitation occurs because Setup for Windows Server 2003 recognizes only dynamic volumes that have an entry in the partition table. You can, however, extend the volume (if it is a simple or spanned volume).

  Do not convert basic disks to dynamic disks if they contain multiple installations of Windows 2000, Windows XP Professional, or Windows Server 2003 operating systems. After the conversion, it is unlikely that you will be able to start the computer using that operating system.

  For information about basic volumes, see Basic disks and volumes.

- **Portable computers and removable media**. Dynamic disks are not supported on portable computers, removable disks, detachable disks that use Universal Serial Bus (USB) or IEEE 1394 (also called FireWire) interfaces, or on disks connected to shared SCSI buses. If you are using a portable computer and right-click a disk in the graphical or list view in Disk Management, you will not see the option to convert the disk to dynamic.

- **Boot and system partitions**. You can convert a basic disk containing the system or boot partitions to a dynamic disk. After the disk is converted, these partitions become simple system or boot volumes (after restarting the computer). You cannot mark an existing dynamic volume as active. You can convert a basic disk containing the boot partition (which contains the operating system) to a dynamic disk. After the disk is converted, the boot partition becomes a simple boot volume (after restarting the computer).

- **Mirroring the boot and system volumes**. If you convert the disk containing the boot and system partitions to a dynamic disk, you can mirror the boot and system volumes onto another dynamic disk. Then, if the disk containing the boot and system volumes fails, you can start the computer from the disk containing the mirrors of these volumes. For more information, see Create and test a mirrored system or boot volume.

- **Converting dynamic disks to basic disks**. After you convert a basic disk into a dynamic disk, you cannot change the dynamic volumes back to partitions. Instead, you must move or back up your data, delete all dynamic volumes on the disk and then convert the disk. For more information, see Change a dynamic disk back to a basic disk.

- **Shadow copies storage area**. If you are using a basic disk as a storage area for shadow copies and you intend to convert the disk into a dynamic disk, it is important to take the following precaution to avoid data loss. If the disk is a non-boot volume and is a different volume from where the original files reside, you must first dismount and take offline

the volume containing the original files before you convert the disk containing shadow copies to a dynamic disk. You must bring the volume containing the original files back online within 20 minutes, otherwise, you will lose the data stored in the existing shadow copies. If the shadow copies are located on a boot volume, you can convert the disk to dynamic without losing shadow copies.

You can use the **mountvol** command with the **/p** option to dismount the volume and take it offline. You can mount the volume and bring it online using the **mountvol** command or the Disk Management snap-in.

# Remote disk management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote disk management**

Using Disk Management, you can remotely manage disks on another computer in your network. To manage disks that are connected to remote computers, you must be a member of the Backup Operators group or Administrators group on both the local and remote computers. In addition, the user account and both computers must be members of the same domain or within trusted domains.

Mirrored volumes, RAID-5 volumes, and GUID partition table (GPT) disks are not available on all versions of Windows XP or Windows Server 2003 operating systems. The types of volumes and disks you can create depend on the operating system running on the remote computer, not the local computer. For example, you can use a local computer running Windows XP Professional to create mirrored and RAID-5 volumes on a remote computer that is running Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, or Windows Server 2003 operating systems.

For information on administering the disk system on another computer, see Manage disks on a remote computer.

# Using Disk Management

Updated: January 21, 2005

# Adding a disk

Updated: December 5, 2012

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Adding a disk**

**Note**

This topic does not apply to Windows Server® 2008, Windows Server® 2008 R2, or Windows® 7. For information on adding disks when using these operating systems, see the following:

- Overview of Disk Management
- Manage Disks
- Adding Hard Disk Drives

When you attach a new disk to your computer, you must initialize the disk before you can create volumes or partitions. When you first start Disk Management after installing a new disk, a wizard appears that provides a list of the new disks detected by the operating system. When you complete the wizard, the operating system initializes the disk(s) by writing a disk signature, the end of sector marker (also called signature word), and a master boot record (MBR) or GUID partition table (GPT) on the disk. If you cancel the wizard before the disk signature is written, the disk status remains **Not Initialized**.

You can use either basic storage or dynamic storage. Use basic storage, which uses basic volumes, if you want to create partitions and logical drives on the disk or if you want to use the disk with other operating systems. Later, you can convert basic storage to dynamic storage, which uses dynamic volumes. Dynamic volumes cannot be accessed by computers running MS-DOS, Windows 95, Windows 98, Windows Millennium Edition, Windows NT 4.0, or Windows XP Home Edition that are configured to dual-boot with Windows XP Professional or Windows Server 2003 operating systems.

There are five types of dynamic volumes: simple, spanned, striped, mirrored, and RAID-5. You can create simple, spanned, or striped volumes on computers running Windows 2000 Professional, Windows XP Professional, or Windows XP 64-bit Edition (Itanium). You can create all five types of dynamic volumes on computers running Windows 2000 Server or Windows Server 2003 operating systems. You can, however, use a computer running Windows XP Professional to remotely create mirrored and RAID-5 volumes on these operating systems.

For information about which partition style or volume type you can use on computers running Windows XP or Windows Server 2003 operating systems, see Partition styles.

For information on how to initialize a new disk, see Initialize new disks.

To install a disk that is already initialized, see Update disk information.

To change the storage type for which a disk is initialized, see Change a basic disk into a dynamic disk or Change a dynamic disk back to a basic disk.

# Using NTFS mounted drives

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using NTFS mounted drives**

NTFS mounted drives are a convenient way to add additional volumes to a computer when you no longer have any drive letters remaining. In addition, you can add more space to a volume without having to recreate the volume on another, larger disk by mounting other disks as folders on the volume. Growing the folder structure with mounted drives gives the volume a scalable, larger capacity. You can use Disk Management to mount a local volume at any empty folder on a local NTFS volume. You can format a mounted drive with any file system supported by Windows XP Professional or Windows Server 2003 operating systems.

When you mount a local drive at an empty folder on an NTFS volume, Disk Management assigns a drive path to the drive rather than a drive letter. Mounted drives are not subject to the 26-drive limit imposed by drive letters, so you can use mounted drives to access more than 26 drives on your computer. Windows ensures that drive paths retain their association to the drive, so you can add or rearrange storage devices without the drive path failing.

For example, if you have a hard disk drive with the drive letter D and an NTFS-formatted volume with the drive letter C, you can mount the hard disk drive at an empty folder with the following path: C:\datadisk. You can then access the hard disk drive directly through the path C:\datadisk. Also, you can choose to remove the drive letter D from the hard disk drive and continue to access it through the mounted drive path.

Mounted drives make data more accessible and give you the flexibility to manage data storage based on your work environment and system usage. For example, you can:

- Make the C:\Users folder a mounted drive with NTFS disk quotas in order to track or constrain disk usage without doing the same on drive C.
- Make the C:\Temp folder a mounted drive to provide additional disk space for temporary files.
- Move the My Documents folder to another, larger drive when space is low on drive C, and mount it as C:\My Documents.

When using NTFS mounted drives with server clusters:

- Make sure that you create unique mounted drives so that they do not conflict with existing local drives on any node in the cluster.
- Do not create mounted drives between disks on the cluster storage device (cluster disks) and local disks.
- Do not create mounted drives from the cluster disk that contains the quorum resource (the quorum disk). You can, however, create a mounted drive from the quorum disk to a clustered disk.
- Mounted drives from one cluster disk to another must be in the same cluster resource group, and must be dependent on the root disk.

  For more information on server clusters, see Server clusters overview.
- Use Event Viewer to check the system log for any Cluster service errors or warnings indicating mount point failures. These errors would be listed as ClusSvc in the Source column and Physical Disk Resource in the Category column.

  For more information on how to use Event Viewer to check the system log, see Event Viewer.

  For more information on how to resolve errors with mounted drives on server clusters, see Cluster disk and drive connection problems.

# Support for removable media

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Support for removable media**

In the **Graphical View** in Disk Management, removable media devices are labeled **Removable**.

Most removable media devices, such as Zip and Jaz drives and optical discs (for example, DVD-RAM), already have a primary partition equal to the total size of the media. If the removable media has a primary partition, you cannot mark the partition as active or delete it. You cannot create extended partitions, logical drives, or dynamic volumes on removable media devices.

In addition, you cannot use the GUID partition table (GPT) partitioning style on removable media.

**Important**

- For better interoperability in storage area network (SAN) environments, on Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition, volumes on new basic disks are not automatically mounted and assigned drive letters by default when added to the system. You must manually mount basic volumes and assign the drive letters using Disk Management or the **DiskPart** and **mountvol** commands. Dynamic disks, removable media devices (such as Zip or Jaz drives), and optical discs (such as CD-ROM or DVD-RAM) are always automatically mounted by the system when they are detected.

For information about the other types of storage you can use with Disk Management, see Using Disk Management.

# Using Basic Disks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using basic disks**

This section covers:

- Converting a basic disk to dynamic
- Using Windows NT 4.0 multidisk storage

# Converting a basic disk to dynamic

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Converting a basic disk to dynamic**
Setup and Disk Management ensure that disks initialized by Windows Server 2003 operating systems can be converted to dynamic disks. Dynamic disks provide features that basic disks do not, such as the ability to create multidisk volumes, such as striped, mirrored, and RAID-5 volumes.

Before you convert disks, close any programs that are running on those disks. If you convert a boot disk, or if a volume or partition is in use on the disk you attempt to convert, you must restart the computer for the conversion to succeed. The conversion may fail if you change the disk layout of a disk to be converted or if the disk has I/O errors during the conversion. After you convert a basic disk into a dynamic disk, any existing partitions on the basic disk become (dynamic) simple volumes. You cannot change the dynamic volumes back to partitions.

**Caution**

- If you are using a basic disk as a storage area for shadow copies and you intend to convert the disk into a dynamic disk, it is important to take the following precaution to avoid data loss. If the disk is a non-boot volume and is a different volume from where the original files reside, you must first dismount and take offline the volume containing the original files before you convert the disk containing shadow copies to a dynamic disk. You must bring the volume containing the original files back online within 20 minutes. Otherwise, you will lose the data stored in the existing shadow copies. If the shadow copies are located on a boot volume, you can convert the disk to dynamic without losing shadow copies.

  You can use the **mountvol** command with the **/p** option to dismount the volume and take it offline. You can mount the volume and bring it online using the **mountvol** command or the Disk Management snap-in.

Dynamic disks cannot be directly accessed by MS-DOS, Windows 95, Windows 98, Windows Millennium Edition, Windows NT, or Windows XP Home Edition, so you cannot start these operating systems on dynamic disks. However, shared folders on dynamic disks are available across a network to computers running all of these operating systems.

Access to dynamic disks is further restricted by the partition style used on the dynamic disk:

- Only x86-based computers running Windows 2000, Windows XP Professional, or Windows Server 2003 operating systems, and Itanium-based computers running the 64-bit version of Windows Server 2003, Enterprise Edition, or the 64-bit version of Windows Server 2003, Datacenter Edition, can access dynamic MBR disks.

- Only Itanium-based computers, x86-based computers running Windows Server 2003 with Service Pack 1 (SP1), and x64-based computers can access dynamic GUID partition table (GPT) disks.

For instructions on how to convert a basic disk into a dynamic disk, see Change a basic disk into a dynamic disk.

For more information about dynamic disks and volumes, see Dynamic disks and volumes.

# Using Windows NT 4.0 multidisk storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Windows NT 4.0 multidisk storage**

Windows Server 2003 operating systems do not support mirror sets, stripe sets, stripe sets with parity, or volume sets created in Windows NT 4.0. These multidisk volumes must be backed up and deleted, or otherwise converted to dynamic disks prior to installing Windows Server 2003 operating systems. If you did not back up the volumes before you upgraded to Windows Server 2003, you can access these volumes using the FTOnline utility. You can install the FTOnline utility using the Support Tools setup program located in the \Support\Tools folder on the Windows XP Professional and on the Windows Server 2003 operating system CDs.

In Windows Server 2003 operating systems, you can use dynamic disks to create the equivalent types of multidisk storage found on basic disks in Windows NT 4.0.

| Windows NT 4.0 Storage Type | Windows Server 2003 family Storage Type |
|---|---|
| mirror set | mirrored volume |
| stripe set | striped volume |
| stripe set with parity | RAID-5 volume |
| volume set | spanned volume |

Mirrored volumes and RAID-5 volumes are not available on Windows XP Home Edition or Windows XP Professional and cannot be extended.

For more information about dynamic disks, see Using Dynamic Disks.

# Using Dynamic Disks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using dynamic disks**

- Using spanned volumes
- Using striped volumes
- Using mirrored volumes
- Using RAID-5 volumes

# Using simple volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using simple volumes**

A simple volume is a portion of a physical disk that functions as though it were a physically separate unit. Simple volumes are the dynamic storage equivalent of primary partitions in Windows NT 4.0 or earlier. When you have only one dynamic disk, they are the only kind of volume that you can create.

You can create simple volumes only on dynamic disks. Simple volumes (and the data they contain) cannot be accessed by, or created on, computers running MS-DOS, Windows 95, Windows 98, Windows Millennium Edition, Windows NT 4.0, or Windows XP Home Edition that are configured to dual-boot with Windows XP Professional or Windows Server 2003 operating systems. If you want computers running these operating systems to be able to access the data, store the data on basic volumes.

You can increase the size of an existing simple volume by extending the volume onto unallocated space on the same disk or a different disk. To extend a simple volume, the volume must be unformatted or formatted with the version of NTFS used in Windows 2000 or Windows Server 2003 operating systems. With Windows Server 2003, simple volumes can be extended unless they are system partitions, boot partitions, or simple volumes that were formerly partitions on basic disks that were converted to dynamic using Windows 2000. By extending the simple volume on the same disk, the volume remains a simple volume and you can still mirror it.

You can also extend a simple volume to regions on other dynamic disks on the same computer. When you extend a simple volume to one or more other disks, it becomes a spanned volume. After a spanned volume is extended, no portion of it can be deleted without deleting the entire spanned volume. Spanned volumes cannot be mirrored.

For procedures on creating and extending simple volumes, see Manage Simple Volumes.

**Assigning drive letters**

You can create more than 26 volumes with Windows, but you cannot assign more than 26 drive letters for accessing these volumes. Drive letters A and B are typically reserved for floppy disk drives. If the computer does not have a floppy disk drive, you can assign drive letters A and B to removable drives, hard disk drives, or mapped network drives. Hard disk drives are typically assigned drive letters C through Z, while mapped network drives are assigned drive letters in reverse order (Z through C).

You should be careful when making drive-letter assignments because many programs for MS-DOS and Windows make references to a specific drive letter. The path environment variable shows specific drive letters with program names.

Volumes created after the 26th drive letter has been used must be accessed using volume mount points, as described in Using NTFS mounted drives.

**Formatting and labeling volumes**

Before you can store files and directories on the volumes that you have created, you must first format each volume for use with the file system that you want to work with. You can also assign descriptive volume labels at this time.

If a volume uses NTFS formatting, you can enable data compression. Before you can format a volume, you must assign it either a drive letter or a mount point, if it does not already have one.

To format a volume, see Format a dynamic volume.

**Deleting volumes**

Before deleting volumes, you need to make sure the information on them has been backed up onto another storage medium and verified, or that the data is no longer needed. Windows XP and Windows Server 2003 operating systems do not allow you to delete the system volume or boot volume.

# Using spanned volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using spanned volumes**

Spanned volumes combine areas of unallocated space from multiple disks into one logical volume, allowing you to more efficiently use all of the space and all drive letters on a multiple-disk system.

When you need to create a volume but do not have enough unallocated space for the volume on a single disk, you might be able to create a volume of sufficient size by combining sections of unallocated space from multiple disks into one spanned volume. The areas of unallocated space used to create spanned volumes can be different sizes. Spanned volumes are organized so that the space allocated to the volume on one disk gets filled up and then, starting at the next disk, the space allocated to the volume on that disk gets filled up.

