- Messages can no longer be delivered to a particular computer or queue.
- Express messages are missing or lost.
- Transactional messaging does not function for dependent clients.
- A test message cannot be sent to a particular queue.
- You cannot access messaging files stored locally on disk.
- You cannot locate the audit messages for a particular operation.
- There are problems communicating with IPX computers.
- Dependent clients cannot run Message Queuing applications.
- Resources for Message Queuing have timed out in a server cluster.
- A foreign site to which a Windows Server 2003 Message Queuing server with a connector application belongs does not appear in the list of sites for that server.

- You cannot register a user certificate for Message Queuing.

**You cannot find Message Queuing under Services and Applications in Computer Management.**
**Cause:** The Message Queuing service is not running.

**Solution:** In the Computer Management console tree, under **Services and Applications**, click **Services**. In the details pane, under **Name**, right-click **Message Queuing**, and then click **Start**. Restart Computer Management.

**You cannot find any objects for Message Queuing in Active Directory.**
**Cause:** You have not selected the necessary view options for these snap-ins.

**Solution:** In Active Directory Users and Computers, on the **View** menu, click **Users, Groups, and Computers as containers**, and then click **Advanced Features**. Message Queuing objects are typically located under the Computers container or the Domain Controllers container.

When Message Queuing is running in offline mode, you can see public queues, but not messages, queue properties, private queues, system queues, and triggers.

**Solution:** In Active Directory Sites and Services, on the **View** menu, click **Show Services Node**. Message Queuing objects are under the Servers object and under the Services object.

So that these views are always enabled by default, you can save these changes by creating your own .msc file for these snap-ins. In such a case, the first time you open a .msc file that you previously created, on the **File** menu, click **Options**, and then select one of the three user mode entries in **Console mode**. Now the console will subsequently open in a user mode with the correct views enabled. Opening a snap-in console in one of the user modes (rather than in author mode) is safer from an administrative standpoint, because no one else can potentially change the behavior or the look of the console.

**See also:** Message Queuing and Active Directory

**You cannot access any objects for Message Queuing in Active Directory.**
**Cause:** The Message Queuing service may have been changed to run under a specific user account. To provide access to objects in Active Directory for earlier Windows MSMQ clients, this service must run under the Local System account on Windows Server 2003 or Windows 2000 domain controllers.

**Solution:** Verify that the Message Queuing service is running under the Local System account on the applicable Message Queuing server.

**You are unable to establish a connection with Active Directory.**
**Cause:** The Message Queuing server with which you are communicating may be offline, or the Message Queuing service may be stopped.

**Solution:** Verify that the Message Queuing server with which you are communicating is online and that the Message Queuing service is running.

**Cause:** Your computer may be offline, your network adapter may be malfunctioning, or your computer may not have an IP address assigned (or may have an IP address of 0.0.0.0.).

**Solution:** Verify that your computer is online, your network adapter is functioning properly, and TCP/IP is properly configured.

**Cause:** The DNS server is offline, is not configured properly, or the Message Queuing server's IP address has recently changed and has not been replicated yet to the DNS server.

**Solution:** Verify that the DNS server is online and properly configured.

**Cause:** The site that you are in does not contain a Message Queuing server running on a Windows Server 2003 or Windows 2000 domain controller that is configured as a global catalog server. This affects MSMQ 1.0 users running Windows NT 4.0 and all users running under a local user account.

**Solution:** Verify the Message Queuing server you communicate with is properly configured.

**Cause:** You may have insufficient permissions to access Active Directory.

**Solution:** Grant yourself the proper permissions to perform this operation.

**Changes you made do not show up in Active Directory.**

**Cause:** Replication can delay information updates displayed in the snap-ins, so that changes you make using the snap-ins do not appear until after replication takes place.

**Solution:** Press F5 after making the change, or wait at least 15 minutes.

**Windows NT 4.0 clients and local users cannot access Active Directory.**
**Cause:** Weakened security was not selected during an installation of Message Queuing with Downlevel Client Support on a Windows Server 2003 domain controller or an installation of a Message Queuing server on a Windows 2000 domain controller in your forest. To effectively support MSMQ 1.0 clients running Windows NT 4.0 and users running under a local user account, security for Active Directory must be weakened. (Dependent clients cannot run under a local user account. Any computer that sends queries about Message Queuing objects to Active Directory on a domain controller directly, rather than through the Message Queuing directory service (Downlevel Client Support), will not be able to access Active Directory when it logs on with a local user account, even if the security for Active Directory is weakened.)

**Solution:** Use the ADSI Editor provided with the Windows Server 2003 family Resource Kit to weaken security.

**See also:** Message Queuing security overview

**You cannot access the contents of a particular queue.**
**Cause:** You may not have the proper permissions for viewing the queue. Message Queuing displays all queues that are viewable by default. However, you can view the contents of only those queues that you have proper permissions to open. Therefore, there may be public queues whose contents are not viewable in the snap-ins.

**Solution:** Ensure that the Peek Message or Receive Message permissions for the queue are granted to you. To view the contents of a queue journal, you must have the Peek Journal permission granted for the queue.

**See also:** Managing queues

**You cannot create queues.**
**Cause:** You may have insufficient permissions to perform this operation.

**Solution:** Grant yourself the proper permissions to perform this operation.

**See also:** Access control for Message Queuing

**You cannot send messages to another site.**
**Cause:** A routing link may not be defined between the two sites, or a designated site gate may be unavailable. As a result, messages can be sent by an application, but they cannot leave the outgoing queue.

**Solution:** Create a routing link between the two sites and define site gates for the routing link. It is recommended that you create multiple routing links between all sites for redundancy.

**See also:** Routing links

**You cannot send or receive authenticated messages.**
**Cause:** The user certificate for the computer may have been removed, expired, or not registered in Active Directory. The user certificate is required for sending authenticated messages. The user certificate is installed for you during Message Queuing Setup and is registered in Active Directory the first time you log on.

**Solution:** Use the **Message Queuing Properties** dialog box, which can be opened from Computer Management, to renew the certificate and then register it.

**Cause:** The Microsoft Base cryptographic service provider (CSP) provided with Windows Server 2003 family is not being used by Message Queuing applications. The Microsoft Base CSP is required for all Message Queuing applications that send or receive authenticated messages.

**Solution:** Verify that Message Queuing applications use the Microsoft Base (or Enhanced) CSP when sending or receiving messages.

**See also:** Authentication for Message Queuing

**Messages sent to a queue are rejected.**
**Cause:** The queue may restrict access.

**Solution:** Make sure that the queue is located in the same domain as the computer that sent the message or is in a trusted domain.

**Cause:** The default permission is that everyone can send messages to a queue. However if this default setting is changed, the

Message Queuing service on the receiving computer performs an access check to check the sender's SID (security ID) context against the SD (security descriptor) of the destination queue. If the access check is carried out and the sender has permissions to send to the queue, the message is accepted. If the access check is carried out and the sender does not have permissions, it is rejected. If the access check itself cannot be carried out and fails, the message is also rejected.

**Solution:** Check that the permissions settings for the queue. If the default setting to allow everyone to send messages to a queue has been modified, check that the message sender has permissions to send to the queue. If the access check itself cannot be completed (this might be indicated in Event Viewer), ensure that Message Queuing has access to the TokenGroupsGlobalAndUniversal attribute of the sender's user object. To provide this access, add the Message Queuing service account to the Windows Authorization Access Group, which has access to this attribute. Note that only users with domain administration permissions can add members to this group. You can add the Message Queuing service account to the group in one of two ways. You can manually add the relevant accounts to the Windows Authorization Access Group, repeating the operation for each Message Queuing computer requiring this permission. Alternatively, as a less secure practice, you can add the Authenticated Users group to the Windows Authorization Access Group. This grants every authenticated user, including the Message Queuing service on any computer, access to the TokenGroupsGlobalAndUniversal attribute for all users, and requires no further manual administration.

**See also:** Access control for Message Queuing

**You cannot retrieve messages from a queue.**
**Cause:** To retrieve messages from a queue, you must be granted the Receive Messages permission for the queue. It is not sufficient to have the Read permission granted for the queue.

**Solution:** Grant yourself the Receive Messages permission for the queue.

**See also:** Managing messages

**Messages can no longer be delivered to a particular computer or queue.**
**Cause:** The computer quota or the queue quota for the particular computer may have been exceeded.

You can verify this in the following two ways:

- By requesting negative acknowledgment messages and checking their class. (This technique is applicable to the quotas of destination queues, not to computer quotas.)

- By using performance counters to compare the queue or computer quota to the actual volume of messages.

**Solution:** Process and remove messages from the applicable queues or increase the appropriate quota value.

**See also:** Setting message quotas

**Express messages are missing or lost.**
**Cause:** Undelivered express messages are lost whenever the Message Queuing service is stopped on the computer where they reside in volatile memory, or the computer shuts down or fails.

**Solution:** Use recoverable or transactional messages. (Note that only transactional messages provide a complete guarantee against data loss.)

**See also:** Backing up and restoring messages

**Transactional messaging does not function for dependent clients.**
**Cause:** MSMQ 1.0 dependent clients running Windows NT 4.0 whose supporting server is running Windows Server 2003 family or Windows 2000 may not have Windows NT 4.0 Service Pack 4 (SP4) installed. SP4 or later is required for transactional messaging.

**Solution:** Install Windows NT 4.0 SP4 or later on the applicable dependent clients.

**Cause:** The Microsoft Distributed Transaction Coordinator (DTC) may not be running. The DTC is required for external transactions.

**Solution:** Start the DTC.

**A test message cannot be sent to a particular queue.**
**Cause:** Test messages can be sent from the MMC snap-in only to test queues, which have a queue type ID of {55EE8F33-CCE9-11CF-B108-0020AFD61CE9}.

**Solution:** Verify that the queue to which you want to send the test message has the correct queue type ID. Do not change a transactional queue or a queue requiring authentication to a test queue, because any test messages sent will not be delivered to such a queue. Note that you can send test messages programmatically to queues with any queue type ID.

**See also:** Sending test messages

**You cannot access messaging files stored locally on disk.**
**Cause:** By default, only members of the Administrators group for the local computer have full access to all locally stored message files, log files, and local queue storage (LQS) files.

**Solution:** Grant yourself administrative permissions for the computer, or add yourself to the local Administrators group.

**See also:** Access control for Message Queuing

**You cannot locate the audit messages for a particular operation.**
**Cause:** Audit messages are stored in the security log on the Message Queuing server that performs the operation, which may not be the server that owns the object. In addition, audit messages are created in the security log only when a queue is opened, not each time a message is received or sent.

**Solution:** Use Event Viewer to view information in the security log of the appropriate computer.

**See also:** Auditing Message Queuing objects

**There are problems communicating with IPX computers.**
**Cause:** The Message Queuing service no longer supports the IPX protocol.

**Solution:** Add the IP protocol to any computers that use only the IPX protocol.

**Dependent clients cannot run Message Queuing applications.**
**Cause:** You may be logged on using a local user account or other unauthenticated account. Message Queuing applications cannot run under unauthenticated accounts.

**Solution:** Log on using a domain user account, which is authenticated.

**Resources for Message Queuing have timed out in a server cluster.**
**Cause:** Cluster resources have a default time-out setting of three minutes for coming online. Message Queuing may take longer than three minutes, depending on recovery scenarios and the number of messages stored.

**Solution:** Increase the default time-out setting for Message Queuing resources.

**A foreign site to which a Windows Server 2003 Message Queuing server with a connector application belongs does not appear in the list of sites for that server.**
**Cause:** Adding a foreign site to the list of sites to which the Windows Server 2003 Message Queuing server with a connector application belongs does not ensure that the foreign site appears in the server's site list.

**Solution:** For a Windows Server 2003 Message Queuing server running connector applications, after adding the foreign site to the list of sites for the server, restart the Message Queuing service on the domain controller of the domain to which the Message Queuing server running the connector application belongs.

**You cannot register a user certificate for Message Queuing.**
**Cause:** By default, users have permission to register certificates for Message Queuing. However, if default user permissions are changed, this might affect your ability to register certificates.

**Solution:** Check that the user object is granted Write Personal Information permissions in the Active Directory schema.

**Cause:** Active Directory sets a multi-valued attribute limit of approximately 800 user certificates for a specific user account. This limit is usually exceeded when obsolete user certificates have not been deleted from Active Directory. If multiple certificates exist for a user account, only the latest is used.

**Solution:** Manually delete obsolete user certificates. For instructions, see Remove certificates for Message Queuing.

# Troubleshooting triggers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting triggers**
This topic discusses the most common problems encountered when using the Message Queuing Triggers service.

What problem are you having?

- The Message Queuing Triggers service fails to start.
- A trigger is defined, but it does not appear to be firing.
- The processing of messages by the Message Queuing Triggers service slows disproportionately as more messages arrive at a monitored queue.
- I cannot see my triggers application on the desktop, although I see in Task Manager that the application is running.

**The Message Queuing Triggers service fails to start.**
**Cause:** The Message Queuing Triggers service has been configured to run under a domain user account without proper administrative permissions.

**Solution:** Configure the Message Queuing Triggers service to run under the default Network Service account, which has sufficient permissions to run the Message Queuing Triggers service, or grant yourself the necessary permissions. The Triggers service must run under an account with administrator permissions.

**Cause:** The Message Queuing Triggers service has failed. In-process Component Object Model (COM) components that are invoked can sometimes fail and thereby cause the Message Queuing Triggers service to fail.

**Solution:** Rectify the condition that causes the COM component to fail, and then restart the Message Queuing Triggers service.

**A trigger is defined, but it does not appear to be firing.**
**Cause:** The trigger is currently disabled.

**Solution:** Verify that the trigger has been enabled.

**See also:** View or change properties of triggers and rules for triggers

**Cause:** The account under which the Message Queuing Triggers service is running has not been granted the Peek Message permission for the monitored queue. Or, if the message processing type of the trigger is "retrieval" or "transactional retrieval," the account has not been granted the Receive Message permission for that queue.

**Solution:** Change the permissions for the queues, and then restart the Message Queuing Triggers service.

**See also:** Set permissions for computer and queue objects

**Cause:** The Message Queuing Triggers service is not running.

**Solution:** Verify that this service has been started.

**Cause:** The Message Queuing Triggers service has been paused.

**Solution:** Verify that this service is not in a paused state.

**Cause:** The trigger conditions are not all satisfied. If any trigger condition evaluates as false, the trigger will not fire.

**Solution:** Verify that all conditions of the rule are true.

**Cause:** The Message Queuing Triggers service cannot be initialized when running under a non-administrator account.

**Solution:** By default, the Message Queuing Triggers service runs under the Network Service account. If you have changed this default, ensure that the account you have specified has administrator permissions.

**The processing of messages by the Message Queuing Triggers service slows disproportionately as more messages arrive at a monitored queue.**

**Cause:** This is normal when the Message Queuing Triggers service runs under heavy loads. It occurs because the maximum number of threads is reached.

**Solution:** You can accelerate the processing of messages by increasing the maximum number of allowable threads. You can increase the number of working threads in the Computer Management snap-in. To do this, open Computer Management, click **Services and Applications**, click **Message Queuing**, right-click **Triggers**, and then click **Properties**. Increase the maximum number of threads in **Max number of threads**.

**I cannot see my triggers application on the desktop, although I see in Task Manager that the application is running.**

**Cause:** The Triggers service runs by default under the Network Service account, and interaction with the desktop functionality is only available for the Local System account.

**Solution:** Configure the Triggers service to run under the Local System account and enable it to interact with the desktop. To do this, in Computer Management, click **Services**, and in the details pane, double-click **Message Queuing Triggers**. Click the **Log On** tab, click **Local System** and select the **Allow service to interact with desktop** check box.

# Additional Message Queuing resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Additional Message Queuing resources**
This section provides sources of additional information for Message Queuing and other software products that work with Message Queuing.

**Microsoft Platform Software Development Kit**
The Message Queuing Software Development Kit (SDK) is available as part of the Microsoft Platform SDK in the Microsoft Developer Network (MSDN) Library. The Message Queuing SDK includes background information on developing Message Queuing applications and a reference section that thoroughly describes the functions, properties, structures, and COM components supplied and used by Message Queuing. The Message Queuing SDK also contains sample code and program files for representative types of applications.

The Microsoft Platform SDK is released on a regular basis in the MSDN Library, which is available both on CDs and on the Web. To access the Message Queuing SDK on the Web, refer to the MSDN Library Web site. (http://msdn.microsoft.com/library/default.asp)

**Web Sites**

- For the latest information on Message Queuing, see the Message Queuing Web page.(http://www.microsoft.com/msmq)
- For the latest Frequently Asked Questions (FAQs) on Message Queuing, see the Message Queuing FAQ Web page. (http://support.microsoft.com/msmq/faq.htm)
- For the information on Message Queuing available from Microsoft Product Support Services, see the Microsoft Product Support Services home page.(http://support.microsoft.com/directory/default.asp)

**Internet newsgroups**
You can subscribe to the following newsgroups by following the instructions provided with your Web browser or newsreader software for connecting to an Internet news server:

- microsoft.public.msmq.deployment
- microsoft.public.msmq.interop
- microsoft.public.msmq.networking
- microsoft.public.msmq.performance
- microsoft.public.msmq.programming
- microsoft.public.msmq.security
- microsoft.public.msmq.setup

**Books**
If you are interested in reading books that pertain to application development for Message Queuing, see the following list:

- Dickman, Alan. *Designing Applications With MSMQ: Message Queuing for Developers*. Addison-Wesley Publishing Co., 1998.
- Homer, Alex, and David Sussman. *Professional MTS and MSMQ Programming with VB and ASP*. Wrox Press Inc., 1998.
- Sessions, Roger. Chapter 11 in *COM and DCOM: Microsoft's Vision for Distributed Objects*. John Wiley & Sons, 1998.

# Using Data Sources (ODBC)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Data Sources (ODBC)**
You can use Data Sources Open Database Connectivity (ODBC) to access data from a variety of database management systems. For example, if you have a program that accesses data in a SQL database, Data Sources (ODBC) will let you use the same program to access data in a Visual FoxPro database. To do this, you must add software components called drivers to your system. Data Sources (ODBC) helps you add and configure these drivers.

### Notes

- To open Data Sources (ODBC), click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Data Sources (ODBC)**.

- For information about using Data Sources (ODBC), in the **ODBC Data Source Administrator** dialog box, click **Help**.

# Windows Management Instrumentation Control

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Management Instrumentation Control**

- For help on using WMI Control, see Windows Management Instrumentation Control How To....
- To understand more about WMI Control, see Windows Management Instrumentation Control Concepts.

# Using MSDN

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using MSDN**

The Microsoft Developer Network (MSDN) is a complete resource for developers. You can find downloads, guidelines for hardware and driver compatibility testing, and how-to guides to help you build device drivers for Windows operating systems. For more information, see MSDN at the Microsoft Web site.

# Windows Deployment and Resource Kits

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft Windows Deployment and Resource Kits**
The Microsoft® Windows® Deployment and Resource Kits provide IT professionals with the technical information and tools they need to successfully deploy and operate Windows.

See the topics in this Help and Support site for the content in the Microsoft® Windows® Server 2003 Deployment Kit, the Microsoft® Windows® Server 2003 Resource Kit, and Microsoft® Windows® XP Professional Resource Kit Documentation. For more information about purchasing the kits, or to browse the documentation on the Web, go to the Windows Deployment and Resource Kits Web site. This Web site also contains other important documentation developed by the Windows Resource Kit teams, including the Windows Server 2003 System Administration Scripting Guide and Windows 2000 documentation.

**Important**

- Some of the links on this page are to English-only content on the Web, regardless of the language of your operating system. In addition, if you install a Windows Deployment or Resource Kit on a non-English operating system, you will see English content mixed with non-English content in the Help and Support Center table of contents.

**Using Windows Server 2003 Help and Support Center from Windows XP Professional**
Windows Server 2003 Help and Support Center contains technical content for the IT professional that you won't find in Windows XP Professional. If you administer servers running Windows Server 2003 from a computer running Windows XP Professional, you should install Windows Server 2003 Help and Support Center. When you do this, your installed Windows Deployment and Resource Kits can be viewed and searched from within the Windows Server 2003 Help and Support Center. This way you have easy access to a more complete documentation set for server deployment and administration.

To install Windows Server 2003 Help and Support Center on a computer running Windows XP Professional, follow the steps in the Help topic Install Help content from a Windows Server 2003 server operating system onto a computer running Windows XP Professional. Windows Server 2003 family Help content is available on the Windows Server 2003 Deployment Kit companion CD, the Windows Server 2003 Resource Kit companion CD, and the Windows Server 2003 operating system CD.

# Microsoft Windows Server 2003 Deployment Kit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft Windows Server 2003 Deployment Kit**
The Microsoft® Windows Server™ 2003 Deployment Kit provides guidelines and recommended processes for designing and deploying Windows Server 2003 family technologies to meet your business needs and IT goals.

**Important**

- Some of the links on this page are to English-only content on the Web, regardless of the language of your operating system. In addition, if you install a Windows® Deployment or Resource Kit on a non-English operating system or on an operating system with a Multilingual User Interface Pack (MUI), you will see some English content mixed with non-English content in Help and Support Center.

**Windows Server 2003 Deployment Kit**
For more information about the Windows Server 2003 Deployment Kit, see the Windows Server 2003 Deployment Kit Web site.

Planning for Deployment

Provides guidelines for creating a deployment project plan, setting up a deployment test lab, creating software and hardware inventories, choosing a licensing method, and conducting a deployment pilot project.

Deploying Network Services

Provides guidelines to help you build a TCP/IP network, deploy DHCP and DNS, and deploy WINS. This book also includes information about wireless networking, network security, and remote access connectivity.

Designing and Deploying Directory and Security Services

Provides guidelines to help you design and deploy directory services, including upgrading and restructuring domains. This book also includes planning and deployment guidelines for distributed security services, including authentication, access control, public key infrastructures, and smart cards.

Planning Server Deployments

Provides guidelines to help you design and deploy file servers, print servers, server clusters, Network Load Balancing clusters, and terminal services. This book also provides information on planning for storage, high availability, and remote server management.

Automating and Customizing Installations

Provides deployment planning information for automated installations, multilingual deployments, and compatibility testing, and includes design information for unattended installations, image-based installations, and Remote Installation Services (RIS) installations.

Designing a Managed Environment

Provides guidelines to help you design and deploy Group Policy infrastructure, security policy, Group Policy-based software deployment, update management, and a user data and settings management strategy.

Deploying Internet Information Services (IIS) 6.0

Provides prescriptive guidance on designing and deploying IIS 6.0 solutions for medium to large application server environments.

Tools and Technical References

Provides the complete set of Resource Kit tools and tools help, plus a technical reference on the Windows registry.

For more information about purchasing the Windows Deployment and Resource Kits, or to browse additional Windows

Deployment and Resource Kit documentation on the Web, go to the Windows Deployment and Resource Kits Web site.

# Microsoft Windows Server 2003 Resource Kit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft Windows Server 2003 Resource Kit**
Looking for The *Microsoft® Windows Server™ 2003 Resource Kit*? See the Windows Server 2003 Technical Reference documentation, which provides comprehensive information about the technologies included in the Microsoft® Windows Server™ 2003 operating system. This set of Technical Reference documentation is designed to assist IT planners and administrators by providing the foundational information about the technology components of the operating system

**Important**

- Some of the links on this page are to English-only content on the Web, regardless of the language of your operating system. In addition, if you install a Windows Deployment or Resource Kit on a non-English operating system or on an operating system with a Multilingual User Interface Pack (MUI), you will see some English content mixed with non-English content in Help and Support Center.

**Windows Server 2003 Technical Reference**
Technical Reference documentation for the Windows Server 2003 family of operating systems includes the following technology collections:

Active Directory Collection

This collection provides in-depth technical reference information about the Windows Server 2003 Active Directory® directory service and its components. These components include logical structure, physical structure, data storage, replication, and service publication. In addition, this collection includes technical reference information about the tools that are used to install, upgrade, and migrate an Active Directory environment.

Core Operating System Collection

This collection describes the core Windows Server 2003 operating system technologies. These technologies provide basic functionality such as printing services, data recovery, and troubleshooting.

Group Policy Collection

This collection provides in-depth technical information about Windows Server 2003 Group Policy and its supporting technologies, including core Group Policy, Group Policy components, and Group Policy administrative tools. These technologies enable you to deliver, apply, and centrally manage one or more configurations, including Administrative Templates (registry-based policy), folder redirection, scripts, security, and software installation settings, to a set of targeted users and computers within an Active Directory environment.

High Availability and Scalability Collection

This collection describes the Windows Server 2003 high availability technologies that are designed to reduce unscheduled outages and mitigate the impact of scheduled downtime for servers. This collection also describes the Windows Server 2003 scalability technologies used to increase or decrease computing capacity in order to address the capacity needs of an organization.

Networking Collection

This collection provides in-depth technical reference information about Windows Server 2003 technologies that make up a networking infrastructure based on the TCP/IP suite of protocols, services, and other industry-standard networking protocols and technologies.

Storage Technologies Collection

This collection describes the Windows Server 2003 storage technologies that are designed to help you store, access, and manage data on servers.

Windows Security Collection

This collection describes Windows Server 2003 security technologies, including authentication, authorization, and public key infrastructure (PKI), and provides detailed information about security policy settings.

### Internet Information Services 6.0 Technical Reference

Provides information about running IIS as a Web application platform, ensuring that IIS stays secure, monitoring and tuning IIS, administering the server programmatically, and capitalizing on built-in IIS scalability features to manage large-scale deployments.

### Tools and Technical References

Provides the complete set of Resource Kit tools and tools help, plus a technical reference on the Windows registry.

For more information about purchasing the Windows Deployment and Resource Kits, or to browse additional Windows Deployment and Resource Kit documentation on the Web, go to the Windows Deployment and Resource Kits Web site.

# Microsoft Windows XP Professional Resource Kit Documentation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft Windows XP Professional Resource Kit Documentation**
Microsoft® Windows® XP Professional Resource Kit Documentation is a comprehensive technical resource for installing, configuring, and supporting Microsoft® Windows® XP Professional and Windows XP 64-Bit Edition in networks that use Windows 2000 Server, Windows NT® Server 4.0, and other server systems.

### Important

- All of the links on this page are to English-only content on the Web, regardless of the language of your operating system.

  The links on this page are to Windows XP Professional Resource Kit Documentation on the Web. If you have installed Windows XP Professional Resource Kit Documentation, you can access this information locally on your computer from the **Start** menu.

**Windows XP Professional Resource Kit Documentation**
To see a browsable version of Windows XP Professional Resource Kit Documentation on the Web, go to the Windows XP Professional Resource Kit Web site, or use the links below. To view specific chapters online, click a chapter link.

**Part I Deployment and Installation**
Ch. 1 Planning Deployments

Ch. 2 Automating and Customizing Installations

Ch. 3 Multilingual Solutions for Global Business

Ch. 4 Supporting Installations

**Part II Desktop Management**
Ch. 5 Managing Desktops

Ch. 6 Managing Files and Folders

Ch. 7 Supporting Mobile Users

Ch. 8 Configuring Remote Desktop

Ch. 9 Managing Devices

Ch. 10 Managing Digital Media

Ch. 11 Enabling Printing and Faxing

Ch. 12 Disk Management

Ch. 13 File Systems

Ch. 14 Backup and Restore

**Part III Security**
Ch. 15 Logon and Authentication

Ch. 16 Authorization and Access Control

Ch. 17 Encrypting File System

**Part IV Networking**
Ch. 18 Connecting Clients to Windows Networks

Ch. 19 Configuring TCP/IP

Ch. 20 Configuring IP Addressing and Name Resolution

Ch. 21 Connecting Remote Offices

Ch. 22 Configuring Telephony and Conferencing

**Part V Interoperability**

# Microsoft Services for Network File System

Applies To: Windows Server 2003 R2

Microsoft® Services for Network File System (NFS) provides a file sharing solution for enterprises that have a mixed Windows and UNIX environment. With Microsoft Services for NFS, you can transfer files between computers running Microsoft Windows Server™ 2003 R2 and UNIX operating systems using the NFS protocol.

Microsoft Services for NFS is an update to the NFS components that were previously available in Windows® Services for UNIX 3.5. Microsoft Services for NFS includes the following new features:

- Active Directory Lookup. The Identity Management for UNIX Active Directory schema extension, available in Windows Server 2003 R2, includes UNIX user identifier (UID) and group identifier (GID) fields, which enables NFS clients to look up UNIX identity information directly from Active Directory.

- 64-bit support. Microsoft Services for NFS components can be installed on all editions of Windows Server 2003 R2, including 64-bit editions.

- Enhanced server performance.

- Support for UNIX special devices (mknod).

Microsoft Services for NFS enables you to support a mixed environment of Windows-based and UNIX-based operating systems. It also allows you to update your company's computers while supporting older technology during the transition phase. The following scenarios are examples of how enterprises can benefit from deploying Microsoft Services for NFS.

- Allow UNIX clients to access resources on computers running Windows Server 2003 R2. Your company may have UNIX clients accessing resources, such as files, on UNIX file servers. To take advantage of new Windows Server 2003 features, such as Shadow Copies for Shared Folders, you can move resources from your UNIX servers to computers running Windows Server 2003 R2 and then configure Microsoft Services for NFS to enable access by UNIX clients that are running NFS software. All of your UNIX clients will be able to access the resources using the NFS protocol with no changes required.

- Allow computers running Windows Server 2003 R2 to access resources on UNIX file servers. Your company may have a mixed Windows and UNIX environment with resources, such as files, stored on UNIX file servers. You can use Microsoft Services for NFS to enable computers running Windows Server 2003 R2 to access these resources when the file servers are running NFS software.

- Take advantage of new 64-bit hardware. You can run Microsoft Services for NFS components on 64-bit editions of Windows Server 2003 R2.

# What's new in Microsoft Services for NFS

Applies To: Windows Server 2003 R2

Microsoft Services for Network File System (NFS) provides many improvements that make it easier than ever to integrate Windows and UNIX networks effectively.

**Active Directory Lookup**
The Identity Management for UNIX Active Directory schema extension, available in Microsoft Windows Server 2003 R2, includes UNIX user identifier (UID) and group identifier (GID) fields, which enables Server for NFS and Client for NFS to look up Windows-to-UNIX user account mappings directly from Active Directory. Identity Management for UNIX simplifies Windows-to-UNIX user account mapping management in Active Directory.

| **Note** |
| --- |
| After this release, the User Name Mapping component will no longer ship with Microsoft Services for NFS. |

**64-bit support**
You can install Microsoft Services for NFS components on all editions of Windows Server 2003 R2, including 64-bit editions.

**Enhanced server performance**
Microsoft Services for NFS includes a file filter driver, which significantly reduces common server file access latencies.