Spanned volumes allow you to get more data on a disk without using mount points. By combining the space used by multiple disks into one spanned volume, you can free drive letters for other uses and enable the creation of a large volume for file system use.

Increasing the capacity of an existing volume is called *extending*. Existing spanned volumes formatted with the NTFS file system can be extended by the amount of unallocated space on all disks. However, after a spanned volume is extended, no portion of it can be deleted without deleting the entire spanned volume. Disk Management formats the new area without affecting any existing files on the original spanned volume. You cannot extend spanned volumes formatted with the FAT file system.

Before making any changes to spanned volumes, you should first back up all the information on the volume.

For procedures on working with spanned volumes, see Manage Spanned Volumes.

**Caution**

- Spanned volumes cannot be mirrored and do not offer fault tolerance. If one of the disks containing a spanned volume fails, the entire volume fails and all the data on it is lost.

You can create spanned volumes on dynamic disks only. You need at least two dynamic disks to create a spanned volume. MS-DOS, Windows 95, Windows 98, Windows NT 4.0, Windows XP Home Edition, and other operating systems lacking dynamic storage capability cannot recognize any spanned volumes created by Windows 2000, Windows XP Professional, or Windows Server 2003 operating systems. Therefore, if you create a spanned volume on a dual-boot computer, the disks that make up that volume become unusable by those operating systems.

# Using striped volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using striped volumes**

Striped volumes are created by combining areas of free space on two or more disks into one logical volume. Striped volumes use RAID-0, which stripes data across multiple disks. Striped volumes cannot be extended or mirrored, and do not offer fault tolerance. If one of the disks containing a striped volume fails, the entire volume fails. When creating striped volumes, it is best to use disks that are the same size, model, and manufacturer.

With a striped volume, data is divided into blocks and spread in a fixed order among all the disks in the array, similar to spanned volumes. Striping writes files across all disks so that data is added to all disks at the same rate.

Despite their lack of fault tolerance, striped volumes offer the best performance of all the Windows disk management strategies and provide increased I/O performance by distributing I/O requests across disks. For example, striped volumes offer improved performance when:

- Reading from or writing to large databases.
- Collecting data from external sources at very high transfer rates.
- Loading program images, dynamic-link libraries (DLLs), or run-time libraries.

MS-DOS, Windows 95, Windows 98, Windows Millinnium Edition, Windows NT 4.0, Windows XP Home Edition, and other operating systems lacking dynamic storage capability cannot recognize any striped volumes created by Windows 2000, Windows XP Professional, or Windows Server 2003 operating systems. Therefore, if you create a striped volume on a dual-boot computer, that volume becomes unusable by those operating systems.

For instructions on creating a striped volume, see Create a striped volume.

# Using mirrored volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using mirrored volumes**

A mirrored volume is a fault-tolerant volume that provides data redundancy by using two copies, or mirrors, of the volume to duplicate the data stored on the volume. All data written to the mirrored volume is written to both mirrors, which are located on separate physical disks.

If one of the physical disks fails, the data on the failed disk becomes unavailable, but the system continues to operate using the unaffected disk. When one of the mirrors in a mirrored volume fails, you must break the mirrored volume to expose the remaining mirror as a separate volume with its own drive letter. You can then create a new mirrored volume with unused free space of equal or greater size on another disk. When creating mirrored volumes, it is best to use disks that are the same size and model and from the same manufacturer. You cannot extend a mirrored volume to increase the size of the volume later.

Because dual-write operations can degrade system performance, many mirrored volume configurations use duplexing, where each disk in the mirrored volume resides on its own disk controller. A duplexed mirrored volume has the best data reliability because the entire input/output (I/O) subsystem is duplicated. This means that if one disk controller fails, the other controller (and thus the disk on that controller) continues to operate normally. If you do not use two controllers, a failed controller makes both mirrors in a mirrored volume inaccessible until the controller is replaced.

When you mirror the system or boot volumes, you can make the configuration more fault tolerant by using a separate disk controller for each disk in the mirrored volume. This enables your computer to survive hard-disk or disk-controller failures. When creating mirrored volumes, it is best to use disks that are the same size and model, and from the same manufacturer. If you are using duplexing, it is recommended that you use identical disks and controllers, especially if you plan to mirror the system or boot volumes. For more information, see Create and test a mirrored system or boot volume. On Itanium-based computers, you cannot mirror the Extensible Firmware Interface (EFI) system partition on GUID partition table (GPT) disks. Instead, you must use the **bootcfg** command to clone the EFI system partition.

**Important**

- When mirroring the system volume, always test to make sure you can start the operating system from each mirror if one of the disks fails. To help prevent startup problems, always use identical disks and controllers.

You can create mirrored volumes using a combination of master boot record (MBR) and GUID partition table (GPT) disks, but the MBR cylinder-alignment restriction may cause some difficulties in creating mirrored volumes. Always mirror the MBR disk to the GPT disk to avoid cylinder-alignment difficulties.

For step-by-step procedures on how to create, break, or repair a mirrored volume, or to add or remove a mirror from an existing mirrored volume, see Manage Mirrored Volumes.

For information about which operating systems support mirrored volumes, see Partition styles.

For more information about mirrored volumes, see "Disk Management" at the Microsoft Windows Resource Kits Web site.

# Using RAID-5 volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using RAID-5 volumes**

A RAID-5 volume is a fault-tolerant volume with data and parity striped intermittently across three or more physical disks. If a portion of a physical disk fails, you can recreate the data that was on the failed portion from the remaining data and parity. RAID-5 volumes are a good solution for data redundancy in a computer environment where most activity consists of reading data.

You can create a RAID-5 volume using hardware- or software-based solutions. With hardware-based RAID, an intelligent disk controller handles the creation and regeneration of redundant information on the disks that make up the RAID-5 volume. Windows Server 2003 operating systems provide software-based RAID, where the creation and regeneration of redundant information on the disks in the RAID-5 volume is handled by Disk Management. In either case, data is stored across all members in the disk array.

In general, hardware-based RAID offers performance advantages over software-based RAID because hardware-based RAID incurs no overhead on the system processor. For example, you can improve data throughput significantly by implementing RAID-5 through hardware that does not use system software resources. This is accomplished by using more disks at a given capacity than would typically be available in a conventional storage solution. Read and write performance and total storage size can be further improved by using multiple disk controllers.

RAID-5 volumes have better read performance than mirrored volumes. When a member is missing, however, such as when a disk has failed, the read performance is degraded by the need to recover the data with the parity information. Nevertheless, this strategy is recommended over mirrored volumes for programs that require redundancy and are primarily read-oriented. Write performance is reduced by the parity calculation. A write operation also requires three times more memory than a read operation during normal operation. Moreover, when a volume fails, reading requires at least three times more memory than before the failure. Both conditions are caused by the parity calculation.

RAID-5 volumes include one parity block per stripe. Therefore, you must use at least three disks, rather than two, to allow for the parity information. Parity stripes are distributed across all the volumes to balance the input/output (I/O) load. When regenerating a RAID-5 volume, the parity information with the data on the healthy disks is used to recreate the data on the failed disk.

For step-by-step information about how to create and repair RAID-5 volumes, see Manage RAID-5 Volumes.

For information about which operating systems support RAID-5 volumes, see Partition styles.

For more information about mirrored volumes, see "Disk Management" at the Microsoft Windows Resource Kits Web site.

# Managing disks and volumes from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing disks and volumes from the command line**
In addition to using the Disk Management snap-in, you can use command-line utilities to manage disks and volumes.

For example, you can use:

- chkdsk to check disks for errors and repair any errors found.
- Convert to change FAT or FAT32 volumes into NTFS volumes.
- DiskPart to extend basic or dynamic volumes, add or break mirrors, assign or remove a disk's drive letter, create or delete partitions and volumes, convert basic disks to dynamic disks, or convert master boot record (MBR) disks to GUID partition table (GPT) disks, import disks and bring offline disks and volumes online.
- Format to format a volume or mounted drive with a file system.
- Fsutil to perform many NTFS file system related tasks, such as managing disk quotas, dismounting a volume, or querying volume information. Because **fsutil** is quite powerful, it should be used only by advanced users who have a thorough knowledge of Windows XP Professional or Windows Server 2003 operating systems.
- Mountvol to mount a volume at an NTFS folder or unmount the volume from the NTFS folder.

For information about other command-line utilities, see Command-line reference A-Z.

# Disk Management Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

- You can learn more about Disk Management in "Disk Management" at the Microsoft Resource Kits Web site. The Microsoft Windows Resource Kits provide information technology professionals with the technical information and tools they need to successfully deploy, manage, and support Windows operating systems.

# Troubleshooting Disk Management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2, Windows Server 8 Beta

**Troubleshooting**
What problem are you having?

- Partitions on basic disks added to the system do not appear in the Disk Management volume list view.
- A basic disk's status is Not Initialized.
- A basic or dynamic disk's status is Unreadable.
- A dynamic disk's status is Foreign.
- A dynamic disk's status is Online (Errors).
- A dynamic disk's status is Offline or Missing.
- A basic or dynamic volume's status is Failed.
- A basic or dynamic volume's status is Unknown.
- A dynamic volume's status is Data Incomplete.
- Cannot manage striped, mirrored, or RAID-5 volumes using Disk Management or DiskPart.
- A dynamic volume's status is Healthy (At Risk).
- A mirrored volume's status is Data Not Redundant.
- A mirrored volume's status is Failed.
- A mirrored volume's status is Failed Redundancy.
- A mirrored volume's status is Stale Data.
- A RAID-5 volume's status is Data Not Redundant.
- A RAID-5 volume's status is Failed.
- A RAID-5 volume's status is Failed Redundancy.
- A RAID-5 volume's status is Stale Data.

**Partitions on basic disks added to the system do not appear in the Disk Management volume list view.**
**Cause:** For better interoperability in storage area network (SAN) environments, on Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition, volumes on basic disks added to the system are not automatically mounted and assigned drive letters by default.

Dynamic disks appear as **Foreign** when they are added to the system. To use the volumes, you must import the **Foreign** disks and then bring the volumes **Online**.

Removable media devices (such as Zip or Jaz drives), and optical discs (such as CD-ROM or DVD-RAM) are always

automatically mounted by the system.

**Solution:** Manually mount the basic volumes by assigning drive letters, or by creating mount points using Disk Management or the **DiskPart** or **mountvol** commands.

For instructions describing how to assign a drive letter, see Assign, change, or remove a drive letter.

For more information about the **DiskPart** or **mountvol** commands, see DiskPart or Mountvol.

**A basic disk's status is Not Initialized.**

**Cause:** The disk does not contain a valid signature. After you install a new disk, the operating system must write a disk signature, the end of sector marker (also called signature word), and a master boot record or GUID partition table before you can create partitions on the disk. When you first start Disk Management after installing a new disk, a wizard appears that provides a list of the new disks detected by the operating system. If you cancel the wizard before the disk signature is written, the disk status remains **Not Initialized**.

**Solution:** Initialize the disk. The disk status briefly changes to **Initializing** and then **Online** status. For instructions describing how to initialize a disk, see Initialize new disks.

For more information about disk status descriptions, see Disk status descriptions.

**A basic or dynamic disk's status is Unreadable.**

**Cause:** The basic or dynamic disk is not accessible and might have experienced hardware failure, corruption, or I/O errors. The disk's copy of the system's disk configuration database might be corrupted. An error icon appears on disks that display the **Unreadable** status.

Disks might also display the **Unreadable** status while they are spinning up or when Disk Management is rescanning all of the disks on the system. In some cases, an unreadable disk has failed and is not recoverable. For dynamic disks, the **Unreadable** status usually results from corruption or I/O errors on part of the disk, rather than failure of the entire disk.

**Solution:** Rescan the disks or restart the computer to see if the disk status changes. For instructions describing how to rescan the disks, see Update disk information.

For more information about disk status descriptions, see Disk status descriptions.

**A dynamic disk's status is Foreign.**

**Cause:** The **Foreign** status occurs when you move a dynamic disk to the local computer from another computer running Windows 2000, Windows XP Professional, Windows XP 64-bit Edition (Itanium), or the Windows Server 2003 family of operating systems. A warning icon appears on disks that display the **Foreign** status.

In some cases, a disk that was previously connected to the system can display the **Foreign** status. Configuration data for dynamic disks is stored on all dynamic disks, so the information about which disks are owned by the system is lost when all dynamic disks fail.

**Solution:** Add the disk to your computer's system configuration so that you can access data on the disk. To add a disk to your computer's system configuration, import the foreign disk (right-click the disk and then click **Import Foreign Disks**). Any existing volumes on the foreign disk become visible and accessible when you import the disk.

For more information about disk status descriptions, see Disk status descriptions.

**A dynamic disk's status is Online (Errors).**

**Cause:** The dynamic disk has I/O errors on a region of the disk. A warning icon appears on the dynamic disk with errors.

**Solution:** If the I/O errors are temporary, reactivate the disk to return it to **Online** status. For instructions describing how to bring the disk back online, see Reactivate a missing or offline dynamic disk.

For more information about disk status descriptions, see Disk status descriptions.

**A dynamic disk's status is Offline or Missing.**

**Cause:** An **Offline** dynamic disk might be corrupted or intermittently unavailable. An error icon appears on the offline dynamic disk.

If the disk status is **Offline** and the disk's name changes to **Missing**, the disk was recently available on the system but can no longer be located or identified. The missing disk may be corrupted, powered down, or disconnected.

**Solution:**

**To bring a disk that is Offline and Missing back online**

Repair any disk, controller, or cable problems and make sure that the physical disk is turned on, plugged in, and attached to the computer. Next, use the **Reactivate Disk** command to bring the disk back online. For instructions describing how to reactivate missing or offline disks, see Reactivate a missing or offline dynamic disk.

If the disk status remains **Offline** and the disk name remains **Missing**, and you determine that the disk has a problem that cannot be repaired, you can remove the disk from the system (right-click the disk and then click **Remove Disk**). However, before you can remove the disk, you must delete all volumes (or mirrors) on the disk. You can save any mirrored volumes on the disk by removing the mirror instead of the entire volume. Deleting a volume destroys the data in the volume, so you should remove a disk only if you are absolutely certain that the disk is permanently damaged and unusable.

**To bring a disk that is Offline and is still named Disk # (not Missing) back online, try one or more of the following:**

- In Disk Management, right-click the disk and then click **Reactivate Disk** to bring the disk back online. If the disk status remains **Offline**, check the cables and disk controller, and make sure that the physical disk is healthy. Correct any problems and try to reactivate the disk again. If the disk reactivation succeeds, any volumes on the disk should automatically return to the **Healthy** status.

- In Event Viewer, check the event logs for any disk related errors such as “no good config copies”. If the event logs contain the "no good config copies" error, contact Microsoft Product Support Services.

- Try moving the disk to another computer. If you can get the disk to go **Online** on another computer, the problem is most likely due to the configuration of the computer where the disk does not go **Online**.

- Try moving the disk to another computer that has dynamic disks. Import the disk on that computer and then move it back to the computer where it would not go **Online**.

For more information about disk status descriptions, see Disk status descriptions.

**A basic or dynamic volume's status is Failed.**
**Cause:** The basic or dynamic volume cannot be started automatically, the disk is damaged, or the file system is corrupt. Unless the disk or file system can be repaired, the **Failed** status indicates data loss.

**Solution:** If the volume is a basic volume with **Failed** status, make sure that the underlying physical disk is turned on, plugged in, and attached to the computer. No other user action is possible for basic volumes.

If the volume is a dynamic volume with **Failed** status, make sure the underlying disks are online. If not, return the disks to the **Online** status. If this succeeds, the volume automatically restarts and returns to the **Healthy** status. For instructions describing how to bring a disk online, see Reactivate a missing or offline dynamic disk.

If the dynamic disk returns to the **Online** status, but the dynamic volume does not return to the **Healthy** status, you can reactivate the volume manually. For instructions describing how to reactivate a volume, see Reactivate a dynamic volume.