**UNIX special device support**
Microsoft Services for NFS supports UNIX special devices (mknod).

**Enhanced UNIX support**
Microsoft Services for NFS now supports the following versions of UNIX:

- Sun Microsystems Solaris version 9
- Red Hat Linux version 9
- IBM AIX version 5L 5.2
- Hewlett Packard HP-UX version 11i

**Deprecated features**
To streamline and simplify Microsoft Services for NFS, the following features were removed from this release:

- Gateway for NFS
- Server for PCNFS
- All PCNFS components of Client for NFS

# Best practices for configuring and using Microsoft Services for NFS

Applies To: Windows Server 2003 R2

**Use the correct utilities to administer Microsoft Services for NFS.**
You cannot use Microsoft Services for Network File System (NFS) or command-line utilities to administer earlier versions of Microsoft Services for NFS. Also, you cannot use earlier versions of Microsoft Services for NFS or command-line utilities to administer newer versions of Microsoft Services for NFS.

You can use Microsoft Services for NFS to administer NFS components on a remote computer if both computers are running a Windows Server 2003 R2 operating system.

**Open firewall ports.**
Microsoft Services for NFS requires several ports, which must be open on Windows Firewall and other firewalls. When prompted, make sure you allow Microsoft Services for NFS components.

For information about changing port settings, see Microsoft Services for NFS troubleshooting.

# Server for NFS best practices

Applies To: Windows Server 2003 R2

**General best practices**

**Provide user-level security.**

With Server for NFS, you can control access by users and groups to Network Files System (NFS) resources. You must configure and populate Active Directory with user identifier (UID) and group identifier (GID) information or install User Name Mapping on one computer in your network to associate Windows user accounts with UNIX user accounts. In some cases you may also need to install Server for NFS Authentication, see Server for NFS Authentication for more details.

**Secure files.**

Server for NFS only supports storage volumes that are formatted for NTFS. NTFS volumes enable you to provide file-level security by allowing and denying file access to specific users and groups. When you want anonymous users to access files, make sure directory and file permissions provide appropriate access for anonymous users. In addition, when sharing the directory, use host-level NFS access control when creating the NFS share to provide an additional level of security to protect the files in the directory.

**Secure new drives.**

When you add a new drive to a computer running Server for NFS, be sure to modify the permissions protecting the root directory of the drive to ensure untrusted users, including Everyone users, cannot write to the directory. This will prevent untrusted users from being able to compromise Server for NFS security by protecting shared directories on the drive.

**Allow users to disconnect before stopping the Server for NFS service.**

Before you stop Server for NFS or uninstall it, notify users who are connected to NFS shares that you are about the stop the service. You can then stop the service after the users have had the opportunity to close open files and disconnect from shared directories.

**Use naming conventions to identify shares with EUC encoding.**

If a directory is shared with one type of Extended UNIX Code (EUC) encoding (such as EUC-JP), and a client that is configured to use a different EUC encoding (such as EUC-TW) attempts to connect to the shared directory, unexpected results can occur. To prevent this, establish a naming convention to use when sharing directories with EUC encoding so users of client computers can know how shared directories are encoded.

**Protect configuration files.**

If you create configuration files (such as a character translation file or an audit log file), be sure to protect them with a discretionary access control list (DACL) that grants Full Control to the built-in System account and to the Administrators group. The DACL should contain no other entries.

**Best practices for running Server for NFS in a server cluster**

**Stop Server for NFS before stopping the server cluster.**

To ensure proper operation of Server for NFS in a server cluster, when stopping the server cluster, first stop Server for NFS, then stop the server cluster.

**Ensure share availability when a node fails.**

To ensure that a shared directory cluster resource will be available after the node containing the resource fails, make the cluster resource dependent on the appropriate physical disk resource.

**Use the appropriate tool to manage Network File System (NFS) share cluster resources.**

Although you can use Windows Explorer to view properties of an NFS share cluster resource, you should not use it to change those properties. You should only use Cluster Administrator or the **cluster** command to create and administer shared NFS directories on a server cluster.

**Avoid conflicting share names.**

Ensure that the share name of every shared directory on the server cluster is unique. Otherwise, if one node in the cluster fails over to another node, and if shared directories on the two nodes have the same name, then only one of the shared directories will be available.

**Ensure the availability of audit logs.**

Do not designate a shared disk resource as the location of the Server for NFS audit log. Only one node in the cluster can own the log file. This means that if the ownership of a group is moved to another node, the audit events for the remaining shares on the original node cannot be recorded in the file. To ensure the availability of Server for NFS audit logs, you should log events to the Event Viewer event log.

**Move file shares or take them offline before stopping Server for NFS.**

When Server for NFS is stopped on a cluster node hosting active NFS share resources, the Cluster service responds as though this were a failure of one of its managed resources. Consequently, the Cluster service will try to restart the service in an attempt to keep the resource available. Before you attempt to stop Server for NFS on a server cluster node, either move all groups containing NFS file shares to another node on the cluster, or take all NFS file shares on the node offline.

**Take resources offline before modifying.**
Be sure to take an NFS share directory resource offline before modifying its properties. Failing to do so might produce unexpected results.

**Administer Server for NFS only from computers in a trusted domain.**
To ensure that Server for NFS configuration changes are properly replicated, always use a computer that belongs to a trusted domain when you administer Server for NFS running on a cluster. This is necessary because Server for NFS configuration changes are not properly replicated among nodes in a cluster if you run Microsoft Services for NFS Administration or **nfsadmin** on a computer that belongs to a domain that is not trusted by the domain of the cluster.

**Restart the Server for NFS service after the Cluster service restarts.**
If the Cluster service must be restarted on a node in the cluster, stop and then restart the Server for NFS service on that node. This will ensure that Server for NFS configuration changes will be replicated properly among the nodes of the cluster.

**Choose the appropriate sharing mode.**
When you create an NFS share directory resource, you have the option of sharing the root of the specified directory or all the subdirectories in the directory. Before choosing this option, first decide whether you will need to control access to the subdirectories or change their share names. If you need to do this, you must share the subdirectories separately because when you create an NFS share directory resource to share the subdirectories, you cannot set access permissions, allow (or deny) anonymous access, or change the share name of the subdirectories separately.

If you choose to share all the subdirectories in the directory, make sure that the permissions protecting the directory do not allow untrusted users to create subdirectories. Otherwise, a malicious user can overwhelm the Cluster service by creating a very large number of subdirectories that would automatically be shared as a cluster resource.

**Use the command line properly when creating or modifying NFS share cluster resources.**
If you use the **cluster** command to create and modify NFS share cluster resources, the following considerations apply:

- When you create the cluster resource using the cluster **command**, you can set some nonprivate properties, but not all.
- When using the **cluster** command to set properties, do not rely on default values because they might be invalid for an NFS share cluster resource. Always set property values explicitly.
- To set or view permissions on an NFS share cluster resource, use Cluster Administrator. You can also use the **nfsshare** command to view permissions, but not to set them.

**Use hard mounts.**
Users of client computers should be instructed to use hard mounts when mounting NFS directories shared on the server cluster. This will ensure that, if the node sharing the directory fails, the client computer will not time out before the failover to another node is complete.

**Use the correct virtual server name.**
Users of client computers should be instructed to mount NFS directories shared on the server cluster using the virtual server name from the same group as the shared directory. Using a virtual server name from another group, or the node name, allows the client computer to mount the directory, but the mount can be lost in case of a failover.

# User Name Mapping best practices

Applies To: Windows Server 2003 R2

**Install User Name Mapping on a domain controller.**
If you have a large number of user maps, installing User Name Mapping on a domain controller improves performance by reducing network traffic when maps are first created or refreshed.

**Create a User Name Mapping server pool.**
You can use DNS round robin to create a pool of computers running User Name Mapping. This will provide improved performance on wide area networks as well as provide failover capability when one of the servers is no longer available. For more information, see Creating a User Name Mapping pool.

**Configure User Name Mapping on a server cluster.**
You can use a User Name Mapping server cluster to provide high availability of User Name Mapping. To ensure proper operation of User Name Mapping on a server cluster, when stopping the server cluster, first stop User Name Mapping, then stop the server cluster. For more information, see Configuring User Name Mapping on a server cluster.

**Make sure User Name Mapping can download users from all domains.**
In order to download users from a Windows domain, make sure that the User Name Mapping server belongs to a domain that is trusted by the Windows domain which it is trying to access.

If Active Directory was installed with permissions compatible with the Windows Server 2000 Server option, do one of the following:

- If the computer running User Name Mapping is a member of the domain, add the computer to the **Pre-Windows 2000 Compatible Access** security group.

- If the computer running User Name Mapping does not belong to the domain (that is, it belongs to a trusted domain), add the special group **Everyone** to the **Pre-Windows 2000 Compatible Access** security group of the Active Directory domain.

**Refresh data whenever a user is added or changed.**
To ensure that the user will have immediate access to Network File System (NFS) resources, refresh the User Name Mapping database immediately after you add a user or otherwise make changes to the user's Windows or UNIX accounts that would affect the user's mapping. For information about refreshing the database, see Refreshing maps.

**Place password and group files on the User Name Mapping server.**
If User Name Mapping is configured to use password and group files, these files must be located on a hard drive on the server to ensure that User Name Mapping can access the files whenever it refreshes the mapping database.

**Use appropriate permissions to protect password and group files.**
Protect password and group files with permissions that allow access only by appropriate users. We recommend that the permissions list contain only entries that grant Full Access to SYSTEM and the Administrators group. Also, do not change the permissions that Microsoft Services for NFS applies to other User Name Mapping configuration files.

**Back up complex maps whenever you make changes.**
To avoid loss of complex advanced maps in case of system difficulty, or to aid in transferring maps to another server, be sure to back up your User Name Mapping data whenever you change advanced maps.

**Ensure consistency of group mapping.**
To ensure proper file access, Windows and UNIX groups that are mapped to each other should contain the same users, and the members of the Windows and UNIX groups should be properly mapped to each other.

**Specify the computers that can access User Name Mapping.**
User Name Mapping requires you to identify the computers that can access User Name Mapping in the .maphosts file. (If the list in this file is empty, only the computer that is running User Name Mapping can access the service.) To maintain a high level of security, you should explicitly specify the computers that can access User Name Mapping, rather than using the plus sign (+) by itself to grant access to all computers. For more information, see Securing access to the User Name Mapping server.

# Client for NFS best practices

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

**Use the correct command prompt.**
If you are running Client for NFS and using a command prompt, you should use the 32-bit version (Cmd.exe), which is available through the **Start** menu. Do not use the 16-bit version (Command.com). You must run Nfsadmin.exe from an elevated privilege command prompt to change Client for NFS configuration settings.

**Avoid using hard mounts.**
Regardless of the mount type, Client for NFS will not indefinitely try to mount an NFS shared resource. Once the shared resource has been successfully mounted, if the mount type is a hard mount and the Network File System (NFS) server becomes unavailable, Client for NFS will retry accessing the shared resource until the NFS server is once again available. As a result, Windows applications that are trying to access the shared resource will appear to stop responding.

| **Note** |
| --- |
| The **umount** command will disconnect a hard mount — even if the server is unavailable. |

# Understanding the Server for NFS component

Applies To: Windows Server 2003 R2

With Server for NFS, a computer running the Microsoft Windows Server 2003 R2 operating system can act as a Network File System (NFS) server. Users can then share files in a mixed environment of computers, operating systems, and networks.

Users on computers running NFS client software can gain access to directories (called shares) on the NFS server by connecting (mounting) those directories to their computers. From the viewpoint of the user on a client computer, the mounted files are indistinguishable from local files.

UNIX computers follow advisory locking for all lock requests. This means that the operating system does not enforce lock semantics on a file, and applications that check for the existence of locks can use these locks effectively. However, Server for NFS implements mandatory locks even for those locking requests that are received through NFS. This ensures that locks acquired through NFS are visible through the server message block (SMB) protocol and to applications accessing the files locally. Mandatory locks are enforced by the operating system.

# Starting and stopping Server for NFS

Applies To: Windows Server 2003 R2

Starting Server for NFS

Stopping Server for NFS

# Starting Server for NFS

Applies To: Windows Server 2003 R2

**To start Server for NFS from the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **Server for NFS**, and then click **Start**.

**To start Server for NFS from the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **nfsadmin server** [*ComputerName*] **start**

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer on which you want to start Server for NFS. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **nfsadmin server /?** |

# Stopping Server for NFS

Setting the lock grace period

Releasing locks

Setting up audit logging

Specifying Server for NFS TCP and UDP settings

Enabling NFS version 3

Configuring file-name character translation

Configuring the authentication renewal period

Configuring case sensitivity for file and folder names

Running Server for NFS on a server cluster

# Specifying how Server for NFS obtains Windows user and group information

Applies To: Windows Server 2003 R2

In a UNIX environment, authentication is the process of providing a user identifier (UID) and group identifier (GID) to a user who presents a valid user name and password. UNIX hosts provide these identifiers when a user logs on to the host. When the user logs on, the user's name and password are compared to those in a password file. If they correspond with a user name and password in the file, the server returns a corresponding UID and GID. The UID and GID identify the user for Network File System (NFS) browsing and mounting operations.

Server for NFS makes it possible for clients to access NFS resources without separately logging on to Server for NFS. Instead, the first time you try to access an NFS resource, Server for NFS looks up your UNIX UID and GID information in either Active Directory or User Name Mapping. If your UNIX UID and GID information is mapped to a Windows user and group accounts, the Windows names are returned to Server for NFS, which then uses the Windows user and group names to grant file access.

If your UNIX UID and GID information is not mapped, then Server for NFS will deny file access.

**Specifying how Server for NFS obtains Windows user and group information**
You can perform this procedure using the following methods:

- Using the Windows interface
- Using a command line

### To specify how Server for NFS obtains UID and GID information using the Windows interface

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **Microsoft Services for NFS**, and then click **Properties**.
4. Specify how Server for NFS obtains user identifier (UID) and group identifier (GID) information for users:
   - To use Active Directory Lookup, select the **Active Directory Lookup** check box, type the domain name, and then click **Apply**.
   - To use User Name Mapping, type the name of the mapping server you want to use for authentication, and then click **Apply**.

| **Note** |
| --- |
| Before using Active Directory Lookup, you must install and populate the Identity Management for UNIX Active Directory schema extension, included in Windows Server 2003 R2, or have an equivalent schema which includes UNIX UID and GID fields. Identity Management for UNIX greatly simplifies this aspect of Windows-to-UNIX user account management in Active Directory.<br><br>You can specify the Internet Protocol (IP) address of the User Name Mapping server instead of the name of the server.<br><br>Before using User Name Mapping, the computer running Server for NFS must be listed in the .maphosts file on the computer running User Name Mapping. For more information, see Securing access to the User Name Mapping server |

### To specify how Server for NFS obtains UID and GID information using the command line

1. Open the command prompt.
2. Specify how Server for NFS obtains user identifier (UID) and group identifier (GID) information for users:

- To use User Name Mapping, at a command prompt, type:

  **nfsadmin mapping [***ComputerName***] config adlookup=yes addomain=***DomainName***

- To use User Name Mapping, at a command prompt, type:

  **nfsadmin mapping [***ComputerName***] config mapsvr=***ServerName***

| Argument | Description |
|---|---|
| *DomainName* | The name of the domain controller you want to use. |
| *ComputerName* | The name of the computer you want to manage. |
| *ServerName* | The name of the mapping server you want to use. |

**Note**

To view the complete syntax for this command, at a command prompt, type: **nfsadmin mapping /?**

Before using Active Directory Lookup, you must install and populate the Identity Management for UNIX Active Directory schema extension, included in Windows Server 2003 R2, or have an equivalent schema which includes UNIX UID and GID fields. Identity Management for UNIX simplifies this aspect of Windows-to-UNIX user account management in Active Directory.

Before using User Name Mapping, the computer running Server for NFS must be listed in the .maphosts file on the computer running User Name Mapping. For more information, see Securing access to the User Name Mapping server

# Setting the lock grace period

Applies To: Windows Server 2003 R2

**To set the lock grace period using the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **Server for NFS** and then click **Properties**.
4. Click the **Locking** tab.
5. In **Waiting Period**, type the number of seconds within which Network File System (NFS) clients can reestablish file locks after a network or server service interruption..
6. To save this setting, click **Apply**.

**To set the lock grace period using the command line**

1. Open the command prompt.
2. At a command prompt, type:

   **nfsadmin server [Computer** *Name* **] config lockperiod=** *LockingGracePeriod*

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *LockingGracePeriod* | The time period (in seconds) within which users can reestablish locks after the server restarts. |

| Note |
|---|
| To view the complete syntax for this command, at a command prompt, type: **nfsadmin server /?** |

# Releasing locks

Applies To: Windows Server 2003 R2

**To release locks using the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **Server for NFS**, and then click **Properties**.
4. Click the **Locking** tab.
5. In the list of clients, click the client whose locks you want to release, click **Release Locks**, and then click **Apply**.

**To release locks using the command line**

1. Open the command prompt.
2. To list all locks, type:

   **nfsadmin server [Computer** *Name* **] –l**

3. To release locks, type:

   **nfsadmin server [Computer** *Name* **] –r [C** *lient***| all]**

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *Client* | The client whose locks you want to release. |
| **All** | Releases all locks. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type:<br>**nfsadmin server /?** |

# Setting up audit logging

Applies To: Windows Server 2003 R2

**To set up logging using the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **Server for NFS**, and then click **Properties**.
4. Click the **Audit Logging** tab.
5. To record audited events in the Event Viewer application log, select **Log events to event log**.
6. To record audited events in a file, select **Log events to the following text file**. In the text box, type the name of the log file, or click **Browse** to find the file, and then in **Maximum file size**, increase the maximum size for the log file, if desired (default: 64MB).
7. In **Server for NFS Events**, select the events to audit from the following options:
   - **Mount and unmount shares.**
   - **Lock and unlock files**.
   - **Read** files.
   - **Write** files.
   - **Create** files.
   - **Delete** files.
   - **All events listed above**.
8. To save the settings, click **Apply**.

| **Note** |
| --- |
| By default, no events are audited. If recording audited events to a text file, the log file must be on your local computer. To stop logging an event, clear its check box. If you choose to record Server for NFS audited events in the event log, the string corresponding to the file name could be truncated due to a system limitation.<br><br>One solution to this problem is to record audited events to a text file. On a server cluster, it is recommended that you record audited events to the Event Viewer because its data replicates to all the nodes in the cluster. In this scenario, recording audited events to a text file in addition to the event log can help associate complete file names with a particular audit log entry. |

# Specifying Server for NFS TCP and UDP settings

Applies To: Windows Server 2003 R2

**To specify Server for NFS TCP and UDP settings using the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System.**
2. If necessary, connect to the computer you want to manage.
3. Right-click **Server for NFS**, and then click **Properties**.
4. Click the **Server Settings** tab.
5. Select the desired transport protocol setting from the **Transport protocol** drop-down list, and then click **Apply**.

| **Important** |
|---|
| These changes will not take effect until Server for NFS is restarted. For information about how to stop and start Server for NFS, see Starting and stopping Server for NFS. |

**To specify Server for NFS TCP and UDP settings using the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **nfsadmin server [** *ComputerName* **] config [** *Protocol* **]= [** *Transport* **]**

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *Protocol* | The name of the Network File System (NFS) protocol you want to configure. See the list of "Protocol types" below. |
| *Transport* | The transport or combination of transports to enable for the given NFS protocol. See the list of "Transport types" below. |

**Protocol types:**

| Protocol | Description |
|---|---|
| PortmapProtocol | Specifies the Portmap protocol. |
| MountProtocol | Specifies the Mount protocol. |
| NLMProtocol | Specifies the Network Lock Manager protocol. |
| NSMProtocol | Specifies the Network Status Manager protocol. |

**Transport types:**

| Transport | Description |
|---|---|
| TCP | Enables only the TCP transport. |
| UDP | Enables only the UDP transport. |

| | |
|---|---|
| TCP+UDP | Enables both the TCP and UDP transports. |

**Important**

These changes will not take effect until Server for NFS is restarted. For information about how to stop and start Server for NFS, see Starting and stopping Server for NFS.

**Note**

To view the complete syntax for this command, at a command prompt, type: **nfsadmin server /?**

# Enabling NFS version 3

Applies To: Windows Server 2003 R2

**To enable NFS Version 3 using the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **AdministrativeTools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **Server for NFS**, and then click **Properties**.
4. Click the **Server Settings** tab.
5. Select the **Enable NFS v3 support** check box, and then click **Apply**.

| **Important** |
|---|
| These changes will not take effect until Server for NFS is restarted. For information about how to stop and start Server for NFS, see Starting and stopping Server for NFS. |

**To enable NFS Version 3 using the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **nfsadmin server [** *remoteMachineName* **] config enablev3={yes | no}**

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to configure. |

| **Important** |
|---|
| These changes will not take effect until Server for NFS is restarted. For information about how to stop and start Server for NFS, see Starting and stopping Server for NFS. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type:<br>**nfsadmin server /?**<br>NFS v3 support is enabled by default. |

# Configuring file-name character translation

Applies To: Windows Server 2003 R2

**To configure file-name character translation using the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **Server for NFS**, and then click **Properties**.
4. Click the **Filename Handling** tab.
5. Select the **Translate file names**check box.
6. In the **Character translation file** box, type the fully qualified path of the file containing the character-translation map, or click **Browse** to find the file, and then click **Apply**.

| **Important** |
|---|
| These changes will not take effect until Server for NFS is restarted. For information about how to stop and start Server for NFS, see Starting and stopping Server for NFS. |

| **Important** |
|---|
| To prevent unauthorized users from tampering with the file-name character translation file and causing Server for NFS to fail, ensure that the file is protected with a discretionary access control list (DACL) that grants Full Control to the built-in System account and to the Administrators group. The DACL should contain no other entries. |

**To configure file-name character translation using the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **nfsadmin server [** *ComputerMachineName* **] config translationfile=** *file*

| Argument | Description |
|---|---|
| *remoteMachineName* | The name of the computer you want to configure. |
| *file* | The fully qualified path and name of the file containing the character-translation map list. If you do not specify a file, character translation will be disabled. |

| **Important** |
|---|
| These changes will not take effect until Server for NFS is restarted. For information about how to stop and start Server for NFS. |

| **Important** |

Starting and stopping Server for NFS

# Configuring the authentication renewal period

Applies To: Windows Server 2003 R2

**To configure how often authentication is renewed using the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **Server for NFS**, and then click **Properties**.
4. Click the **Server Settings** tab.
5. Do one of the following:
   - To prevent Server for NFS from periodically renewing authentication, click **Do not renew authentication**.
   - To configure Server for NFS to renew authentication periodically, click **Renew authentication every:** and type how many seconds will elapse before authentication will be renewed. The default is 600 seconds.
6. Click **Apply**.

**To configure how often authentication is renewed using the command line**

1. Open the command prompt.
2. To configure Server for NFS to renew authentication periodically, type the following at the command prompt:

   **nfsadmin server [** *ComputerName* **] config renewauth=yes**

   **nfsadmin server [** *ComputerName* **] config renewauthinterval=** *seconds*
3. To configure Server for NFS to not renew authentication periodically, type the following at the command prompt:

   **nfsadmin server [** *ComputerName* **] config renewauth=no**

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to configure. |
| *seconds* | The number of seconds that will elapse before authentication is renewed. The default is 600. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **nfsadmin server /?** |

# Configuring case sensitivity for file and folder names

Applies To: Windows Server 2003 R2

**To configure case sensitivity for file and folder names using the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System.**
2. If necessary, connect to the computer you want to manage.
3. Right-click **Server for NFS**, and then click **Properties**.
4. Click the **Filename Handling** tab.
5. Do one of the following:
   - To enable case-sensitive file and directory name lookups, select the **Enable case sensitive lookups** check box.
   - To disable case-sensitive file and directory name lookups, clear the **Enable case sensitive lookups** check box.
6. Click **Apply**.

**Important**

These changes will not take effect until Server for NFS is restarted. For information about how to stop and start Server for NFS, see Starting and stopping Server for NFS.

You also need to disable Windows kernel case-insensitivity in order for Server for NFS to support case-sensitive file names. You can disable Windows kernel case-insensitivity by clearing the following registry key to 0:

HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\kernel

DWORD "obcaseinsensitive"

**To configure case sensitivity for file and folder names using the command line**

1. Open the command prompt.
2. To enable case sensitivity, type the following:

   **nfsadmin server [** *ComputerName* **] config casesensitivelookups=yes**
3. To disable case sensitivity and optionally specify the case of file names returned by Server for NFS, at a command prompt, type the following:

   **nfsadmin server [** *ComputerName* **] config casesensitivelookups=no [ntfscase={upper | lower | preserve}]**

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to configure. |

**Important**

These changes will not take effect until Server for NFS is restarted. For information about how to stop and start Server for NFS, see Starting and stopping Server for NFS.

**Note**

The ntfscase option sets the case sensitivity for the NTFS file system. The default case sensitivity is preserve (preserve case).

To view the complete syntax for this command, at a command prompt, type:

**nfsadmin server /?**

Starting and stopping Server for NFS

# Running Server for NFS on a server cluster

Applies To: Windows Server 2003 R2

Sharing directories as cluster resources

Modifying shared directory cluster resources

Deleting shared directory cluster resources

# Sharing directories as cluster resources

Applies To: Windows Server 2003 R2

**To share a directory as a cluster resource using the Windows interface**

1. Open Cluster Administrator: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Cluster Administrator**.
2. In the console tree (usually the left pane), double-click the **Groups** folder.
3. In the details pane (usually the right pane), click the group to which you want the resource to belong.
4. On the **File** menu, point to **New**, and then click **Resource**.
5. In the New Resource Wizard, type the appropriate information in **Name** and **Description**. In **Resource type**, click **NFS Sharing**. Click **Next**.
6. Add or remove possible owners of the resource, and then click **Next**.
7. To add or remove dependencies, do one of the following:
   - To add dependencies, under **Available resources**, click a resource, and then click **Add**.
   - To remove dependencies, under **Resource dependencies**, click a resource, and then click **Remove**.
8. In **Share Name**, type the name of the shared folder.
9. In **Share Path**, type the fully qualified path of the folder to be shared.
10. Do one of the following:
    - To share the folder and its contents as a single shared folder, click **Share Root Only**.
    - To share all folders (except hidden folders) in the folder specified in the previous step as separate shared folders, click **Share Subdirectories Only**.
11. To allow access by users who have not been authenticated, click **Allow anonymous access**.
12. To change the user identifier (UID) and group identifier (GID) values assigned to anonymous users, type the new values in the **Anonymous UID** and **Anonymous GID** boxes.
13. In the **Encoding** list, select the type of encoding to be used for file and directory names in the shared directory. In addition to the default American National Standards Institute (ANSI) encoding, the following encoding is available:
    - BIG5 (Chinese)
    - EUC-JP (Japanese)
    - EUC-KR (Korean)
    - EUC-TW (Chinese)
    - GB2312-80 (Simplified Chinese)
    - KSC5601 (Korean)
    - SHIFT-JIS (Japanese)

    If this option is set to ANSI on systems configured for non-English locales, the encoding scheme is set to the default encoding scheme for the locale. The following are the default encoding schemes for the indicated locales:

- Japanese: SHIFT-JIS
- Korean: KS_C_5601-1987
- Simplified Chinese: GB2312-80
- Traditional Chinese: BIG5

14. To specify permissions for the client computers that can access the shared folder, click **Permissions**.
15. Click **Finish**.

| **Important** |
| --- |
| Before adding a resource to your cluster, you must verify the following: |

- The NFS Share resource type is available. This resource type was created when you installed Server for NFS on the cluster node.
- A group already exists within the cluster to which your resource will belong.
- All dependent resources have been created.

| **Note** |
| --- |
| In Windows Server 2003 operating systems, the Everyone group does not include anonymous users by default. For information about providing anonymous access when Server for NFS is running on these operating systems, see Allowing anonymous access to resources by NFS clients. |

**To share a directory as a cluster resource using the command line**

1. Open the command prompt.
2. Type the following:

   **cluster [** *ClusterName* **] resource "** *ResourceName* **" /create /restype:"NFS Share" /group:"** *GroupName* **" /privproperties ShareName="** *ShareName* **":STRING Path="** *SharePath* **":STRING ShareSubDirs=** *ShareType* **:DWORD GlobalPerm=** *PermType* **:DWORD Encoding=** *EncodingType* **:DWORD AnonymousAccessAllowed=** *AccessType* **:DWORD**

3. Then, type:

   **cluster [** *ClusterName* **] resource "** *ResourceName* **" /online /wait[:** *Timeout* **]**

| **Argument** | **Description** |
| --- | --- |
| *ClusterName* | The name of the cluster you want to manage. |
| *ResourceName* | The name of the cluster resource. |
| *GroupName* | The name of the group to which you want to add the resource. |
| *ShareName* | The name of the shared directory you want to create. This value is ignored if ShareType is **0x1** |
| *SharePath* | The fully qualified path of the directory to be shared. |

| | |
|---|---|
| *ShareType* | **0x0** if only the directory specified by SharePath is to be shared. **0x1** if the subdirectories (except hidden subdirectories) in the directory specified by SharePath are to be shared individually. |
| *PermType* | Specifies root-access and read-write permission combinations. PermType must be one of the following values:<br>**0x1**—No access<br>**0x9**—No Access + Root<br>**0x2**—Read only<br>**0xa**—Read only + Root<br>**0x4**—Read/write<br>**0xc**—Read/write + Root |
| *EncodingType* | Specifies the default encoding used for file and directory names and, if used, must be set to one of the following:<br>• **0x7**—ANSI<br>• **0x5**—BIG5 (Chinese)<br>• **0x0**—EUC-JP (Japanese)<br>• **0x1**—EUC-KR (Korean)<br>• **0x2**—EUC-TW (Chinese)<br>• **0x6**—GB2312-80 (Simplified Chinese)<br>• **0x4**—KS_C_5601-1987 (Korean)<br>• **0x3**—SHIFT-JS (Japanese)<br><br>If this is option is set to **0x7**, the encoding scheme is ANSI or, on systems configured for non-English locales, the default encoding scheme for the locale. The following are the default encoding schemes for the indicated locales:<br>• Japanese: SHIFT-JIS<br>• Korean: KS_C_5601-1987<br>• Simplified Chinese: GB2312-80<br>• Traditional Chinese: BIG5 |
| *AccessType* | **0x0**if anonymous access to the shared directory is not allowed. **0x1** if anonymous access is allowed. |
| *Timeout* | The number of seconds **cluster** waits before canceling the command if it does not successfully complete. If **/wait** is specified without this value, **cluster** waits indefinitely or until the resource state changes. |

| **Important** |
|---|
| Before adding a resource to your cluster, you must verify the following: |

- The NFS Share resource type is available. This resource type was created when you installed Server for NFS on the cluster node.
- A group already exists within the cluster to which your resource will belong.
- All dependent resources have been created.

| **Note** |
| --- |
| All arguments listed above are required. Using default values might produce unexpected results.<br><br>You must use the Windows interface to set permissions on shared directories.<br><br>If the attempt to share the directory fails, **cluster** displays an error message, and detailed information about the failure is recorded in the cluster log.<br><br>You cannot set the user identifier (UID) and group identifier (GID) values assigned to anonymous users using the command line.<br><br>In Windows Server 2003 operating systems, the Everyone group does not include anonymous users by default. # Modifying shared directory cluster resources

Applies To: Windows Server 2003 R2

**To modify a shared directory cluster resource using the Windows interface**

1. Open Cluster Administrator: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Cluster Administrator**.
2. In the console tree (usually the left pane), double-click the **Groups** folder.
3. In the details pane (usually the right pane), double-click the group that contains the resource you want to modify, and then click the resource.
4. On the **File** menu, click **Take Offline**.
5. When the resource is offline, on the **File** menu, click **Properties**.
6. Change the properties you want to modify, and then click **OK**.
7. On the **File** menu, click **Bring Online**.