If the dynamic volume is a mirrored or RAID-5 volume with old data, bringing the underlying disk online will not automatically restart the volume. If the disks that contain current data are disconnected, you should bring those disks online first (to allow the data to become synchronized). Otherwise, restart the mirrored or RAID-5 volume manually, and then run the Error-checking tool or Chkdsk.exe.

For instructions describing how to reactivate a volume, see Reactivate a dynamic volume. For instructions describing how to run the Error-checking tool, see Detecting and repairing disk errors. To run Chkdsk.exe, click **Start**, click **Run**, type **chkdsk**, and then click **OK**.

For more information about volume status descriptions, see Volume status descriptions.

**A basic or dynamic volume's status is Unknown.**
**Cause:** The **Unknown** status occurs when the boot sector for the volume is corrupted (possibly due to a virus) and you can no longer access data on the volume. The **Unknown** status also occurs when you install a new disk but do not successfully complete the wizard to create a disk signature.

**Solution:** Initialize the disk. For instructions describing how to initialize a disk, see Initialize new disks.

For more information about volume status descriptions, see Volume status descriptions.

**A dynamic volume's status is Data Incomplete.**
**Cause:** You moved some but not all of the disks in a multidisk volume. Data on this volume will be destroyed unless you

move and import the remaining disks that contain this volume.

**Solution:** Move all of the disks that comprise the multidisk volume to the computer and then import the disks. For instructions describing how to move and import disks, see Move disks to another computer.

If you no longer require the multidisk volume, you can import the disk and create new volumes on it. Right-click the volume with **Failed** or **Failed Redundancy** status and then click **Delete Volume**. Right-click the disk and then click **New Volume**.

For more information about volume status descriptions, see Volume status descriptions.

**A dynamic volume's status is Healthy (At Risk).**
**Cause:** Indicates that the dynamic volume is currently accessible, but I/O errors have been detected on the underlying dynamic disk. If an I/O error is detected on any part of a dynamic disk, all volumes on the disk display the **Healthy (At Risk)** status and a warning icon appears on the volume.

When the volume status is **Healthy (At Risk)**, an underlying disk's status is usually **Online (Errors)**.

**Solution:** Return the underlying disk to the **Online** status. Once the disk is returned to **Online** status, the volume should return to the **Healthy** status. If the **Healthy (At Risk)** status persists, the disk might be failing. Back up the data and replace the disk as soon as possible. For instructions describing how to bring the disk back online, see Reactivate a missing or offline dynamic disk.

For more information about volume status descriptions, see Volume status descriptions.

**Cannot manage striped, mirrored, or RAID-5 volumes using Disk Management or DiskPart.**
**Cause:** Some non-Microsoft disk management products replace Microsoft Logical Disk Manager (LDM) for advanced disk management, which can disable the LDM.

**Solution:** If you are using non-Microsoft disk management software that has disabled LDM, you must contact the vendor on the non-Microsoft disk management software for support or assistance in troubleshooting problems with the disk configuration.

**A mirrored volume's status is Data Not Redundant.**
**Cause:** One half, but not both halves, of a mirrored volume was imported. In Disk Management, the imported half of the mirrored volume receives **Failed Redundancy** status, while the disk that holds the half of the mirror that was not imported receives **Missing** status. You can import the **Missing** disk at a later time to restore redundancy.

**Solution:** Move all disks that span this volume to the new computer at the same time, and then import all of the disks together. For instructions describing how to move and import disks, see Move disks to another computer.

If you no longer require a mirrored volume, you can break the mirror and retain the imported half of the mirror as a simple volume. Right-click the mirrored volume with **Failed Redundancy** status and then click **Remove Mirror**. In the **Remove Mirror** dialog box, click the disk with **Missing** status and then click **Remove Mirror**. The imported half of the mirror with **Failed Redundancy** status becomes a simple volume with **Healthy** status. For more information about how to break a mirrored volume, see Remove a mirror from a mirrored volume.

For more information about volume status descriptions, see Volume status descriptions.

For more information about disk status descriptions, see Disk status descriptions.

**A mirrored volume's status is Failed.**
**Cause:** The mirrored volume cannot be started automatically, or the disk is damaged. Unless the disk can be repaired, the **Failed** status indicates data loss.

**Solution:** Make sure that the underlying physical disks are turned on, plugged in, and attached to the computer. Make sure that the underlying physical disks are online. If not, return the disks to the **Online** status. If this succeeds, the volume automatically restarts and changes to **Failed Redundancy** status. For instructions describing how to bring a disk online, see Reactivate a missing or offline dynamic disk.

If the dynamic disk returns to the **Online** status, but the dynamic volume does not return to the **Healthy** status, you can reactivate the volume manually. For instructions describing how to reactivate a volume, see Reactivate a dynamic volume.

If the dynamic volume is a mirrored volume with old data, bringing the underlying physical disk online will not automatically restart the volume. If the disks that contain current data are disconnected, you should bring those disks online first (to allow the data to become synchronized). Otherwise, restart the mirrored volume manually, and then run the Error-checking tool or **Chkdsk.exe**.

For instructions describing how to reactivate a volume, see Reactivate a dynamic volume. For instructions describing how to run the Error-checking tool, see Detecting and repairing disk errors. To run Chkdsk.exe, click **Start**, click **Run**, type **chkdsk**, and then click **OK**.

For more information about volume status descriptions, see Volume status descriptions.

**A mirrored volume's status is Failed Redundancy.**
**Cause:** One or both of the members of the mirrored volume has failed, and the volume is no longer fault tolerant. To avoid data loss, you should attempt to repair the volume as soon as possible.

**Solution:** If the dynamic disk's status is **Offline** or **Missing** (it cannot be accessed at all), an icon **(X)** appears in the graphical view of the Missing or Offline disk. For instructions describing how to repair the mirrored volume, see Reconnect the disk and repair the mirrored volume.

If the disk's status is **Online (Errors)**, an icon **(!)** appears in the graphical view of the disk. For instructions describing how to reactivate the disk, see Reactivate a mirrored volume.

For more information about volume status descriptions, see Volume status descriptions.

For more information about disk status descriptions, see Disk status descriptions.

**A mirrored volume's status is Stale Data.**
**Cause:** If you attempt to import disks that contain a mirrored volume, but one of the volumes on the disks contains stale mirror information, the status **Stale Data** appears in the **Import Foreign Disks** dialog box. This problem can occur when the volumes on the disks you moved had a status other than **Healthy** before you moved them.

**Solution:** Move the disks back to the computer that they came from. In Disk Management, click **Action**, and then click **Rescan Disks**; or restart the computer to make sure all of the disks are installed correctly.

If the volume showed the **Failed Redundancy** status before the disks were moved, the volume will still show the **Failed Redundancy** status when the disks are moved back. Make sure that the status of the disk with stale mirror information is not **Offline**. If the status is **Offline**, check for any hardware problems, reconnect the disk if necessary, and then bring the disk back online. For instructions describing how to bring a mirrored volume back online, see Reconnect the disk and repair the mirrored volume.

If the volume still shows the **Failed Redundancy** status, reactivate the volume. Disk Management will attempt to bring the volume back online. You will see a warning message indicating that Disk Management might not be able to bring back all of the data on the volume. For instructions describing how to reactivate a volume, see Reactivate a dynamic volume.

If Disk Management successfully brings the volumes back online, the status of the volume becomes **Healthy** and any mirrored volumes on the disk will be resynchronized. Now you can move all of the disks that contain this volume to another computer, attach them, and import all of the disks at the same time.

For more information about volume status descriptions, see Volume status descriptions.

For more information about disk status descriptions, see Disk status descriptions.

**A RAID-5 volume's status is Data Not Redundant.**
**Cause:** You moved some but not all of the disks in a RAID-5 volume. If you choose to import all but one of the disks, the RAID-5 volume receives the **Failed Redundancy** status. If more than one disk is missing from the RAID-5 volume, the volume receives the **Failed** status.

**Solution:** Move all disks that comprise this volume to the new computer at the same time, and then import all of the disks together. For instructions describing how to move and import disks, see Move disks to another computer.

If you imported all but one of the disks in the RAID-5 volume, the volume receives **Failed Redundancy** status. Right-click the volume and then click **Repair Volume**. Select another suitable dynamic disk to repair the RAID-5 volume. After the RAID-5 volume returns to **Healthy** status, you can right-click the missing disk and then click **Remove Disk**.

If you no longer require the RAID-5 volume, you can import the disks and create new volumes on them. The RAID-5 volume receives the **Failed Redundancy** or **Failed** status. Right-click the volume and then click **Delete Volume**. Right-click each disk and then click **New Volume**.

For more information about volume status descriptions, see Volume status descriptions.

**A RAID-5 volume's status is Failed.**
**Cause:** The RAID-5 volume cannot be started automatically, or the disk is damaged. Unless the disk can be repaired, the

**Failed** status indicates data loss.

**Solution:** Make sure that the underlying physical disk is turned on, plugged in, and attached to the computer. Make sure that the underlying physical disks are online. If not, return the disks to the **Online** status. If this succeeds, the volume automatically restarts and returns to the **Healthy** status. For instructions describing how to bring a disk online, see Reactivate a missing or offline dynamic disk.

If the RAID-5 volume returns to the **Online** status, but the volume does not return to the **Healthy** status, you can reactivate the volume manually. For instructions describing how to reactivate a volume, see Reactivate a dynamic volume.

If the dynamic volume is a RAID-5 volume with old data, bringing the underlying disk online will not automatically restart the volume. If the disks that contain current data are disconnected, you should bring those disks online first (to allow the data to become synchronized). Otherwise, restart the RAID-5 volume manually, and then run the Error-checking tool or **Chkdsk.exe**.

For instructions describing how to reactivate a volume, see Reactivate a dynamic volume. For instructions describing how to run the Error-checking tool, see Detecting and repairing disk errors. To run Chkdsk.exe, click **Start**, click **Run**, type **chkdsk**, and then click **OK**.

For more information about volume status descriptions, see Volume status descriptions.

**A RAID-5 volume's status is Failed Redundancy.**
**Cause:** One of the members of the RAID-5 volume has failed and the volume is no longer fault tolerant. To avoid data loss, you should attempt to repair the volume as soon as possible.

**Solution:** If the dynamic disk's status is **Offline** or **Missing** (it can not be accessed at all), an icon **(X)** appears in the graphical view of the Missing or Offline disk. For instructions describing how to repair a RAID-5 volume, see Reconnect the disk and repair the RAID-5 volume.

If the disk's status is **Online (Errors)**, an icon **(!)** appears in the graphical view of the partially failed disk. For instructions describing how to reactivate the disk, see Reactivate a RAID-5 disk.

For more information about volume status descriptions, see Volume status descriptions.

For more information about disk status descriptions, see Disk status descriptions.

**A RAID-5 volume's status is Stale Data.**
**Cause:** If you attempt to import disks that contain a RAID-5 volume, but one of the volumes on the disks contains stale parity information, the status **Stale Data** appears in the **Import Foreign Disks** dialog box. This problem can occur when the volumes on the disks you moved had a status other than **Healthy** before you moved them.

**Solution:** Move the disks back to the computer that they came from. In Disk Management, click **Action**, and then click **Rescan Disks**; or restart the computer to make sure all of the disks are installed correctly.

If the volume showed the **Failed Redundancy** status before the disks were moved, the volume will still show the **Failed Redundancy** status when the disks are moved back. Make sure that the status of the disk that contained the stale parity information is not **Offline**. If the status is **Offline**, check for any hardware problems, reconnect the disk if necessary, and then bring the disk back online. For instructions describing how to bring a RAID-5 volume back online, see Reactivate a RAID-5 disk.

If the volume still shows the **Failed Redundancy** status, reactivate the volume. Disk Management will attempt to bring the volume back online. You will see a warning message indicating that Disk Management might not be able to bring back all of the data on the volume. For instructions describing how to reactivate a volume, see Reactivate a dynamic volume.

If Disk Management successfully brings the volumes back online, the status of the volume becomes **Healthy** and any RAID-5 volumes will regenerate parity. Now you can move all of the disks that contain this volume to another computer. However, if you move all but one of the disks, then the volume will show the **Data Not Redundant** status in the **Import Foreign Disk** dialog box. You should attach the missing disks and import all of the disks at the same time.

For more information about volume status descriptions, see Volume status descriptions.

For more information about disk status descriptions, see Disk status descriptions.

# Disk Defragmenter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Disk Defragmenter**

Disk Defragmenter is a system utility for analyzing local volumes and locating and consolidating fragmented files and folders. You can also defragment disks from a command line using the Defrag command.

- Before defragmenting files or folders, see Checklist: Defragmenting volumes.
- For tips about using Disk Defragmenter, see Best practices for Disk Defragmenter.
- For help with specific tasks, see Disk Defragmenter How To....
- For general background information, see Disk Defragmenter Concepts.
- For problem-solving instructions, see Troubleshooting Disk Defragmenter.

# Checklist: Defragmenting volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Defragmenting volumes**

# Best practices for Disk Defragmenter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Analyze before defragmenting a volume**

- Analyze volumes before defragmenting them. After analyzing a volume, a dialog box tells you the percentage of fragmented files and folders on the volume and recommends whether to defragment the volume. Analyze volumes regularly and defragment them only when Disk Defragmenter recommends it. A good guideline is to analyze volumes at least once a week. If you seldom need to defragment volumes, analyze volumes monthly instead of weekly.

**Analyze after large numbers of files are added**

- Volumes might become excessively fragmented when users add a large number of files or folders, so be sure to analyze volumes after this happens. Generally, volumes on busy file servers should be defragmented more often than those on single-user workstations.

**Ensure that your volume has at least 15% free space**

- A volume must have at least 15% free space for Disk Defragmenter to completely and adequately defragment it. Disk Defragmenter uses this space as a sorting area for file fragments. If a volume has less than 15% free space, Disk Defragmenter will only partially defragment it. To increase the free space on a volume, delete unneeded files or move them to another disk.

**Defragment during low-usage periods**

- Defragment file server volumes during low-volume usage periods to minimize the effect that the defragmentation process has on file server performance. The time that Disk Defragmenter takes to defragment a volume depends on several factors, including the size of the volume, the number of files on the volume, the number of fragmented files, and available system resources.

**Defragment after installing software or installing Windows**

- Defragment volumes after installing software or after performing an upgrade or clean install of Windows. Volumes often become fragmented after installing software, so running Disk Defragmenter helps to ensure the best file system performance.

# Disk Defragmenter How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Analyze a volume
- Defragment a volume

# Analyze a volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To analyze a volume**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Disk Defragmenter.
2. Click the volume that you want to check for fragmented files and folders, and then click **Analyze**.

   When Disk Defragmenter finishes analyzing the volume, it displays its analysis of the volume in **Estimated disk usage before defragmentation**. It also displays a dialog box that tells you whether you need to defragment the volume.
3. Click **View Report** to view the analysis report, which displays more detailed volume information and a list of the most fragmented files.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Disk Defragmenter, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Disk Defragmenter**.
- Running the **defrag** command and Disk Defragmenter are mutually exclusive. If you are using Disk Defragmenter to defragment a volume and you run the **defrag** command at a command prompt, the **defrag** command fails. Conversely, if you run the **defrag** command, and open Disk Defragmenter, the defragmentation options in Disk Defragmenter are unavailable.

**Using a command line**

1. Open Command Prompt.
2. Type **defrag***volume* [**/a**] [**/v**]

| Value | Description |
|---|---|
| *volume* | The drive letter or a mount point of the volume to be analyzed. |
| **/a** | Analyzes the volume, displays a summary of the analysis report, and indicates whether you should defragment the volume. |
| **/v** | Displays the complete analysis report. |

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group

might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, type **defrag /?**

- While **defrag** is analyzing and defragmenting a volume, it displays a blinking cursor. When **defrag** is finished analyzing and defragmenting the volume, it displays the analysis report, the defragmentation report, or both reports, and then exits to the command prompt.

- By default, **defrag** displays a summary of both the analysis and defragmentation reports if you do not specify the **/a** or **/v** parameters.

- You can send the reports to a text file by typing >*filename.txt*, where *filename.txt* is a file name you specify. For example:

  **defrag** *volume* **/v** >*filename.txt*

- Running the **defrag** command and Disk Defragmenter are mutually exclusive. If you are using Disk Defragmenter to defragment a volume and you run the **defrag** command at a command prompt, the **defrag** command fails. Conversely, if you run the **defrag** command, and open Disk Defragmenter, the defragmentation options in Disk Defragmenter are unavailable.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Defragment a volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To defragment a volume**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Disk Defragmenter.
2. Click the volume that you want to defragment, and then click **Defragment**.

   After the defragmentation is complete, Disk Defragmenter displays the results in **Estimated disk usage after defragmentation**.
3. Click **View Report** to view the Defragmentation Report, which displays detailed information about the volume you defragmented.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Disk Defragmenter, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Disk Defragmenter**.
- You should analyze volumes before defragmenting them. This tells you whether you need to take the time to defragment them.
- A volume must have at least 15% free space for Disk Defragmenter to completely and adequately defragment it. Disk Defragmenter uses this space as a sorting area for file fragments. If a volume has less than 15% free space, Disk Defragmenter will only partially defragment it. To increase the free space on a volume, delete unneeded files or move them to another disk.
- You cannot defragment volumes that the file system has marked as dirty, which indicates possible corruption. You must run **chkdsk** on a dirty volume before you can defragment it. You can determine if a volume is dirty by using the **fsutil dirty query** command. For more information about **chkdsk** and **fsutil dirty**, see Related Topics.
- The time that Disk Defragmenter takes to defragment a volume depends on several factors, including the size of the volume, the number and size of files on the volume, the percentage of fragmentation in the volume, and available system resources.
- You can defragment only local file system volumes, and you can run only one instance of Disk Defragmenter at a time.
- To stop or temporarily interrupt defragmenting a volume, click **Stop** or **Pause**, respectively.
- If you start Disk Defragmenter while performing a backup on the same volume, Disk Defragmenter stops.
- Running the **defrag** command and Disk Defragmenter are mutually exclusive. If you are using Disk Defragmenter to

defragment a volume and you run the **defrag** command at a command prompt, the **defrag** command fails. Conversely, if you run the **defrag** command, and open Disk Defragmenter, the defragmentation options in Disk Defragmenter are unavailable.

#### Using a command line

1. Open Command Prompt.

2. Type **defrag***volume* [**/v**]

| Value | Description |
|---|---|
| *volume* | The drive letter or a mount point of the volume to be defragmented. |
| **/v** | Displays the complete analysis and defragmentation reports. |

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, type **defrag /?**

- A volume must have at least 15% free space for **defrag** to completely and adequately defragment it. **Defrag** uses this space as a sorting area for file fragments. If a volume has less than 15% free space, **defrag** will only partially defragment it. To increase the free space on a volume, delete unneeded files or move them to another disk.

- You cannot defragment volumes that the file system has marked as dirty, which indicates possible corruption. You must run **chkdsk** on a dirty volume before you can defragment it. You can determine if a volume is dirty by using the **fsutil dirty query** command. For more information about **chkdsk** and **fsutil dirty**, see Related Topics.

- While **defrag** is analyzing and defragmenting a volume, it displays a blinking cursor. When **defrag** is finished analyzing and defragmenting the volume, it displays the analysis report, the defragmentation report, or both reports, and then exits to the command prompt.

- By default, **defrag** displays a summary of both the analysis and defragmentation reports if you do not specify the **/a** or **/v** parameters.

- You can send the reports to a text file by typing >*filename.txt*, where *filename.txt* is a file name you specify. For example:

  **defrag***volume***/v** >*filename.txt*

- To stop the defragmentation process, at the command prompt, press CTRL+C.

- If you run **defrag** while performing a backup on the same volume, **defrag** stops.

- Running the **defrag** command and Disk Defragmenter are mutually exclusive. If you are using Disk Defragmenter to defragment a volume and you run the **defrag** command at a command prompt, the **defrag** command fails. Conversely, if you run the **defrag** command, and open Disk Defragmenter, the defragmentation options in Disk Defragmenter are unavailable.

#### Information about functional differences

- Understanding Disk Defragmenter
- Resources for Disk Defragmenter

# Disk Defragmenter overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Disk Defragmenter overview**

Disk Defragmenter and the Defrag command analyze local volumes and consolidate fragmented files and folders so that each occupies a single, contiguous space on the volume. As a result, your system can access files and folders and save new ones more efficiently. By consolidating your files and folders, Disk Defragmenter also consolidates a volume's free space, making it less likely that new files will be fragmented. The process of consolidating fragmented files and folders is called defragmentation.

The amount of time that defragmentation takes depends on several factors, including the size of the volume, the number and size of files on the volume, the amount of fragmentation, and the available local system resources. You can find the fragmented files and folders before defragmenting them by analyzing the volume first. You can then see how fragmented the volume is and decide whether you would benefit from defragmenting the volume. For step-by-step instructions describing how to analyze or defragment a volume, see Analyze a volume and Defragment a volume.

Disk Defragmenter can defragment volumes that are formatted with the file allocation table (FAT) file system, the FAT32 file system, and the NTFS file system.

# Understanding Disk Defragmenter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Disk Defragmenter**

This section covers:

- Why volumes become fragmented
- Why files are not moved to some regions of NTFS-formatted volumes
- Disk Defragmenter window
- Analysis and defragmentation reports

# Why volumes become fragmented

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Why volumes become fragmented**

Volumes become fragmented as users create and delete files and folders, install new software, or download files from the Internet. Computers typically save files in the first contiguous free space that is large enough for the file. If a large enough free space is not available, the computer saves as much of the file as possible in the largest available space and then saves the remaining data in the next available free space, and so on.

After a large portion of a volume has been used for file and folder storage, most of the new files are saved in pieces across the volume. When you delete files, the empty spaces left behind fill in randomly as you store new ones.

The more fragmented the volume is, the slower the computer's file input/output performance will be.

# Why files are not moved to some regions of NTFS-formatted volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Why files are not moved to some regions of NTFS-formatted volumes**

On volumes formatted with the NTFS file system, Windows reserves a portion of the free space called the master file table (MFT) Zone, as a space where the MFT can grow. Windows stores all the information necessary to retrieve files from the volume in the MFT.

Disk Defragmenter does not move files to the MFT Zone because it is reserved by Windows. However, Windows allows other files to be saved in the space reserved for the MFT Zone when no other disk space is available.

# Disk Defragmenter window

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Disk Defragmenter window**

The Disk Defragmenter window consists of two main areas. The upper portion lists the volumes on the local computer. The lower portion displays a graphical representation of the amount of fragmentation on the volume in colored horizontal displays called **Estimated disk usage before defragmentation** and **Estimated disk usage after defragmentation**.

Each bar under **Estimated disk usage before defragmentation** and **Estimated disk usage after defragmentation** represents a grouping of dozens or even hundreds of clusters, depending on the size of the volume and the cluster. The displays are not large enough to depict each disk cluster in a volume as a vertical colored bar.

Disk Defragmenter does not attempt to consolidate all of the free space on a volume. Although free space fragmented into hundreds of pieces adversely affects performance, free space split into a few pieces does not. Having all of the free space consolidated in a single location provides very little performance benefit. Because fragmented files, contiguous files, files that cannot be relocated from their current positions on the disk (unmovable files), and free space can all reside in the same group of clusters, the color of each vertical bar is determined by the following rules:

| Color | Description |
|---|---|
| Red | Most of the clusters are part of a fragmented file. |
| Blue | Most of the clusters are contiguous files with clusters in the group that contain only free space and contiguous clusters. |
| Green | Most of the clusters are part of a file that cannot be moved from its current location.<br><br>On volumes formatted using the file allocation table (FAT), FAT32, or NTFS file system, the green areas typically represent paging files, which are also called swap files. On volumes formatted using the NTFS file system, however, they may also represent space used by the NTFS Change journal and the NTFS log file. |
| White | Most of the clusters are free space and contiguous clusters. |

By comparing **Estimated disk usage before defragmentation** to **Estimated disk usage after defragmentation**, you can view the improvement in your volume after defragmenting it. The display shows less detail than the reports, so if you compare the results, you might notice discrepancies. For precise, numerical figures, see Analysis and defragmentation reports.

For step-by-step instructions describing how to analyze or defragment a volume, see Analyze a volume and Defragment a volume.

# Analysis and defragmentation reports

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Analysis and defragmentation reports**

You can view the Analysis and Defragmentation Reports after analyzing or defragmenting a volume. The Analysis and Defragmentation Reports provide detailed information about the volume that was scanned for fragmented files, including the volume size, the amount of free space available, the number of fragmented files and folders, and the average number of fragments per file.

For instructions on how to analyze a volume and view the report, see Analyze a volume. For instructions on how to defragment a volume and view the report, see Defragment a volume.

**Analysis Report**

You can view or print the Analysis Report only after you analyze a volume. The **Analysis Report** dialog box displays detailed information about the volume that was scanned for fragmented files and folders, including the path and name of the most fragmented files on the volume, and the number of fragments those files are in, the volume size, the amount of free space available, and the average number of fragments per file. If you use these files frequently, the impact on your system performance might be greater than indicated in **Average fragments per file**.

The average number of fragments per file is a good indicator of how fragmented the files on the volume are. The following table describes the possible averages and what they indicate:

| Average fragments per file | Description |
|---|---|
| 1.00 | Most or all files are contiguous. |
| 1.10 | About ten percent of the files are in fragments of two or more pieces. |
| 1.20 | About twenty percent of the files are in fragments of two or more pieces. |
| 1.30 | About thirty percent of the files are in fragments of two or more pieces. |
| 2.00 | Most or all of the files are in fragments of two or more pieces. |

**Defragmentation Report**

You can view or print the Defragmentation Report only after you defragment a volume. The **Defragmentation Report** dialog box displays detailed information about the volume that was defragmented. The second half of the Defragmentation Report lists any files that were not defragmented.

If the volume is formatted with the NTFS file system and a file is open and writable, the defragmentation report might show small files (for example, 1 KB in size) with a large number of fragments. This is because when a writable file is open, NTFS attempts to allocate additional space to help prevent fragmentation as the file grows. Because Disk Defragmenter does not allow the extra space to be moved and consolidated while the file is open, the extra space is shown as additional fragments in the report.

# Resources for Disk Defragmenter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

- Disk Defragmenter was developed by Executive Software International in cooperation with Microsoft. For more information about Executive Software International, see the Executive Software International Web site.

- You can learn more about Disk Defragmenter in "Troubleshooting Disks and File Systems" at the Microsoft Windows Resource Kits Web site. The Microsoft Windows Resource Kits provide information technology professionals with the technical information and tools they need to successfully deploy, manage, and support Windows operating systems.

  Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

# Troubleshooting Disk Defragmenter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Computer is running slowly or opening programs on the hard disk has become slow.
- The display and report do not agree.
- There appear to be unmovable files on volumes other than the system volumes and boot volumes.
- The defragmentation report on an NTFS volume shows small files with a large number of fragments.

**Computer is running slowly or opening programs on the hard disk has become slow.**
**Cause:** The volumes on your hard disk may have become excessively fragmented, possibly because you have recently created a large number of files or folders or have installed new software.

**Solution:** Analyze and then defragment the volumes on your hard disk if necessary. For more information, see Best practices for Disk Defragmenter.

**The display and report do not agree.**
**Cause:** The **Estimated disk usage before defragmentation** and **Estimated disk usage after defragmentation** displays provide a general view of a volume's fragmentation. The displays show less detail than the Analysis and Defragmentation reports, so if you compare the results you might notice discrepancies. For precise, numerical figures, always use the reports.

**Solution:** Use the **Estimated disk usage before defragmentation** and **Estimated disk usage after defragmentation** displays only for a general idea of the volume's fragmentation. Use the Analysis and Defragmentation reports for precise, numerical figures. For more information, see Analysis and defragmentation reports.

**There appear to be unmovable files on volumes other than the system volumes and boot volumes.**
**Cause:** Paging files appear as unmovable files in Disk Defragmenter. On NTFS volumes the NTFS change journal also appears as an unmovable file.

**Solution:** This is intentional because paging files cannot be moved and therefore cannot be defragmented. For more information, see Why files are not moved to some regions of NTFS-formatted volumes.

**The defragmentation report on an NTFS volume shows small files with a large number of fragments.**
**Cause:** When a file is open for write access, the NTFS file system attempts to allocate additional space to help prevent fragmentation as the file grows. When you defragment a volume, Disk Defragmenter does not allow the extra space to be moved and consolidated while the file is open. The extra space is shown as additional fragments in the report.

**Solution:** Close the file to release the additional fragments and reduce the size of the file. The **Size on disk** value (right-click the file and then click **Properties**) reports the size that you would obtain if you closed the file.

# Disk Quotas

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Disk quotas**
You use disk quotas to monitor and limit disk space use on NTFS volumes.

- Before setting up disk quotas, see Checklist: Setting up disk quotas.
- For a list of best practices for disk quotas, see Best practices for Disk Quotas.
- For help with specific tasks, see Disk Quotas How To....
- For general background information, see Disk Quotas Concepts.
- For problem-solving instructions, see Troubleshooting Disk Quotas.

# Checklist: Setting up disk quotas

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Setting up disk quotas**

| Step | Reference |
| --- | --- |
| Review key concepts. | Disk quotas overview |
| Confirm that you are a member of the Administrators group. | Default local groups |
| Enable disk quotas. | Enable disk quotas |
| Set disk quotas for an NTFS volume. | Assign default quota values |

# Best practices for Disk Quotas

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Apply appropriate disk quota limits**

- Apply disk quota limits according to realistic disk space requirements for your users. Start by classifying users by the amount of disk space that you anticipate they will require (for example, users who work with scanned photographs or artwork may require a large amount of disk space). Next, structure your volumes by those classes, and then use disk quotas to limit the amount of disk space allowed for the users on each volume.

  Ensure that you have enough disk space to accommodate both existing users and future additions. Each file stored on the volume can use up to 64 kilobytes (KB) of NTFS metadata that is not applied to a user's quota limit. To avoid running out of disk space, ensure that there is sufficient disk space to accommodate this metadata.

**Set default limits**

- Set moderately restrictive default limits for all user accounts, and then modify the limits to allow more disk space to users who work with large files. It may be better to increase disk quota limits for a few user accounts than to force some users to work with a quota limit that does not meet their needs. User Policies occupy at least 2 megabytes (MB) of disk space, so you should set the default limits for all user accounts above 2 MB.

**Allow for growth**

- Set quota limits at a level that will allow for growth in disk space use. When quota increases are warranted, increase them by a percentage of the current quota setting.

**Delete users' quota entries**

- When a user no longer needs the use of a particular volume (for example, when he or she leaves the company), delete the user's quota entry for that volume and then delete, move, or take ownership of any files that the user owns. This helps you eliminate the use of volume space by unneeded files.

**Limit installation to administrators**

- If you enable disk quota settings on the same volume where the Windows operating system and other programs are installed, it is important that the user accounts that are used to install programs and Windows components have a sufficiently high disk quota. You can ensure this in one of two ways:

  - Install all programs and Windows components using the local Administrator account. This account has no quota limit.

  - Configure the disk quota to unlimited (do not limit disk usage) or to a sufficiently large amount of disk space for the user accounts that you use to install programs and Windows components.