**To modify a shared directory cluster resource using the command line**

1. Open the command prompt.
2. Type the following:

   **cluster [** *ClusterName* **] resource "** *ResourceName* **" /offline /wait[:** *Timeout* **]**
3. Then, type:

   **cluster [** *ClusterName* **] resource "** *ResourceName* **" /** *Option*
4. Then, type:

   **cluster [** *ClusterName* **] resource "** *ResourceName* **" /online /wait[:** *Timeout* **]**

| Argument | Description |
|---|---|
| *ClusterName* | The name of the cluster you want to manage. |
| *ResourceName* | The name of the cluster resource. |
| *Timeout* | The number of seconds **cluster** waits before canceling the command if it does not successfully complete. If **/wait** is specified without this value, **cluster** waits five minutes or until the resource state changes. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **cluster /?** |

**Cluster Resource Options**

The following table describes the available cluster resource options:

| Option | Use to... |
|---|---|
| **/status** | Display the status of a cluster resource (Online, Offline, or Failed). The resource name is optional. If you do not provide a resource name, the status of all cluster resources is displayed. |
| **/create /group:***group name***/type:***resource type***[/separate]** | Create a new resource in a specified group. Use **/separate** to specify that the resource should run in a separate Resource Monitor. |
| **/delete** | Delete a resource. |

| | |
|---|---|
| **/rename:***new resource name* | Rename a resource. |
| **/addowner:** *node name* | Add a node name to the list of possible owners. |
| **/removeowner:node name** | Remove a node name from the list of possible owners. |
| **/listowners** | Display a list of possible owners. |
| **/moveto:** *group* | Move the resource to a different group. |
| **/properties [** *property list* **]** | View or set the resource common properties. The resource name is optional. If you do not provide a resource name, properties for all resources are displayed. |
| **/privproperties [** *property list* **]** | View or set the resource private properties. Resource name is optional. If you do not provide a resource name, private properties for all resources are displayed. |
| **/fail** | Initiate resource failure. |
| **/online [/wait[:** *timeout in seconds* **]]** | Bring the resource online. |
| **/offline [/wait[:** *timeout in seconds* **]]** | Take the resource offline. |
| **/listdependencies** | List the dependencies for a resource. |
| **/adddependency:** *resource* | Add a dependency for a resource. |
| **/removedependency:** *resource* | Remove a dependency for a resource. |
| **/addcheckpoints:** *key* **[** *subkey* **...][,** *key* **[** *subkey* **...]...]** | Add a registry checkpoint for a resource. |
| **/removecheckpoints:** *key* **[** *subkey* **...][,** *key* **[** *subkey* **...]...]** | Remove a registry checkpoint for a resource. |
| **/checkpoints** | List registry checkpoints for a resource. The resource name is optional. Checkpoints for all cluster resources are displayed if you do not provide a resource name. |
| **/addcryptocheckpoints:** *key* **[** *subkey* **...][,** *key* **[** *subkey* **...]...]** | Add a cryptographic key checkpoint for a resource. |
| **/removecryptocheckpoints:** *key* **[** *subkey* **...][,** *key* **[** *subkey* **...]...]** | Remove a cryptographic key checkpoint for a resource. |
| **/cryptocheckpoints** | List cryptographic key checkpoints for a resource. The resource name is optional. If you do not provide a resource name, checkpoints for all cluster resources are displayed. |
| **/?** or **/help** | Display **cluster resource** syntax. |

**Cluster resource common property names**

The following table describes the common cluster resource property names, their uses, and valid settings:

| **Common property names** | **Use** |
|---|---|
| **Description** | Describes a resource. |
| **Type** | Specifies the resource type. |
| **DebugPrefix** | Specifies the appropriate debugger for the resource. For more information, see the Microsoft Platform Software Development Kit. |
| **SeparateMonitor** | Indicates whether a resource shares a Resource Monitor. Valid values are True (1) and False (0). |

| | |
|---|---|
| **PersistentState** | Describes the last known persistent state of a resource. In order to save the resource's PersistentState property, the resource must be offline. |
| **LooksAlivePollInterval** | Recommended interval (in milliseconds) that the Cluster service polls a resource to determine whether it appears to be operational. If a value is not specified, a default value is taken from the LooksAlivePollInterval property for the resource type. |
| **IsAlivePollInterval** | Interval (in milliseconds) that the Cluster service polls a resource to determine whether it is operational. If a value is not specified, a default value is taken from the IsAlivePollInterval property for the specific resource type. IsAlivePollInterval cannot be zero. |
| **RestartAction** | Describes the action to perform if the resource fails. The choices are as follows:<br><br>ClusterResourceDontRestart (0): Do not restart following a failure.<br><br>ClusterResourceRestartNoNotify (1): If the resource exceeds its restart threshold within its restart period, the Cluster service does not attempt to failover the group to another node.<br><br>ClusterResourceRestartNotify (2): If the resource exceeds its restart threshold within its restart period, the Cluster service attempts to failover the group to another node.<br><br>If you do not enter a value, the default allows the resource to affect the group, which can cause the group to failover to another system. |
| **RestartThreshold** | Specifies how many times the Cluster service attempts to restart the resource in the RestartPeriod before failing over the group. |
| **RestartPeriod** | Specifies the amount of time allowed for the restart attempts to reach the RestartThreshold before the Cluster service fails over the group. |
| **PendingTimeout** | Specifies the amount of time that a Pending Online or Pending Offline resource has to resolve its status before the Cluster service puts the resource in Offline or Failed status.<br><br>The default value is three minutes. |

# Deleting shared directory cluster resources

Applies To: Windows Server 2003 R2

**To delete a shared directory cluster resource using the Windows interface**

1. Open Cluster Administrator: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Cluster Administrator**
2. In the console tree (usually the left pane), double-click the **Groups** folder.
3. In the details pane (usually the right pane), double-click the group that contains the resource you want to delete, and then click the resource.
4. On the **File** menu, click **Take Offline**.
5. When the resource is offline, on the **File** menu, click **Delete**.

**To delete a shared directory cluster resource using the command line**

1. Open the command prompt.
2. Type the following:

   **cluster [** *ClusterName* **] resource "** *ResourceName* **" /offline /wait[:** *Timeout* **]**

3. Then, type:

   **cluster [** *ClusterName* **] resource "** *ResourceName* **" /delete**

| Argument | Description |
|---|---|
| *ClusterName* | The name of the cluster you want to manage. |
| *ResourceName* | The name of the cluster resource. |
| *Timeout* | The number of seconds **cluster** waits before canceling the command if it does not successfully complete. If **/wait** is specified without this value, **cluster** waits indefinitely or until the resource state changes. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type:<br>**cluster /?** |

# Changing the directory cache memory setting

Applies To: Windows Server 2003 R2

Server for NFS maintains a cache of directory information that it can search instead of directories on the physical disk. By default, this cache is configured to use 128 kilobytes (KB) of memory per directory that Server for NFS caches. However, you can reduce the amount of memory that the directory cache uses. You can do this by configuring the folder cache size using the command line.

**To configure the folder cache size using the command line**

1. Open the command prompt.
2. Type the following:

   **nfsadmin server [** *remoteMachineName* **] config dircache=** *size*

| Value | Description |
|---|---|
| *remoteMachineName* | The name of the computer you want to configure. |
| *size* | The size in kilobytes (KB) to set the directory cache to. The default size is 128 KB. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type:<br>**nfsadmin server /?** |

# Securing Server for NFS

Applies To: Windows Server 2003 R2

Allowing root access to resources by NFS clients

Allowing anonymous access to resources by NFS clients

Using Windows security descriptors with Server for NFS

Using DACLs with Server for NFS

Using setuid, setgid, and sticky bits with Server for NFS

# Allowing root access to resources by NFS clients

Applies To: Windows Server 2003 R2

You can allow UNIX users to have root access to resources. Some of these methods include:

- Assigning the client computer root access when the share is exported. See Securing access to the User Name Mapping server.

- Mapping (through either Active Directory Lookup or User Name Mapping) the UNIX user root (UID 0) to the Windows user Administrator. Also, mapping the group to which root belongs to the Windows group Administrators.

For example, consider a situation in which the directory Testdir is owned by Administrators. This directory was created with an account that is a member of the Windows group Administrators. The permissions listed were set after the directory was created. At the UNIX client, the permissions look like this:

```
ls ld /testdir
drwxrwxr-x 2 root root 64 Nov 3 12:11 /testdir/
```

When the directory is owned by Administrators, Server for NFS reports a user identifier (UID) and group identifier (GID) pair of 0,0.

# Allowing anonymous access to resources by NFS clients

Applies To: Windows Server 2003 R2

By default, Server for NFS does not allow anonymous users to access a shared directory. When you share a directory, you can allow anonymous access to the directory and you can change the default anonymous UID and GID values to the UID and GID of any valid UNIX user and group accounts. If you change the anonymous UID and anonymous GID for a share, those values will be used when reporting the owner of a file owned by a Windows user which is not mapped to UNIX user, even if anonymous access is not allowed. For more information about configuring anonymous access for a shared directory, see Allowing anonymous access to an NFS share.

# Using Windows security descriptors with Server for NFS

Applies To: Windows Server 2003 R2

Server for NFS uses the Windows security descriptor when implementing Network File System (NFS) access permissions. The security descriptor is the structure that governs security assignments for Windows. The security descriptor contains the following components:

- File owner
- File group
- Discretionary access control list (DACL)
- System access control list (SACL)

| **Note** |
| --- |
| The SACL is used for auditing and does not affect file permissions. |

Within the security descriptor, the file owner and group refer to security identifiers (SIDs). A SID can be thought of as the internal representation for an individual user or group. The primary reason for using SIDs is to differentiate among accounts across different domains that share the same account name. Even though the names are the same, they represent different accounts and can be given different permissions to the same file.

For more information, see Using DACLs with Server for NFS.

# Using DACLs with Server for NFS

Applies To: Windows Server 2003 R2

The discretionary access control list (DACL) within the security descriptor provides the core of Windows security. The DACL is a list of entries that grant or deny certain rights to specific users or groups. A list entry is called an access control entry (ACE). Each ACE consists of the following:

- A security identifier (SID) to identify a particular user or group.
- An access list that specifies the permissions allowed or denied for the user or group.

The following is an example of a DACL:

- DACL: Mrjones Full Control (All)
- ToolGroup:Read(RX)
- Everyone:Read (RX)

In this DACL, Mrjones has read, write, and execute access to the file. Members of the group ToolGroup have read-and-execute access. Members of the group Everyone (all users) have read-and-execute access.

The following rules govern access to a file:

- If no DACL is present, everyone is granted full access.
- If a DACL is present, but contains no entries, everyone is denied access.
- The file owner always has the ability to change the DACL.

In turn, these rules apply to the DACL:

- DACL entries are searched sequentially.
- All permissions are implicitly denied.
- Once a permission has been denied, it cannot be granted.
- Once a permission has been granted, it cannot be denied.

For more information, see Using Windows security descriptors with Server for NFS.

# Using setuid, setgid, and sticky bits with Server for NFS

Applies To: Windows Server 2003 R2

Users of client computers can use the chmod utility to set the setuid (set-user-identifier-on-execution), setgid (set-group-identifier-on-execution), and sticky file mode bits on files or directories that are stored on an NTFS file system partition and shared through Server for NFS. When the file or directory is subsequently accessed by a UNIX-based client, the standard semantics for these bits will apply. For example, an executable file that has the setuid bit set will execute under the user ID of the file's owner, not the user ID of the user who is executing the file.

Typically, when the setuid or setgid bit is set on a file, the owner or group of the file is changed to the owner or group under whose ID the file will be executed. Unless a user has the right to restore files or directories, Windows security allows a user to take ownership of a file (if the file's permissions allow it), but not to transfer ownership to a second user. Consequently, to use chown or chgrp to change the owner or group of a file to another user or group, you must have the privilege to restore files and directories. By default, this privilege is assigned to members of the Administrators and Backup Operators groups, although it can be assigned to other groups or to individual users. In addition, the account of the user running chown or chgrp and the user or group to whom ownership is being transferred must be properly mapped through Active Directory Lookup or User Name Mapping.

Some UNIX-based Network File System (NFS) servers apply special interpretations or restrictions for the setuid, setgid, and sticky bits. Some versions of UNIX, for example, enforce mandatory locking on a directory with the setgid bit set but no execute permissions. Server for NFS does not implement special interpretations or restrictions on using these bits.

**Security issue**
Typical UNIX setuid and setgid behavior present a known security issue in UNIX. An intruder can exploit setuid and setgid behavior by overwriting an executable file with a Trojan horse, and then running the executable file. The executable file runs with the rights of the owner, instead of running as the intruder.

To prevent this known security issue, by default, setuid and setgid are disabled and will not affect the UID or GID settings if the file or directory has both of the following characteristics:

- One or both of the following bits is set: setgid or setuid.
- The file or directory is group writable, group executable, world writable, or world executable.

Some customers may find this security measure problematic because it is different from the typical behavior of UNIX, although the typical behavior of UNIX setuid and setgid is not specified as part of the Network File System (NFS) protocol.

Procedures

**To change setuid and setgid behavior**

1. Open the Registry Editor.
2. Set the following registry key:

   ```
   HKEY_Local_Machine\System\CurrentControlSet\Services\NfsSvr\Parameters\SafeSetUidGidBits = (DWORD)
   ```

   - A value of 1 causes the bits the safer setuid and setgid behavior.
   - A value of 0 causes the standard UNIX behavior.

# Optimizing Server for NFS performance

Applies To: Windows Server 2003 R2

Adding performance counters

Monitoring and tuning performance

Changing the directory cache memory setting

# Adding performance counters

Applies To: Windows Server 2003 R2

**To add performance counters**

1. Open **Performance**: click **Start**, point to **Programs** or **All Programs**, point to **Control Panel**, point to **Administrative Tools**, and then click **Performance**.
2. Click the plus-sign (+) button.
3. In the **Performance** object list, click **Server for NFS**, and then do one of the following:
   - Click **All counters**, and then click **Add**.
   - Or, click **Select counters from list**, click the counters you want to add, and then click **Add**.

| **Note** |
| --- |
| There is no command-line method for this procedure. |

# Monitoring and tuning performance

Applies To: Windows Server 2003 R2

Server for NFS includes several tools for monitoring Network File System (NFS) use and for probing the network for other NFS servers and resources. These tools include Windows System Monitor, rpcinfo, showmount, and nfsstat.

You can use Windows System Monitor to display NFS statistics, including the number and type of requests received and the number of bytes read and written.

You can use the **rpcinfo** utility to:

- List all programs registered with the port mapper on a local or remote host (**rpcinfo -p**).
- Find all network nodes that have a specified program and version registered with the port mapper (**rpcinfo -b**). You must specify a program name and number and version.
- Use the Transmission Control Protocol (TCP) to call the specified program (**rpcinfo -t**). You must specify a node name and program name. If a version is not specified, the program calls all versions.
- Use the User Datagram Protocol (UDP) to call the specified program (**rpcinfo -u**). You must specify a node name and program name. If a version is not specified, the program calls all versions.

You can use the **showmount** utility to:

- List all file systems exported on the specified NFS server (**showmount -e**).
- List all remotely mounted clients and the directories each has mounted on the specified NFS server (**showmount -a**).
- List all directories remotely mounted on the specified NFS server (**showmount -d**).

You can use the **nfsstat** utility to display the number of NFS v2, NFS v3, and Mount v3 calls made to the server since the counters were set to 0, either when the service started or when the counters were reset using **nfsstat –z**.

Understanding NFS and file names

Using CDFS with NFS

Using NTFS file systems with NFS

# Understanding NFS and file names

Applies To: Windows Server 2003 R2

Because Network File System (NFS) has its origins on UNIX-based computers, the conventions used for naming files and directories on NFS file systems differ in several respects from those used by Windows. This topic covers three of these differences and describes how you can configure Server for NFS to deal appropriately with them. These differences are:

- Special characters
- Case sensitivity
- Hidden files

In addition, this topic also discusses directory- and file-name encoding for client computers localized for East Asian languages.

**Special characters**
Every file system has characters that cannot be used in directory and file names, usually because those characters are reserved for use in path and command syntax. For example, a file stored on the NTFS file system cannot contain a colon (:) character because that character is used to separate the drive letter from the rest of the path in a fully qualified path name. UNIX file systems do not use letters to identify drives, so this syntax is not used, and consequently, colon characters can appear in UNIX file names.

Server for NFS stores files on Windows-based file systems on behalf of NFS clients, which assume UNIX file system conventions. Because of this, you can use Server for NFS to specify how characters in directory and file names will be converted (mapped) when files are moved between Server for NFS and client computers. To accomplish this, you must create a file that defines how these characters are to be mapped, and then specify where Server for NFS can find the file containing these character maps. For information about creating the character map file, see Overview of file-name character translation. To learn how to configure Server for NFS to use this file, see Configuring file-name character translation.

**Case sensitivity**
Windows and UNIX computers typically differ in the way they use the case of letters in directory and file names.

UNIX computers are usually case sensitive when handling directory and file names. That is, a UNIX computer will distinguish between a file named MYFILE and a file named MyFile, allowing both to coexist in the same directory and accessing them only when the case used in the file name matches the stored file name exactly.

Windows-based computers, on the other hand, are case preserving, but not case sensitive. That is, they will allow a file to be named MyFile or MYFILE and will preserve the case difference, but will not allow two files with the same name, differing only in letter case, to be stored in the same directory. Nor do they use case as a criterion when locating files. In other words, either MyFile or MYFILE can exist in the same directory, but not both, and either file can be accessed using the name MYFILE or MyFile.

By default, Server for NFS is case sensitive when matching directory-access and file-access requests to directories and files in its shared directories, and it preserves the case of the names of directories and files when creating files on behalf of NFS client computers. You can instruct Server for NFS not to be case sensitive when returning directory and file names. For more information, see Configuring case sensitivity for file and folder names.

**Hidden files**
Files can be hidden (that is, not displayed when the directory they are store in is listed) on both Windows and UNIX computers. In the case of Windows-based computers, files are hidden by setting a special attribute for the file. UNIX file systems simply do not list files whose names begin with a period (.) character. By default, Server for NFS does not create files with names beginning with a period as hidden files in the Windows file system.

**Directory- and file-name encoding**
Client computers that are localized for an East Asian language require special support by NFS servers to be able to use characters in that language when creating directory and file names. This support, called encoding, determines how two-byte character codes exchanged between the server and a client computer will be interpreted. You can configure an NFS share to provide a default language-specific encoding scheme for all clients that access the share; you can also specify an encoding scheme for each client in the permissions list of the share. For more information, see Setting default encoding for an NFS share and Creating an NFS share.

# Using CDFS with NFS

Applies To: Windows Server 2003 R2

Unlike the NTFS file system, the CD-ROM file system (CDFS) does not provide any type of access control. The mount permissions granted by the Network File System (NFS) server administrator govern all access control. The CDFS file system always shares data as a read-only resource, regardless of the type of share permission you give it.

The characteristics of the CDFS file system include the following:

- Because this file system was designed around single-user computers, there is no such thing as a file owner.
- Just as no file owner exists, neither does a file group.
- There is no support for file links. This file system uses a single-name/single-file format with no support for multiple directory entries referring to the same file.

Because of these limitations, the following conventions are a part of the Server for NFS implementation:

- The file owner and group are always returned as the owner and group given in the UNIX verification of the request. This means that every individual user is reported as the owner of all files. Having different users of the same file both reported as owners can seem confusing at first, but it is in keeping with the concept that anyone with access to the file system owns it. Any attempt to modify the owner or group of a file fails. If no UNIX verification is passed, the anonymous user identifier (UID) and the anonymous group identifier (GID) are reported. By default, the anonymous UID and anonymous GID are both –2 (65534 when used as an unsigned 2-byte integer), although these values can be changed for a share.
- Permissions are reported as read-and-execute for owner, group, and other (in UNIX notation:

  ```
  -r-xr-xr-x
  ```

Any attempt to modify data or attributes on the shared resource fails.

# Using NTFS file systems with NFS

Applies To: Windows Server 2003 R2

Under UNIX, a file has a single owner and a single group, with certain permissions (read, write, and/or execute) granted to each. Separate permissions are also granted for others, meaning any other users who are not members of the group that owns the file.

The NTFS file system, however, allows permissions to be assigned to many users or groups independently. For example, an NTFS file can specify that User A is to have read-and-write access, while User B is to have only read access. The same file can also have certain permissions for one or more groups. The objective of Server for NFS is to provide a consistent, intuitive mapping of file permissions that UNIX clients can work with, and that users can understand.

# Accessing a Windows NFS share from a UNIX client

Applies To: Windows Server 2003 R2

**To access a Windows NFS share from a UNIX client**

1. Open the UNIX command prompt.
2. Create a directory that will act as the mount point for the Windows Network File System (NFS) share.
3. Type the following command:

   **mount [-f nfs] [-o** *options* **]** *remote_host_name* **:/** *directory mount_point*

| Argument | Description |
|---|---|
| *options* | Options include **hard** for hard mounts, **soft** for soft mounts, and more. For more information, refer to the UNIX man pages. |
| *remote_host_name* **:/** *directory* | The name of the computer and directory to mount. |
| *mount_point* | The local directory that you created which will act as a mount point. |

| **Note** |
|---|
| To view the complete syntax for this command, at the UNIX command prompt, type: **man mount** |

# Overview of file-name character translation

Applies To: Windows Server 2003 R2

Although Windows and UNIX file systems do not allow certain characters in file names, the characters that are prohibited by each operating system are not the same. For example, a valid Windows file name cannot contain a colon (:), but a valid UNIX file name can. If a UNIX user attempts to create a file in a Network File System (NFS) share on Server for NFS, and that file contains an illegal character in its name, the attempt will fail.

To prevent this problem, use file-name character mapping to replace characters that are not allowed in a file system. To enable file-name character translation, create a text file that maps Windows to UNIX characters, and then configure Server for NFS to specify the path and name of the translation file.

A file-name character translation file is simply a list of mapped characters in the format:

**0x** *nn* **0x** *nn* **: 0x** *nn* **0x** *nn* **[ ;** *comment* **]**

where *nn* is the hexadecimal value of one byte of a two-byte Unicode character, and *comment* is an optional comment, which is preceded by a semicolon (;). Everything from the semicolon to the end of the line is ignored. The first character in the entry is the character on the client (UNIX) computer, while the second is the character used on the Windows-based Server for NFS computer.

For example, the following maps the UNIX colon (:) to a Windows dash (-):

**0x00 0x3a : 0x00 0x2d ; replace client : with - on server**

If this entry appears in the file-name character translation file on a Server for NFS computer, when an NFS client creates a file named re:salesquotas on a Server for NFS share, Server for NFS names the file re-salesquotas. This is the name that appears in Windows Explorer when local or remote Windows users display the contents of the shared folder. NFS clients that list the contents of the shared directory, however, see the file name as re:salesquotas. Character translation takes place for all files shared by the server, regardless of whether they were created by an NFS client.

Do not map a given character to more than one character. Mapping a character to two or more different characters, as shown in the following example, will produce unexpected results:

**0x00 0x11 : 0x00 0x22**

**0x00 0x11 : 0x00 0x33**

Do not map a period (.) because it is used in the file-name syntax of both Windows and UNIX file systems.

After you have created the file-name character translation file, you must specify its location.

| **Important** |
| --- |
| To prevent unauthorized users from tampering with the file-name character translation file and causing Server for NFS to fail, ensure that the file is protected with a discretionary access control list (DACL) that grants Full Control to the built-in System account and to the Administrators group. The DACL should contain no other entries. |

# Specifying the NFS protocol to use

Applies To: Windows Server 2003 R2

Network File System (NFS) is a network protocol that, in its most widely adopted forms, is defined in RFC 1094 for NFS version 2 and in RFC 1813 for NFS version 3. By default, Server for NFS supports clients using either version. You can override this, however, and configure Server for NFS to allow access only by version 2 client computers. See Enabling NFS version 3.

NFS relies on two transport protocols: Transmission Control Protocol (TCP) and User Datagram Protocol (UDP). Server for NFS supports both protocols. You can specify the transport protocol supported by Server for NFS. For more information about this,

see Specifying Server for NFS TCP and UDP settings.

# Creating an NFS share

Applies To: Windows Server 2003 R2

**To create a share using the Windows interface**

1. Open Windows Explorer: click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, and then click **Windows Explorer**.
2. In the details pane, right-click the shared directory you want to manage.
3. Click **NFS Sharing**.
4. Select **Share this Folder**.
5. Type a name for the share in the **Share Name** text box.
6. Click **Apply**.

**To create a share using the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **nfsshare ShareName=** *drive:path*

| Argument | Description |
|---|---|
| *sharename* | The name of the directory to share. |

| Note |
|---|
| To view the complete syntax for this command, at a command prompt, type:<br>*nfsshare /?*<br>This command only works with Windows Server 2003 operating systems. |

# Setting default encoding for an NFS share

Applies To: Windows Server 2003 R2

**To set default encoding for a shared directory using the Windows interface**

1. Open Windows Explorer: click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, and then click **Windows Explorer**.
2. In the details pane, right-click the shared directory you want to manage.
3. Click **Sharing**.
4. Click **NFS Sharing**.
5. In the **Encoding** list, select the type of encoding to be used for file and directory names in the shared directory. In addition to the default American National Standards Institute (ANSI) encoding, the following encoding is available:
   - BIG5 (Chinese)
   - EUC-JP (Japanese)
   - EUC-KR (Korean)
   - EUC-TW (Chinese)
   - GB2312-80 (Simplified Chinese)
   - KSC5601 (Korean)
   - SHIFT-JIS (Japanese)
6. If this option is set to ANSI on systems configured for non-English locales, the encoding scheme is set to the default encoding scheme for the locale. The following are the default encoding schemes for the indicated locales:
   - Japanese: SHIFT-JIS
   - Korean: KS_C_5601-1987
   - Simplified Chinese: GB
   - Traditional Chinese: BIG5

**To set default encoding for a shared directory using the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **nfsshare -o encoding={big5|euc-jp|euc-kr|euc-tw|gb2312-80|ksc5601|shift-jis}***sharename*

| Argument | Description |
|---|---|
| *sharename* | The name of the directory to share. |

| | |
|---|---|
| **-o encoding=** *type* | Specifies the default encoding. You must specify one of the following types:<br>• **big5** (Chinese)<br>• **euc-jp** (Japanese)<br>• **euc-kr** (Korean)<br>• **euc-tw** (Chinese)<br>• **gb2312-80** (Simplified Chinese)<br>• **ksc5601** (Korean)<br>• **shift-jis** (Japanese)<br><br>If you do not specify an encoding type, the default encoding scheme is ANSI or, on systems configured for non-English locales, the default encoding scheme for the locale. The following are the default encoding schemes for the indicated locales:<br>• Japanese: SHIFT-JIS<br>• Korean: KS_C_5601-1987<br>• Simplified Chinese: GB2312-80<br>• Traditional Chinese: BIG5 |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **nfsshare /?** |

# Adding clients and groups to the NFS share permissions list

Applies To: Windows Server 2003 R2

**To add clients and groups to the NFS share permissions list using the Windows interface**

1. Open Windows Explorer: click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, and then click **Windows Explorer**.
2. In the details pane, right-click the shared directory you want to manage.
3. Click **Sharing**.
4. Click **NFS Sharing**.
5. If the directory is not already shared, click **Share this folder**, and then, in the **Share name** box, type a name for the share.
6. Click **Permissions**, click **Add**, and then do one of the following:
7. Do either of the following:
   - In the **Names** list, click the clients and groups you want to add, and then click Add.
   - Or, in the **Add Names** box, type the names of clients or groups you want to add, separating names in the list with a semicolon (;).
8. To see a list of the members of a group, in the **Names** list, click a group, click **Members**.
9. In the **Type of Access** list, click the type of access you want to allow the selected clients and groups.
10. Select **Allow Root Access** if you want a user identified as root to have access other than as an anonymous user. By default, the user identifier (UID) root user is coerced to the anonymous UID.
11. In the **Encoding** list, click the type of directory- and file-name encoding to be provided to the selected clients and groups. In addition to the default American National Standards Institute (ANSI) encoding, the following encoding is available:
    - BIG5 (Chinese)
    - EUC-JP (Japanese)
    - EUC-KR (Korean)
    - EUC-TW (Chinese)
    - GB2312-80 (Simplified Chinese)
    - KSC5601 (Korean)
    - SHIFT-JIS (Japanese)

| **Note** |
| --- |
| If this option is set to ANSI on systems configured for non-English locales, the encoding scheme is set to the default encoding scheme for the locale. The following are the default encoding schemes for the indicated locales: |

- Japanese: SHIFT-JIS
- Korean: KS_C_5601-1987

- Simplified Chinese: GB
- Traditional Chinese: BIG5

12. To close the dialog box, click **OK**.

**To add clients and groups to the NFS share permissions list using the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **nfsshare -o***option***[=***host***[:***host***]...]***sharename*

| Argument | Description |
|---|---|
| *sharename* | The name of the shared directory. |
| **-o***option* | Specifies one or more options to set and must be set to at least one of the following:<br>• **big5** (Chinese)<br>• **euc-jp** (Japanese)<br>• **euc-kr** (Korean)<br>• **euc-tw** (Chinese)<br>• **gb2312-80** (Simplified Chinese)<br>• **ksc5601** (Korean)<br>• **shift-jis** (Japanese)<br><br>If this option is not set, the default encoding scheme is used.<br>**noroot[=** *host* **[:** *host* **]...]**<br>Denies root access to the shared directory by the clients or client groups specified by host. Separate client and group names with a colon (:). If you do not specify a host, root access is denied to all clients and groups for which root access is not explicitly granted.<br>**ro[=** *host* **[:** *host* **]...]**<br>Provides read-only access to the shared directory by the clients or client groups specified by host. Separate client and group names with a colon (:). If you do not specify a host, read-only access is granted to all clients and groups for which access is not explicitly granted or denied.<br>**root[=** *host* **[:** *host* **]...]**<br>Provides root access to the shared directory by the clients or client groups specified by host. Separate client and group names with a colon (:). If you do not specify a host, root access is granted to all clients and groups for which root access is not explicitly denied.<br>**rw[=** *host* **[:** *host* **]...]**<br>Provides read/write access to the shared directory by the clients or client groups specified by host. Separate client and group names with a colon (:). If you do not specify a host, read/write access is granted to all clients and groups for which access is not explicitly granted or denied. |

**Note**

To view the complete syntax for this command, at a command prompt, type:

**nfsshare /?**

By default, when a directory is shared, all client computers are granted read-only access, and anonymous access is not allowed.