# Disk Quotas How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Manage Disk Quotas
- Manage Disk Quota Entries

# Manage Disk Quotas

Updated: January 21, 2005

**Concepts**
Enable disk quotas
Disable disk quotas

# Enable disk quotas

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable disk quotas**

1. Open My Computer.
2. Right-click the disk volume for which you want to enable disk quotas, and then click **Properties**.
3. In the **Properties** dialog box, click the Quota tab.
4. On the **Quota** tab, click the **Enable quota management** check box.
5. Select one or more of the following options, and then click **OK**:

**Deny disk space to users exceeding quota limit**

Users who exceed their quota limit receive an "insufficient disk space" error from Windows and cannot write additional data to the volume without first deleting or moving some existing files from it.

Individual programs determine their own error handling for this condition. To the program, it appears that the volume is full. If you clear this check box, users can exceed their quota limit. Enabling quotas and not limiting disk space use are useful when you do not want to deny users access to a volume but want to track disk space use on a per-user basis. You can also specify whether or not to log an event when users exceed either their quota warning level or their quota limit.

**Limit disk space to**

Enter the amount of disk space that new users of the volume are allowed to use and the amount of disk space that has to be used before an event is written to the system log. Administrators can view these events in Event Viewer. You can use decimal values (for example, 20.5) For the disk space and warning levels, select the appropriate units from the drop-down list (for example, KB, MB, GB). For more information about Event Viewer, see Related Topics.

**Log event when a user exceeds their quota limit**

If quotas are enabled, an event is written to the system log on the local computer whenever users exceed their quota limit. Administrators can view these events in Event Viewer, filtering for disk event types.

By default, quota events are written hourly to the system log on the local computer. You can change the interval at which quota events are written to the system log on the local computer using the **fsutil behavior** command. For more information about Event Viewer or the **fsutil behavior** command, see Related Topics.

**Log event when a user exceeds their warning level**

If quotas are enabled, an event is written to the system log on the local computer whenever users exceed their quota warning level. Administrators can view these events in Event Viewer, filtering for disk event types.

By default, quota events are written hourly to the system log on the local computer. You can change the interval at which quota events are written to the system log on the local computer using the **fsutil behavior** command. For more information about Event Viewer or the **fsutil behavior** command, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.

- If the volume is not formatted with the NTFS file system, or if you are not a member of the Administrators group, the **Quota** tab is not displayed in the volume`s **properties** dialog box.

- Event Viewer builds a historical, chronological record of which users exceeded their quota warning level and quota limits, and when they exceeded them. However, it does not provide information about which users are currently over their quota warning level. To find that information, click the **Quota Entries** button.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable disk quotas**

1. Open My Computer.
2. Right-click the disk volume for which you want to disable disk quotas, and then click **Properties**.
3. In the **Properties** dialog box, click the **Quota** tab.
4. On the **Quota** tab, clear the **Enable quota management** check box, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- If the volume is not formatted with the NTFS file system, or if you are not a member of the Administrators group, the **Quota** tab is not displayed in the volume`s **properties** dialog box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Deny disk space to users who exceed their limit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To deny disk space to users who exceed their limit**

1. Open My Computer.
2. Right-click the volume for which you want to deny disk space use, and then click **Properties**.
3. In the **Properties** dialog box, click the Quota tab.
4. On the **Quota** tab, select the **Enable quota management** check box, select the **Deny disk space to users exceeding quota limit** check box, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- If the volume is not formatted with the NTFS file system, or if you are not a member of the Administrators group, the **Quota** tab is not displayed in the volume`s **properties** dialog box.
- When the disk quota system is configured to deny disk space to users of the volume who exceed their assigned quota limit, users cannot write additional data to the volume without first deleting or moving some existing files from the volume. The response of the system to a user exceeding the quota limit depends on each individual program. To the program, it will appear that the volume is full.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign default quota values

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign default quota values**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open My Computer.
2. Right-click the volume for which you want to assign default quota values, and then click **Properties**.
3. In the **Properties** dialog box, click the **Quota** tab.
4. On the **Quota** tab, select the **Enable quota management** check box, and then select the **Limit disk space to** option.
5. Type numeric values for the disk space limit and warning levels, select the appropriate units from the drop-down lists, and then click **OK**.

   You can use decimal values (for example, 20.5 MB).

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- If the volume is not formatted with the NTFS file system, or if you are not a member of the Administrators group, the **Quota** tab is not displayed in the volume`s **properties** dialog box.
- When you enable disk quotas on a volume, any users with write access to the volume who have not exceeded their quota limit can store data on the volume. The first time a user writes data to a quota-enabled volume, default values for disk space limit and warning level are automatically assigned by the quota system.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **fsutil quota modify** [*VolumePathname*] [*threshold*] [*limit*] [*username*]

| Value | Description |
|---|---|
| *VolumePathname* | The drive letter (followed by a colon). |

| | |
|---|---|
| *Threshold* | The limit, in bytes, at which warnings are issued. |
| *limit* | The maximum allowed disk usage, in bytes. |
| *username* | The domain and user name of the user whose disk usage you want to limit. |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- In order to assign default quota values, the volume must be formatted with the NTFS file system.

- For more information about **fsutil**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage disk quotas on a remote computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manage disk quotas on a remote computer**

1. Right-click **My Computer**, and then click **Map Network Drive**.
2. In the **Map Network Drive** dialog box, in the **Folder** box, type the path to the volume on the remote computer for which you want to manage disk quotas, and then click **Finish**.
3. After you connect to the remote computer's volume, open **My Computer**.
4. Right-click the remote volume for which you want to manage disk quotas, and then click **Properties**.
5. In the **Properties** dialog box, click the **Quota** tab.
6. On the **Quota** tab, click **Quota Entries**.

   The **Quota Entries** window appears. Each row in the list contains information for a user of the volume.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- If the volume is not formatted with the NTFS file system, or if you are not a member of the Administrators group, the **Quota** tab is not displayed in the volume's **Properties** dialog box.
- To manage disk quotas on a remote computer volume, you must create a share from the remote volume's root directory and you must be a member of the Administrators group on the remote computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Disk Quota Entries

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage disk quota entries**

- View disk quota information for volume users
- Add new quota entries
- Delete quota entries
- Modify user disk space limits and warning levels
- Find a quota entry in the Quota Entries window
- Sort quota entries
- Change column order in the Quota Entries window
- Create quota reports
- Import quota settings from another volume
- Export quota settings to another volume

# View disk quota information for volume users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view disk quota information for volume users**

Using the Windows interface

Using a command line

**Using the Windows interface**

1. Open My Computer.
2. Right-click the volume for which you want to view quota information, and then click **Properties**.
3. In the **Properties** dialog box, click the **Quota** tab.
4. On the **Quota** tab, click **Quota Entries**.

   The Quota Entries window appears. Each row contains information for a volume user.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- If the volume is not formatted with the NTFS file system, or if you are not a member of the Administrators group, the **Quota** tab is not displayed in the volume`s **properties** dialog box.
- When the Quota Entries window is first opened, volume quota information must be obtained from the network domain controller. This information is filled in dynamically as it is obtained, and then it is saved so that it is immediately available the next time the Quota Entries window is opened.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **fsutil quota query** [*volumepathname*]

| Value | Description |
|---|---|
| *Volumepathname* | The drive letter for the volume, for example, C: |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- In order to view quota information, the volume must be formatted with the NTFS file system.
- For more information about **fsutil**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add new quota entries

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add new quota entries**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open My Computer.
2. Right-click the volume for which you want to add new disk quota entries, and then click **Properties**.
3. In the **Properties** dialog box, click the **Quota** tab.
4. On the **Quota** tab, click **Quota Entries**.
5. In the Quota Entries window, on the **Quota** menu, click **New Quota Entry**.
6. In the **Select Users** dialog box, in the **Enter the object names to select** text box, type the domain or workgroup name, followed by a back slash and the user name of the user for which you want to impose quotas. Click **OK**.
7. In the **Add New Quota Entry** dialog box, specify one of the following options, and then click **OK**:

   **Do not limit disk usage.** Tracks disk space usage without limiting disk space.

   **Limit disk space to.** Activates fields for limiting disk space and setting warning levels. Type a numeric value in the text field, and then select a disk space limit unit from the drop-down list. You can use decimal values (for example, 20.5 MB).

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- If the volume is not formatted with the NTFS file system, or if you are not a member of the Administrators group, the **Quota** tab is not displayed in the volume`s **properties** dialog box.
- You use the **New Quota Entry** feature to set up quota limits and warning levels before the user actually writes data to the volume. This is useful when you do not want to use the default disk space limit and warning level values for a particular user. Typically, the default disk space limit and warning level values established by the volume administrator are sufficient for new users of the volume.

**Using a command line**

1. Open Command Prompt.
2. Type:

**fsutil quota modify** [*VolumePathname*] [*threshold*] [*limit*] [*domain\username*]

| Value | Description |
|---|---|
| *VolumePathname* | The drive letter (followed by a colon). |
| *threshold* | The limit, in bytes, at which warnings are issued. |
| *limit* | The maximum allowed disk usage, in bytes. |
| *domain\username* | The domain and user name of the user whose disk usage you want to limit. |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- In order to add new quota entries, the volume must be formatted with the NTFS file system.

- For more information about **fsutil**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete quota entries

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete quota entries**

1. Open My Computer.
2. Right-click the volume for which you want to delete quota entries, and then click **Properties**.
3. In the **Properties** dialog box, click the **Quota** tab.
4. On the **Quota** tab, click **Quota Entries**.
5. In the Quota Entries window, click the entries for the users you want to delete, and then on the **Quota** menu, click **Delete Quota Entry**.
6. If the **Disk Quota** dialog box appears, click **Yes**, click the files or folders that you want to take action on, click one of the following buttons, and then click **Close**.

| Button | Action |
|---|---|
| **Delete** | Deletes selected files from the volume. You cannot delete folders. |
| **Take ownership** | Gives you ownership of the selected files or folders on the volume. |
| **Move** | Moves selected files to a specified volume. You cannot move folders. |

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- If the volume is not formatted with the NTFS file system, or if you are not a member of the Administrators group, the **Quota** tab is not displayed in the volume`s **properties** dialog box.
- You can filter the files and folders list to show only files or only folders using the **Show folders only** and **Show files only** check boxes. When working with large numbers of files and folders, it is best to first delete, take ownership, or move files, and then to take ownership of folders.
- User quota entries cannot be deleted if a user still owns files or folders on the volume. Before the record can be deleted, all files owned by that user on the volume must either be deleted or moved to another volume, or you must take ownership of the files and folders.
- You are prompted to delete or move files, or take ownership of files and folders, only if the user still has files or folders on the volume at the time that you want to delete the quota entry.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modify user disk space limits and warning levels

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To modify user disk space limits and warning levels**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open My Computer.
2. Right-click the volume for which you want to modify quota values, and then click **Properties**.
3. In the **Properties** dialog box, click the **Quota** tab.
4. On the **Quota** tab, click **Quota Entries**.
5. In the Quota Entries window, click the entries for the users whose options you want to modify, and on the **Quota** menu, click **Properties**.
6. In the **Quota Settings** dialog box, modify any of the following options you want to change, and then click **OK**:

   **Do not limit disk usage.** Click to track disk space usage without limiting disk space.

   **Limit disk space to.** Activates fields for limiting disk space and setting warning levels. Type a numeric value in the text field, and select a disk space limit unit from the drop-down list. You can use decimal values (for example, 20.5 MB).

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. # Find a quota entry in the Quota Entries window

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To find a quota entry in the Quota Entries window**

1. Open My Computer.
2. Right-click the volume for which you want to find quota entries, and then click **Properties**.
3. In the **Properties** dialog box, click the **Quota** tab.
4. On the **Quota** tab, click **Quota Entries**.
5. In the Quota Entries window, on the **Edit** menu, click **Find**.
6. In the **Find Quota Entry** dialog box, enter the user name that you want to find as either *domain_name\user_name* or *user_name@domain_name*, and then click **OK**.

   Found entries appear highlighted in the Quota Entries window.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- If the volume is not formatted with the NTFS file system, or if you are not a member of the Administrators group, the **Quota** tab is not displayed in the volume`s **properties** dialog box.
- You can find more than one volume user by repeatedly using the **Find Quota Entry** dialog box. Each found entry remains highlighted in the Quota Entries window.
- After you have used the **Find Quota Entry** dialog box to find one or more user quota entries, you can modify the settings for all of the found entries by clicking **Properties** on the **Quota** menu.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Sort quota entries

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To sort quota entries

1. Open My Computer.
2. Right-click the volume for which you want to sort quota entries, and then click **Properties**.
3. In the **Properties** dialog box, click the **Quota** tab.
4. On the **Quota** tab, click **Quota Entries**.
5. In the Quota Entries window, on the **View** menu, click **Arrange Items**, and then click one of the following options:

   **By Folder**
   Sorts according to folder.

   **By User Name**
   Sorts according to the full name.

   **By Logon Name**
   Sorts according to logon name.

   **By Status**
   Sorts according to quota status.

   **By Amount Used**
   Sorts according to the amount of space the users have used on the volume.

   **By Quota Limit**
   Sorts according to disk space limits.

   **By Warning Level**
   Sorts according to warning levels.

   **By Percent Used**
   Sorts according to the percentage of disk space limit used.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- If the volume is not formatted with the NTFS file system, or if you are not a member of the Administrators group, the **Quota** tab is not displayed in the volume`s **properties** dialog box.
- You can click a column's title in the **Quota Entries** window to sort based on the entries in that column. To reverse the order, click the column title again.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change column order in the Quota Entries window

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change column order in the Quota Entries window**

1. Open My Computer.
2. Right-click the volume for which you want to view quota entries, and then click **Properties**.
3. In the **Properties** dialog box, click the **Quota** tab.
4. On the **Quota** tab, click **Quota Entries**.
5. In the Quota Entries window, click the column header you want to move, and then drag it horizontally to a new position in the list.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- If the volume is not formatted with the NTFS file system, or if you are not a member of the Administrators group, the **Quota** tab is not displayed in the volume`s **properties** dialog box.
- When the Quota Entries window is closed, the ordering and size of the columns are saved and automatically restored the next time the window is opened.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create quota reports

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create quota reports**

1. Open My Computer.
2. Right-click the volume for which you want to create a report, and then click **Properties**.
3. In the **Properties** dialog box, click the **Quota** tab.
4. On the **Quota** tab, click **Quota Entries**.
5. While the **Quota Entries** window is open, open a document in the program that you will use to create the report; for example, a Microsoft Excel spreadsheet.
6. In the **Quota Entries** window, click the entries for the users you want to include in your quota report, and drag the rows to the program you are using to create the report; for example, you can drag the objects to a Microsoft Excel spreadsheet or a Microsoft Word document. The transferred data retains the same column and entry order as in the **Quota Entries** window.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- If the volume is not formatted with the NTFS file system, or if you are not a member of the Administrators group, the **Quota** tab is not displayed in the volume`s **properties** dialog box.
- The supported Clipboard formats for reports are: Rich Text Format, Comma Separated Value, CF_UNICODETEXT, and CF_TEXT.

**Information about functional differences**

# Import quota settings from another volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To import quota settings from another volume**

1. Open My Computer.
2. Right-click the volume to which you want to import quota settings, and then click **Properties**.
3. In the **Properties** dialog box, click the **Quota** tab.
4. On the **Quota** tab, click **Quota Entries**.
5. In the Quota Entries window, on the **Quota** menu, click **Import**.
6. In the **Import Quota Settings** dialog box, select the name of the file that contains the quota settings you want to import, and then click **Open**.

   When you are importing quota records, a dialog box appears if imported settings will overwrite existing settings for a volume user. Specify whether you want to overwrite the existing user settings.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- If the volume is not formatted with the NTFS file system, or if you are not a member of the Administrators group, the **Quota** tab is not displayed in the volume`s **properties** dialog box.
- You can open two instances of the Quota Entries window: one for the volume from which you are importing the quota records, and one for the volume into which you want to import quota records. Then you can drag quota records from the source volume's Quota Entries window to the destination volume's Quota Entries window.
- For entries that already exist on the destination volume, the settings transferred are the user's disk space limit and quota warning level values. If the entries do not exist, new entries are created.
- Disk quota settings are saved in a file format that is exclusive to the Disk Quotas utility and that is used only for importing and exporting quota settings from one volume to another. The **Import Quota Settings** dialog box does not show the file name extension for the settings file, even if the folder that contains it shows file name extensions for all files.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Export quota settings to another volume

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To export quota settings to another volume**

1. Open My Computer.
2. Right-click the volume from which you want to export quota settings, and then click **Properties**.
3. In the **Properties** dialog box, click the **Quota** tab.
4. On the **Quota** tab, make sure the **Enable quota management** check box is selected, and then click **Quota Entries**.
5. Click the user quota records you want to export.
6. On the **Quota** menu, click **Export**.
7. In the **Export Quota Settings** dialog box, specify a destination folder, type the file name for the saved settings, and then click **Save**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Computer, click **Start**, and then click **My Computer**.
- If the volume is not formatted with the NTFS file system, or if you are not a member of the Administrators group, the **Quota** tab is not displayed in the volume`s **properties** dialog box.
- Alternatively, you can open two instances of the **Quota Entries** window: one for the source disk volume from which you want to export quota records, and one for the destination volume into which you are exporting the quota records. Then you can drag quota records from the source volume's **Quota Entries** window to the destination volume's **Quota Entries** window.
- For entries that already exist on the destination volume, the settings transferred are the user's disk space limit and quota warning level values. If the entries do not exist, new entries are created.
- Disk quota settings are saved in a file format that is exclusive to the Disk Quotas utility and that is used only for importing and exporting quota settings from one volume to another. The **Export Quota Settings** dialog box does not reveal the file name extension for the settings file, even if the folder that contains it shows file name extensions for all files.
- You can drag a selected quota setting to a folder where an export file is automatically created.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disk Quotas Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about disk quotas:

- Disk quotas overview
- Understanding Disk Quotas
- Using Disk Quotas
- Resources for Disk Quotas

# Disk quotas overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Disk quotas overview**

Disk quotas track and control disk space usage for NTFS volumes. Administrators can configure Windows to:

- Prevent further disk space use and log an event when a user exceeds a specified disk space limit, that is, the amount of disk space a user is allowed to use.
- Log an event when a user exceeds a specified disk space warning level, that is, the point at which a user is nearing his or her quota limit.

When you enable disk quotas, you can set two values: the disk quota limit and the disk quota warning level. For example, you can set a user's disk quota limit to 500 megabytes (MB), and the disk quota warning level to 450 MB. In this case, the user can store no more than 500 MB of files on the volume. If the user stores more than 450 MB of files on the volume, you can configure the disk quota system to log a system event. You must be a member of the Administrators group to administer quotas on a volume. For instructions on setting disk quota values, see Assign default quota values.

You can specify that users can exceed their quota limit. Enabling quotas and not limiting disk space use are useful when you do not want to deny users access to a volume but want to track disk space use on a per-user basis. You can also specify whether or not to log an event when users exceed either their quota limit or their quota warning level.

When you enable disk quotas for a volume, volume usage is automatically tracked for all users from that point on.

You can enable quotas on local volumes, network volumes, and removable drives as long as they are formatted with the NTFS file system. In addition, network volumes must be shared from the volume's root directory and removable drives must be shared. Volumes formatted with the version of NTFS used in Windows NT 4.0 are upgraded automatically by Windows Setup.

You cannot use file compression to prevent users from exceeding their quota limits because compressed files are tracked based on their uncompressed size. For example, if you have a 50 MB file that is 40 MB after it is compressed, Windows counts the file's original 50 MB size toward the quota limit.

# Understanding Disk Quotas

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding disk quotas**
This section covers:

- Quotas and users
- Quotas and volumes
- Quota entry updates
- Quotas and converted NTFS volumes
- Local and remote implementation of disk quotas

# Quotas and users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Quotas and users**

Because disk quotas monitor volume use by individual user, each user's utilization of disk space does not affect the disk quotas for other users of the same volume. For example, if Volume F has a quota limit of 500 megabytes (MB) and a user saves 500 megabytes (MB) worth of files to Volume F, that user cannot write additional data to the volume without first deleting or moving some existing files from it. However, each of the other users can continue to save up to 500 MB worth of files on that volume as long as there is sufficient free space.

Disk quotas are based on file ownership and are independent of the folder location of the user's files within the volume. For example, if users move their files from one folder to another on the same volume, their volume space usage does not change. However, if users copy their files to a different folder on the same volume, their volume space usage doubles. Or, if another user creates a 200 kilobyte (KB) file and you take ownership of that file, that user's disk use decreases by 200 KB and your disk use increases by 200 KB.

For instructions on enabling disk quotas, see Enable disk quotas.

# Quotas and volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Quotas and volumes**

Disk quotas apply only to volumes and are independent of folder structures of volumes and their layout on physical disks.

If a volume has multiple folders, the quotas assigned to that volume apply equally to all of the folders. For example, if \\Production\QA and \\Production\Public are shared folders on Volume F, files stored by users in these folders cannot use more disk space than the quota limit set for Volume F.

If a single physical disk contains multiple volumes, and you apply quotas to each of the volumes, each volume quota applies only to its specific volume. For example, if you share two different volumes as Volume F and Volume G, quotas are tracked independently for the two volumes, even if they exist on the same physical disk.

If a volume spans multiple physical disks, the same quota for that volume applies to the entire spanned volume. For example, if Volume F has a quota limit of 500 megabytes (MB), then users cannot save more than 500 MB to Volume F, regardless of whether Volume F resides on one physical disk or whether it spans three.

For instructions on enabling disk quotas, see Enable disk quotas.

# Quota entry updates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Quota entry updates**

Within the NTFS file system, volume usage information is stored by user security ID (SID), not user account name. When the Quota Entries window is opened for the first time, disk quotas must obtain user account names from either the network domain controller or Local Users and Groups, match them to the SIDs for current volume users, and populate the entries in the **Name** column with user names. These names appear in this field as they are obtained from the domain controller or Local Users and Groups. This process begins immediately the first time you view quota entries.

After the names have been obtained, they are saved to cache files in the DiskQuota folder in the user's Application Data directory (\Application Data\Microsoft\Windows NT\DiskQuota) so that they are immediately available the next time the Quota Entries window is opened. However, because these cache files might go several days without being updated by Windows, the Quota Entries window might not reflect changes you have made to the domain's user accounts list since viewing quota entries.

To obtain current user names, press F5. Windows then refreshes the user names for each user from the network domain controller or Local Users and Groups. Depending on the number of volume users and the current network speed, this process could take a few minutes. During this process, if you want to see a particular user's name more quickly, you can select that entry to move it to the top of the list.

For instructions, see View disk quota information for volume users.

# Quotas and converted NTFS volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Quotas and converted NTFS volumes**

Disk quotas work with all NTFS volumes on computers running the Windows 2000, the Windows XP, or the Windows Server 2003 family of operating systems. However, files on volumes that have been converted from FAT or FAT32 to NTFS automatically belong to the administrator, and so quota on these files are charged against the administrator account. This is seldom a problem because administrators have unlimited volume use. This issue only applies to files that existed before conversion to NTFS; files created after conversion belong to the appropriate user.

Because disk quotas are based on file ownership, any changes to a volume that affect ownership status of the files on it, including file system conversion, might affect disk quotas for the volume. Therefore, you should understand the changes to ownership that the conversion might cause before converting existing volumes from one file system to another. For more information about file ownership issues, see Deleting disk quota entries.

For more information about file system compatibility and limitations, see Choosing a file system: NTFS, FAT, or FAT32.

# Local and remote implementation of disk quotas

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Local and remote implementation of disk quotas**

You can enable disk quotas on NTFS volumes residing on both local computers and remote computers. You can use quotas to limit the amount of volume space available to different users who log on to the local computer and limit volume usage by remote users.

You can use quotas to make sure that:

- Multiple users who log on to the same computer do not interfere with the other users' ability to work.
- Disk space on public servers is not monopolized by one or more users.
- Users do not use excessive disk space on a shared folder on your personal computer.

To enable quotas on remote computer volumes, those volumes must be shared from the volume's root directory and you must be a member of the Administrators group on the remote computer. In addition, those volumes must be formatted NTFS and exist on a computer running Windows 2000, Windows XP, or the Windows Server 2003 family of operating systems. For instructions describing how to enable quotas on remote computers, see Manage disk quotas on a remote computer.

When you implement disk quotas on a system volume, take into account the disk space used by the Windows files. Depending on the free space available on the volume, you might have to set either a high quota limit or no limit at all for the user who installed Windows. If Windows was installed by an administrator, you do not need to do this because administrators and members of the Administrators group have an unlimited quota limit.

For instructions describing how to enable quotas, see Enable disk quotas.

# Using Disk Quotas

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using disk quotas**

This section covers:

- Enabling disk quotas
- Deleting disk quota entries
- Tracking disk space use
- Managing disk quotas from the command line

# Enabling disk quotas

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enabling disk quotas**

If you are a member of the Administrators group, you can enable quotas on NTFS volumes. On volumes that already contain files, Windows calculates the disk space used by all users who have copied, saved, or taken ownership of files on the volume up to that point. The quota limit and warning level are then applied to all current users based on those calculations, and to users who begin using the volume from that point on. You can then set different quotas, or disable quotas, for individual or multiple users. You can also set quotas for specific users who have not yet copied, saved, or taken ownership of files on the volume.

For example, if \\Production\Public is shared from the root directory of an NTFS volume, you might want to set a quota limit of 50 megabytes (MB) for all users of \\Production\Public, while making sure two users who work with larger files on the server have a 100 MB limit. If both of these users already have files stored on \\Production\Public, you can select both users and set their quota limit to 100 MB. However, if one or both users do not have files stored on the server when you enable quotas, you need to select the users in the Quota Entries window and then set their quota limit to a value higher than the default for new users.

For instructions about enabling disk quotas, see Enable disk quotas. For instructions describing how to enable quotas on remote computers, see Manage disk quotas on a remote computer.

# Deleting disk quota entries

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deleting disk quota entries**

When a user no longer needs to use a volume on which quotas are enabled, you can eliminate that user's warning level and quota limit by deleting his or her entry from the Quota Entries window. However, you can do so only after all of the volume files owned by that user have either been deleted or removed from the volume, or after another user has taken ownership of the files.

Because disk quotas track files by owner, locating these files and then moving, deleting, or taking ownership of them is made simple with a dialog box that appears when you delete a quota entry. For instructions describing how to delete quota entries, see Delete quota entries.

For instructions describing how to take ownership of a file, see Take ownership of a file or folder.

# Tracking disk space use

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Tracking disk space use**

You can specify a disk quota limit without denying users further disk space use. This is useful when you do not want to deny users access to a volume, but want to track disk space use on a per-user basis. You can also specify whether to log an event when users exceed either their quota warning level or their quota limit. Tracking disk space use is helpful if you want to:

- Keep historical records of disk space use.
- Show additional disk space needs.
- Show distribution of disk space on a per-user basis.
- Notify users when they exceed their allotted disk space.

For instructions on documenting disk space use, see Create quota reports.

# Managing disk quotas from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing disk quotas from the command line**
In addition to using **My Computer** to manage disk quotas (right-click a volume, click **Properties**, and then click the **Quota** tab), you can use the **fsutil** command-line utility to manage disks and volumes.

**Important**

- **Fsutil** is an advanced tool that is only intended to be used by advanced users who have a thorough understanding of Windows.

You can use:

- Fsutil: quota to create and modify disk quotas for a specific user, query disk quotas for a specific volume, search the system log for any quota violations, or to perform these tasks using scripts.

- Fsutil: behavior to change how often quota events are written to the system log.

For information about other command-line utilities, see Command-line reference A-Z.

# Resources for Disk Quotas

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

- You can learn more about Disk Quotas in "File Systems" at the Microsoft Windows Resource Kits Web site. The Microsoft Windows Resource Kits provide information technology professionals with the technical information and tools they need to successfully deploy, manage, and support Windows operating systems.

# Troubleshooting Disk Quotas

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- The Quota tab does not appear on the Properties dialog box.
- Cannot delete a quota entry.
- A user gets an "insufficient disk space" message when trying to add files to a volume.
- Users exceeded their quota limits when Windows NT 4.0 was running.
- Quota entries appear to be outdated.
- Cannot enable quotas for a volume on a remote computer.

**The Quota tab does not appear on the Properties dialog box.**
**Cause:** Disk quotas can only be set by members of the Administrators group on volumes formatted with the NTFS file system. Therefore, the **Quota** tab does not appear if you are not a member of the Administrators group, if the volume is not shared from the volume's root directory, or if the volume is not formatted with NTFS.

**Solution:** If you want to track or limit disk space usage, ensure that you are a member of the Administrators group, that the volume is shared from the volume's root directory, and that the volume is formatted with NTFS.

**See also** Quotas and converted NTFS volumes.

**Cannot delete a quota entry.**
**Cause:** You cannot delete a quota entry for a user account until all files that the user owns have been removed from the volume or another user has taken ownership of the files.

**Solution:** Move, delete, or take ownership of all files that the user owns on that volume.

**See also** Delete quota entries.

**A user gets an "insufficient disk space" message when trying to add files to a volume.**
**Cause:** The user has exceeded the quota limit.

**Solution:** Increase the user's quota limit, move or delete files from the volume, or clear the **Deny disk space to users exceeding quota limit** check box in Disk Quotas.

**See also** Enable disk quotas.

**Users exceeded their quota limits when Windows NT 4.0 was running.**
**Cause:** Disk quotas work under the Windows 2000, the Windows XP, and the Windows server 2003 families of operating systems only. For example, if you set disk quota limits on a computer that is configured to run both Windows NT 4.0 and Windows Server 2003, Standard Edition, users can exceed their quota limit while Windows NT 4.0 is running. If this happens, the next time that Windows Server 2003, Standard Edition, is started, users who have exceeded their quota limit while Windows NT 4.0 was running cannot add files to the volume to which the quota is applied.

**Solution:** To enable users to add more files to the volume while Windows Server 2003, Standard Edition, is running, see the previous issue. To prevent users from exceeding their quota limit on a volume under Windows NT 4.0, change permissions on the volume so that users do not have Write permission.

**See also** File and folder permissions.

**Quota entries appear to be outdated.**
**Cause:** The **Enable quota management** check box on the **Quota** tab for the volume is not selected. Windows retains any pre-existing quota information but cannot update it unless quotas are enabled.

**Solution:** Enable disk quotas. For instructions describing how to enable disk quotas, see Enable disk quotas.

**Cannot enable quotas for a volume on a remote computer.**
**Solution:** Establish a connection to the remote volume and then enable quotas. For instructions on how to establish a connection to a remote volume and manage quotas on that volume, see Manage disk quotas on a remote computer. For instructions on how to enable disk quotas, see Enable disk quotas.

# Hardware

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Hardware**
This section covers:

- Hardware overview
- Driver signing for Windows
- Hardware compatibility
- Designed for Microsoft Windows logo
- Device Manager

In addition, for information about managing printers and faxes, see Printers and Faxes.

# Hardware overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Hardware overview**

Hardware includes any device that is connected to your computer and is controlled by your computer's microprocessor. This includes equipment that was connected to your computer when it was manufactured, as well as peripheral equipment that you added later. The following are examples of devices:

- Universal Serial bus (USB)
- IEEE 1394
- Modems
- Disk drives
- CD-ROM drives
- Digital video disc (DVD) drives
- Printers
- Network adapters
- Keyboards
- Video adapter cards
- Monitors
- Game controllers

Devices (Plug and Play and non-Plug and Play) can be connected to your computer in several ways. Some devices, such as network adapters and sound cards, are connected to expansion slots inside your computer. Other devices, such as printers and scanners, are connected to ports on the outside of your computer. Some devices, known as PC Cards, connect only to PC Card slots on a portable computer.