# Configuring access to an NFS share for a client computer or group

Applies To: Windows Server 2003 R2

**To configure access to an NFS share for a client or group using the Windows interface**

1. Open Windows Explorer: click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, and then click **Windows Explorer**.
2. In the details pane, right-click the shared directory you want to manage.
3. Click **Sharing**.
4. Click **NFS Sharing**, and then, if the folder has not already been shared, click **Share this folder**.
5. Click **Permissions**.
6. Click the client or group for which you want to set permissions.
7. In the **Type of Access** list, click the type of access you want to allow the client or group.
8. Select **Allow Root Access** if you want a user identified as root to have access other than as an anonymous user. By default, the user identifier (UID) root user is coerced to the anonymous UID.
9. In the **Encoding** list, click the type of directory- and file-name encoding to be provided to the client or group. In addition to the default American National Standards Institute (ANSI) encoding, the following encoding is available:

   - BIG5 (Chinese)
   - EUC-JP (Japanese)
   - EUC-KR (Korean)
   - EUC-TW (Chinese)
   - GB2312-80 (Simplified Chinese)
   - KSC5601 (Korean)
   - SHIFT-JIS (Japanese)

   | **Note** |
   | --- |
   | If this option is set to ANSI on systems configured for non-English locales, the encoding scheme is set to the default encoding scheme for the locale. The following are the default encoding schemes for the indicated locales: |

   - Japanese: SHIFT-JIS
   - Korean: KS_C_5601-1987
   - Simplified Chinese: GB
   - Traditional Chinese: BIG5

10. Click **OK** twice.

**To configure access to an NFS share for a client or group using the command line**

1. Open the command prompt.

2. At the command prompt, type:

   **nfsshare -o***option***[=***host***[:***host***]...]***sharename*

| Argument | Description |
|---|---|
| *sharename* | The name of the shared directory. |
| **-o** | Specifies one or more options to set and must be set to at least one of the following:<br>**{big5\|euc-jp\|euc-kr\|euc-tw\|gb2312-80\|ksc5601\|shift-jis}=** *host* **[:** *host* **]...**<br>Specifies the file- and directory-name encoding for individual client computers or client groups. The following encoding schemes are available:<br>• **big5** (Chinese)<br>• **euc-jp** (Japanese)<br>• **euc-kr** (Korean)<br>• **euc-tw** (Chinese)<br>• **gb2312-80** (Simplified Chinese)<br>• **ksc5601** (Korean)<br>• **shift-jis** (Japanese)<br>If this option is not set, the default encoding scheme is used.<br>**na**<br>Specifies that no client or group is granted access to the NFS share unless you explicitly grant it access.<br>**noroot[=** *host* **[:** *host* **]...]**<br>Denies root access to the shared directory by the clients or client groups specified by host. Separate client and group names with a colon (:). If host is not specified, root access is denied to all clients and groups for which root access is not explicitly granted.<br>**removeclient[=** *host* **[:** *host* **]...]**<br>Removes the specified clients from the list of permissions of the shared directory. Separate client and group names with a colon (:).<br>**ro[=** *host* **[:** *host* **]...]**<br>Provides read-only access to the shared directory by the clients or client groups specified by host. Separate client and group names with a colon (:). If host is not specified, read-only access is granted to all clients and groups for which access is not explicitly granted or denied.<br>**root[=** *host* **[:** *host* **]...]**<br>Provides root access to the shared directory by the clients or client groups specified by host. Separate client and group names with a colon (:). If host is not specified, root access is granted to all clients and groups for which root access is not explicitly denied.<br>**rw[=** *host* **[:** *host* **]...]**<br>Provides read/write access to the shared directory by the clients or client groups specified by host. Separate client and group names with a colon (:). If host is not specified, read/write access is granted to all clients and groups for which access is not explicitly granted or denied. |

**Note**

To view the complete syntax for this command, at a command prompt, type:

**nfsshare /?**

By default, when a directory is shared, all client computers are granted read-only access, and anonymous access is not allowed.

# Allowing anonymous access to an NFS share

Applies To: Windows Server 2003 R2

**To allow anonymous access to an NFS share using the Windows interface**

1. Open Windows Explorer: click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, and then click **Windows Explorer**.
2. In the details pane, right-click the shared directory you want to manage.
3. Click **Sharing**.
4. Click **NFS Sharing**.
5. Select **Allow anonymous access**.
6. To specify a nondefault value for the anonymous user identifier (UID) or anonymous group identifier (GID), type the value in the **Anonymous UID** or **Anonymous GID** box.
7. Click **Apply**.

| **Note** |
|---|
| The anonymous UID and anonymous GID values for a share will be used when reporting the owner of a file owned by an unmapped user, even if Allow Anonymous Access is disabled.<br><br>In Windows Server 2003 operating systems, the Everyone group does not include anonymous users by default. For information about providing anonymous access, see Allowing anonymous access to resources by NFS clients. |

**To allow anonymous access to an NFS share using the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **nfsshare -o***option*=*value*...*sharename*

| Argument | Description |
|---|---|
| *sharename* | The name of the shared directory. |
| **-o** | Specifies one or more options to be set and must be set to at least one of the following:<br><br>**anon={yes \| no}**<br><br>Specifies whether anonymous (unmapped) users can access the shared directory. The default is no.<br><br>**anonuid=** *uid*<br><br>Specifies that anonymous (unmapped) users will access the share directory using uid as their user identifier (UID). The default is -2. The anonymous UID will be used when reporting the owner of a file owned by an unmapped user, even if anonymous access is disabled.<br><br>**anongid=** *gid*<br><br>Specifies that anonymous (unmapped) users will access the share directory using gid as their group identifier (GID). The default is -2. The anonymous GID will be used when reporting the owner of a file owned by an unmapped user, even if anonymous access is disabled. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **nfsshare /?**<br><br>In Windows Server 2003 operating systems, the Everyone group does not include anonymous users by default. For information about providing anonymous access, see Allowing anonymous access to resources by NFS clients. |

# Configuring DFS shares for NFS

Applies To: Windows Server 2003 R2

You can use Distributed File System (DFS) to connect to a Network File System (NFS) share.

**To configure DFS shares for NFS**

1. Set up an NFS server and create an NFS share.
2. Install Client for NFS on the computer that is running DFS.
3. On the DFS server, add a link in DFS that points to the share on the NFS server.
4. To access the NFS share from any computer, connect to the DFS server as you would normally connect to any Windows file server.
5. Browse to the link you created.

# Configuring shared folders on a server cluster

Applies To: Windows Server 2003 R2

Configuring an NFS share as a cluster resource

Modifying an NFS shared cluster resource

Deleting an NFS shared cluster resource

# Configuring an NFS share as a cluster resource

Applies To: Windows Server 2003 R2

**To share a directory as a cluster resource using the Windows interface**

1. Open Cluster Administrator: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Cluster Administrator**.
2. In the console tree (usually the left pane), double-click the **Groups** folder.
3. In the details pane (usually the right pane), click the group to which you want the resource to belong.
4. On the **File** menu, point to **New**, and then click **Resource**.
5. In the New Resource wizard, type the appropriate information in **Name** and **Description**, and in **Resource type**, click **NFS Sharing**. Click **Next**.
6. Add or remove possible owners of the resource, and then click **Next**.
7. To add or remove dependencies, do one of the following:
   - To add dependencies, under **Available resources**, click a resource, and then click **Add**.
   - To remove dependencies, under **Resource dependencies**, click a resource, and then click **Remove**.
8. In **Share Name**, type the name of the shared folder.
9. In **Share Path**, type the fully qualified path of the folder to be shared.
10. Do one of the following:
    - To share the folder and its contents as a single shared folder, click **Share Root Only**.
    - To share all folders (except hidden folders) in the folder specified in the previous step as separate shared folders, click **Share Subdirectories Only**.
11. To allow access by users who have not been authenticated, click **Allow anonymous access**.
12. To change the user identifier (UID) and group identifier (GID) values assigned to anonymous users, type the new values in the **Anonymous UID** and **Anonymous GID** boxes.
13. In the **Encoding** list, select the type of encoding to be used for file and directory names in the shared directory. In addition to the default American National Standards Institute (ANSI) encoding, the following encoding is available:
    - BIG5 (Chinese)
    - EUC-JP (Japanese)
    - EUC-KR (Korean)
    - EUC-TW (Chinese)
    - GB2312-80 (Simplified Chinese)
    - KSC5601 (Korean)
    - SHIFT-JIS (Japanese)

    **Note**

| |
|---|
| If this option is set to ANSI on systems configured for non-English locales, the encoding scheme is set to the default encoding scheme for the locale. The following are the default encoding schemes for the indicated locales: |

- Japanese: SHIFT-JIS
- Korean: KS_C_5601-1987
- Simplified Chinese: GB2312-80
- Traditional Chinese: BIG5

14. To specify permissions for the client computers that can access the shared folder, click **Permissions**.
15. Click **Finish**.

| **Important** |
|---|
| Before adding a resource to your cluster, you must verify the following: |

- The NFS Share resource type is available. This resource type was created when you installed Server for NFS on the cluster node.
- A group already exists within the cluster to which your resource will belong.
- All dependent resources have been created.

| **Note** |
|---|
| In Windows Server 2003 operating systems, the Everyone group does not include anonymous users by default. For information about providing anonymous access when Server for NFS is running on these operating systems, see Allowing anonymous access to resources by NFS clients. |

**To share a directory as a cluster resource using the command line**

1. Open the command prompt.
2. Type the following:

   **cluster [** *ClusterName* **] resource "** *ResourceName* **" /create /restype:"NFS Share" /group:"** *GroupName* **" /privproperties ShareName="** *ShareName* **":STRING Path="** *SharePath* **":STRING ShareSubDirs=** *ShareType* **:DWORD GlobalPerm=** *PermType* **:DWORD Encoding=** *EncodingType* **:DWORD AnonymousAccessAllowed=** *AccessType* **:DWORD**

3. Then, type:

   **cluster [** *ClusterName* **] resource "** *ResourceName* **" /online /wait[:** *Timeout* **]**

| Argument | Description |
|---|---|
| *ClusterName* | The name of the cluster you want to manage. |
| *ResourceName* | The name of the cluster resource. |
| *GroupName* | The name of the group to which you want to add the resource. |
| *ShareName* | The name of the shared directory you want to create. This value is ignored if ShareType is **0x1** |

| | |
|---|---|
| *SharePath* | The fully qualified path of the directory to be shared. |
| *ShareType* | **0x0** if only the directory specified by SharePath is to be shared. **0x1** if the subdirectories (except hidden subdirectories) in the directory specified by SharePath are to be shared individually. |
| *PermType* | Specifies root-access and read-write permission combinations. PermType must be one of the following values:<br>**0x1**—No access<br>**0x9**—No Access + Root<br>**0x2**—Read only<br>**0xa**—Read only + Root<br>**0x4**—Read/write<br>**0xc**—Read/write + Root |
| *EncodingType* | Specifies the default encoding used for file and directory names and, if used, must be set to one of the following:<br>• **0x7**—ANSI<br>• **0x5**—BIG5 (Chinese)<br>• **0x0**—EUC-JP (Japanese)<br>• **0x1**—EUC-KR (Korean)<br>• **0x2**—EUC-TW (Chinese)<br>• **0x6**—GB2312-80 (Simplified Chinese)<br>• **0x4**—KS_C_5601-1987 (Korean)<br>• **0x3**—SHIFT-JS (Japanese)<br>If this is option is set to 0x7, the encoding scheme is ANSI or, on systems configured for non-English locales, the default encoding scheme for the locale. The following are the default encoding schemes for the indicated locales:<br>• Japanese: SHIFT-JIS<br>• Korean: KS_C_5601-1987<br>• Simplified Chinese: GB2312-80<br>• Traditional Chinese: BIG5 |
| *AccessType* | **0x0** if anonymous access to the shared directory is not allowed. **0x1** if anonymous access is allowed. |
| *Timeout* | The number of seconds **cluster** waits before canceling the command if it does not successfully complete. If **/wait** is specified without this value, **cluster** waits indefinitely or until the resource state changes. |

**Important**

Before adding a resource to your cluster, you must verify the following:

- The **NFS Share** resource type is available. This resource type was created when you installed Server for NFS on the cluster node.
- A group already exists within the cluster to which your resource will belong.
- All dependent resources have been created.

**Note**

In Windows Server 2003 operating systems, the Everyone group does not include anonymous users by default. For information about providing anonymous access when Server for NFS is running on these operating systems, see Allowing anonymous access to resources by NFS clients.

To view the complete syntax for this command, at a command prompt, type:

**cluster /?**

All arguments listed above are required. Using default values might produce unexpected results.

You must use the Windows interface to set permissions on shared directories.

If the attempt to share the directory fails, **cluster** displays an error message, and detailed information about the failure is recorded in the cluster log.

You cannot set the user identifier (UID) and group identifier (GID) values assigned to anonymous users using the command line.

# Modifying an NFS shared cluster resource

Applies To: Windows Server 2003 R2

**To modify a shared directory cluster resource using the Windows interface**

1. Open Cluster Administrator: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Cluster Administrator**.
2. In the console tree (usually the left pane), double-click the **Groups** folder.
3. In the details pane (usually the right pane), double-click the group that contains the resource you want to modify, and then click the resource.
4. On the **File** menu, click **Take Offline**.
5. When the resource is offline, on the **File** menu, click **Properties**.
6. Change the properties you want to modify, and then click **OK**.
7. On the **File** menu, click **Bring Online**.

**To modify a shared directory cluster resource using the command line**

1. Open the command prompt.
2. Type the following:

   **cluster [** *ClusterName* **] resource "** *ResourceName* **" /offline /wait[:** *Timeout* **]**
3. Then, type:

   **cluster [** *ClusterName* **] resource "** *ResourceName* **" /** *Option*
4. Then, type:

   **cluster [** *ClusterName* **] resource "** *ResourceName* **" /online /wait[:** *Timeout* **]**

| Argument | Description |
|---|---|
| *ClusterName* | The name of the cluster you want to manage. |
| *ResourceName* | The name of the cluster resource. |
| *Timeout* | The number of seconds **cluster** waits before canceling the command if it does not successfully complete. If **/wait** is specified without this value, **cluster** waits indefinitely or until the resource state changes. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type:<br>**cluster /?** |

# Deleting an NFS shared cluster resource

Applies To: Windows Server 2003 R2

**To delete a shared directory cluster resource using the Windows interface**

1. Open Cluster Administrator: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Cluster Administrator**.
2. In the console tree, double-click the **Groups** folder.
3. In the details pane, double-click the group that contains the resource you want to delete, and then click the resource.
4. On the **File** menu, click **Take Offline**.
5. When the resource is offline, on the **File** menu, click **Delete**.

**To delete a shared directory cluster resource using the command line**

1. Open the command prompt.
2. Type the following:

   **cluster [** *ClusterName* **] resource "** *ResourceName* **" /offline /wait[:** *Timeout* **]**

3. Then, type:

   **cluster [** *ClusterName* **] resource "** *ResourceName* **" /delete**

| Argument | Description |
|---|---|
| *ClusterName* | The name of the cluster you want to manage. |
| *ResourceName* | The name of the cluster resource. |
| *Timeout* | The number of seconds **cluster** waits before canceling the command if it does not successfully complete. If **/wait** is specified without this value, **cluster** waits indefinitely or until the resource state changes. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type:<br>**cluster /?** |

# Resolving file permission conflicts

Applies To: Windows Server 2003 R2

UNIX uses three levels of file permission settings: user permissions, group permissions, and permissions for everyone else. Additionally, root has full permissions to all files, regardless of the file settings.

In Windows, the administrator can access all files, but cannot modify the files without first modifying the permissions. Consequentially, automated activities such as virus checking can change the UNIX permissions and potentially cause problems for UNIX clients.

To resolve this problem, you must modify the KeepInheritance registry value, add the Windows group to the share, and configure Access Control Entries (ACEs) to apply to newly created directories.

**To modify the KeepInheritance registry value**

1. Open the Registry Editor: click **Start**, and then click **Run**. Then, enter **regedit** and click **OK**.
2. Set the following registry key to **1**:

   `HKLM\Software\Microsoft\Server for NFS\CurrentVersion\Mapping\KeepInheritance`

   | **Note** |
   | --- |
   | Setting this registry key can affect how permissions appear in UNIX. |

**To configure ACEs to apply to newly created directories**

1. Open Windows Explorer: click **Start**, point to **Programs or All Programs**, point to **Accessories**, and then click **Windows Explorer**.
2. Right-click a folder and select **Properties**.
3. Click the **Security** tab.
4. Click **Advanced**.
5. Select the **Allow inheritable permissions** check box.
6. Click **OK**.

# Enabling advisory file locking

Applies To: Windows Server 2003 R2

In Windows, file locking is mandatory. In UNIX, file locking is advisory.

By default, Server for NFS file shares use mandatory file locking. This is generally not a problem, but can affect some UNIX applications.

To configure Windows to use advisory file locking, you must clear the EnableSMBLocking registry key.

**To modify the Advisory Locking registry value**

1. Open the Registry Editor.
2. Set the following registry key to **0**:

   `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\NfsSvr\NlmNsm\EnableSMBLocking`

| **Caution** |
| --- |
| Setting this registry value turns off mandatory locks only for Network File System (NFS) lock requests. Windows applications continue to use mandatory locks. As a result, if one NFS client obtains a read/write lock on a file, then other NFS clients that are also using NLM locks before accessing a file for read/write will honor that lock. However, any Windows application can still modify the file, either through a server message block (SMB) share, or when running on the computer where the file is located, because advisory locks do not actually lock the file on the server. Additionally, although an NFS client may have obtained a lock on a file, a Windows application (either running locally or accessing the file through a CIFS share) can get a mandatory lock on the file, thereby preventing the NFS client from accessing the file, even though the NFS client has a read/write lock on the file. |

# Managing NFS client groups

Creating an NFS client group

Renaming an NFS client group

Deleting an NFS client group

Adding an NFS client computer to an NFS client group

Deleting an NFS client computer from an NFS client group

# Creating an NFS client group

Applies To: Windows Server 2003 R2

**To create an NFS client group using the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **nfsadmin server [** *ComputerName* **] creategroup** *GroupName*

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *GroupName* | The name of the group to create. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type:<br>**nfsadmin server /?**<br>You cannot give a group the same name as a client in the group. |

# Renaming an NFS client group

Applies To: Windows Server 2003 R2

**To rename an NFS client group using the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **nfsadmin server [** *ComputerName* **] renamegroup** *OldName NewName*

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *OldName* | The current name of the group you want to change. |
| *NewName* | The new name for the group. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type:<br>**nfsadmin server /?**<br>You cannot give a group the same name as a client in the group. |

# Deleting an NFS client group

Applies To: Windows Server 2003 R2

**To delete an NFS client group using the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **nfsadmin server [** *ComputerName* **] deletegroup** *GroupName*

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *GroupName* | The name of the group to delete. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type:<br>**nfsadmin server /?** |

# Adding an NFS client computer to an NFS client group

Applies To: Windows Server 2003 R2

**To add an NFS client computer to an NFS client group using the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **nfsadmin server [** *ComputerName* **] addmembers***GroupName Member***[,***Member***...]**

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *GroupName* | The name of the group to which you want to add members. |
| *Member* | The host name or IP address of the member you want to add. |

**Note**

To view the complete syntax for this command, at a command prompt, type: **nfsadmin server /?**

You cannot give a group the same name as a client in the group.

You can add a range of IP addresses as a group member, for example, 127.0.0.*. However, you cannot remove a single computer in the range specified in this manner. You must remove the entire range.

# Deleting an NFS client computer from an NFS client group

Applies To: Windows Server 2003 R2

**To delete an NFS client computer from an NFS client group using the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **nfsadmin server [** *ComputerName* **] deletemembers***GroupNameMember***[,***Member***...]**

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *GroupName* | The name of the group from which you want to delete members. |
| *Member* | The host name or IP address of the member you want to delete. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **nfsadmin server /?** |

# Using Microsoft Services for NFS with server clusters

Applies To: Windows Server 2003 R2

Understanding how Server for NFS works with server clusters

Using Server for NFS on a server cluster

# Understanding how Server for NFS works with server clusters

Applies To: Windows Server 2003 R2

A server cluster is a group of independent computer systems, known as nodes, that work together as a single system to ensure that mission-critical applications and resources remain available to clients. Every node is attached to one or more cluster storage devices. Clustering allows users and administrators to access and manage the nodes as a single system rather than as separate computers.

Server for NFS is specifically designed to make use of the server cluster. Because of this, when Server for NFS is installed on a server cluster, you can share a directory as a cluster resource. This ensures that if the node sharing the directory fails, another node in the cluster will resume sharing the directory until the failed node is restored. Running Server for NFS on a server cluster also allows you to provide static load balancing by distributing file shares among two or more nodes in the cluster. For more information about Windows clustering, see "Server Clusters" in Windows Help.

# Using Server for NFS on a server cluster

Applies To: Windows Server 2003 R2

Because Server for NFS is specifically designed to make use of server clusters, you can use Cluster Administrator to configure Network File System (NFS) shared directories as cluster resources. This provides for high availability of those shared directories. This ensures that if the cluster node sharing the directory should be shut down or fail, another node in the cluster will assume sharing the NFS shared directory until the first node restarts. In addition to enhancing availability, distributing NFS shares among nodes in the cluster can provide for static load balancing among several servers. For more information about sharing NFS directories on a server cluster, see Configuring shared folders on a server cluster.

Because the NFS shared directory is the cluster resource (instead of the Server for NFS service itself), ownership of individual NFS shares can move easily from one node to the other, as circumstances require. However, configuration changes to Server for NFS (such as the name of the User Name Mapping server) on one node are automatically replicated to instances of Server for NFS running on other cluster nodes. This simplifies administration of multiple servers because you only have to configure Server for NFS on one computer.

| **Note** |
| --- |
| To ensure proper operation of Server for NFS in a server cluster, when stopping the server cluster, first stop Server for NFS, then stop the server cluster. |

# Server for NFS Authentication

Applies To: Windows Server 2003 R2

When a UNIX user attempts to access a file shared by Server for NFS, Server for NFS uses either Active Directory Lookup or User Name Mapping to obtain the corresponding Windows user name of that UNIX user. When the Windows user name is obtained, Server for NFS then passes this information to either a domain controller or the security authority of the local server, depending on the type of account (domain or local):

- If the Windows user name is a domain account, then the domain controller authenticates the user with Kerberos extensions called Services-For-User (S4U).
- If the Windows user name is a local account, then the local security authority needs the assistance of Server for NFS Authentication. Without Server for NFS Authentication, the local security authority cannot authenticate the user and access will be denied.

| **Note** |
| --- |
| Active Directory Lookup always associates UNIX users to Windows domain user accounts. If Server for NFS is configured to only use Active Directory Lookup, then you will not need to install Server for NFS Authentication on the local computer. If you want to associate UNIX users with Windows user accounts, you must use User Name Mapping. |

| **Important** |
| --- |
| Domain controllers running Windows 2000 and earlier operating systems do not support S4U authentication. UNIX users associated with Windows domain accounts on Windows 2000 and earlier domain controllers will be denied access unless you download and install a prior version of Server for NFS Authentication. For more information, see the Microsoft Web site. |

**To install Server for NFS Authentication**

1. In Control Panel, click **Add or Remove Programs**. Then click **Add/Remove Windows Components**.
2. From the list of components, in the **Windows Components Wizard** dialog box, select **Other Network File and Print Services**, and click **Details**.
3. From the list of subcomponents, select **Microsoft Services for NFS**, and click **Details** again.
4. Select **Server For NFS Authentication**, and click **OK**.
5. Click **OK** again and then **Next**, and after the configuration of the new component has completed, click **Finish**.

# User Name Mapping administration

Applies To: Windows Server 2003 R2

User Name Mapping associates Windows and UNIX user names for Client for NFS and Server for NFS. This allows users to connect to Network File System (NFS) resources without having to log on to UNIX and Windows systems separately.

| **Note** |
| --- |
| Most of the functionality of User Name Mapping has been replaced by Active Directory Lookup. Active Directory Lookup enables Client for NFS and Server for NFS to obtain user identifier (UID) and group identifier (GID) information directly from Active Directory. For information about storing UNIX user data in Active Directory, refer to the accompanying Identity Management for UNIX documentation. For information about enabling Active Directory Lookup, see Specifying how Server for NFS obtains Windows user and group information or Specifying how Client for NFS retrieves UNIX-style identity data. |

This section includes the following topics:

Understanding the User Name Mapping component

Starting and Stopping User Name Mapping

Configuring User Name Mapping

Securing access to the User Name Mapping server

Managing maps

Mapping groups

# Understanding the User Name Mapping component

Applies To: Windows Server 2003 R2

User Name Mapping acts as a single clearinghouse that provides centralized user mapping services for Client for NFS and Server for NFS.

User Name Mapping lets you create maps between Windows and UNIX user and group accounts even though the user and group names in both environments may not be identical. Perhaps most importantly, User Name Mapping lets you maintain a single mapping database for the entire enterprise. This makes it easy to configure account mapping for multiple computers running Microsoft Services for Network File System (NFS).

In addition to one-to-one mapping between Windows and UNIX user and group accounts, User Name Mapping permits one-to-many mapping. This lets you associate multiple Windows accounts with a single UNIX account. This can be useful, for example, when you do not need to maintain separate UNIX accounts for individuals and would rather use a few accounts to provide different classes of access permission.

You can use simple maps, which map Windows and UNIX accounts with identical names. You can also create advanced maps to associate Windows and UNIX accounts with different names, which you can use in conjunction with simple maps. For information about simple and advanced maps, see Understanding user maps.

User Name Mapping can obtain UNIX user, password, and group information from one or more Network Information Service (NIS) servers or from password and group files located on a local hard drive. The password and group files can be copied from a UNIX host or from a NIS server. See Configuring User Name Mapping for more information about specifying the source for UNIX user information.

User Name Mapping periodically refreshes its mapping database from the source databases, ensuring that it is always kept up-to-date as changes occur in the Windows and UNIX name spaces. You can also refresh the database anytime you know the source databases have changed. For information about how to refresh the database automatically and manually, see Configuring the refresh interval for maps and Refreshing maps.

You can back up and restore User Name Mapping data at any time. Because the database is backed up to a file, you can use that file to copy the mapping database to another server. This provides redundancy for the sake of fault tolerance. To learn how to back up and restore the mapping database, see Backing up and restoring maps.

| **Note** |
| --- |
| If you obtain information from multiple NIS domains, it is assumed that each domain has unique users and user identifiers (UIDs). User Name Mapping does not perform any checks. |

# Starting and Stopping User Name Mapping

Applies To: Windows Server 2003 R2

Starting User Name Mapping

Stopping User Name Mapping

# Starting User Name Mapping

Applies To: Windows Server 2003 R2

**To start User Name Mapping from the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **User Name Mapping**, and then click **Start Service**.

**To start User Name Mapping from the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **mapadmin [** *ComputerName* **] [–u***User***] [–p***Password***] start**

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer on which you want to start User Name Mapping. |
| *User* | The name of the user who has administrative privileges on the computer, if different from the current user. |
| *Password* | The password for the person who has administrative privileges on the computer, if different from the current user. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type:<br>**mapadmin /?** |

# Stopping User Name Mapping

Applies To: Windows Server 2003 R2

**To stop User Name Mapping from the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **User Name Mapping**, and then click **Stop Service**.

**To stop User Name Mapping from the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **mapadmin [** *ComputerName* **] [–u***User***] [–p***Password***] stop**

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer on which you want to stop User Name Mapping. |
| *User* | The name of the user who has administrative privileges on the computer, if different from the current user. |
| *Password* | The password for the person who has administrative privileges on the computer, if different from the current user. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type:<br>**mapadmin /?** |

# Configuring User Name Mapping

Applies To: Windows Server 2003 R2

Selecting the UNIX user name source

Configuring the refresh interval for maps

Creating a User Name Mapping pool

Configuring User Name Mapping on a server cluster

# Selecting the UNIX user name source

Applies To: Windows Server 2003 R2

**To specify the UNIX user name source using the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **User Name Mapping**, and then click **Properties**.
4. Do one of the following:
   - Select **Use Network Information Service (NIS)**, or
   - Select **Use Password and Group files**, and in the **Password file path and name** and the **Group file path and name** boxes type or browse to the password and group files.
5. You can use the default refresh interval provided or change it by typing a new day, hour and minute interval.
6. To save the settings, click **Apply**.

| **Note** |
| --- |
| If you use password and group files, the files must be stored on the local computer that is running User Name Mapping. Typically, these files are the /etc/passwd and /etc/group files that are copied from a UNIX server and then periodically updated by the administrator of the computer that is running User Name Mapping.<br><br>If you are using password and group files and need to map users from multiple UNIX servers, you must combine the multiple password files so that each user is assigned a unique user identifier (UID) and combine the multiple group files so that each group is assigned a unique group identifier (GID).<br><br>You should not set up User Name Mapping to use password and group files which are using Microsoft Services for Network File System (NFS) to set up maps that use password and group files that are stored on a remote computer.<br><br>The refresh interval determines how often User Name Mapping refreshes password and group information from the NIS server or the password and group files. |

**To specify the UNIX user name source using the command line**

1. Open the command prompt.
2. To select the UNIX user name source, do one of the following:
   - To use Network Information Service (NIS), at a command prompt, type:

   **mapadmin [** *ComputerName* **] [–u** *User* **] [–p** *Password* **] config –d** *ntDomain* **–y** *nisDomain* **[–n** *nisServer* **]**

   - To use password and group files, at a command prompt, type:

   **mapadmin [** *ComputerName* **] [–u** *User* **] [–p** *Password* **] config –d** *ntDomain* **–f** *Password/GroupDirectory*

3. To select simple or advanced maps, at a command prompt, type:

   **mapadmin [** *ComputerName* **] [–u** *User* **] [–p** *Password* **] config –i {yes|no}**

4. To specify the refresh interval for password and group information, at a command prompt, type:

   **mapadmin [** *ComputerName* **] [–u** *User* **] [–p** *Password* **] config –r** *dddd:hh:mm*

| **Argument** | **Description** |
| --- | --- |

| | |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *User* | The name of the user who has administrative privileges on the computer, if different from the current user. |
| *Password* | The password for the person who has administrative privileges on the computer, if different from the current user. |
| *ntDomain* | The name of the Windows domain. |
| *Password/GroupDirectory* | The fully qualified path of the directory where the password and group files are located on the computer that is running User Name Mapping. |
| *nisDomain* | The name of the NIS domain. |
| *nisServer* | The name of the NIS server (optional). |
| *dddd:hh:mm* | How often, in days, hours, and minutes, User Name Mapping will refresh password and group information from the NIS server or the password and group files. |

**Note**

If you use password and group files, the files must be stored on the local computer that is running User Name Mapping. Typically, these files are the /etc/passwd and /etc/group files that are copied from a UNIX server and then periodically updated by the administrator of the computer that is running User Name Mapping.