For a device to work properly with Windows, software known as a device driver must be installed on the computer. Each device is supported by one or more device drivers, which are typically supplied by the device manufacturer. However, some device drivers are included with Windows. If the device is Plug and Play, Windows can automatically detect it and install the appropriate device drivers.

If the device is not automatically installed by Windows, the Found New Hardware Wizard will appear and ask you to insert any media (such as compact discs or floppy disks) that were provided with the device. Non-Plug and Play devices are installed using the Add Hardware Wizard in Control Panel. If you want to manually install device drivers, you must use Device Manager. Before manually installing device drivers, you should consult the device documentation provided by the manufacturer.

**Important**

- You must be logged on as an administrator or as a member of the Administrators group in order to install or configure a device if:
- The device driver does not have the Designed for Windows Logo or a digital signature.

- Further action is required to install the device, requiring Windows to display a user interface.
- The device driver is not already on your computer.
- You need to configure a device using Device Manager.
- Your computer is connected to a network; network policy settings may also prevent you from installing hardware.

**Note**

- For the latest updates, including security fixes, service packs, new Help files, and device drivers, see Windows Update Web site.

# Driver signing for Windows

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Driver signing for Windows**

Device drivers and operating system files included with Windows have a Microsoft digital signature. The digital signature indicates that a particular driver or file has met a certain level of testing and that it was not altered or overwritten by another program's installation process. Device drivers for hardware products that have the **Designed for Microsoft Windows XP** or **Designed for Microsoft Windows Server 2003** logos have a digital signature from Microsoft which indicates that the product was tested for compatibility with Windows and has not been altered since testing. For more information about the **Designed for Microsoft Windows** logo, see **Related Topics**.

Depending on how your administrator configured your computer, Windows either ignores device drivers that are not digitally signed, displays a warning when it detects device drivers that are not digitally signed (the default behavior), or prevents you from installing device drivers that do not have digital signatures.

Windows includes the following features to ensure that your device drivers and system files remain in their original, digitally-signed state:

- Windows File Protection
- System File Checker
- File Signature Verification

# Hardware compatibility

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Hardware compatibility**

One of the most important steps to take before running Setup on a server is to confirm that your hardware is compatible with products in the Windows Server 2003 family. You can do this by running a preinstallation compatibility check from the Setup CD or by checking the hardware compatibility information available from Microsoft. Also, as part of confirming hardware compatibility, check to see that you have obtained updated hardware device drivers and an updated system BIOS (or for an Itanium architecture-based computer, the correct firmware).

Regardless of whether you run a preinstallation compatibility check, Setup checks hardware and software compatibility at the beginning of an upgrade or new installation and displays a report if there are incompatibilities.

**Running a preinstallation compatibility check from the Setup CD**

You can run a hardware and software compatibility check from the Setup CD. The compatibility check does not require you to actually begin an upgrade or an installation. To run the check, insert the Setup CD in the CD-ROM drive and, when a display appears, follow the prompts for checking system compatibility. You will be offered the option to download the latest Setup files (through Dynamic Update) when you run the check. If you have Internet connectivity, it is recommended that you allow the download.

For more information about downloading the latest Setup files, see Using Dynamic Update for updated drivers and other setup files.

Another way to run the compatibility check is to insert the Setup CD in the CD-ROM drive, open a command prompt, and type

***d*:\i386\winnt32 /checkupgradeonly**

where *d* represents the CD-ROM drive.

**Checking hardware and software compatibility information available from Microsoft**

Another way to confirm that your hardware and software are designed for products in the Windows Server 2003 family is to click the appropriate links for compatibility information in Support resources.

Note that one type of hardware no longer supported is the microchannel bus.

**Checking drivers and system BIOS or firmware**

Check that you have obtained updated drivers for your hardware devices and that you have the latest system BIOS (for an x86-based or x64-based computer) or the correct firmware (for an Itanium architecture-based computer). The device manufacturers can help you obtain these items. For information about the Advanced Configuration and Power Interface (ACPI) standard for the BIOS, see Understanding the ACPI BIOS for an x86-based computer.

Finally, if you have devices that do not use Plug and Play, or you are aware that your Plug and Play devices are not implemented exactly to the standards, consider taking a device inventory of the hardware devices in your computer. For more information, see Taking an inventory of devices that do not use Plug and Play.

# Designed for Microsoft Windows logo

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Designed for Microsoft Windows logo**
Hardware products displaying the **Designed for Microsoft Windows XP** or **Designed for Microsoft Windows Server 2003** logos have been tested for compatibility with Microsoft Windows operating systems through use of Microsoft-provided testing procedures. For the best performance, Microsoft recommends using hardware products that display the **Designed for Microsoft Windows XP** or **Designed for Microsoft Windows Server 2003** logos on the external packaging and on the device itself.

Device drivers for hardware products with the **Designed for Microsoft Windows XP** or **Designed for Microsoft Windows Server 2003** logos have a digital signature from Microsoft, indicating that the product was tested for compatibility with Windows and has not been altered since testing. For information on accessing the latest updates, including security fixes, service packs, new Help files, and device drivers, see Support resources. You may also want to contact the hardware vendor directly and ask for a device driver that has met the **Designed for Microsoft Windows XP** or **Designed for Microsoft Windows Server 2003** logo requirements. For more information, visit the Microsoft Windows Logo Program on the Microsoft Web site.

**Caution**

- Microsoft strongly recommends that you use only device drivers with the **Designed for Microsoft Windows XP** or **Designed for Microsoft Windows Server 2003** logos. Installing device drivers that have not been digitally-signed by Microsoft might disable the system, allow viruses onto your computer, or otherwise impair the correct operation of your computer either immediately or in the future.

# Device Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Device Manager**
You can use Device Manager to update the drivers (or software) for hardware devices, modify hardware settings, and troubleshoot problems.

- For help with specific tasks, see Device Manager How To....
- For general background information, see Device Manager Concepts.

**Caution**

- Incorrectly altering your hardware configuration can damage your system. Be sure to read the appropriate instructions before making changes to your hardware configuration.

# Printers and Faxes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Printers and faxes**
This section covers:

- Using Fax
- Printing

# Using Fax

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Fax**
Fax provides a complete fax solution for your organization. As a fax administrator you can share fax resources between multiple users, and manage network fax resources from a central location. Using Fax Service Manager you can configure fax devices, and share fax printers to enable network users to send and receive faxes through remote fax printer connections. You can set up routing policies for incoming faxes, and specify outgoing fax rules to route outbound faxes to specific device groups based on dialing destinations. You can set up archiving to provide access to faxes that have been previously sent or received, and configure activity logging to track the use of fax resources.

Fax users can send, receive, and manage faxes using a local fax device attached to their computer, or through a remote fax printer connection. Fax Console provides a central point for sending and receiving faxes, and for monitoring and managing incoming, outgoing, and archived faxes. Fax is not installed by default during Windows Setup.

For more information about Fax Service Manager, see Fax Service Manager Help. For more information about Fax Console, see Fax Console Help.

**To install Fax**

1. Open the Windows Components Wizard.

2. In the Windows Components Wizard, select the **Fax Services** check box, and then follow the instructions on your screen.

## Notes

- To open the Windows Components Wizard, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.

- To open Fax Console after you install Fax, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, point to **Fax**, and then click **Fax Console**.

- Fax sharing is not supported on Windows Server 2003, Web Edition.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Printing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Printing**
The ability to share printers is a major advantage of networking with the Microsoft® Windows Server 2003 family. By putting one high-end printer on a network, you can spread its cost and usage among all users.

- Before setting up a printer, see Checklist: Setting up a printer.
- If you are familiar with Microsoft® Windows NT® version 4.0, see New ways to do familiar Printing tasks.
- For tips on printing, see Printing Best practices.
- For procedures on specific tasks, see Printing How To...
- For general background information, see Printing Concepts
- For problem-solving instructions, see Printing Troubleshooting

# Checklist: Setting up a printer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Setting up a printer**

| | Step | Reference |
|---|---|---|
| | If you are new to printing administration, review key concepts. | Printing Concepts |
| | If you are familiar with printing administration, read about new features. | New printing features |
| | Plan your printing environment. | Planning for Printing |
| | Verify that your printer is in the Windows Catalog. | Support resources |
| | Physically install the printer, and verify that it is ready to print. | Printer's vendor documentation |
| | Log on as a member of the Administrators group. | |
| | If you set up a printer that is connected directly to a computer (typically through a parallel port) and the printer connects through a USB or IEEE 1394 port, the printer will be detected and configured automatically. | Add a printer attached to your computer |
| | If you set up a printer that is attached directly to your network (by way of a network adapter), first install the communication protocol and network services it uses. | Add a printer attached directly to the network |
| | Share a printer with other users and advertise it (if not done while adding the printer). | Share a Printer with Users Across the Network |
| | Assign printer permissions. | Set or remove permissions for a printer |
| | Set the printer's installable options. | Set installable options for a printer |
| | Set the default printing preferences. | Set printing defaults |
| | Install additional printer drivers for other computers and operating systems to allow automatic driver distribution to clients other than Windows XP or Windows 2000. | Add printer drivers for other versions of Windows |
| | Set up network clients to use the printer. | Connect clients to a printer |
| | For Windows NT 4.0, Windows 98, and Windows 95 clients, install the appropriate printer driver on the print server. | Connect Windows NT 4.0, Windows 95, and Windows 98 clients |
| | For MS-DOS, Windows 3.*x*, and OS/2 clients, install a printer driver on the client. | Connect MS-DOS, Windows 3.x, and OS/2 clients |
| | For other clients, install the network services that the clients use. | Connect clients to a printer |
| | Set advanced printer tasks. | Use Advanced Options |
| | Enable printer location tracking. | Enable printer location tracking |
| | Set Group Policy for printers. | Set Group Policy for printers |

# New ways to do familiar Printing tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**
This table lists common tasks for printing. The user interface for performing these tasks is different in the Windows Server 2003 family than it was in Windows NT 4.0.

### Note

- There are no significant user interface differences between Windows 2000, Windows XP, and the Windows Server 2003 family for this component.

| If you want to | In Windows NT 4.0 use | In this version of Windows |
|---|---|---|
| Add a printer that uses the TCP/IP protocol | Add Printer Wizard, **Add Port**, and click **LPR port**. | Printers and Faxes, Add Printer Wizard.<br><br>For more information, see Add a printer attached directly to the network. |
| Set printer availability, priority, and spool options | Printer's property page, **Schedule** tab | Printers and Faxes, Printer's property page, **Advanced** tab.<br><br>For more information, see Set printer properties. |
| Set a printer separator page or print processor, or add a new driver | Printer's property page, **General** tab | Printers and Faxes, Printer's property page, **Advanced** tab.<br><br>For more information, see Set printer properties. |
| Start and stop the Print Spooler service | **Services** in Control Panel | Computer Management.<br><br>For more information, see Start and stop the print spooler. |

# Printing Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **Planning your printing environment.**

  Consider the physical location of your users and their printing needs to determine the number and types of printers and print servers you need, and where to physically locate them.

- **Using the search for printers utility.**

  The best and fastest way to find and connect to a printer is by using the search for printers utility. From the **Start** menu click **Search**, then click **For Printers**, and then type the criteria for the printers you are searching for. For more information see, Connect to a printer published in Active Directory.

- **Installing additional printer drivers.**

  If you share printers with clients other than Windows XP or Windows 2000 clients, install the required additional printer drivers for these clients.

- **Using the same guidelines that apply to any shared resource.**

  Create a local *printer_name* Users group with Print permission, and then put global groups in the local group.

- **Removing Print permission from the default group Everyone.**

  Instead, assign the Print permission to the built-in group Users. This limits printer use to those users in the domain for which you have created accounts.

- **Distributing the administrative load.**

  If security is not an issue, assign the *printer_name* Users group the Manage Documents or Manage Printers print permission.

- **Maintaining physical security.**

  Secure the printer in a locked room if it is used for printing confidential information. When printing confidential documents, you may want to set the paper source to manual so the document will not print until the user is physically at the printer. Let only members of the Administrators group manage the printer.

- **Maintaining data security.**

  To help mitigate client-to-server eavesdropping, consider deploying IPSec. For more information, see Internet Protocol Security (IPSec). To help mitigate server-to-print device document interception, deploy an IPv4 or IPv6-compatible printer. You can use a printer that provides password authentication (that is, the printer does not print until the user enters a password that was sent with the print job). You can also print to a local printer.

- **Choosing a physical location for printing pools.**

  For printing pools, place the printers physically close to each other so users do not have to check separate locations for their printed documents.

- **Managing printer traffic.**

Create multiple logical printers with different schedules to reduce printer traffic during peak hours. Have users send large documents, such as accounting reports, to a logical printer that is available only at night so that those documents wait until off-peak hours to be printed.

- **Maintaining records.**

  Document information about printers and the users who have the ability to administer them.

- **Auditing printers.**

  Use the audit feature to keep track of changes made by administrators who manage shared printers.

- **Using network adapters.**

  It is better to use printers that connect directly to the network with a network adapter than to use a parallel port (LPT) printer that connects directly to print servers. A printer attached with a parallel port prints slower, and the parallel port requires considerably more CPU time.

- **Using the printer troubleshooter.**

  To solve problems quickly, use the printing troubleshooter. Also, you can use the networking (TCP/IP) troubleshooter for networking problems.

- **Creating a custom folder for printers.**

  To ease printer administration, create a custom folder for the printers and for the folders of any print server you manage regularly. You can also create a shortcut for that folder on the Desktop.

# Printing How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

# Set Up a Printer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up a printer**

- Add a printer attached to your computer
- Add a printer attached directly to the network
- Set or remove permissions for a printer
- Specify your default printer
- Print a test page
- Install new or updated printer drivers
- Add printer drivers for other versions of Windows
- Set printing defaults
- Set personal printing preferences
- Choose a separator page
- Set printer properties
- Share a Printer with Users Across the Network
- Set Printing Preferences
- Configure Printer Options

# Add a printer attached to your computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a printer attached to your computer**

1. Connect the printer to the appropriate port on your computer according to the printer manufacturer's documentation, and verify that it is ready to print.

2. Although Windows automatically detects and installs most printers, you might need to provide additional information to complete the installation. Choose from the following, depending on the type of printer you have.

   Install a parallel port (LPT) attached printer

   Install a USB or IEEE 1394 printer

   Install an infrared printer

**Install a parallel port (LPT) attached printer**
If your printer attaches to your computer with a parallel port (LPT port), connect the printer to your computer, and then open Printers and Faxes. Double-click **Add Printer** to start the Add Printer Wizard, and then click **Next**. Click **Local printer attached to this computer**, make sure the **Automatically detect and install my Plug and Play printer** check box is selected, and then click **Next**. Depending on the printer you are installing, a Found New Hardware message or the Found New Hardware Wizard appears to notify you that the printer has been detected and that installation has begun. Follow the instructions on the screen to complete the printer installation. (You do not need to continue with the following instructions.)

Alternatively, after connecting your printer, you can start or restart your computer to allow your operating system to automatically detect and start the Found New Hardware Wizard.

The printer icon will be added to your Printers and Faxes folder.

**Install a USB or IEEE 1394 printer**
If you install a universal serial bus (USB) or IEEE 1394 printer, your Windows Server 2003 family operating system detects it and automatically starts the Found New Hardware Wizard. You do not need to shut down or restart your computer; just follow the instructions on the screen to finish the setup.

The printer icon will be added to your Printers and Faxes folder.

**Install an infrared printer**
If you install an infrared printer, it is automatically detected and installed. You do not need to shut down or restart your computer. First, make sure that the infrared-enabled computer and the printer are turned on. Then, position the computer and printer within approximately 1 meter of each other to establish a wireless infrared connection. After several seconds, the computer recognizes the printer, and the appropriate drivers are installed on the computer. If the drivers are not installed, you will be prompted to insert a manufacturer's disk containing the drivers. (You do not need to continue with the rest of the steps in this topic.)

The printer icon will be added to your Printers and Faxes folder.

If your computer is not infrared-capable, you can attach an infrared transceiver to your serial (COM) port. For more information, see Related Topics.

1. If you could not install your printer using Plug and Play, or if the printer is attached to your computer with a serial (COM) port, then open Printers and Faxes.

2. Double-click **Add Printer** to start the Add Printer Wizard, and then click **Next**.

3. Clear the **Automatically detect and install my Plug-n-Play printer** check box to avoid having to wait for the completion of another printer search.

4. Click **Local printer attached to this computer**, and then click **Next**.

5. Follow the instructions on the screen to finish setting up the printer by selecting a printer port, selecting the manufacturer and model of your printer, and typing a name for your printer.

   In Windows Server 2003 family products, the Add Printer Wizard shares the printer and publishes it in Active Directory by default, unless you select **Do not share this printer** in the wizard's **Printer Sharing** screen. The Add Printer Wizard does not share the printer automatically on a computer running Windows XP Professional. You need to select **Share as** to share and publish the printer.

### Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.

- Infrared functionality is not present on the following operating systems: Windows XP 64-bit Edition (Itanium); 64-bit version of Windows Server 2003, Datacenter Edition; and 64-bit version of Windows Server 2003, Enterprise Edition.

- If you add and set up a Plug-and-Play printer (for example, USB, IEEE 1394, LPT, or Infrared), you do not need to have administrative credentials. However, to add and set up a non-Plug-and-Play printer connected directly to your computer, you must be logged on as an administrator or a member of the Administrators group. If your computer is connected to a network, network policy settings may also prevent you from completing this procedure.

- If you intend to share the printer with client computers running operating systems other than Windows XP or Windows 2000, you need to install the appropriate printer drivers for these clients on the print server. When clients running Windows NT 4.0, Windows 95, and Windows 98 connect to the printer, the server automatically downloads the correct driver to the client.

- When you are adding a new printer that is connected to a computer and the Add Printer Wizard prompts you to select the printer port, you normally select from the **Existing** list one of the parallel (LPT) ports. For some plotters you might need to select one of the serial (COM) ports.

- The following Group Policy settings can change the default behavior of the Windows Server 2003 family Server Add Printer Wizard:

  **Allow printers to be published** is enabled by default; you can disable it to prevent printers from being published.

  **Automatically publish new printers in the Active Directory** is enabled by default; you can disable it to prevent the Add Printer Wizard from automatically publishing printers when adding a new printer.

  **Browse the network to find printers** is enabled by default; you can disable it to prevent the Add Printer Wizard from browsing the network for shared printers.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a printer attached directly to the network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a printer attached directly to the network**

1. Open Printers and Faxes.
2. Double-click **Add Printer** to start the Add Printer Wizard, and then click **Next**.
3. Click **Local printer attached to this computer**, clear the **Automatically detect and install my Plug and Play printer** check box, and then click **Next**.
4. Follow the instructions on the screen to finish setting up the printer by selecting a printer port, selecting the manufacturer and model of your printer, and typing a name for your printer.
5. When the Add Printer Wizard prompts you to select the printer port, click **Create a new port**.
6. From the list, click the appropriate port type and follow the instructions. (By default, only **Local Port** and **Standard TCP/IP Port** appear in the list.)

## Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- To add a new port type, see Related Topics.
- To add and set up a printer connected directly to the network, you must be logged on as a member of either the Power Users group or the Administrators group.
- The Add Printer Wizard shares the printer and publishes it in Active Directory by default, unless you select **Do not share this printer** in the **Printer Sharing** screen. In Windows 2000 Professional, the Add Printer Wizard does not share the printer automatically; you must select **Share as** to share and publish the printer.
- You must clear the **Automatically detect and install my Plug and Play printer** check box because the printer is attached directly to the network, not to a Windows 2000 computer.
- If you intend to share the printer with clients other than those running Windows XP or Windows 2000, you need to install the appropriate printer drivers for these clients on the print server. When clients running Windows NT 4.0, Windows 95, and Windows 98 connect to the printer, the server automatically downloads the correct driver to the client.
- The following Group Policy settings can change the default behavior of the Add Printer Wizard:

  **Allow printers to be published** is enabled by default; you can disable it to prevent printers from being published.

  **Automatically publish new printers in the Active Directory** is enabled by default; you can disable it to prevent the Add Printer Wizard from automatically publishing printers when adding a new printer.

  **Browse the network to find printers** is enabled by default; you can disable it to prevent the Add Printer Wizard from browsing the network for shared printers.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set or remove permissions for a printer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set or remove permissions for a printer**

1. Open Printers and Faxes.
2. Right-click the printer for which you want to set permissions, click **Properties**, and then click the **Security** tab.
3. Do one of the following:
   - To change or remove permissions from an existing user or group, click the name of the user or group.
   - To set up permissions for a new user or group, click **Add**. In **Select Users, Computers, or Groups**, type the name of the user or group you want to set permissions for, and then click **OK** to close the dialog box.
4. In **Permissions**, click **Allow** or **Deny** for each permission you want to allow or deny, if necessary. Or, to remove the user or group from the permissions list, click **Remove**.

## Notes

- To change device settings, you must have the Manage Printers permission. For information about printing security permissions, see Related Topics.
- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- To view or change the underlying permissions that make up Print, Manage Printers, and Manage Documents, click the **Advanced** button.
- A printer must be shared in order for the permission settings to affect the users and groups listed.
- You can also view the permissions assigned to you by clicking the group you belong to on the **Security** tab. For information on finding out what group you belong to, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**

# Specify your default printer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify your default printer**

The default printer is used when you click **Print** on the **File** menu of many Windows-based programs.

1. Open Printers and Faxes.

2. Right-click the printer you want to use as the default printer, and then click **Set as Default Printer**.

   A check mark appears next to the printer icon in **Printers and Faxes**.

## Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.

- For more information on administering printers from the command line, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Print a test page

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To print a test page**

To print a test page, you must have the Print permission, which is one of several printer permissions. You can also print a test page when you first install a printer. For more information, click **Related Topics**.

1. Open Printers and Faxes.
2. Right-click the printer you want to test, and then click **Properties**.
3. On the **General** tab, click **Print Test Page**.
4. Click **OK** if the test page printed correctly. If the test page did not print correctly, click **Troubleshoot** to open the Print Troubleshooter for help resolving the printing problem.

**Notes**

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- You can also open printer properties from the **Printers and Faxes** folder by clicking a printer, and then clicking **Set printer properties** under **Tasks** on the left side of the window. This option is available only if folders are set to look like a Web page and a printer is selected. For more information, click **Related Topics**.
- Another way to open the Printing Troubleshooter is to click **Troubleshoot printing** under **See Also** on the left side of Printers and Faxes. This option is available only if folders are set to look like a Web page, and if a printer is not currently selected. For more information, click **Related Topics**.
- For more information on administering printers from the command line, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install new or updated printer drivers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install new or updated printer drivers**

1. Open Printers and Faxes.
2. Right-click the printer for which you want to change drivers, and then click **Properties**.
3. On the **Advanced** tab, click **New Driver** to install a new or updated version of the printer driver using the Add Printer Driver Wizard.
4. Click **Next**, and then do one of the following:
   - Click the appropriate printer manufacturer and printer model if the new or updated driver is on the list.
   - Click **Have Disk** if the printer driver is not included in the list or if you have received a new or updated driver on CD or diskette from the printer manufacturer. Type the path where the driver is located, and then click **OK**.
5. Click **Next**, and then follow the instructions on the screen to finish installing the printer driver.

## Notes

- To install new or updated printer drivers, you must be logged on to your computer as a member of the Administrators group. When using Windows 2000 Professional, you may be able to install new or updated printer drivers when logged on as a member of the Power Users group, depending on the components required by the printer driver.
- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- If the printer driver you want to use already exists on the print server, you can install it by selecting it in the **Driver** list.
- For information about updating printer drivers and other system files using Windows Update, see Related Topics.
- For more information about administering printers from the command line, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add printer drivers for other versions of Windows

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add printer drivers for other versions of Windows**
The following procedure describes how to install additional drivers on the print server, as a distribution point for clients running older versions of Windows.

If you share a printer with users running other versions of Windows (Windows 95, Windows 98, or Windows NT 4.0), you can install additional printer drivers on your computer so those users can connect to your printer without being prompted to install the drivers missing from their systems. The drivers are located on the Support CD. Printer drivers for Windows NT 3.1 and Windows NT 3.5 are not included.

1. Open Printers and Faxes.
2. Right-click the printer for which you want to install the additional drivers, and then click **Properties**.
3. On the **Sharing** tab, click **Additional Drivers**.
4. In the **Additional Drivers** dialog box, select the check boxes for the additional environments and operating systems you need, and then click **OK**.

### Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- You can also open printer properties in Printers and Faxes by clicking a printer, and then clicking **Set printer properties** under **Tasks** on the left side of the window. This option is available only if folders are set to look like a Web page and a printer is selected. For more information, click **Related Topics**.
- A client running Windows NT 4.0, Windows 2000, or Windows XP Home Edition checks the printer driver each time it reconnects to the network. A Windows NT 3.*x* client checks each time the spooler service on the client is started. If the driver is not current, a copy of the new driver is downloaded automatically. The printer driver for a Windows 95-based or Windows 98-based client is not automatically kept current. If you update the driver on the print server, you must manually install the driver on Windows 95-based and Windows 98-based clients.
- For more information on administering printers from the command line, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set printing defaults

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set printing defaults**

You can change a printer's default printing preferences only if you have the Manage Printers permission, which is one of several printer permissions. For more information, click **Related Topics**.

1. Open Printers and Faxes.
2. Right-click the printer for which you want to set the default printing preferences, and then click **Properties**.
3. On the **Advanced** tab, click **Printing Defaults**.
4. Click the **Layout** and **Paper/Quality** tabs and the **Advanced** button to see the available choices, and specify the new default settings.

**Notes**

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- The preferences you set become the default settings for any user who connects to the printer. These preferences include the page orientation, the tray from which paper is fed to the printer, and the number of copies printed. Individual users can customize these settings by right-clicking the printer in Printers and Faxes, and then clicking **Printing Preferences**.
- You can also open printer properties in Printers and Faxes by clicking a printer, and then clicking **Set printer properties** under **Tasks** on the left side of the window. This option is available only if folders are set to look like a Web page and a printer is selected. For more information, click **Related Topics**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set personal printing preferences

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set personal printing preferences**

1. Open Printers and Faxes.
2. Right-click the icon for the printer you are using, and then click **Printing Preferences**.
3. Click the **Layout** and **Paper/Quality** tabs and the **Advanced** button to see the available choices, and make changes as needed.

## Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- When you set personal printing preferences using Printers and Faxes, the default settings are changed for all documents you print to that printer. These preferences include the page orientation, the tray from which paper is sent, and the number of copies printed. Making these changes requires that you have the Print permission, which is one of several printer permissions. For more information, click **Related Topics**.
- You can change printing preferences for individual documents from within a software program. To do so, click **Page Setup** (or **Print Setup**) on the program's **File** menu, and then make selections. To set the printing default for all users connected to the printer, see Set printing defaults.
- You can also open printing preferences in Printers and Faxes by clicking a printer, and then clicking **Select printing preferences** under **Tasks** on the left side of the window. This option is available only if folders are set to look like a Web page and a printer is selected. For more information, click **Related Topics**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Choose a separator page

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To choose a separator page**

To set up separator pages, you must have the Manage Printers permission, which is one of several printer permissions. For more information, click **Related Topics**.

1. Open Printers and Faxes.
2. Right-click the icon for the printer you are using, and then click **properties**.
3. On the **Advanced** tab, click **Separator Page**.
4. Click **Browse** and find your systemroot\System32 folder.
5. Specify one of the separator page files that Windows provides in the System32 folder:
   - Pcl.sep, which prints a page after switching the printer to PCL printing.
   - Sysprint.sep, which prints a page after switching the printer to PostScript printing.
   - Pscript.sep, which does not print a page after switching the printer to Postscript printing.

### Note

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.

**Information about functional differences**

# Set printer properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set printer properties**

Printer properties cover many categories of options, including those related to printer drivers, printer ports, printer sharing, setting printer permissions for other users, deciding when the printer is available on a network, printing a test page, and so on.

Changing the printer properties affects only the selected printer, and can only be made if you have the Manage Printers permission, which is one of several printer permissions. For more information, click **Related Topics**.

1. Open Printers and Faxes.
2. Right-click the printer for which you want to change settings, and then click **Properties**.
3. Click each tab to see the available choices, and change options as needed.

### Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- You can also open printer properties in Printers and Faxes by clicking a printer, and then clicking **Set printer properties** under **Tasks** on the left side of the window. This option is available only if folders are set to look like a Web page and a printer is selected. For more information, click **Related Topics**.
- For more information on administering printers from the command line, see Related Topics.

# Share a Printer with Users Across the Network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Share a printer with users across the network**

- Share your printer
- Stop sharing your printer
- Publish a printer in Active Directory

# Share your printer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To share your printer**

1. Open Printers and Faxes.
2. Right-click the printer you want to share, and then click **Sharing**.
3. On the **Sharing** tab, click **Share this printer**, and then type a name for the shared printer.

   If you share the printer with users on different hardware or different operating systems, click **Additional Drivers**. Click the environment and operating system for the other computers, and then click **OK** to install the additional drivers.

   If you are logged on to a Windows 2000 or Windows Server 2003 family domain, you can make the printer available to other users on the domain by clicking **List in the Directory** to publish the printer in the Directory.
4. Click **OK**, or if you have installed additional drivers, click **Close**.

## Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.
- Printers are not shared by default when you install them on computers running Windows XP Professional, but you can choose to share any printer you install on your computer. (On any Windows Server 2003 family product, the printer is shared by default when you add the printer.)
- When you publish a printer in Active Directory, other users logged onto the domain will be able to search for the printer based on its location and features such as how many pages it prints per minute and whether color printing is supported.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Stop sharing your printer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To stop sharing your printer**

1. Open Printers and Faxes.
2. Right-click the printer you want to stop sharing, and then click **Sharing**.
3. On the **Sharing** tab, click **Do not share this printer**.

## Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

# Publish a printer in Active Directory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To publish a printer in Active Directory**

1. Open Printers and Faxes.
2. Right-click the printer you want to publish, and then click **Sharing**.
3. On the **Sharing** tab, click **Share this printer**, and then type a name for the shared printer.
4. Select the **List in the Directory** check box to publish the printer in Active Directory.

## Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- Only a shared printer can be published. If you stop sharing a printer, the printer is no longer published.
- If you add a printer using the Add Printer Wizard and click **Share this printer**, the printer will be published by default if the Group Policy settings **Automatically publish new printers in Active Directory** and **Allow printers to be published** are enabled, as they are by default.
- You must open Active Directory Users and Groups to publish printers that are managed through print servers that are running Windows NT 4.0 or an earlier operating system.
- Printers you add using the Add Printer Wizard are shared by default if you add them from a computer running a product in the Windows Server 2003 family. However, printers are not shared by default if you add them using the Add Printer Wizard from a computer running Windows XP.
- You must have the Manage Printers permission for the printer you want to share or to publish.
- You can create printer names that contain spaces, special characters, and more than eight characters. However, some clients do not recognize or correctly handle such names. The entire qualified name of a shared printer (for example \\PRINTER2\PSCRIPT) must contain 32 or fewer characters.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set Printing Preferences

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set printing preferences**

- Set page orientation
- Specify paper size
- Set printing resolution
- Print on one or both sides of the paper
- Print multiple pages per sheet
- Set the number of copies to print

# Set page orientation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set page orientation**

To change printing preferences, you must have the Print permission, which is one of several printer permissions. For more information, click **Related Topics**.

Any changes you make in **Printing Preferences** will alter the default document settings for the printer and will affect all documents you send to the printer. To change print settings for individual documents from within a program, click **Page Setup** (or **Print Setup**) on the program`s **File** menu, and then make selections.

1. Open Printers and Faxes.