If you are using password and group files and need to map users from multiple UNIX servers, you must combine the multiple password files so that each user is assigned a unique user identifier (UID) and combine the multiple group files so that each group is assigned a unique group identifier (GID).

You cannot use the **mapadmin** command to set up mappings that use password and group files on a remote computer.

The refresh interval determines how often User Name Mapping refreshes password and group information from the NIS server or from the password and group files.

# Configuring the refresh interval for maps

Applies To: Windows Server 2003 R2

**To configure the refresh interval from the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **User Name Mapping** and click **Properties**.
4. Click the **Configuration** tab.
5. In **Days, Hours**, and **Minutes**, type the refresh interval. The minimum interval is five minutes.
6. To save the settings, click **Apply**.

**To configure the refresh interval from the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **mapadmin [** *ComputerName* **] [–u***User***] [–p***Password***] config –r [[***days***:]***hh***:]***mm*

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *User* | The name of the user who has administrative privileges on the computer, if different from the current user. |
| *Password* | The password for the person who has administrative privileges on the computer, if different from the current user. |
| *days:hh:mm* | The refresh interval for updating from the Windows and Network Information Service (NIS) databases in days, hours, and minutes. The minimum interval is five minutes. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **mapadmin /?** |

# Creating a User Name Mapping pool

Applies To: Windows Server 2003 R2

In larger networks, especially networks that extend across a wide area network (WAN), it is often desirable to run User Name Mapping on multiple computers. In the case of a WAN, running User Name Mapping on computers on the local area networks (LANs) as other computers running Microsoft Services for Network File System (NFS) can help ensure a high level of performance. Even if your network is not geographically dispersed, you might want to run User Name Mapping on more than one computer to improve performance and availability.

When you run User Name Mapping on multiple computers, you can create a pool of servers using Domain Name System (DNS) round robin. Doing this provides a number of benefits:

- You can enhance performance by locating computers running User Name Mapping near other computers running Microsoft Services for NFS.
- You can achieve load balancing by alternating which servers respond to mapping requests.
- High availability can be ensured by providing redundant servers so that if one fails, other servers in the pool can continue to respond to mapping requests.

The first step in creating a User Name Mapping server pool is to install User Name Mapping on two or more servers. These servers must be configured and maintained identically to ensure that they provide consistent responses to mapping requests. The easiest way to do this is to use batch (.cmd) files that repeat the same **mapadmin** command for each server in the pool.

For example, you could install User Name Mapping on three servers named UNM1, UNM2, and UNM3. You would then create a batch file that would apply the same **mapadmin** command and arguments to all three servers:

```
REM POOLADMIN.CMD

REM Used to administer three User Name Mapping servers: UNM1, UNM2, and UNM3

REM Syntax: POOLADMIN mapadmin_argument[...]

mapadmin UNM1 %0 %1 %2 %3 %4 %5 %6 %7 %8 %9 -u UNM1\administrator -p admUNM1pwd

mapadmin UNM2 %0 %1 %2 %3 %4 %5 %6 %7 %8 %9 -u UNM2\administrator -p admUNM2pwd

mapadmin UNM3 %0 %1 %2 %3 %4 %5 %6 %7 %8 %9 -u UNM3\administrator -p admUNM3pwd
```

Use a file like this, or a similar technique, to configure and administer all the User Name Mapping servers in the pool, both before and after the pool has been created.

Once you have set up and configured the servers that will belong to the pool, the next step is to create the pool itself. You do this by configuring a DNS server to map a single name to the Internet Protocol (IP) addresses of all three User Name Mapping servers. For example, you could map the name UNMpool to the IP addresses for UNM1, UNM2, and UNM3. Whenever a client computer asks the DNS server to resolve the name UNMpool, the DNS server will return all three IP addresses, the first of which is the one most clients will use. Because the DNS server rotates (in a round-robin fashion) the order in which it returns the three IP addresses, this automatically provides for load balancing.

The final step in setting up a User Name Mapping pool is to configure computers on the network running Client for NFS or Server for NFS to use the virtual server name of the pool (UNMpool in the example). Because the DNS server rotates the order of the IP addresses it returns when it resolves this name, each of these User Name Mapping clients will receive a different primary IP address than the one given to the previous client, thereby automatically providing load balancing among the three User Name Mapping servers. In addition, these Microsoft Services for NFS components are designed to send mapping requests to each IP address it receives if requests to the previous IP address times out. This provides for automatic failover if one of the servers in the pool should fail.

As noted earlier, it is essential that all servers that belong to a pool are configured and maintained identically. If password and group files are used to provide UNIX account information for mapping users, for example, identical password and group files must be copied to and maintained on all servers in the pool. Similarly, if you use .maphosts files to control access to servers in the pool, you must maintain identical .maphosts files on all servers in the pool.

# Configuring User Name Mapping on a server cluster

Applies To: Windows Server 2003 R2

A server cluster is a group of independent computer systems, known as nodes, working together as a single system to ensure that mission-critical applications and resources remain available to clients. Every node is attached to one or more cluster storage devices. Clustering allows users and administrators to access and manage the nodes as a single system rather than as separate computers.

User Name Mapping is specifically designed to make use of the server cluster and the server cluster's ability to replicate configuration settings among its nodes. This means that when User Name Mapping is installed on the nodes of a cluster, all changes to the configuration of User Name Mapping on one node are automatically replicated to User Name Mapping on all other nodes of the cluster. Consequently, you can manage User Name Mapping on all the nodes in the cluster simply by administering User Name Mapping on any one node. This ensures that user and group mappings and other settings will be identical on all servers in the cluster, thereby allowing you to easily achieve static load balancing by distributing User Name Mapping clients among the nodes of the cluster.

**To install User Name Mapping on a cluster**

1. Create one cluster group for each node with its own Internet Protocol (IP) address and network name resource, and assign the preferred owner for each group so that it is primarily owned by a different node. This allows you to achieve static load balancing.
2. Install User Name Mapping on the nodes of the cluster one at a time. Before installing User Name Mapping on a node, move all groups away from the node.
3. When User Name Mapping has been installed on all nodes, return all groups to their primary owners.
4. Configure User Name Mapping on any node. Settings changed on one node are automatically replicated to all other nodes in the cluster.
5. Configure each client computer to use the virtual server name from one of the cluster groups as its User Name Mapping server. This will ensure that client computers will continue to be served by User Name Mapping in case of node failure. To provide static load balancing, evenly distribute clients among the virtual servers of the cluster.

**Note**

To ensure proper operation of User Name Mapping on a server cluster, when stopping the server cluster, first stop User Name Mapping, then stop the server cluster.

To run User Name Mapping on a server cluster, you must install User Name Mapping on the nodes of an existing cluster. Adding a stand-alone computer that is already running User Name Mapping as a new node in an existing cluster is not supported.

When running User Name Mapping on a server cluster, do not create maps using local Windows user and group accounts. Because the security identifiers (SIDs) of local accounts are recognized only by the server where those accounts were created, other nodes in the cluster will not be able to resolve those accounts when the server fails. Instead, you should create maps using domain accounts only.

If the cluster service is restarted on a node, you must also restart the User Name Mapping service. Until you do, configuration changes will not be replicated to and from User Name Mapping on the node.

User Name Mapping configuration changes are not properly replicated among nodes in a cluster if you run Microsoft Services for Network File System (NFS) or **mapadmin** on a computer that belongs to a domain that is not trusted by the domain of the cluster. To ensure that User Name Mapping configuration changes are properly replicated, always administer User Name Mapping running on a cluster using a computer that belongs to a trusted domain.

You must maintain identical .maphosts files on all servers in the pool. For more information about the .maphosts file, see Securing access to the User Name Mapping server.

If you use password and group files to provide user and group information for User Name Mapping running on a cluster, you must store the password and group files on local disk drives on each node, and the system administrator must update these files as required. In addition, if you restore mapping settings from a backup file, you must also copy the restored password and group files to the appropriate location on all of the nodes in the server cluster and ensure that all nodes in the cluster are configured to use password and group files located in the same local path. For more information about backing up and restoring User Name Mapping data, see Backing up and restoring maps.

If you are running User Name Mapping as well as Server for NFS on a server cluster, configure each node of the cluster to use **localhost** as its User Name Mapping server.

# Securing access to the User Name Mapping server

Applies To: Windows Server 2003 R2

The authentication mechanism used by the Network File System (NFS) protocol is based on trust relationships between host computers. That is, an NFS server accepts the user identifiers (UIDs) and group identifiers (GIDs) from a given client computer because the server is configured to recognize the client computer as trustworthy.

User Name Mapping acts as an intermediary between NFS servers and NFS clients on a network containing UNIX hosts and Windows-based computers. To maintain the implicit trust relationship between NFS client and host computers, it is essential that you control which computers can access User Name Mapping and hence act as a trusted host on the NFS network.

You control which computers can access User Name Mapping by editing a file named .maphosts in the %windir%\msnfs directory of the computer User Name Mapping. By adding entries in this file, you can easily permit or deny access by any other computer to User Name Mapping. If the .maphosts file is present but not empty, then only those computers allowed access by entries in the file can access User Name mapping. If the .maphosts file is present but empty (the default), no computers except the computer running User Name Mapping itself can access User Name Mapping. If the .maphosts file is not present, no computers (including the computer running User Name Mapping) can access User Name Mapping.

The .maphosts file consists of a list of one or more of the elements described in the following table, each on a separate line. When matching a computer making a request against the elements in the list, User Name Mapping searches from the top down until it finds a match. Consequently, order is essential.

| Element | Description |
|---|---|
| *host* | Specifies one or more computers that can access User Name Mapping. The host can be specified as an Internet Protocol (IP) address (IP version 4), or as a host name that resolves to one or more IP addresses. |
| *host –* | Specifies one or more computers that are denied access to User Name Mapping. The host can be specified as an IP address (IP version 4), or as a host name that resolves to one or more IP addresses. Note that there must be at least one blank space between host and the dash (–). |
| **+** | Specifies that all computers can access User Name Mapping unless disallowed by an earlier entry in the list. All entries in the list following this element are ignored. |
| **-** | Specifies that all computers are disallowed access to User Name Mapping unless allowed by an earlier entry in the list. All entries in the list following this element are ignored. |

The # character can be used to add comments to the file; everything on a line following the # character is ignored.

Access by the computer running User Name Mapping (the local host) is always allowed unless specifically denied in the .maphosts file, or the .maphosts file is not present. In case of a multihomed User Name Mapping server, access to the service running on other nodes from any of the nodes is also allowed, unless explicitly denied.

**Examples**

The following example file allows access only by computers named mktg_nfs and sales_nfs:

```
mktg_nfs

sales_nfs

-
```

The following example file allows access by all computers except computers named rogue_host and malicious_host:

```
rogue_host -

malicious_host -

+
```

In the next example, rogue_host is denied access even though it appears in the list without a minus sign (–) because it follows a minus sign on its own line:

```
mktg_nfs
```

sales_nfs

-

rogue_host

# Managing maps

Applies To: Windows Server 2003 R2

Refreshing maps

Backing up and restoring maps

Mapping users

# Refreshing maps

Applies To: Windows Server 2003 R2

**To refresh user data from the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **User Name Mapping** and select **Properties**.
4. In **Days**, **Hours**, and **Minutes**, type the refresh interval. The minimum interval is five minutes.
5. To refresh the user data now, click **Synchronize Now**.
6. To save the settings, click **Apply**.

**To refresh user data from the command line**

1. Open the command prompt.
2. At the command prompt, type:

   **mapadmin [** *ComputerName* **] [–u***User***] [–p***Password***] config –r [[***days***:]***hh***:]***mm*

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *User* | The name of the user who has administrative privileges on the computer, if different from the current user. |
| *Password* | The password for the person who has administrative privileges on the computer, if different from the current user. |
| *days:hh:mm* | The refresh interval for updating from the Windows and Network Information Service (NIS) databases in days, hours, and minutes. The minimum interval is five minutes. |

| **Note** |
|---|
| There is no command-line method for immediately refreshing maps.<br><br>To view the complete syntax for this command, at a command prompt, type: **mapadmin /?** |

# Backing up and restoring maps

Applies To: Windows Server 2003 R2

**To backup and restore data from the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. To back up maps, right-click **User Name Mapping** and select **Backup Maps**.

   Type the fully qualified path and name of the file to which you want to back up the maps, or click **Browse** to find the file. When you have identified or found the file, click **Backup**.
4. To restore maps, right-click **User Name Mapping** and select **Restore Maps**.

   Type the fully qualified path and name of the file from which you want to restore maps, or click **Browse** to find the file. When you have identified or found the file, click **Restore**.

   The following settings and maps are backed up and restored:

   - Configuration type (either Network Information Service [NIS], or password and group files)
   - Domain maps
   - Advanced user and group maps
   - Password and group files, if applicable

   | **Note** |
   | --- |
   | If you back up settings and maps on a remote computer that is configured to use password and group files, the password and group maps are not backed up. |

   If you are using password and group files as the source for UNIX user and group names, and if you are running User Name Mapping in a server cluster or a server pool, you must perform the following tasks after restoring maps:

   - You must copy the restored password and group files to the appropriate directories on all nodes in the server cluster or pool. On a server cluster, the files must be copied to directories with identical path names on each node in the cluster.
   - After copying the files on a server pool, you must configure each node in the pool to use the files in the directories where you copied the files.
   - After copying the files on a server cluster, you must configure User Name Mapping on one node to use the files in the directory where you copied the files, and then click Apply. This will cause the updated settings to be replicated to other nodes in the cluster.

**To backup and restore data from the command line**

1. Open the command prompt.
2. At the command prompt, type one of the following:

   - To create a backup file and perform the backup, type:

     **mapadmin [***ComputerName***] [–u***User***] [–p***Password***] backup***file***

   - To restore, type:

**mapadmin** [*ComputerName*] [**–u***User*] [**–p***Password*] **restore** *file*

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *User* | The name of the user who has administrative privileges on the computer, if different from the current user. |
| *Password* | The password for the person who has administrative privileges on the computer, if different from the current user. |
| *File* | The fully qualified path and name of the file to be used for backup. |

The following settings and maps are backed up and restored:

- Configuration type (either Network Information Service (NIS), or password and group files)
- Domain maps
- Advanced user and group maps
- Password and group files, if applicable

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **mapadmin /?**<br>If you back up settings and maps on a computer configured to use password and group files, the password and group maps are not backed up. |

If you are using password and group files as the source for UNIX user and group names, and if you are running User Name Mapping in a server cluster or a server pool, you must perform the following tasks after restoring maps:

- You must copy the restored password and group files to the appropriate directories on all nodes in the server cluster or pool. On a server cluster, the files must be copied to directories with identical path names on each node in the cluster.
- After copying the files on a server pool, you must configure each node in the pool to use the files in the directories where you copied the files.
- After copying the files on a server cluster, you must configure User Name Mapping on one node to use the files in the directory where you copied the files, and then click **Apply**. This will cause the updated settings to be replicated to other nodes in the cluster.

Removing a user map

# Understanding user maps

Applies To: Windows Server 2003 R2

User Name Mapping acts as a single clearinghouse that provides centralized user mapping services for Client for NFS and Server for NFS.

User Name Mapping enables you create maps between Windows and UNIX user and group accounts even though the user and group names in both environments may not be identical. Perhaps most importantly, User Name Mapping lets you maintain a single mapping database for the entire enterprise. This makes it easy to configure authentication for multiple computers running Microsoft Services for NFS.

In addition to one-to-one mapping between Windows and UNIX user and group accounts, User Name Mapping permits one-to-many mapping. This lets you associate multiple Windows accounts with a single UNIX account. This can be useful, for example, when you do not need to maintain separate UNIX accounts for individuals and would rather use a few accounts to provide different classes of access permission.

You can use simple maps, which map Windows and UNIX accounts with identical names. You can also create advanced maps to associate Windows and UNIX accounts with different names, which you can use in conjunction with simple maps. For information about simple and advanced maps, see Understanding user maps.

User Name Mapping can obtain UNIX user, password, and group information from one or more Network Information Service (NIS) servers or from password and group files located on a local hard drive. The password and group files can be copied from a UNIX host or from a Windows-based computer that is running Server for NIS. See Configuring User Name Mapping for more information about specifying the source for UNIX user information.

User Name Mapping periodically refreshes its mapping database from the source databases, ensuring that it is always kept up-to-date as changes occur in the Windows and UNIX name spaces. You can also refresh the database anytime you know the source databases have changed. For information about how to refresh the database automatically and manually, see Configuring the refresh interval for maps and Refreshing maps.

You can back up and restore User Name Mapping data at any time. Because the database is backed up to a file, you can use that file to copy the mapping database to another server. This provides redundancy for the sake of fault tolerance. To learn how to back up and restore the mapping database, see Backing up and restoring maps.

If you obtain information from multiple NIS domains, it is assumed that each domain have unique users and user identifiers (UIDs). User Name Mapping does not perform any checks.

# Viewing user maps

Applies To: Windows Server 2003 R2

**To view user maps from the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Expand **User Name Mapping** and select **User Maps**.

| **Note** |
|---|
| Maps are displayed in the **Mapped users** and **Mapped groups** lists in the order in which the maps are evaluated. Primary maps are always listed and evaluated first, followed by secondary maps. To change the order in which maps are evaluated within the list of secondary maps, right-click **User Name Mapping** and click **Properties**. Then, click the **Simple Maps** tab and use the **Move up** or **Move down** buttons to reposition the map within the list. |

**To view user maps from the command line**

1. Open the command prompt.
2. At the command prompt, type one of the following:

   **mapadmin [** *ComputerName* **] [–u***User***] [–p***Password***] list {–all|–advanced|–simple}**

   **mapadmin [** *ComputerName* **] [–u***User***] [–p***Password***] list –wu***Windows_User_Name***

   **mapadmin [** *ComputerName* **] [–u***User***] [–p***Password***] list –uu***unix_User_Name***

   **mapadmin [** *ComputerName* **] [–u***User***] [–p***Password***] list –wg***WindowsGroupName***

   **mapadmin [** *ComputerName* **] [–u***User***] [–p***Password***] list –ug***unixGroupName***

| **Argument** | **Description** |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *User* | The name of the user who has administrative credentials on the computer, if different from the current user. |
| *Password* | The password for the person who has administrative credentials on the computer, if different from the current user. |
| **–all** | View details of both simple and advanced maps. |
| **–advanced** | View all advanced maps for users and groups. |
| **–simple** | View the simple-mapped domains. |
| *Windows_User_Name* | The Windows user for which you want to see details. |
| *Unix_User_Name* | The UNIX user for which you want to see details. |
| *WindowsGroupName* | The Windows group for which you want to see details. |
| *UnixGroupName* | The UNIX group for which you want to see details. |

| **Note** |
|---|

Maps are displayed in the order in which the maps are evaluated. Primary maps are always listed and evaluated first, followed by secondary maps. You can use the Windows interface to change the order in which secondary maps are evaluated. For information about how to do this, see "Using the Windows interface" in this topic.

To view the complete syntax for this command, at a command prompt, type: **mapadmin /?**

# Creating a simple user map

Applies To: Windows Server 2003 R2

**To create a simple user map from the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **User Name Mapping** and select **Properties**.
4. Click the **Simple Maps** tab.
5. Select **Use simple maps**.
6. Click **Add**.
7. If you are creating a simple map using Network Information Service (NIS) data, in the **NIS domain name** box, type the name of the NIS domain. If the master server of the NIS domain is located on a different subnet than the User Name Mapping server, then in the **NIS Server name** box, type the name of the master server.
8. Select the Windows domain for which you are creating a simple map.
9. Click **OK**.
10. To add another simple map between a Windows and an NIS domain, repeat the previous step.
11. To remove a simple map between a Windows and an NIS domain, select the map, and then click **Remove**.
12. To reposition a simple map between a Windows and an NIS domain in the list, select the map, and then click **Move up** or **Move down**.
13. To save the settings, click **Apply**.

| **Note** |
| --- |
| You can create multiple simple maps between Windows and NIS domains. Maps are evaluated from the top of the list of maps to the bottom. |

**To create a simple user map from the command line**

1. Open the command prompt.
2. At the command prompt, do one of the following:
   - To supply required information for authentication using password and group files, type:

     **mapadmin [***ComputerName***] [–u***User***] [–p***Password***] adddomainmap –d***ntDomain***–f***Password***/***GroupDirectory***

   - To supply required information for Network Information Service (NIS) authentication, type:

     **mapadmin [***ComputerName***] [–u***User***] [–p***Password***] adddomainmap –d***ntDomain***–y***nisDomain***

| **Argument** | **Description** |
| --- | --- |
| *ComputerName* | The name of the computer you want to manage. |
| *User* | The name of the user who has administrative privileges on the computer, if different from the current user. |

| | |
|---|---|
| *Password* | The password for the person who has administrative privileges on the computer, if different from the current user. |
| *ntDomain* | The name of the Windows domain. |
| *Password/GroupDirectory* | The fully qualified path of the directory on the User Name Mapping computer where the password and group files are located. |
| *nisDomain* | The name of the NIS domain. |

**Note**

Password and group files must be stored on the computer that is running User Name Mapping. Typically, these files are the /etc/passwd and /etc/group files that are copied from a UNIX host and then periodically updated by the administrator of the computer that is running User Name Mapping.

To view the complete syntax for this command, at a command prompt, type:

**mapadmin /?**

# Creating an advanced user map

Applies To: Windows Server 2003 R2

**To create an advanced map from the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Expand **User Name Mapping**.
4. Right-click **User Maps** and select **Create Map**.
5. In the **Windows domain name** list, click the domain for which you want to list users, and then click **List Windows Users**.
6. If you are obtaining UNIX user information from a Network Information Service (NIS) domain, in the **NIS Domain name** box, type the name of the NIS domain from which you are getting account information. If the master server of the NIS domain is located on a different subnet than the User Name Mapping server, then in the **NIS Server name box**, type the name of the master server.
7. Click **List UNIX Users**.
8. In the **Windows Account** and **UNIX Account** lists, click the two accounts you want to map to each other, and then click **Add**.
9. To save the settings, click **Apply**.

| **Note** |
| --- |
| As you add maps, new maps are listed below existing maps. This does not reflect the order in which the maps are evaluated, however. To view the actual order, click **Apply**, press **F5** to refresh the User Name Mapping page, and then reopen the list of advanced maps. Primary maps are always listed and evaluated first, followed by secondary maps. To change the order in which maps are evaluated within the list of secondary maps, select a map and then click **Move up** or **Move down** to reposition the map within the list. |

**To create an advanced map from the command line**

1. Open the command prompt.
2. At the command prompt, to supply required information for authentication using password and group files, type:

   **mapadmin [** *ComputerName* **] [–u***User***] [–p***Password***] add –wu***WindowsDomain******UserName***–uu***UserName***[–setprimary]**

| Argument | Description |
| --- | --- |
| *ComputerName* | The name of the computer you want to manage. |
| *User* | The name of the user who has administrative privileges on the computer, if different from the current user. |
| *Password* | The password for the person who has administrative privileges on the computer, if different from the current user. |
| *WindowsDomain* **** *UserName* | The name of the Windows user. |
| *UserName* | The name of the UNIX user, specified as domain\user_name or user_name@domain, where domain is the name of the Network Information Service (NIS) domain or **PCNFS**, if you are using password and group files. |

| | |
|---|---|
| **–setprimary** | Make this the primary mapping. |

**Note**

The command-line method maps one pair of users or groups at a time. To map more users or groups, repeat the command.

When you use **mapadmin** to create multiple maps for a UNIX user, use the **–setprimary** option to specify the primary map. If necessary, you can use the **mapadmin setprimary** command later to change the primary map.

Maps cannot be evaluated in the order in which they are created. Primary maps are always evaluated before secondary maps.
To view the complete syntax for this command, at a command prompt, type: **mapadmin /?**

# Determining the file GID

Applies To: Windows Server 2003 R2

**To determine the GID of a file**

1. Open Windows Explorer: click **Start**, point to **Programs or AllPrograms**, point to **Accessories**, and then click **Windows Explorer**.
2. Double-click **My Network Places**, and then double-click **Entire Network**.
3. Double-click **NFS Network**.
4. Double-click the local area network (LAN) whose servers you want to view.
5. Double-click the server whose shared directories you want to view.
6. Locate and right-click the file or folder and click **Properties**. The file information and group identifier (GID) are displayed.

| **Note** |
| --- |
| When you double-click **NFS Network**, it might take several seconds for the local area network (LAN) to appear, depending on the broadcast network configuration and the number of computers in the broadcast. |

# Determining the file UID

Applies To: Windows Server 2003 R2

**To determine the UID of a file**

1. Open Windows Explorer: click **Start**, point to **Programs or AllPrograms**, point to **Accessories**, and then click **Windows Explorer**.
2. Double-click **My Network Places**, and then double-click **Entire Network**.
3. Double-click **NFS Network**.
4. Double-click the local area network (LAN) whose servers you want to view.
5. Double-click the server whose shared directories you want to view.
6. Locate and right-click the file or folder and click **Properties**. The file information and user identifier (UID) are displayed.

| **Note** |
| --- |
| When you double-click **NFS Network**, it might take several seconds for the local area network (LAN) to appear, depending on the broadcast network configuration and the number of computers in the broadcast. |

# Removing a user map

Applies To: Windows Server 2003 R2

**To remove a user map from the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **User Name Mapping** and click **Properties**.
4. Click the **Simple Maps** tab.
5. To disable simple maps, clear the **Use simple maps** box.
6. To remove a simple map between a Windows and an NIS domain, select the map, and then click **Remove**.
7. To save the settings, click **Apply**.

**To remove a user map from the command line**

1. Open the command prompt.
2. At the command prompt, do one of the following:
   - To remove a specific map between a Windows domain and an NIS domain, type:

     **mapadmin [***ComputerName***] [–u***User***] [–p***Password***] removedomainmap –d***WindowsDomain***–y***nisDomain*

   - To remove all simple maps, type:

     **mapadmin [***ComputerName***] [–u***User***] [–p***Password***] removedomainmap -all**

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *User* | The name of the user who has administrative privileges on the computer, if different from the current user. |
| *Password* | The password for the person who has administrative privileges on the computer, if different from the current user. |
| *WindowsDomain* | The Windows domain of the map to be deleted. |
| *nisDomain* | The NIS domain of the map to be deleted. |
| **-all** | Deletes all simple maps. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **mapadmin /?** |

# Mapping groups

Applies To: Windows Server 2003 R2

Understanding group maps

Viewing group maps

Creating a simple group map

Creating an advanced group map

Removing a group map

# Understanding group maps

Applies To: Windows Server 2003 R2

User Name Mapping acts as a single clearinghouse that provides centralized user mapping services for Client for NFS and Server for NFS.

User Name Mapping enables you to create maps between Windows and UNIX user and group accounts even though the user and group names in both environments may not be identical. Perhaps most important, User Name Mapping lets you maintain a single mapping database for the entire enterprise. This makes it easy to configure authentication for multiple computers running Microsoft Services for Network File System (NFS).

In addition to one-to-one mapping between Windows and UNIX user and group accounts, User Name Mapping permits one-to-many mapping. This lets you associate multiple Windows accounts with a single UNIX account. This can be useful, for example, when you do not need to maintain separate UNIX accounts for individuals and would rather use a few accounts to provide different classes of access permission.

You can use simple maps, which map Windows and UNIX accounts with identical names. You can also create advanced maps to associate Windows and UNIX accounts with different names, which you can use in conjunction with simple maps. For information about simple and advanced maps, see Understanding user maps.

User Name Mapping can obtain UNIX user, password, and group information from one or more Network Information Service (NIS) servers or from password and group files located on a local hard drive. The password and group files can be copied from a UNIX host or from a Windows-based computer that is running Server for NIS. See Configuring User Name Mapping for more information about specifying the source for UNIX user information.

User Name Mapping periodically refreshes its mapping database from the source databases, ensuring that it is always kept up-to-date as changes occur in the Windows and UNIX name spaces. You can also refresh the database anytime you know the source databases have changed. For information about how to refresh the database automatically and manually, see Configuring the refresh interval for maps and Refreshing maps.

You can back up and restore User Name Mapping data at any time. Because the database is backed up to a file, you can use that file to copy the mapping database to another server. This provides redundancy for the sake of fault tolerance. To learn how to back up and restore the mapping database, see Backing up and restoring maps.

If you obtain information from multiple NIS domains, it is assumed that each domain have unique users and user identifiers (UIDs). User Name Mapping does not perform any checks.

# Viewing group maps

Applies To: Windows Server 2003 R2

**To view group maps from the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Expand **Username Mapping Server** and select **Group Maps**.

| **Note** |
| --- |
| Maps are displayed in the **Mapped users** and **Mapped groups** lists in the order in which the maps are evaluated. Primary maps are always listed and evaluated first, followed by secondary maps. To change the order in which maps are evaluated within the list of secondary maps, right-click **Username Mapping Server** and click **Properties**. Then, click the **Simple Maps** tab and use the **Move up or Move down** buttons to reposition the map within the list. |

**To view group maps from the command line**

1. Open the command prompt.
2. At the command prompt, type one of the following:

   **mapadmin [** *ComputerName* **] [–u***User***] [–p***Password***] list {–all|–advanced|–simple}**

   **mapadmin [** *ComputerName* **] [–u***User***] [–p***Password***] list –wg***WindowsGroupName***

   **mapadmin [** *ComputerName* **] [–u***User***] [–p***Password***] list –ug***UnixGroupName***

| **Argument** | **Description** |
| --- | --- |
| *ComputerName* | The name of the computer you want to manage. |
| *User* | The name of the user who has administrative credentials on the computer, if different from the current user. |
| *Password* | The password for the person who has administrative credentials on the computer, if different from the current user. |
| **–all** | View details of both simple and advanced maps. |
| **–advanced** | View all advanced maps for users and groups. |
| **–simple** | View the simple-mapped domains. |
| *WindowsGroupName* | The Windows group for which you want to see details. |
| *UnixGroupName* | The UNIX group for which you want to see details. |

| **Note** |
| --- |
| Maps are displayed in the order in which the maps are evaluated. Primary maps are always listed and evaluated first, followed by secondary maps. You can use the Windows interface to change the order in which secondary maps are evaluated. For information about how to do this, see "Using the Windows interface" in this topic.<br><br>To view the complete syntax for this command, at a command prompt, type: **mapadmin /?** |

# Creating a simple group map

Applies To: Windows Server 2003 R2

**To create a simple group map from the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **User Name Mapping** and select **Properties**.
4. Click the **Simple Maps** tab.
5. Select **Use simple maps**.
6. Click **Add**.
7. If you are creating a simple map using Network Information Service (NIS) data, in the **NIS domain name** box, type the name of the NIS domain. If the master server of the NIS domain is located on a different subnet than the User Name Mapping server, then in the **NIS Server name** box, type the name of the master server.
8. Select the Windows domain for which you are creating a simple map.
9. Click **OK**.
10. To add another simple map between a Windows and an NIS domain, repeat the previous step.
11. To remove a simple map between a Windows and an NIS domain, select the map, and then click **Remove**.
12. To reposition a simple map between a Windows and an NIS domain in the list, select the map, and then click **Move up** or **Move down**.
13. To save the settings, click **Apply**.

| **Note** |
| --- |
| You can create multiple simple maps between Windows and NIS domains. Maps are evaluated from the top of the list of maps to the bottom. |

**To create a simple group map from the command line**

1. Open the command prompt.
2. At the command prompt, do one of the following:
   - To supply required information for authentication using password and group files, type:

     **mapadmin [***ComputerName***] [–u***User***] [–p***Password***] adddomainmap –d***ntDomain***–f***Passwd***/***GroupDirectory*

   - To supply required information for Network Information Service (NIS) authentication, type:

     **mapadmin [***ComputerName***] [–u***User***] [–p***Password***] adddomainmap –d***ntDomain***–y***nisDomain*

| Argument | Description |
| --- | --- |
| *ComputerName* | The name of the computer you want to manage. |
| *User* | The name of the user who has administrative credentials on the computer, if different from the current user. |

| | |
|---|---|
| *Password* | The password for the person who has administrative credentials on the computer, if different from the current user. |
| *ntDomain* | The name of the Windows domain. |
| *Password* **/** *GroupDirectory* | The fully qualified path of the directory on the User Name Mapping computer where the password and group files are located. |
| *nisDomain* | The name of the NIS domain. |

**Note**

Password and group files must be stored on the computer that is running User Name Mapping. Typically, these files are the /etc/passwd and /etc/group files that are copied from a UNIX host and then periodically updated by the administrator of the computer that is running User Name Mapping.

To view the complete syntax for this command, at a command prompt, type: **mapadmin /?**

# Creating an advanced group map

Applies To: Windows Server 2003 R2

**To create an advanced group map from the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Expand **User Name Mapping**.
4. Right-click **Group Maps** and select **Create Map**.
5. In the **Windows domain** list, select the domain for which you want to list users, and then click **List Windows Groups**.
6. If you are obtaining UNIX user information from a Network Information Service (NIS) domain, in the **NIS Domain name** box, type the name of the NIS domain from which you are getting account information. If the master server of the NIS domain is located on a different subnet than the User Name Mapping server, then in the **NIS Server name box,** type the name of the master server.
7. Click **List UNIX Groups**.
8. In the **Windows Group** and **UNIX Group** lists, click the two accounts you want to map to each other and click **Add**.
9. To save the settings, click **Apply**.

| **Note** |
|---|
| As you add maps, new maps are listed below existing maps. This does not reflect the order in which the maps are evaluated, however. To view the actual order, click **Apply**, press **F5** to refresh the User Name Mapping page, and then reopen the list of advanced maps. Primary maps are always listed and evaluated first, followed by secondary maps. To change the order in which maps are evaluated within the list of secondary maps, select a map and then click **Move up** or **Move down** to reposition the map within the list. |

**To create an advanced group map from the command line**

1. Open the command prompt.
2. At the command prompt, to supply required information for authentication using password and group files, type:

   **mapadmin [** *ComputerName* **] [–u***User***] [–p***Password***] add –wg***WindowsGroup***–ug***UnixGroup***[–setprimary]**

| **Argument** | **Description** |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *User* | The name of the user who has administrative credentials on the computer, if different from the current user. |
| *Password* | The password for the person who has administrative credentials on the computer, if different from the current user. |
| *WindowsGroup* | The name of the Windows group. |
| *UnixGroup* | The name of the UNIX group. |
| **– setprimary** | Make this the primary mapping. |

| **Note** |
|---|

The command-line method maps one pair of groups at a time. To map more groups, repeat the command.

When you use **mapadmin** to create multiple maps for a UNIX user, use the **–setprimary** option to specify the primary map. If necessary, you can use the **mapadmin setprimary** command later to change the primary map.

Maps cannot be evaluated in the order in which they are created. Primary maps are always evaluated before secondary maps. To view the complete syntax for this command, at a command prompt, type: **mapadmin /?**

# Removing a group map

Applies To: Windows Server 2003 R2

**To remove a group map from the Windows interface**

1. Open Microsoft Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Microsoft Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **User Name Mapping** and click **Properties**.
4. Click the **Simple Maps** tab.
5. To disable simple maps, clear the **Use simple maps** box.
6. To remove a map between a Windows and an NIS domain, select the map, and then click **Remove**.
7. To save the settings, click **Apply**.

**To remove a group map from the command line**

1. Open the command prompt.
2. At the command prompt, type one of the following:
   - To remove a specific map between a Windows domain and an NIS domain, at a command prompt, type:

     **mapadmin [***ComputerName***] [–u***User***] [–p***Password***] removedomainmap–d***WindowsDomain***–y***nisDomain***

   - To remove all simple maps, at a command prompt, type:

     **mapadmin [***ComputerName***] [–u***User***] [–p***Password***] removedomainmap -all**

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| *User* | The name of the user who has administrative privileges on the computer, if different from the current user. |
| *Password* | The password for the person who has administrative privileges on the computer, if different from the current user. |
| *WindowsDomain* | The Windows domain of the map to be deleted. |
| *nisDomain* | The NIS domain of the map to be deleted. |
| **-all** | Deletes all simple maps. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **mapadmin /?** |

# Client for NFS administration

Applies To: Windows Server 2003 R2

Client for NFS enables Windows-based computers to access files on UNIX Network File System (NFS) servers. Users can connect to and disconnect from an NFS share as though it were any other shared drive on their network.

Understanding the Client for NFS component

Using Client for NFS

Configuring Client for NFS

Mounting an NFS shared resource to a drive letter

Viewing NFS mount options and properties

Viewing NFS server properties

# Understanding the Client for NFS component

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

Client for NFS gives a Windows-based computer the ability to act as a client to a Network File System (NFS) server. With Client for NFS, you can access files in a mixed environment of computers, operating systems, and networks.

Accessing files on NFS servers requires each Windows user to also have a UNIX-style identity. To enable users to access NFS shared resources using Client for NFS, you can include UNIX-style identity attributes in Active Directory.

Windows Server 2003 R2 domain controllers include the appropriate UNIX-style identity attributes from Internet Engineering Task Force (IETF) Request for Comments (RFC) 2307 (http://go.microsoft.com/fwlink/?LinkId=70027) in the Active Directory schema. They also include Identity Management for UNIX, an optional component, which facilitates managing UNIX-style identities in Active Directory.

Besides retrieving UNIX-style identity data from Active Directory, Client for NFS can also retrieve UNIX-style identity data from a User Name Mapping server. User Name Mapping is an optional component in Windows Server 2003 R2, Server Appliance Kit, and Services for UNIX, and it may already be available on your network. We do not recommend using User Name Mapping for new Client for NFS deployments.

Once Client for NFS is installed and configured, you can access files on the NFS server by mounting those files to your computer using either the UNIX **server:/export** format or the Windows **\\server\share** format. You can also browse shared folders by using the **\\server\share** format in Windows Explorer.

# Using Client for NFS

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

- Starting Client for NFS
- Stopping Client for NFS
- Mounting an NFS shared resource to a drive letter
- Unmounting an NFS shared resource from a drive letter
- Configuring NFS permissions on a file or folder
- Viewing NFS mount options and properties
- Viewing NFS server properties

# Starting Client for NFS

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

**To start Client for NFS from the Windows interface**

1. Open Services for Network File System: click **Start**, point to **Programs or All Programs**, point to **Administrative Tools**, and then click **Services for Network File System (NFS)**.
2. If necessary, connect to the computer that you want to manage.
3. Right-click **Client for NFS**, and then click **Start Service**.

**To start Client for NFS from the command line**

1. Open an elevated privilege command prompt.
2. At a command prompt, type:

   **nfsadmin client** [*ComputerName*] **start**

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer on which you you want to start Client for NFS. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **nfsadmin client /?** |

# Stopping Client for NFS

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

**To stop Client for NFS from the Windows interface**

1. Open Services for Network File System: click **Start**, point to **Programs or All Programs**, point to **Administrative Tools**, and then click **Services for Network File System (NFS)**.
2. If necessary, connect to the computer that you want to manage.
3. Right-click **Client for NFS**, and then click **Stop**.

**To stop Client for NFS from the command line**

1. Open an elevated privilege command prompt.
2. At a command prompt, type:

   **nfsadmin client** [*ComputerName*] **stop**

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer on which you you want to stop Client for NFS. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **nfsadmin client /?** |

# Configuring Client for NFS

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

- Specifying how Client for NFS retrieves UNIX-style identity data
- Selecting the network protocol
- Setting the default mount type
- Specifying default UNIX permissions for new files

# Specifying how Client for NFS retrieves UNIX-style identity data

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

Access to Network File System (NFS) file servers requires UNIX-style user and group identities, which are not the same as Windows user and group identities. To enable users to access NFS shared resources, Client for NFS can retrieve UNIX-style identity data from Active Directory (if the schema includes the appropriate attributes), or from a User Name Mapping server. If Active Directory does not include UNIX-style identity attributes and a User Name Mapping server is not available on your network, then Client for NFS will attempt to access NFS resources anonymously.

NFS servers often limit anonymous access to read-only operations, or simply do not allow anonymous access.

**To specify how Client for NFS retrieves UNIX-style identity data using the Windows interface**

1. Open Services for Network File System: click **Start**, point to **Programs or All Programs**, point to **Administrative Tools**, and then click **Services for Network File System (NFS)**.
2. If necessary, connect to the computer that you want to manage.
3. Right-click **Services for NFS**, and then click **Properties**.
4. Specify how Client for NFS retrieves UNIX-style identity data:
   - To use Active Directory, select the **Active Directory domain name** check box, type the domain name, and then click **Apply**.
   - To use User Name Mapping, select the User Name Mapping check box, type the name of the mapping server, and then click **Apply**.

| **Note** |
| --- |
| Before using User Name Mapping, the computer running Client for NFS must be listed in the .maphosts file on the computer running User Name Mapping. |

**To specify how Client for NFS retrieves UNIX-style identity data using the command line**

1. Open an elevated privilege command prompt.
2. Specify how Client for NFS retrieves UNIX-style identity data:
   - To use Active Directory, at a command prompt, type:

     **nfsadmin mapping** [*ComputerName*] **config adlookup=yes addomain=***DomainName*

   - To use User Name Mapping, at a command prompt, type:

     **nfsadmin mapping** [*ComputerName*] **config maplookup=yes mapsvr=***ServerName*

| Argument | Description |
| --- | --- |
| *DomainName* | The name of the domain controller that you want to use. |
| *ComputerName* | The name of the computer that you want to manage. |
| *ServerName* | The name of the mapping server that you want to use. |

| **Note** |
| --- |
| Before using User Name Mapping, the computer running Client for NFS must be listed in the .maphosts file on the computer running User Name Mapping. |

# Selecting the network protocol

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

**To set the network protocol using the Windows interface**

1. Open Services for Network File System: click **Start**, point to **Programs or All Programs**, point to **Administrative Tools**, and then click **Services for Network File System (NFS)**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **Client for NFS**, and then click **Properties**.
4. Click the **Client Settings** tab.
5. From the **Transport Protocol** list box, select the type of protocol that Client for NFS uses.
6. To save this setting, click **Apply**.

**To set the network protocol using the command line**

1. Open an elevated privilege command prompt.
2. At a command prompt, type:

   **nfsadmin client** [*ComputerName*] **config protocol**={**TCP** | **UDP** | **TCP+UDP**}

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer that you want to manage. |
| **protocol**={**TCP** \| **UDP** \| **TCP+UDP**} | Set to TCP for Transmission Control Protocol (TCP), UDP for User Datagram Protocol (UDP), or TCP+UDP for both. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **nfsadmin client /?** |

# Setting the default mount type

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

**To set the type of mount using the Windows interface**

1. Open Services for Network File System: click **Start**, point to **Programs or All Programs**, point to **Administrative Tools**, and then click **Services for Network File System (NFS)**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **Client for NFS**, and then click **Properties**.
4. Click the **Client Settings** tab.
5. To use soft mounts, select **Use soft mounts** and specify the number of times that Client for NFS will attempt to make a connection in **Number of times to retry**. To use hard mounts, select **Use hard mounts**.
6. Specify the amount of time between connection attempts in **Retry interval**.
7. To save these settings, click **Apply**.

**To set the type of mount using the command line**

1. Open an elevated privilege command prompt.
2. At a command prompt, specify the mount type by typing:

   **nfsadmin client** [*ComputerName*] **config mtype=**{**hard** | **soft**}

3. Specify the soft mount retries by typing:

   **nfsadmin client** [*ComputerName*] **config retry=***n*

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer that you want to manage. |
| **mtype=**{**hard** \| **soft**} | The type of mount. |
| **retry=** *n* | The number of times Client for NFS will attempt to make a connection for a soft mount. This value must be in the range 1–10. The default is 1. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **nfsadmin client /?** |

# Specifying read and write buffers

Applies To: Windows Server 2003 R2

**To set the buffer sizes using the Windows interface**

1. Open Services for Network File System: click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Services for Network File System**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **Client for NFS** and then click **Properties**.
4. Click the **Client Settings** tab.
5. From the **Read buffer size** list box, select the size of the read buffer.
6. From the **Write buffer size** list box, select the size of the write buffer.
7. To save these settings, click **Apply**.

**To set the buffer sizes using the command line**

1. Open the command prompt.
2. At a command prompt, specify the size of the read buffer by typing:

   **nfsadmin client [** *ComputerName* **] config rsize=** *n*
3. Specify the size of the write buffer by typing:

   **nfsadmin client [** *ComputerName* **] config wsize=** *n*

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer you want to manage. |
| **config rsize=** *n* | The size of the read buffer, in kilobytes. This value must be 1, 2, 4, 8, 16, or 32; the default is 32 |
| **config wsize=** *n* | The size of the write buffer, in kilobytes. This value must be 1, 2, 4, 8, 16, or 32; the default is 32. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **nfsadmin client /?** |

# Specifying default UNIX permissions for new files

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

When a file is created on a Network File System (NFS) server, a default set of permissions is applied to the file to control access to the file. Client for NFS uses the following default permissions for newly created files on NFS shared resources:

- User:rwx (read, write, and execute)
- Group:r–x (read and execute)
- Others:r–x (read and execute)

**To specify default file permissions using the Windows interface**

1. Open Services for Network File System: click **Start**, point to **Programs or All Programs**, point to **Administrative Tools**, and then click **Services for Network File System (NFS)**.
2. If necessary, connect to the computer you want to manage.
3. Right-click **Client for NFS**, and then click **Properties**.
4. Click the **File Permissions** tab, and select the permissions to use as defaults.
5. To save these settings, click **Apply**.

**To specify default file permissions using the command line**

1. Open an elevated privilege command prompt.
2. At a command prompt, type the following:

   **nfsadmin client** [*ComputerName*] **fileaccess=***ogw*

| Argument | Description |
|---|---|
| *ComputerName* | The name of the computer that you want to manage. |
| *ogw* | o = Code for owner permissions<br>g = Code for group permissions<br>w = Code for permissions for others |

Codes for permissions are shown in the following table.

| Code | Description |
|---|---|
| **0** | None |
| **1** | Execute |
| **2** | Write |
| **3** | Execute and write |
| **4** | Read |
| **5** | Read and execute |

| | |
|---|---|
| **6** | Read and write |
| **7** | Read, write, and execute |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type **nfsadmin client /?** |

# Adding a LAN to the NFS network

Applies To: Windows Server 2003 R2

**To add a LAN to the NFS network**

1. Open Windows Explorer: click **Start**, point to **Programs or AllPrograms**, point to **Accessories**, and then click **Windows Explorer**.
2. Double-click **My Network Places**, and then double-click **Entire Network**.
3. Right-click **NFS Network**, and then click **Add/Remove NFS LANs**.
4. Click **Add LAN**.
5. Type the required information, and then click **OK**.

| **Note** |
| --- |
| You must be a member of the Administrators group to add a local area network (LAN) to the Network File System (NFS) network.<br><br>There is no command-line method for this procedure.<br><br>If necessary, contact your UNIX network administrator for the information needed to complete this procedure.<br><br>When you open NFS Network, it might take several seconds for the new LAN to appear, depending on the broadcast network configuration and the number of computers in the broadcast.<br><br>Do not attempt to create a LAN with the name Default LAN or Favorite LAN. |

# Deleting a LAN from the NFS network

Applies To: Windows Server 2003 R2

**To delete a LAN from the NFS network**

1. Open Windows Explorer: click **Start**, point to **Programs or AllPrograms**, point to **Accessories**, and then click **Windows Explorer**.
2. Double-click **My Network Places**, and then double-click **Entire Network**.
3. Right-click **NFS Network**, and then click **Add/Remove NFS LANs**.
4. In the list of local area networks (LANs), click the one you want to delete, and then click **Delete**.

| **Note** |
| --- |
| You must be a member of the Administrators group to delete a LAN from the Network File System (NFS) network.<br><br>There is no command-line method for this procedure. |

# Adding a server to the Favorite LAN

Applies To: Windows Server 2003 R2

**To add a server to the favorite LAN**

1. Open Windows Explorer: click **Start**, point to **Programs or AllPrograms**, point to **Accessories**, and then click **Windows Explorer**.
2. Double-click **My Network Places**, and then double-click **Entire Network**.
3. Double-click **NFS Network**.
4. Right-click **Favorite LAN**, and then click **Add/Remove Hosts**.
5. Click **Add Host**.
6. Type the name of the host or the Internet Protocol (IP) address of the server to access.

| **Note** |
| --- |
| You must be a member of the Administrators group to delete a local area network (LAN) from the Network File System (NFS) network.<br><br>There is no command-line method for this procedure.<br><br>When you double-click **NFS Network**, it might take several seconds for the LAN to appear, depending on the broadcast network configuration and the number of computers in the broadcast. |

# Deleting a server from the Favorite LAN

Applies To: Windows Server 2003 R2

**To delete a server from the Favorite LAN**

1. Open Windows Explorer: click **Start**, point to **Programs or AllPrograms**, point to **Accessories**, and then click **Windows Explorer**.
2. Double-click **My Network Places**, and then double-click **Entire Network**.
3. Double-click **NFS Network**.
4. Right-click **Favorite LAN**, and then click **Add/Remove Hosts**.
5. Click the name of the host you want to delete, and then click **Delete**.

| **Note** |
| --- |
| You must be a member of the Administrators group to delete a local area network (LAN) from the Network File System (NFS) network.<br><br>There is no command-line method for this procedure.<br><br>When you double-click **NFS Network**, it might take several seconds for the LAN to appear, depending on the broadcast network configuration and the number of computers in the broadcast. |

# Opening an NFS file or folder

Applies To: Windows Server 2003 R2

**To browse the NFS network**

1. Open Windows Explorer: click **Start**, point to **Programs or AllPrograms**, point to **Accessories**, and then click **Windows Explorer**.
2. Double-click **NFS Network**.
3. Double-click the local area network (LAN) whose servers you want to view.
4. Double-click the server whose shared directories you want to view.
5. Double-click the shared directory containing the directory or file you want to open.
6. Double-click the directory or file you want to open.

| **Note** |
| --- |
| When you double-click **NFS Network**, it might take several seconds for the LAN to appear, depending on the broadcast network configuration and the number of computers in the broadcast. |

# Browsing the NFS network

Applies To: Windows Server 2003 R2

**To browse the NFS network**

1. Open Windows Explorer: click **Start**, point to **Programs or AllPrograms**, point to **Accessories**, and then click **Windows Explorer**.
2. Double-click **My Network Places**, and then double-click **Entire Network**.
3. Double-click **NFS Network**.
4. Double-click the local area network (LAN) whose servers you want to view.
5. Double-click the server whose shared directories you want to view.
6. Double-click the shared directory containing the directory or file you want to open.
7. Double-click the directory or file you want to open.

| **Note** |
| --- |
| When you double-click **NFS Network**, it might take several seconds for the LAN to appear, depending on the broadcast network configuration and the number of computers in the broadcast. |

# Mounting an NFS shared resource to a drive letter

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

**To mount an NFS shared resource to a drive letter using the command line**

1. Open a command prompt (this does not need to be an elevated command prompt).
2. At a command prompt, type the following:

   **mount** [**–o** *Options*] *ComputerName:/ShareName* {*DeviceName* | *}

   or

   **mount** [**–o** *Options*] *ComputerName**ShareName* {*DeviceName* | *}

| Argument | Description |
|---|---|
| **–o rsize=** *n* | The read buffer size, in kilobytes. Acceptable values are 1, 2, 4, 8, 16, and 32. The default is 32 kilobytes (KB). |
| **–o wsize=** *n* | The write buffer size, in kilobytes. Acceptable values are 1, 2, 4, 8, 16, and 32. The default is 32 KB. |
| **–o timeout=** *n* | The time-out for a remote procedure call (RPC), in seconds. Acceptable values are 0.8, 0.9, and any integer in the range 1-60. The default is 0.8. |
| **–o retry=** *n* | The number of retries for a soft mount. Acceptable values are integers in the range 1-10. The default is 1. |
| **–o mtype=**{**soft** \| **hard**} | Soft or hard mount. Regardless of the mount type, the mount will return if it cannot immediately mount the shared resource. However, once the shared resource has been successfully mounted, if the mount type is a hard mount and the Network File System (NFS) server becomes unavailable, Client for NFS will retry accessing the shared resource until the NFS server is once again available. As a result, Windows applications that are trying to access the shared resource will appear to stop responding. |
| **–o anon** | Mounts as anonymous user. |
| **–o nolock** | Disables locking. This option might improve performance if you only need to read files. |

| | |
|---|---|
| **-o lang=**{**euc-jp** \| **euc-tw** \| **euc-kr** \| **shift-jis** \| **big5** \| **ksc5601** \| **gb2312-80** \| **ansi**} | Specifies the default encoding used for file and directory names and, if used, must be set to one of the following:<br>• ansi<br>• big5 (Chinese)<br>• euc-jp (Japanese)<br>• euc-kr (Korean)<br>• euc-tw (Chinese)<br>• gb2312-80 (Simplified Chinese)<br>• ksc5601 (Korean)<br>• shift-jis (Japanese)<br><br>If this option is set to ANSI on systems configured for non-English locales, the encoding scheme is set to the default encoding scheme for the locale. The following are the default encoding schemes for the indicated locales:<br>Japanese: SHIFT-JIS<br>Korean: KS_C_5601-1987<br>Simplified Chinese: GB2312-80<br>Traditional Chinese: BIG5 |
| **-o fileaccess=** *mode* | Specifies the default permission mode of new files that are created on the NFS shared resource. Specify the mode as a three-digit number in the form ogw, where o, g, and w are each a digit that represents the access granted to the file owner, group, and the world. The digits must be in the range 0–7 with the following meaning:<br>• 0: No access<br>• 1: x (execute access)<br>• 2: w (write access)<br>• 3: wx (write and execute access)<br>• 4: r (read access)<br>• 5: rx (read and execute access)<br>• 6: rw (read and write access)<br>• 7: rwx (read, write, and execute access) |
| **-o casesensitive** | Forces case-sensitive file lookup (similar to that of UNIX-based NFS clients). |
| *ComputerName* | The name of the server with the shared resource to mount. |

| | |
|---|---|
| *ShareName* | The name of the shared directory to mount. |
| *DeviceName* \| ***** | The drive letter to assign to the mounted shared resource. The asterisk (*) means to use the next available letter. |

**Note**

To view the complete syntax for this command, at a command prompt, type: **mount /?**

When Mounting an NFS shared resource to a drive letter, we recommend the first format shown (*ComputerName*:/*ShareName*).

You can also use the **net use** command to mount an NFS shared resource to a drive letter. For more information about using the **net use** command, see Windows Help or, at a command prompt, type: **net use /?**

# Unmounting an NFS shared resource from a drive letter

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

**To unmount an NFS shared resource from a drive letter using the command line**

1. Open a command prompt (this does not need to be an elevated command prompt).
2. At a command prompt, type the following:

   **umount** [**–f**] {**–a** | *Drive*}

| Argument | Description |
|---|---|
| **–f** | Forces the unmount of a Network File System (NFS) network drive. |
| **–a** | Unmounts all NFS network drives. |
| *Drive* | The drive letter that is mapped to an NFS shared resource. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type: **umount /?** |

# Configuring NFS permissions on a file or folder

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

**To configure NFS permissions using Windows Explorer**

1. Open Windows Explorer: click **Start**, point to **Programs or AllPrograms**, point to **Accessories**, and then click **Windows Explorer**.
2. Right-click the name of the file or directory.
3. Click **Properties**, and then click the **NFS Attributes** tab.
4. In **File attributes (mode)**, select or clear the check boxes corresponding to the mode bits that you want to set or clear, click **Apply**, and then click **OK**. To close the dialog box without making any changes, click **Cancel**.

| **Note** |
| --- |
| Only the owner of a file or a user with appropriate permissions can change the mode of a file.<br><br>There is no command-line method for this procedure. |

# Viewing NFS mount options and properties

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

**To view NFS mount options using Windows Explorer**

1. Open Windows Explorer: click **Start**, point to **Programs or AllPrograms**, point to **Accessories**, and then click **Windows Explorer**.
2. Right-click the name of the file or directory, right-click the drive that is assigned to a Network File System (NFS) mount, and then click **Properties**.
3. To view the NFS mount options for the drive, click **NFS Mount Options**.
4. To view the NFS properties for the mounted directory, click **NFS Attributes**.

| **Note** |
| --- |
| If you are logged on with an account that maps to a UNIX account on the NFS server with appropriate administrative credentials, you can change the UNIX file-mode permissions of the mounted directory when viewing the NFS properties. |

**To view NFS mount options using the command line**

1. Open a command prompt (this does not need to be an elevated command prompt).
2. At a command prompt, type the following:

   **mount**

| **Note** |
| --- |
| The mount command without arguments displays all mounted volumes and their options.<br><br>To view the complete syntax for this command, at a command prompt, type: **mount /?** |

# Viewing NFS server properties

Updated: July 6, 2012

Applies To: Windows Server 2003 R2

**To view NFS server properties using the command line**

1. Open a command prompt (this does not need to be an elevated command prompt).
2. At a command prompt, type the following:

   **showmount -e***Server*

| Argument | Description |
|---|---|
| *Server* | The name of the computer for which you want to view properties. |

| Note |
|---|
| To view the complete syntax for this command, at a command prompt, type: **showmount /?** |

# Microsoft Services for NFS troubleshooting

Applies To: Windows Server 2003 R2

**General Issues**
**I need to modify ports used by Microsoft Services for NFS.**
**Cause**
Port conflicts or security requirements necessitate port changes.

**Solution**
Log on to servers running Microsoft Services for Network File System (NFS) and change the following ports from the Registry Editor:

**NLM and NSM ports**
To modify the NLM and NSM ports, change the following registry settings:

HKLM\SYSTEM\CurrentControlSet\Services\NfsSvr\NlmNsm

DWORD "NlmPort"

DWORD "NsmPort"

**Mount and NFS ports**
To modify the mount protocol port, change the following registry setting:

HKLM\SYSTEM\CurrentControlSet\Services\NfsSvr\Parameters

DWORD "MountPort"

DWORD "NfsPort

**Base port**
The base port specifies the first of four sequential ports used by the mapping server. To modify the base port and the subsequent mapping server ports, change the following registry setting:

HKLM\SYSTEM\CurrentControlSet\Services\Mapsvc\CurrentVersion

DWORD "BasePort"

**Microsoft Services for NFS component troubleshooting**
Troubleshooting Server for NFS

Troubleshooting Client for NFS

Troubleshooting User Name Mapping

# Troubleshooting Server for NFS

Applies To: Windows Server 2003 R2

What problem are you having?

**Issues**
**Despite appearing to have appropriate permissions, the user cannot access folder or file.**
**Cause**
The user belongs to one or more groups that are not mapped consistently, Active Directory is not accessible, or User Name Mapping is not running.

**Solution**
To ensure proper file access, ensure that Windows and UNIX groups that are mapped to each other, in either Active Directory or User Name Mapping, contain the same users, and that the members of the Windows and UNIX groups are properly mapped to each other. Also, ensure that Active Directory is accessible or the User Name Mapping service is running on the designated server.

**Authenticated users cannot access Network File System (NFS) resources.**
**Cause**
Active Directory Lookup or User Name Mapping is not properly configured to work with this computer.

**Solution**
If you are using Active Directory Lookup, ensure that Microsoft Services for Network File System (NFS) is pointing to the proper Active Directory domain.

If you are using User Name Mapping, ensure that the .maphosts file on the computer running User Name Mapping specifies the names or Internet Protocol (IP) addresses of computers that can map user accounts by using User Name Mapping. For more information, see Securing access to the User Name Mapping server. If users cannot access NFS resources intermittently and configuring the .maphosts file does not solve the problem, it might be that too many client computers are trying to access User Name Mapping simultaneously. See "Error message: Unable to perform the requested operation as the mapping service cannot be contacted" in Troubleshooting User Name Mapping.

**Users, including properly mapped users, cannot change the current directory to a shared directory or create files in the directory, even though anonymous access to the directory is allowed.**
**Cause**
Either the NFS client does not support NFS version 3, or Server for NFS is not configured to support NFS 3. Also, the discretionary access control list (DACL) protecting the shared directory does not have an entry for Everyone, and so the access mode bit for Other is reported as 0. Because NFS 2 clients rely on directory mode settings rather than performing a separate access check for the shared directory, the client incorrectly fails the attempted access.

**Solution**
Do one of the following:

- To the DACL protecting the directory being shared, add an entry that grants Everyone read or read/write access, as appropriate.
- Ensure that the NFS client supports NFS 3, and enable NFS 3 support by Server for NFS.
- The shared directory is not accessible even though it is listed as available.

**Cause**
The directory was moved after it was shared.

**Solution**
Return the directory to its original location, or stop sharing the directory and then reshare it.

**All files created on Server for NFS are owned by Anonymous.**
**Cause**
Authentication is not configured properly.

**Solution**
Ensure that mappings are set up correctly in Active Directory or in User Name Mapping and that Server for NFS is correctly configured to use either Active Directory Lookup or User Name Mapping. Also, be sure all Windows Server 2000 domain

controllers are properly configured. For more information, see Server for NFS Authentication

**Files created by a new user are owned by Anonymous.**
**Cause**
If you are using User Name Mapping, then User Name Mapping and Server for NFS have not yet refreshed data from the Network Information Service (NIS) server. Typically, User Name Mapping refreshes data from NIS once an hour, and Server for NFS refreshes data from User Name Mapping once an hour.

**Solution**
The new user should wait at least two hours before attempting to access or create files on Server for NFS, or the administrator of the computer running User Name Mapping can refresh the mapping database.

**A user cannot write to a file.**
**Cause**
File permissions or attributes do not allow write access to the file or its directory.

**Solution**
If the directory is owned by the Administrators group, make an individual user account the owner of the directory. Ensure that the user's UNIX account is mapped to a valid Windows account and that the NTFS file system permissions of the directory and file allow write access to the Windows user account. Ensure that the read-only attribute is not set on the file or the directory.

**Users of Japanese UNIX systems cannot view file names in Japanese.**
**Cause**
Extended UNIX character (EUC) set is not enabled.

**Solution**
Configure the share to use the appropriate character encoding.

**Server for NFS configuration settings are not replicated across nodes in a server cluster.**
**Cause**
The Cluster service is not running, was not running when Server for NFS started, or failed after Server for NFS started.

**Solution**
Take all NFS shares owned by the node offline, or move the cluster groups containing NFS shares to another node. Stop Server for NFS, start the cluster service if needed, and then restart Server for NFS. Return the NFS shares online or move the cluster groups back to the node.

**Server for NFS fails to stop on a server cluster.**
**Cause**
This is by design. When an NFS share is online on a cluster node, the cluster service automatically restarts Server for NFS to keep the shares online.

**Solution**
Before stopping Server for NFS on a server cluster node, take all NFS shares owned by the node offline, or move the cluster groups containing NFS shares to another node.

**An NFS network share on a server cluster node fails to come online.**
**Cause**
An NFS share on that node with the same alias or path already exists on the node.

**Solution**
Make sure that the shared path and alias are unique across the cluster. Also, avoid having nonclustered NFS shares on a server cluster node.

**Cause**
The user who installed the cluster service does not have read permission on the directory that is shared, so the path cannot be validated.

**Solution**
Grant read access to the directory for the user who installed the cluster service.

**Cause**
The disk resource containing the directory being shared is offline, so the cluster service cannot verify the path of the share.

**Solution**
Bring the disk resource online, and then bring the NFS share online. We recommend that the NFS share resource be made dependent on the disk resource that contains the shared folder.

**Cause**

The disk is inaccessible due to hardware error.

**Solution**
Take the NFS shares on the disk offline. Ensure that the disk is accessible from all cluster nodes, and then bring the NFS shares online.

**Cause**
There are a large number of subdirectories under a subdirectories-only share, and the resource times out before all the shares are created when the resource is coming online.

**Solution**
Increase the time-out interval for the resource.

**Creating or modifying an NFS share fails with the error: The share path specified does not exist, or you are trying to modify the properties of an online share.**
**Cause**
The specified directory does not exist.

**Solution**
Make sure that the directory exists and that the path is correct.

**Cause**
The share is online.

**Solution**
Take the share offline, make the required modifications, and then bring the share online.

**Cause**
The disk resource containing the shared directory is offline, so the cluster service cannot verify the path of the share.

**Solution**
Bring the disk online, make the necessary modifications to the NFS share resource, and then bring the NFS share online.

**User Name Mapping is properly configured, but users are not being mapped correctly.**
**Cause**
Server for NFS is not set to use the correct User Name Mapping server.

**Solution**
Ensure that the specified User Name Mapping server is valid. If the User Name Mapping server is on a server cluster, ensure that the following conditions exist:

- User Name Mapping is installed on all cluster nodes
- User Name Mapping data is being replicated to all nodes in the cluster
- Server for NFS is using the name of a Network Name cluster resource as the User Name Mapping server, not localhost or the name of any of the cluster nodes

**Cause**
Server for NFS has not received updated maps from the mapping server. If Server for NFS and User Name Mapping are on different computers, this occurs once every 30 minutes.

**Solution**
Force Server for NFS to refresh the maps by doing one of the following:

- In Microsoft Services for Network File System, click **Server for NFS**, and then click **Apply**.
- Use the **nfsadmin server** command to execute an operation, such as by setting a value to its current value.
- Restart Server for NFS.

**Cause**
Account changes on the Windows domain controller or the Network Information Service (NIS) server have not been received by User Name Mapping.

**Solution**
Force Server for NFS to refresh the maps by doing one of the following:

- In Microsoft Services for Network File System, click **Server for NFS**, and then click **Apply**.
- Use the **nfsadmin server** command to execute an operation, such as by setting a value to its current value.
- Restart Server for NFS.

**Cause**
Local accounts on a cluster node were mapped to UNIX user accounts. Local accounts are not valid on all nodes in a cluster.

**Solution**
Ensure that all Windows accounts mapped to UNIX accounts on User Name Mapping running on a cluster are Windows domain accounts.

**Cause**
The passwd and group files are not at the same location on all nodes of the cluster, or on a network drive.

**Solution**
Ensure that the passwd and group files are identical and at identical locations on local disks of all nodes.

**Cause**
The Server for NFS server is not on the list of permitted User Name Mapping server clients.

**Solution**
Ensure that the .maphosts files on all User Name Mapping server cluster nodes are identical to permit the node running Server for NFS to obtain maps from the User Name Mapping server.

**Cause**
The server running User Name Mapping has failed.

**Solution**
Correct the cause of failure and then restart User Name Mapping on the server.

**Cause**
A Windows account mapped to a UNIX account is disabled or no longer exists.

**Solution**
If the Windows account exists, but is disabled, enable it. If the account does not exist, create a new account and, if necessary, recreate the corresponding advanced map.

**Cause**
A Windows user account has not been granted the credentials to log on to the network.

**Solution**
Grant the required credentials to the Windows user account, and then force Server for NFS to refresh the maps by doing one of the following:

- In Microsoft Services for Network File System, click **Server for NFS**, and then click **Apply**.
- Use the **nfsadmin server** command to execute an operation, such as by setting a value to its current value.
- Restart Server for NFS.

**Cause**
Windows and UNIX groups mapped to each other do not contain the same members.

**Solution**
Ensure that all Windows users in a group are mapped to UNIX users in the corresponding UNIX group, and that all UNIX users in a group are mapped to users in the corresponding Windows group.

**Cause**
User Name Mapping settings are not properly replicated on all nodes in a server cluster.

**Solution**
Ensure that User Name Mapping on a server cluster is configured properly to allow replication on all nodes.

**A group containing an NFS share fails to come online on a particular cluster server node.**
**Cause**
Server for NFS is not installed on the node.

**Solution**
Install Server for NFS on the node.

**Cause**
The node is not configured as the preferred owner of the group.

**Solution**
Configure the group's properties to make the node the preferred owner of the group.

**Cause**
One of the resources in the group does not list the node as a possible owner even though the group specifies the node as a preferred owner.

**Solution**
Configure the resource's properties to specify the node as a possible owner.

**The showmount –e command for a virtual server lists all shares on the node rather than those in the same group as the virtual server.**
**Cause**
This is by design. There is only one instance of Server for NFS running on a node that will enumerate all shares on that node. It does not distinguish between shares in different cluster groups.

**Solution**
Maintain different groups on different nodes.

**The root user is not granted proper permissions.**
**Cause**
The share does not have root access enabled.

**Solution**
Right-click the shared directory, click **Properties**, click **NFS Sharing**, click **Permissions**, and then click **Allow root access**.

**Cause**
The computer from which the root user is accessing the share is not permitted root access.

**Solution**
Right-click the shared directory, click **Properties**, click **Permissions**, and then do one of the following:

- Grant root access to ALL MACHINES.
- Grant root access to a client group containing the computer.
- Grant root access to the computer itself.

**Cause**
The root user does not have read/write permission.

**Solution**
Grant the appropriate permissions to the Windows user mapped to the root user. Right-click the shared directory, click **Properties**, click **Permissions**, and then click **Root access allowed**.

**Cause**
The root user account is not properly mapped to a Windows user account.

**Solution**
Map the root user to a Windows account in the Administrators or Domain Admins group, and map the root user's group to the same Windows group.

**Cause**
Server for NFS has not received updated maps from User Name Mapping.

**Solution**
Force Server for NFS to refresh the maps by doing one of the following:

- In Microsoft Services for Network File System, click **Server for NFS**, and then click **Apply**.
- Use the **nfsadmin server** command to execute an operation, such as by setting a value to its current value.
- Restart Server for NFS.

**Cause**
The root user's user identifier (UID) is not 0. Server for NFS grants root access only to a UNIX user with a UID of 0.

**Solution**
Change the root user's UID to 0.

**Anonymous access fails on Windows Server 2003 operating systems.**
**Cause**
Local security policy is not set to enable Everyone permissions to apply to anonymous users (the default).

**Solution**
Use the Local Security Policy manager to enable **Network Access: Let Everyone permissions to apply to anonymous users** in Security Options in Local Policies.

# Troubleshooting Client for NFS

Applies To: Windows Server 2003 R2

What problem are you having?

**Issues**
**I need Client for NFS to only use "privileged" ports.**
**Cause**
Some Network File System (NFS) servers have a concept of "privileged" ports (meaning ports numbered lower than 1024), and will not accept client connections from ports above that range.

**Solution**
Log onto computers running Client for NFS and set the following registry key to 1 and restart Client for NFS:

HKLM\Software\Microsoft\Client for NFS\CurrentVersion\default

DWORD "UseReservedPorts"

**An error occurred while trying to communicate with the Client for NFS service.**
**Cause**
The Client for NFS service is not started, cannot contact Active Directory or the User Name Mapping server, or is running with credentials that are mapped incorrectly.

**Solution**
In Microsoft Services for Network File System, you can ensure that the service is started by right-clicking **Client for NFS**, and then clicking **Start**. In Microsoft Services for Network File System, ensure that the name of the correct Active Directory domain or User Name Mapping server is specified. Check with the administrator of the Active Directory or the User Name Mapping server to ensure that your Windows user account is properly mapped to your UNIX user account.

**System error 1722 has occurred. The remote procedure call (RPC) server is unavailable.**
**Cause**
The Client for NFS service is not started.

**Solution**
In Microsoft Services for Network File System, right-click **Client for NFS**, and then click **Start**.

**An attempt to mount a shared directory produces a network error 67, the network name was not found.**
**Cause**
The directory is not shared, or the server is unable to resolve the client name.

**Solution**
Use **showmount –e***server* to display the names of shared directories on the server. If this fails with a remote procedure call (RPC) time-out, contact the administrator of the Network File System (NFS) server to ensure that the NFS and portmap services are started on the server. Ensure that the Internet Protocol (IP) address of the client is specified in either the server /etc/hosts file, or in the DNS database, as appropriate.

**I received the message RPC: Timed out or RPC: Port mapper failure – RPC: Timed out.**
**Cause**
Either the port mapper or Network File System (NFS) server daemons are not running on the server, or Client for NFS performance settings need to be adjusted.

**Solution**
Ensure that the services are started. If the port mapper and NFS server daemons are running on the server, in Microsoft Services for Network File System, click **Client for NFS**, and then increase the maximum number of retries and the interval between retries.

**A file I created on a mounted Network File System (NFS) drive is shown as having been created by nobody:nogroup or by –2:–1, or the user identifier (UID) is a very large number (2**32-2).**
**Cause**
Your Windows user name is not properly mapped in Active Directory or User Name Mapping.

**Solution**
Use the server running User Name Mapping for your Windows user account that is not properly mapped. In Microsoft Services for NFS, check to ensure that the name of the correct Active Directory domain or User Name Mapping server is specified. Check with the administrator of the Active Directory or User Name Mapping server to ensure that your Windows user account

is properly mapped to your UNIX user account.

**When I attempt to map a network drive, I am asked for a user name and password, and then the attempt to map the drive fails even though I supply valid credentials.**
**Cause**
Either an Active Directory domain or a User Name Mapping server has not been designated for use by Microsoft Services for NFS.

**Solution**
Specify the correct Active Directory domain or User Name Mapping server. For more information, see Specifying how Client for NFS retrieves UNIX-style identity data.

**I cannot access files on a mapped network drive.**
**Cause**
Neither an Active Directory domain nor a User Name Mapping server has been designated for use by Microsoft Services for NFS.

**Solution**
Specify the correct Active Directory domain or User Name Mapping server. For more information, see Specifying how Client for NFS retrieves UNIX-style identity data.

**I cannot mount a shared root directory (/) on a UNIX computer.**
**Cause**
When a root directory (/) on a UNIX computer is shared, Client for NFS cannot mount it by using the standard path syntax (net use * \\server\ or net use server:/).

**Solution**
To mount the root directory, enter this command:

**net use * ** *server* **\!**

The share name must be an exclamation mark (!).

**MS-DOS-based or earlier Windows-based applications cannot access files on NFS, or a message appears indicating that a 16-bit application cannot be run.**
**Cause**
By default, Client for NFS does not convert UNIX long file names to the MS-DOS–style 8.3 format.

**Solution**
Use Registry Editor (Regedit.exe) to ensure that the following entry is set to a value of 1 (the default):

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Client for NFS\CurrentVersion\Users\Default\Defaults\8.3Format
```

This causes Client for NFS to convert all UNIX file names to the 8.3 format required by MS-DOS-based applications and by applications designed to run with Windows 3.x and earlier. Setting this entry to a value of 0 improves Client for NFS performance somewhat because Client for NFS does not convert file names.

| ⚠Caution |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

**I received a delayed write error message.**
**Cause**
Either the NFS server is not responding or the Client for NFS performance options are not properly adjusted.

**Solution**
Use the **showmount –e***server* command to determine whether the NFS server is running properly.

**Attempting to mount with the net use command produces the error message: 1788: The trust relationship between the primary domain and the trusted domain failed.**
**Cause**
You are attempting to access a computer in an untrusted domain, and either Client for NFS has not started on your computer or the share is not available from the NFS server.

**Solution**
In Microsoft Services for Network File System, right-click **Client for NFS**, and then click **Start**. Use **showmount –e***server* to display the names of shared directories on the server. If this fails with an RPC time-out, contact the administrator of the NFS

server to ensure that the NFS and portmap services are started on the server and that the shared directory is available.

**Even after changing the default permissions for new files, new files on a mount are still created with the previous permissions.**
**Cause**
This is by design. New default permissions are only applied to new mounts.

**Solution**
Unmount and then remount the shared directory.

**After restarting the computer, the mount parameters of a persistent mount are changed.**
**Cause**
You used the **net use** command to mount the directory.

**Solution**
Use the **mount** utility to mount the directory.

**Authenticated users cannot access NFS resources, or all NFS shares are accessed as Anonymous.**
**Cause**
User Name Mapping is not properly configured to work with this computer.

**Solution**
Ensure that the .maphosts file on the computer running User Name Mapping specifies the names or Internet Protocol (IP) addresses of computers that can map user accounts by using User Name Mapping. For more information, see Securing access to the User Name Mapping server. If users cannot access NFS resources intermittently and configuring the .maphosts file does not solve the problem, it could be that too many client computers are trying to access User Name Mapping simultaneously. See "Error message: Unable to perform the requested operation as the mapping service cannot be contacted" in Troubleshooting User Name Mapping.

# Troubleshooting User Name Mapping

Applies To: Windows Server 2003 R2

What problem are you having?

**Issues**
**I cannot download Windows users from a Windows domain.**
**Cause**
You do not have adequate credentials, or the computer running User Name Mapping does not belong to a domain trusted by the Windows user domain.

**Solution**
Log on as a user in a domain trusted by the domain to which the computer running User Name Mapping belongs and that belongs to the Administrators group on the computer running User Name Mapping.

**I cannot download Windows users from an Active Directory domain.**
**Cause**
When installing the Active Directory domain controller, you chose the **Permissions compatible with Windows 2000 Server** option.

**Solution**
Do one of the following:

- If the computer running User Name Mapping is a member of the domain, add the computer to the security group called Pre-Windows 2000 Compatible Access.

- If the computer running User Name Mapping does not belong to the domain (that is, it belongs to a trusted domain), add the special group Everyone to the Pre-Windows  000 Compatible Access security group of the Active Directory domain.

You must restart the domain controller after adding the computer or group to the security group.

If, for some reason, you cannot add Everyone or the computer that is running User Name Mapping to the Pre-Windows 2000 Compatible Access security group, you can enable User Name Mapping to enumerate users in the domain by running the User Name Mapping service with an account that belongs to the Domain Admins group. This method is less secure than the other two solutions, however, and should be avoided if possible.

**I cannot download UNIX users from a Network Information Service (NIS) server.**
**Cause**
You have specified only the domain name, and either the NIS server is on a different subnet, or the NIS server is down.

**Solution**
Ensure that the NIS server is running. Ensure that the computer running User Name Mapping and the NIS server are on the same subnet, or specify the Internet Protocol (IP) address of the NIS server.

**Users of a particular Windows-based computer cannot access Network File System (NFS) shares.**
**Cause**
The Windows-based computer is not granted access in the .maphosts file to User Name Mapping.

**Solution**
Add the Windows-based computer to the .maphosts file. Make sure it does not appear after any – entry.

**Mapped users cannot access Network File System (NFS) resources.**
**Cause**
The .maphosts file has not been modified to specify trusted computers.

**Solution**
Ensure that the .maphosts file specifies the names or Internet Protocol (IP) addresses of computers that can map user accounts by using User Name Mapping. For more information, see Securing access to the User Name Mapping server.

If users still cannot access NFS resources, see "Error message: Unable to perform the requested operation as the mapping service cannot be contacted" later in this topic.

**Error message: Unable to perform the requested operation as the mapping service cannot be contacted.**
**Cause**

The maximum number of concurrent client connections has been exceeded.

**Solution**
If this message appears frequently when you are attempting to administer User Name Mapping, or if properly mapped users can only access NFS resources intermittently and other troubleshooting steps have failed, you can increase the maximum number of concurrent client connections that are allowed by creating a DWORD registry value named RpcMaxConcurrentConnectionsPerIp in the following location:

**HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft \MSNFS**

The value must be between 16 (the default) and 64.

| **Caution** |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

If the problem persists, or if NFS access performance noticeably degrades, consider establishing a User Name Mapping server pool. For more information, see Creating a User Name Mapping pool.

**If you click Reload immediately after creating and saving a map, the new map is not shown.**
**Cause**
Maps are saved to the registry, which notifies User Name Mapping of the new map. Because this process can take a minute or more, if you click **Reload** during that time, you will not see current data.

**Solution**
Wait at least a minute, and then click **Reload** again.

**A user is unable to access NFS resources after being added or changed.**
**Cause**
Maps have not been refreshed with new or changed data in the Windows or UNIX user databases.

**Solution**
After adding or changing a user in the Windows domain, the Network Information Service (NIS) domain, or the password and group files, update User Name Mapping. On the **Configuration** tab, click **Synchronize Now**, and then click **Apply**.

**User Name Mapping configuration settings are not replicated across nodes in a server cluster.**
**Cause**
The Cluster service is not running, was not running when User Name Mapping started, or failed after User Name Mapping started.

**Solution**
Stop User Name Mapping, start the Cluster service if needed, and then restart User Name Mapping.

If replication consistently fails after the computer restarts, it might be because User Name Mapping is starting before the Cluster service completes its startup procedures. In this case, use the Services snap-in to make User Name Mapping dependent on the Cluster service.

**Restoring password and group files on a server cluster node does not recreate the files on other nodes.**
**Cause**
User Name Mapping restores password and group files on one node only.

**Solution**
Copy the password and group files to all other cluster server nodes.

**Maps are not updated to reflect changes in Windows user and group accounts or in NIS or password and group files.**
**Cause**
The User Name Mapping server has not received the changes. By default, User Name Mapping refreshes its maps once every 24 hours.

**Solution**
In Microsoft Services for Network File System, click **User Name Mapping**, click **Map Maintenance**, and then click **Synchronize Now**.

# Microsoft Services for NFS command-line tools

Applies To: Windows Server 2003 R2

The following command-line tools are available for Microsoft Services for Network File System (NFS):

- mapadmin
- mount
- nfsadmin
- nfsshare
- nfsstat
- rpcinfo
- showmount
- umount

For more information about a specific command, type the command name followed by **/?** at the command prompt.

# mapadmin

Applies To: Windows Server 2003 R2

You can use **Mapadmin** to manage User Name Mapping for Microsoft Services for Network File System.

**Syntax**

**mapadmin** [*computer*] [-u *user* [-p *password*]]

**mapadmin** [*computer*] [-u *user* [-p *password*]] {start | stop}

**mapadmin** [*computer*] [-u *user* [-p *password*]] **config** *option*[...]

**mapadmin** [*computer*] [-u *user* [-p *password*]] **add -wu** *WindowsUser* **-uu** *UNIXUser* [**-setprimary**]

**mapadmin** [*computer*] [-u *user* [-p *password*]] **add -wg** *WindowsGroup* **-ug** *UNIXGroup* [**-setprimary**]

**mapadmin** [*computer*] [-u *user* [-p *password*]] **setprimary -wu** *WindowsUser* [-uu *UNIXUser*]

**mapadmin** [*computer*] [-u *user* [-p *password*]] **setprimary -wg** *WindowsGroup* [-ug *UNIXGroup*]

**mapadmin** [*computer*] [-u *user* [-p *password*]] **delete** *option*[...]

**mapadmin** [*computer*] [-u *user* [-p *password*]] **list** *option*[...]

**mapadmin** [*computer*] [-u *user* [-p *password*]] **backup** *filename*

**mapadmin** [*computer*] [-u *user* [-p *password*]] **restore** *filename*

**mapadmin** [*computer*] [-u *user* [-p *password*]] **adddomainmap -d** *WindowsDomain* {-y *NISDomain* | -f *path*}

**mapadmin** [*computer*] [-u *user* [-p *password*]] **removedomainmap -d** *WindowsDomain* **-y** *NISDomain*

**mapadmin** [*computer*] [-u *user* [-p *password*]] **removedomainmap -all**

**mapadmin** [*computer*] [-u *user* [-p *password*]] **listdomainmaps**

**Description**

The **mapadmin** command-line utility administers User Name Mapping on the local or remote computer running Microsoft Services for Network File System. If you are logged on with an account that does not have administrative credentials, you can specify a user name and password of an account that does.

In addition to specific command arguments, **mapadmin** accepts the following arguments and options:

***computer***
Specifies the remote computer running the User Name Mapping service that you want to administer. You can specify the computer using a Windows Internet Name Service (WINS) name or a Domain Name System (DNS) name, or by Internet Protocol (IP) address.

**-u *user***
Specifies the user name of the user whose credentials are to be used. It might be necessary to add the domain name to the user name in the form *domain******username*.

**-p *password***
Specifies the password of the user. If you specify the **-u** option but omit the **-p** option, you are prompted for the user's password.

The specific action that **mapadmin** performs depends on the command argument you specify:

**start**
Starts the User Name Mapping service.

**stop**
Stops the User Name Mapping service.

**config**
Specifies general settings for User Name Mapping. The following options are available with this command argument:

**-r** *dddd:hh:mm*

Specifies the refresh interval for updating from the Windows and NIS databases in days, hours, and minutes. The minimum interval is 5 minutes.

**-i** *yes* | *no*

Turns simple mapping on (**yes**) or off (**no**). By default, simple mapping is on.

**add**

Creates a new mapping for a user or group. The following options are available with this command argument:

| Term | Definition |
|---|---|
| **-wu** *name* | Specifies the name of the Windows user for which a new mapping is being created. |
| **-uu** *name* | Specifies the name of the UNIX user for which a new mapping is being created. |
| **-wg** *group* | Specifies the name of the Windows group for which a new mapping is being created. |
| **-ug** *group* | Specifies the name of the UNIX group for which a new mapping is being created. |
| **-setprimary** | Specifies that the new mapping is the primary mapping. |

**setprimary**

Specifies which mapping is the primary mapping for a UNIX user or group with multiple mappings. The following options are available with this command argument:

| Term | Definition |
|---|---|
| **-wu** *name* | Specifies the Windows user of the primary mapping. If more than one mapping for the user exists, use the **-uu** option to specify the primary mapping. |
| **-uu** *name* | Specifies the UNIX user of the primary mapping. |
| **-wg** *group* | Specifies the Windows group of the primary mapping. If more than one mapping for the group exists, use the **-ug** option to specify the primary mapping. |
| **-ug** *group* | Specifies the UNIX group of the primary mapping. |

**delete**

Removes the mapping for a user or group. The following options are available for this command argument:

| Term | Definition |
|---|---|
| **-wu** *user* | The Windows user for which the mapping will be deleted, specified as *WindowsDomain\UserName*. You must specify either the **-wu** or the **-uu** option, or both. If you specify both options, the particular mapping identified by the two options will be deleted. If you specify only the **-wu** option, all mappings for the specified user will be deleted. |
| **-wg** *group* | The Windows group for which the mapping will be deleted, specified as *WindowsDomain\GroupName*. You must specify either the **-wg** or the **-ug** option, or both. If you specify both options, the particular mapping identified by the two options will be deleted. If you specify only the **-wg** option, all mappings for the specified group will be deleted. |
| **-uu** *user* | The UNIX user for whom the mapping will be deleted, specified as *UserName*. You must specify either the **-wu** or the **-uu** option, or both. If you specify both options, the particular mapping identified by the two options will be deleted. If you specify only the **-uu** option, all mappings for the specified user will be deleted. |

| | |
|---|---|
| **-ug** *group* | The UNIX group for which the mapping will be deleted, specified as *GroupName*. You must specify either the **-wg** or the **-ug** option, or both. If you specify both options, the particular mapping identified by the two options will be deleted. If you specify only the **-ug** option, all mappings for the specified group will be deleted. |

**list**

Displays information about user and group mappings. The following options are available with this command argument:

| Term | Definition |
|---|---|
| **-all** | Lists both simple and advanced mappings for users and groups. |
| **-simple** | Lists all simple mapped users and groups. |
| **-advanced** | Lists all advanced mapped users and groups. Maps are listed in the order in which they are evaluated. Primary maps, marked with an asterisk (*), are listed first, followed by secondary maps, which are marked with a carat (^). |
| **-wu** *name* | Lists the mapping for a specified Windows user. |
| **-wg** *group* | Lists the mapping for a Windows group. |
| **-uu** *name* | Lists the mapping for a UNIX user. |
| **-ug** *group* | Lists the mapping for a UNIX group. |

**backup**

Saves User Name Mapping configuration and mapping data to the file specified by *filename*.

**restore**

Replaces configuration and mapping data with data from the file (specified by *filename*) that was created using the **backup** command argument.

**adddomainmap**

Adds a simple map between a Windows domain and an NIS domain or password and group files. The following options are available for this command argument:

| Term | Definition |
|---|---|
| **-d** *WindowsDomain* | Specifies the Windows domain to be mapped. |
| **-y** *NISDomain* | Specifies the NIS domain to be mapped.<br><br>**-n *nisServer***<br>Specifies the NIS server for the NIS domain specified with the **-y** option. |
| **-f** *path* | Specifies the fully qualified path of directory containing the password and group files to be mapped. The files must be located on the computer being managed, and you cannot use **mapadmin** to manage a remote computer to set up maps based on password and group files. |

**removedomainmap**

Removes a simple map between a Windows domain and an NIS domain. The following options and argument are available for this command argument:

| Term | Definition |
|---|---|
| **-d** *WindowsDomain* | Specifies the Windows domain of the map to be removed. |

| | |
|---|---|
| **-y** *NISDomain* | Specifies the NIS domain of the map to be removed. |
| **-all** | Specifies that all simple maps between Windows and NIS domains are to be removed. This will also remove any simple map between a Windows domain and password and group files. |

**listdomainmaps**

Lists the Windows domains that are mapped to NIS domains or password and group files.

If you do not specify a command argument, **mapadmin** displays the current settings for User Name Mapping.

For all options that specify a user or group name, the following formats can be used:

For Windows users, use the form *domain**username*, *computer**username*, *computer**username*, or *computer**username*

For Windows groups, use the form *domain**groupname*, *computer**groupname*, *computer**groupname*, or *computer**groupname*

For UNIX users, use the form *NISdomain**username*, *username***@***NISdomain*, username@PCNFS, or PCNFS*username*

For UNIX groups, use the form *NISdomain**groupname*, *groupname***@***NISdomain*, groupname@PCNFS, or PCNFS*groupname*

**See Also**
**Concepts**
User Name Mapping administration

# mount

Applies To: Windows Server 2003 R2

You can use **mount** to mount Network File System (NFS) network shares.

**Syntax**
mount [-o <Option>[...]] [-u:<UserName>] [-p:{<Password> | *}] {\\<ComputerName>\<ShareName> | <ComputerName>:/<ShareName>} {<DeviceName> | *}

**Description**
The **mount** command-line utility mounts the file system identified by *ShareName* exported by the NFS server identified by *ComputerName* and associates it with the drive letter specified by *DeviceName* or, if an asterisk (*****) is used, by the first available driver letter. Users can then access the exported file system as though it were a drive on the local computer. When used without options or arguments, **mount** displays information about all mounted NFS file systems.

The **mount** utility is available only if Client for NFS is installed.

The following options and arguments can be used with the **mount** utility.

| Term | Definition |
|---|---|
| -o rsize=<buffersize> | Sets the size in kilobytes of the read buffer. Acceptable values are 1, 2, 4, 8, 16, and 32; the default is 32 KB. |
| -o wsize=<buffersize> | Sets the size in kilobytes of the write buffer. Acceptable values are 1, 2, 4, 8, 16, and 32; the default is 32 KB. |
| -o timeout=<seconds> | Sets the time-out value in seconds for a remote procedure call (RPC). Acceptable values are 0.8, 0.9, and any integer in the range 1-60; the default is 0.8. |
| -o retry=<number> | Sets the number of retries for a soft mount. Acceptable values are integers in the range 1-10; the default is 1. |
| -o mtype={soft \| hard} | Sets the mount type (default is **soft**). Regardless of the mount type, **mount** will return if it cannot immediately mount the share. Once the share has been successfully mounted, however, if the mount type is **hard**, Client for NFS will continue to try to access the share until it is successful. As a result, if the NFS server is unavailable, any Windows program trying to access the share will appear to stop responding, or "hang," if the mount type is **hard**. |
| -o anon | Mounts as an anonymous user. |
| -o nolock | Disables locking (default is **enabled**). |
| -o casesensitive | Forces file lookups on the server to be case sensitive. |

| | |
|---|---|
| -o fileaccess=<mode> | Specifies the default permission mode of new files created on the NFS share. Specify *mode* as a three-digit number in the form *ogw*, where *o*, *g*, and *w* are each a digit representing the access granted the file's owner, group, and the world, respectively. The digits must be in the range 0-7 with the following meaning:<br>• 0: No access<br>• 1: x (execute access)<br>• 2: w (write access)<br>• 3: wx<br>• 4: r (read access)<br>• 5: rx<br>• 6: rw<br>• 7: rwx |
| -o lang={euc-jp\|euc-tw\|euc-kr\|shift-jis\|big5\|ksc5601\|gb2312-80\|ansi} | Specifies the default encoding used for file and directory names and, if used, must be set to one of the following:<br>• **ansi**<br>• **big5** (Chinese)<br>• **euc-jp** (Japanese)<br>• **euc-kr** (Korean)<br>• **euc-tw** (Chinese)<br>• **gb2312-80** (Simplified Chinese)<br>• **ksc5601** (Korean)<br>• **shift-jis** (Japanese)<br><br>If this option is set to **ansi** on systems configured for non-English locales, the encoding scheme is set to the default encoding scheme for the locale. The following are the default encoding schemes for the indicated locales:<br>• Japanese: SHIFT-JIS<br>• Korean: KS_C_5601-1987<br>• Simplified Chinese: GB2312-80<br>• Traditional Chinese: BIG5 |

| | |
|---|---|
| -o sec={sys\|krb5\|krb5i} | Specifies the security flavor. This can be set to one of the following values:<br>• **sys** (Use RPC's AUTH_SYS authentication protocol)<br>• **krb5** (Use Kerberos v5 authentication)<br>• **krb5i** (Use Kerberos v5 authentication with integrity checking) |
| -u:<UserName> | Specifies the user name to use for mounting the share. If *username* is not preceded by a backslash (****), it is treated as a UNIX user name. |
| -p:<Password> | The password to use for mounting the share. If you use an asterisk (*****), you will be prompted for the password. |

**Note**

If you make a persistent connection with **mount**, you must use umount to delete the connection. Neither the **net use** command nor Microsoft Windows Explorer will delete these connections.

**See Also**

**Concepts**

umount

# nfsadmin

Applies To: Windows Server 2003 R2

You can use **nfsadmin** to manage Server for NFS and Client for NFS.

**Syntax**

**nfsadmin server** [ *ComputerName* ] [ -u *UserName* [-p *Password*]] -l

**nfsadmin server** [ *ComputerName* ] [ -u *UserName* [-p *Password*]] -r {*client* | all}

**nfsadmin server** [ *ComputerName* ] [ -u *UserName* [-p *Password*]] {start | stop}

**nfsadmin server** [ *ComputerName* ] [ -u *UserName* [-p *Password*]] config *Option* [...]

**nfsadmin server** [ *ComputerName* ] [ -u *UserName* [-p *Password*]] creategroup *Name*

**nfsadmin server** [ *ComputerName* ] [ -u *UserName* [-p *Password*]] listgroups

**nfsadmin server** [ *ComputerName* ] [ -u *UserName* [-p *Password*]] deletegroup *Name*

**nfsadmin server** [ *ComputerName* ] [ -u *UserName* [-p *Password*]] renamegroup *OldName NewName*

**nfsadmin server** [ *ComputerName* ] [ -u *UserName* [-p *Password*]] addmembers *Name Host* [...]

**nfsadmin server** [ *ComputerName* ] [ -u *UserName* [-p *Password*]] listmembers

**nfsadmin server** [ *ComputerName* ] [ -u *UserName* [-p *Password*]] deletemembers *Group Host* [...]

**nfsadmin client** [ *ComputerName* ] [ -u *UserName* [-p *Password*]] {start | stop}

**nfsadmin client** [ *ComputerName* ] [ -u *UserName* [-p *Password*]] config *Option* [...]

**Description**

The **nfsadmin** command-line utility administers Server for NFS or Client for NFS on the local or remote computer running Microsoft Services for Network File System (NFS). If you are logged on with an account that does not have the required privileges, you can specify a user name and password of an account that does. The action performed by **nfsadmin** depends on the command arguments you supply.

In addition to service-specific command arguments and options, **nfsadmin** accepts the following:

***ComputerName***
Specifies the remote computer you want to administer. You can specify the computer using a Windows Internet Name Service (WINS) name or a Domain Name System (DNS) name, or by Internet Protocol (IP) address.

**-u *UserName***
Specifies the user name of the user whose credentials are to be used. It might be necessary to add the domain name to the user name in the form *domain**UserName*

**-p *Password***
Specifies the password of the user specified using the **-u** option. If you specify the **-u** option but omit the **-p** option, you are prompted for the user's password.

**Administering Server for NFS**

Use the **nfsadmin server** command to administer Server for NFS. The specific action that **nfsadmin server** takes depends on the command option or argument you specify:

**-l**
Lists all locks held by clients.

**-r {*client* | all}**
Releases the locks held by a *client* or, if **all** is specified, by all clients.

**start**
Starts the Server for NFS service.

**stop**

Stops the Server for NFS service.

**config**

Specifies general settings for Server for NFS. You must supply at least one of the following options with the **config** command argument:

**mapsvr=*server***

Sets *server* as the User Name Mapping server for Server for NFS. Although this option continues to be supported for compatibility with previous versions, you should use the **sfuadmin** utility instead.

**auditlocation={eventlog | file | both | none}**

Specifies whether events will be audited and where the events will be recorded. One of the following arguments is required.

**eventlog**

Specifies that audited events will be recorded only in the Event Viewer application log.

**file**

Specifies that audited events will be recorded only in the file specified by **config fname**.

**both**

Specifies that audited events will be recorded in the Event Viewer application log as well as the file specified by **config fname**.

**none**

Specifies that events will not be audited.

**fname=*file***

Sets the file specified by *file* as the audit file. The default is %sfudir%\log\nfssvr.log

**fsize=*size***

Sets *size* as the maximum size in megabytes of the audit file. The default maximum size is 7 MB.

**audit=[+|-]mount [+|-]read [+|-]write [+|-]create [+|-]delete [+|-]locking [+|-]all**

Specifies the events to be logged. To start logging an event, type a plus sign (**+**) before the event name; to stop logging an event, type a minus sign (**-**) before the event name. If the sign is omitted, the plus sign is assumed. Do not use **all** with any other event name.

**lockperiod=*seconds***

Specifies the number of seconds that Server for NFS will wait to reclaim locks after a connection to Server for NFS has been lost and then reestablished or after the Server for NFS service has been restarted.

**Portmapprotocol={TCP | UDP | TCP+UDP}**

Specifies which transport protocols Portmap supports. The default setting is **TCP+UDP**.

**mountprotocol={TCP | UDP | TCP+UDP}**

Specifies which transport protocols mount supports. The default setting is **TCP+UDP**.

**nfsprotocol={TCP | UDP | TCP+UDP}**

Specifies which transport protocols Network File System (NFS) supports. The default setting is **TCP+UDP**

**nlmprotocol={TCP | UDP | TCP+UDP}**

Specifies which transport protocols Network Lock Manager (NLM) supports. The default setting is **TCP+UDP**.

**nsmprotocol={TCP | UDP | TCP+UDP}**

Specifies which transport protocols Network Status Manager (NSM) supports. The default setting is **TCP+UDP**.

**enableV3={yes | no}**

Specifies whether NFS version 3 protocols will be supported. The default setting is **yes**.

**renewauth={yes | no}**

Specifies whether client connections will be required to be reauthenticated after the period specified by **config renewauthinterval**. The default setting is **no**.

**renewauthinterval=*seconds***

Specifies the number of seconds that elapse before a client is forced to be reauthenticated if **config renewauth** is set to **yes**. The default value is 600 seconds.

**dircache=*size***
Specifies the size in kilobytes of the directory cache. The number specified as *size* must be a multiple of 4 between 4 and 128. The default directory-cache size is 128 KB.

**translationfile=[*file*]**
Specifies a file containing mapping information for replacing characters in the names of files when moving them from Windows-based to UNIX-based file systems. If *file* is not specified, then file name character translation is disabled. If the value of **translationfile** is changed, you must restart the server for the change to take effect.

**dotfileshidden={yes | no}**
Specifies whether files that are created with names beginning with a period (.) will be marked as hidden in the Windows file system and consequently hidden from NFS clients. The default setting is **no**.

**casesensitivelookups={yes | no}**
Specifies whether directory lookups will be case sensitive (requiring exact matching of character case).

You also need to disable Windows kernel case-insensitivity in order for Server for NFS to support case-sensitive file names. You can disable Windows kernel case-insensitivity by clearing the following registry key to 0:

HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\kernel

DWORD "obcaseinsensitive"

**ntfscase={lower | upper | preserve}**
Specifies whether the case of characters in the names of files in the NTFS file system will be returned in lowercase, uppercase, or in the form stored in the directory. The default setting is **preserve**. This setting cannot be changed if **casesensitivelookups** is set to **yes**.

**creategroup *name***
Creates a new client group, giving it the specified *name*.

**listgroups**
Displays the names of all client groups.

**deletegroup *name***
Removes the client group specified by *name*.

**renamegroup *OldName NewName***
Changes the name of the client group specified by *OldName* to *NewName*

**addmembers *Name Host*[...]**
Adds *Host* to the client group specified by *Name*.

**listmembers *Name***
Lists the host computers in the client group specified by *Name*.

**deletemembers *Group Host*[...]**
Removes the client specified by *Host* from the client group specified by *Group*.

If you do not specify a command option or argument, **nfsadmin server** displays the current Server for NFS configuration settings.

#### Administering Client for NFS

Use the **nfsadmin client** command to administer Client for NFS. The specific action that **nfsadmin client** takes depends on the command argument you specify:

**start**
Starts the Client for NFS service.

**stop**
Stops the Client for NFS service.

**config**
Specifies general settings for Client for NFS. You must supply at least one of the following options with the **config** command argument:

**fileaccess=*mode***
Specifies the default permission mode for files created on Network File System (NFS) servers. The *mode* argument consists

of a three digits from 0 to 7 (inclusive) representing the default permissions granted the user, group, and others (respectively). The digits translate to UNIX-style permissions as follows: 0=none, 1=x, 2=w, 3=wx, 4=r, 5=rx, 6=rw, and 7=rwx. For example, **fileaccess=750** gives rwx permission to the owner, rx permission to the group, and no access permission to others.

**mapsvr=*server***
Sets *server* as the User Name Mapping server for Client for NFS. Although this option continues to be supported for compatibility with previous versions, you should use the **sfuadmin** utility instead.

**mtype={hard | soft}**
Specifies the default mount type. For a hard mount, Client for NFS continues to retry a failed RPC until it succeeds. For a soft mount, Client for NFS returns failure to the calling application after retrying the call the number of times specified by the **retry** option.

**retry=*number***
Specifies the number of times to try to make a connection for a soft mount. This value must be from 1 to 10, inclusive. The default is 1.

**timeout=*seconds***
Specifies the number of seconds to wait for a connection (remote procedure call). This value must be 0.8, 0.9, or an integer from 1 to 60, inclusive. The default is 0.8.

**Protocol={TCP | UDP | TCP+UDP}**
Specifies which transport protocols the client supports. The default setting is **TCP+UDP**

**rsize=*size***
Specifies the size, in kilobytes, of the read buffer. This value can be 0.5, 1, 2, 4, 8, 16, or 32. The default is 32.

**wsize=*size***
Specifies the size, in kilobytes, of the write buffer. This value can be 0.5, 1, 2, 4, 8, 16, or 32. The default is 32.

**perf=default**
Restores the following performance settings to default values:

- **mtype**
- **retry**
- **timeout**
- **rsize**
- **wsize**

**fileaccess=*mode***
Specifies the default permission mode for files created on Network File System (NFS) servers. The *mode* argument consists of a three digits from 0 to 7 (inclusive) representing the default permissions granted the user, group, and others (respectively). The digits translate to UNIX-style permissions as follows: 0=none, 1=x, 2=w, 3=wx, 4=r, 5=rx, 6=rw, and 7=rwx. For example, **fileaccess=750** gives rwx permission to the owner, rx permission to the group, and no access permission to others.

**SecFlavors=[+|-]sys [+|-]krb5 [+|-]krb5i**
Specifies (**+**) or removes (**-**) permitted security flavors. This can be set to any combination of the following:

- **sys** (Use RPC's AUTH_SYS authentication protocol)
- **krb5** (Use Kerberos v5 authentication)
- **krb5i** (Use Kerberos v5 authentication with integrity checking)

If you do not specify a command option or argument, **nfsadmin client** displays the current Client for NFS configuration settings.

# nfsshare

Applies To: Windows Server 2003 R2

You can use **nfsshare** to control Network File System (NFS) shares.

**Syntax**

nfsshare <ShareName>=<Drive:Path> [-o <Option=value>...]

nfsshare {<ShareName> | <Drive>:<Path> | * } /delete

**Description**

Without arguments, the **nfsshare** command-line utility lists all Network File System (NFS) shares exported by Server for NFS. With *ShareName* as the only argument, **nfsshare** lists the properties of the NFS share identified by *ShareName*. When *ShareName* and *Drive***:***Path* are provided, **nfsshare** exports the folder identified by *Drive***:***Path* as *ShareName*. When the **/delete** option is used, the specified folder is no longer made available to NFS clients.

**Options**

The **nfsshare** command accepts the following options and arguments:

| Term | Definition |
|---|---|
| -o anon={yes \| no} | Specifies whether anonymous (unmapped) users can access the shared directory. The default is **no**. |
| -o rw[=<Host>[:<Host>]...] | Provides read-write access to the shared directory by the hosts or client groups specified by *Host*. Separate host and group names with a colon (**:**). If *Host* is not specified, all hosts and client groups (except those specified with the **ro** option) have read-write access. If neither the **ro** nor the **rw** option is set, all clients have read-write access to the shared directory. |
| -o ro[=<Host>[:<Host>]...] | Provides read-only access to the shared directory by the hosts or client groups specified by *Host*. Separate host and group names with a colon (**:**). If *Host* is not specified, all clients (except those specified with the **rw** option) have read-only access. If the **ro** option is set for one or more clients, but the **rw** option is not set, only the clients specified with the **ro** option have access to the shared directory. |

| | |
|---|---|
| -o encoding={big5\|euc-jp\|euc-kr\|euc-tw\|gb2312-80\|ksc5601\|shift-jis} | Specifies the default encoding used for file and directory names and, if used, must be set to one of the following:<br>• **big5** (Chinese)<br>• **euc-jp** (Japanese)<br>• **euc-kr** (Korean)<br>• **euc-tw** (Chinese)<br>• **gb2312-80** (Simplified Chinese)<br>• **ksc5601** (Korean)<br>• **shift-jis** (Japanese)<br><br>If this is option is not set, the default encoding scheme is ANSI or, on systems configured for non-English locales, the default encoding scheme for the locale. The following are the default encoding schemes for the indicated locales:<br>• Japanese: SHIFT-JIS<br>• Korean: KS_C_5601-1987<br>• Simplified Chinese: GB2312-80<br><br>Traditional Chinese: BIG5 |
| -o anongid=<gid> | Specifies that anonymous (unmapped) users will access the share directory using *gid* as their group identifier (GID). The default is -2. The anonymous GID will be used when reporting the owner of a file owned by an unmapped user, even if anonymous access is disabled. |
| -o anonuid=<uid> | Specifies that anonymous (unmapped) users will access the share directory using *uid* as their user identifier (UID). The default is -2. The anonymous UID will be used when reporting the owner of a file owned by an unmapped user, even if anonymous access is disabled. |
| -o root[=<Host>[:<Host>]...] | Provides root access to the shared directory by the hosts or client groups specified by *Host*. Separate host and group names with a colon (**:**). If *Host* is not specified, all clients have root access. If the **root** option is not set, no clients have root access to the shared directory. |
| -o sec=[<SecurityFlavor>[:<SecurityFlavor>]...] | Specifies permitted security flavors. This can be set to any combination of the following:<br>• **sys** (Use RPC's AUTH_SYS authentication protocol)<br>• **krb5** (Use Kerberos v5 authentication)<br>• **krb5i** (Use Kerberos v5 authentication with integrity checking) |
| /delete | If *ShareName* or *Drive***:***Path* is specified, deletes the specified share. If * is specified, deletes all NFS shares. |

| **Note** |
|---|
| To view the complete syntax for this command, at a command prompt, type:<br><br>**nfsshare /?** |

**See Also**

**Concepts**

Managing NFS shares

# nfsstat

Applies To: Windows Server 2003 R2

You can use **nfsstat** to display or reset counts of calls made to Server for NFS.

**Syntax**
**nfsstat** [-z]

**Description**
When used without the **-z** option, the **nfsstat** command-line utility displays the number of NFS V2, NFS V3, and Mount V3 calls made to the server since the counters were set to 0, either when the service started or when the counters were reset using **nfsstat -z**.

# rpcinfo

Applies To: Windows Server 2003 R2

You can use **rpcinfo** to list programs on remote computers.

**Syntax**

List all programs registered with the port mapper:

**rpcinfo** -p [*Node*]

Request a response from network nodes that have a specified program:

**rpcinfo** -b *Program Version*

Use Transmission Control Protocol (TCP) to call a program:

**rpcinfo** -t *Node Program* [*Version*]

Use User Datagram Protocol (UDP) to call a program:

**rpcinfo** -u *Node Program* [*Version*]

**Description**

The **rpcinfo** command-line utility makes a remote procedure call (RPC) to an RPC server and reports what it finds.

The **rpcinfo** utility accepts the following options:

**-p [*Node*]**
Lists all programs registered with the port mapper on the specified host. If you do not specify a node (computer) name, the program queries the port mapper on the local host.

**-b *Program Version***
Requests a response from all network nodes that have the specified program and version registered with the port mapper. You must specify both a program name or number and a version number.

**-t *Node Program* [*Version*]**
Uses the TCP transport protocol to call the specified program. You must specify both a node (computer) name and a program name. If you do not specify a version, the program calls all versions.

**-u *Node Program* [*Version*]**
Uses the UDP transport protocol to call the specified program. You must specify both a node (computer) name and a program name. If you do not specify a version, the program calls all versions.

# showmount

Applies To: Windows Server 2003 R2

You can use **showmount** to display mounted directories.

**Syntax**

**showmount** { -e | -a | -d} [*Server*]

**Description**

The **showmount** command-line utility displays information about mounted file systems exported by Server for NFS on the computer specified by *Server*. If *Server* is not provided, **showmount** displays information about the computer on which the **showmount** command is run.

You must provide one of the following options:

**-e**

Displays all file systems exported on the server.

**-a**

Displays all Network File System (NFS) clients and the directories on the server each has mounted.

**-d**

Displays all directories on the server that are currently mounted by NFS clients.

**See Also**

**Concepts**

Server for NFS administration

# umount

Applies To: Windows Server 2003 R2

You can use **umount** to remove Network File System (NFS)–mounted drives.

**Syntax**
**umount** [-f] [{-a | *DriveLetter*:[...] | *NetworkMount*[...]}]

**Description**
The **umount** command-line utility disconnects the specified NFS-mounted drive. You must supply at least one of the following options or arguments.

**-f**
Forces deletion of Network File System (NFS) network drives.

**-a**
Deletes all NFS network drives. If there are active connections, **umount** prompts you for confirmation unless you also use the **-f** option.

***DriveLetter***
The letter of the logical drive to be disconnected.

***NetworkMount***
The network mount point to be disconnected. This mount must have been created using the **net use** Windows command-line utility without specifying a drive letter.

**Concepts**
mount

# DFS Management

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can use the Distributed File System (DFS) Management snap-in to manage DFS Namespaces and DFS Replication. When used together, these two technologies offer simplified, fault-tolerant access to files, load sharing, and WAN-friendly replication.

- To install the DFS Management snap-in, see Installing the DFS Management Snap-in and DFS Replication Service.
- For help with specific tasks, see Creating and Managing Namespaces and Configuring and Managing DFS Replication.
- For information about property pages in the DFS Management snap-in, see Namespace Properties and DFS Replication Properties.
- For more information about the DFS solution in the Microsoft® Windows Server™ 2003 R2 operating systems, see the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=39468).

# Installing the DFS Management Snap-in and DFS Replication Service

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

If you plan to use DFS Replication, you must first update the Active Directory® directory service schema to install the Active Directory classes and attributes used by DFS Replication. To upgrade the schema, on the schema operations master, run **adprep.exe /forestprep**. The adprep.exe command-line tool is available in the cmpnents\r2\adprep folder on the second Windows Server 2003 R2 operating system installation CD.

After the Windows Server 2003 R2 operating system is installed, and the schema is updated as necessary, you can install the Distributed File System (DFS) components by using the following procedures.

| **Note** |
| --- |
| Two methods for installing Distributed File System are provided. The method using the **Manage Your Server** file server tool allows you to install Distributed File System as a part of the file server role. This method also installs other file server tools, such as the **File Server Resource Manager** and **File Server Management**. The method using **Add or Remove Programs** allows you to install either the DFS Management snap-in, the DFS Replication service, or both. |

Use the following procedure if the file server role has not been added.

**To install Distributed File System using Manage Your Server**

1. Click **Start**, point to **All Programs**, point to **Administrative Tools**, and then click **Manage Your Server**.
2. Click **Add or remove a role**.
3. In the Configure Your Server Wizard, click **Next**. On the **Server Role** page, click **File Server**, and then click **Next.** Click **Next** again.
4. In the Add File Server Role Wizard, click **Next**, and then click **Replicate data to and from this server**. Follow the steps in the wizard to complete the installation. You will be asked to restart the server when the installation is complete.

Use the following procedure to install the DFS Management snap-in, the DFS Replication service, or both, without installing the File Server role.

**To install Distributed File System using Add or Remove Programs**

1. In Control Panel, double-click **Add or Remove Programs**.
2. Click **Add/Remove Windows Components**, highlight **Distributed File System**, and then click **Details**.
3. Do one of the following:
   - To install the Distributed File System management tools without installing the DFS Replication service, click **DFS Management**.
   - To install the DFS Replication service without installing the management tools, click **DFS Replication Service**.

# Namespaces

- Updated namespace terminology
- New namespace features

# Updated namespace terminology

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

To make namespace concepts easier to understand, namespace terminology has been simplified. The following table describes the previous and updated terms.

| **Previous Term** | **Updated Term** | **Definition** |
|---|---|---|
| Link | Folder | Any folder that appears in the namespace after *ServerOrDomainName**RootName*. A folder can have optional folder targets. |
| Link target | Folder target | A Universal Naming Convention (UNC) path of a shared folder or another namespace that is associated with a folder in a namespace. |
| Not defined | Namespace root | The top-level folder in the namespace. For example, *ServerOrDomainName**RootName* is the namespace root. |
| Root | Namespace | A virtual tree of folders that begins with *ServerOrDomainName**RootName*. |
| Root server | Namespace server | A server that hosts a namespace. |

# New namespace features

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The Distributed File System (DFS) technology in the Microsoft Windows Server 2003 operating systems has been renamed to DFS Namespaces. Although the underlying service and basic functionality are unchanged, there are a number of new namespace settings exposed in the Windows Server 2003 R2 operating systems. These settings are as follows:

**Target priority**

When a client accesses a namespace, the client receives a referral that contains a list of targets associated with the namespace root or folder. These targets are listed according to the current ordering method for the namespace or folder. To fine-tune how particular targets are ordered, you can specify whether a server appears first or last in a referral. Assigning target priority is useful in many scenarios, such as “hot-standby” scenarios where one server is considered the server of last resort. In this scenario, you specify that the standby server always appears last in referrals, and clients will fail over to this server only if all the other servers fail or become unavailable due to network outages. For more information about target priority, see Target priority.

**Client failback**

Client failover in DFS Namespaces is the process in which clients attempt to access another server in a referral after one of the servers fails or is removed from the namespace. Unless client failback is configured, clients will continue using the server they failed over to unless the client is restarted or the client's referral cache is cleared. When client failback is configured, and clients have the appropriate client failback hotfix installed, clients will fail back to a preferred, local server when it is restored. For more information about client failback, see Referral properties.

**Better delegation**

You can easily delegate the ability to create domain-based namespaces and manage individual stand-alone and domain-based namespaces. The DFS Management snap-in sets the appropriate permissions on either the DFS Namespace configuration objects in Active Directory or in the namespace server’s registry (depending on the namespace type). For more information about delegation, see Security requirements for creating and managing namespaces.

**Ability to restructure the namespace**

Renaming or moving folders in the namespace is easy when you use the DFS Management snap-in. You can restructure the namespace to correct mistakes or to adjust the hierarchy as business needs change or as new folders are added to the namespace. You can also move namespace folders by using the updated version of the command-line tool, Dfscmd.exe.

# Namespaces Overview

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

This section covers:

- Introduction to namespaces
- Types of namespaces
- Namespace folders and folder targets
- Namespace servers
- Namespace limits
- Namespace clients
- Security requirements for creating and managing namespaces
- Considerations for hosting namespaces on servers running a mix of Windows Server 2003 and Windows 2000 Server

# Introduction to namespaces

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

With DFS Namespaces technology, you can group shared folders located on different servers by transparently connecting them to one or more namespaces. A *namespace* is a virtual view of shared folders in an organization. When a user views the namespace, the folders appear to reside on a single hard disk. Users can navigate the namespace without needing to know the server names or shared folders hosting the data.

The path to a namespace is similar to a Universal Naming Convention (UNC) path to a shared folder, such as \\Server1\Public\Software\Tools. If you are familiar with UNC paths, you know that in this example, the shared folder Public and its subfolders Software and Tools are all hosted on Server1. Now, assume that you want to give users a single place to locate data, but you want to host data on different servers for availability and performance purposes. To do this, you can deploy a namespace similar to the one shown in the following figure. The elements of this namespace are described after the figure.

- **Namespace server**. A namespace server hosts a namespace. The namespace server can be a member server or domain controller.

- **Namespace root**. The namespace root is the starting point of the namespace. In the previous figure, the name of the root is Public, and the namespace path is \\Contoso\Public. This type of namespace is known as a domain-based namespace because it begins with a domain name (for example, Contoso) and its metadata is stored in the Active Directory® directory service. Although a single namespace server is shown in the previous figure, a domain-based namespace can be hosted on multiple namespace servers to increase the availability of the namespace.

- **Folder**. Folders help build the namespace hierarchy. Folders can optionally have folder targets. When users browse a folder with targets in the namespace, the client computer receives a referral that transparently redirects the client computer to one of the folder targets.

- **Folder targets**. A folder target is a UNC path of a shared folder or another namespace that is associated with a folder in a namespace. In the previous figure, the folder named Tools has two folder targets, one in London and one in New York, and the folder named Training Guides has a single folder target in New York. A user who browses to \\Contoso\Public\Software\Tools is transparently redirected to the shared folder \\LDN-SVR-01\Tools or \\NYC-SVR-01\Tools, depending on which site the user is in.

# Types of namespaces

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

When creating a namespace, you create either a stand-alone namespace or a domain-based namespace. The characteristics of each namespace type are described in the following table.

| Characteristic | Domain-based Namespace | Stand-Alone Namespace |
|---|---|---|
| Path to namespace | *NetBIOSDomainName**RootName*<br>*DNSDomainName**RootName* | *ServerName**RootName* |
| Where namespace information is stored | In Active Directory and in a memory cache on each namespace server | In the registry and in a memory cache on the namespace server |
| Namespace size recommendations | We recommend that you keep the size of the namespace object in Active Directory to less than 5 megabytes (MB) by using fewer than 5,000 folders with targets in domain-based namespaces. (The namespace object is where namespace metadata is stored in Active Directory.) | The largest recommended namespace size for a stand-alone namespace is 50,000 folders with targets. |
| Supported methods to ensure namespace availability | Use multiple namespace servers to host the namespace. (The namespace servers must be in the same domain.) | Create a stand-alone namespace on a server cluster using the Cluster Administrator snap-in. |
| Support for using DFS Replication to replicate folder targets | Supported | Supported |

Use the following guidelines to choose a namespace type.

Choose stand-alone namespaces if:

- Your organization does not use Active Directory.
- You need to create a single namespace with more than 5,000 folders with targets. (If you can divide your folder targets among two or more namespaces, a domain-based namespace is an option.)
- You want to ensure the availability of the namespace by using a server cluster.

Choose domain-based namespaces if:

- You want to ensure the availability of the namespace by using multiple namespace servers.
- You want to hide the name of the namespace server from users because you plan to replace the namespace server or migrate the namespace to another server in the future.

# Namespace folders and folder targets

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Folders are the primary elements of a namespace. They appear after the namespace root (*ServerOrDomainName**RootName*) and help build the hierarchy of the namespace. When you create a folder using the DFS Management snap-in, you type a name for the folder and specify whether to add any folder targets. A folder target is a Universal Naming Convention (UNC) path to one of the following locations:

- A shared folder
- A folder within a shared folder
- A path to another namespace

You can specify multiple folder targets to increase the redundancy of the folder. If one of the folder targets is not available, the client will attempt to access one of the other available targets. (The order in which clients attempt to access targets is defined by the ordering method described in Referral properties.)

When adding folder targets, it is important to follow these guidelines:

- If you specify a domain-based namespace as a folder target (either the namespace root or a folder within that namespace), you cannot specify alternate folder targets. (Windows Server 2003 R2 operating systems enforce this restriction.)
- If you plan to specify a stand-alone namespace as a folder target (either the namespace root or a folder within that namespace), you can specify alternate folder targets that are either stand-alone namespace roots or folders within the stand-alone namespace. Do not specify domain-based namespace roots or shared folders as alternate targets.

# Namespace servers

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

A namespace server is a domain controller or member server that hosts a namespace. The number of namespaces you can host on a server is determined by the operating system running on the namespace server.

Servers running the following operating systems can host a single namespace:

- Windows Server 2003 R2, Standard Edition
- Windows Server 2003, Web Edition
- Windows Server 2003, Standard Edition
- Any version of Windows® 2000 Server

| **Important** |
| --- |
| To create multiple domain-based namespaces on a server running Windows Server 2003, Standard Edition, install the hotfix described in article 903651 in the Microsoft Knowledge Base on the Microsoft Web site (http://go.microsoft.com/fwlink?linkid=53476). |

The following servers can host multiple namespaces:

- Windows Server 2003 R2, Enterprise Edition
- Windows Server 2003 R2, Datacenter Edition
- Windows Server 2003, Enterprise Edition
- Windows Server 2003, Datacenter Edition

The following table describes additional factors to consider when choosing servers to host a namespace.

**Guidelines for Servers That Host Namespaces**

| Server Hosting Stand-Alone Namespaces | Server Hosting Domain-based Namespaces |
| --- | --- |
| • Must contain an NTFS volume to host the namespace.<br>• Can be a member server or domain controller.<br>• Can be a clustered file server. | • Must contain an NTFS volume to host the namespace.<br>• Must be a member server or domain controller in the domain in which the namespace is configured. (This requirement applies to every namespace server that hosts a given domain-based namespace.)<br>• The namespace cannot be a clustered resource in a server cluster. However, you can locate the namespace on a server that also functions as a node in a server cluster if you configure the namespace to use only local resources on that server. |

Microsoft Web site

# Namespace limits

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

When adding folders to namespaces, keep the following recommendations in mind:

- For stand-alone namespaces, we recommend a maximum of 50,000 folders with targets.
- For domain-based namespaces, we recommend keeping the namespace object in Active Directory to 5 megabytes (MB) or less (equivalent to about 5,000 folders with targets).

| **Note** |
| --- |
| Folders without folder targets do not count against these limits. |

To make it easy for you to check the size of your namespace, the namespace size is shown in the **Namespace Properties** dialog box. To view this, right-click the namespace in the console tree, and then click **Properties**.

# Namespace clients

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Clients running versions of the following operating systems can access namespaces:

- Windows Server 2003 R2
- Windows Server 2003
- Windows Storage Server 2003
- Windows XP
- Windows Preinstallation Environment (Windows PE) (Can access stand-alone namespaces, but cannot access domain-based namespaces.)
- Windows 2000 Server
- Windows 2000 Professional
- Windows NT® Server 4.0 with Service Pack 6a
- Windows NT Workstation 4.0 with Service Pack 6a

# Security requirements for creating and managing namespaces

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The following table describes the groups that can perform basic namespace tasks by default, and the method for delegating the ability to perform these tasks.

| Task | Groups That Can Perform This Task By Default | Delegation Method |
|---|---|---|
| Create a domain-based namespace | Domain Admins group in the domain where the namespace is configured | Right-click the **Namespace** node in the console tree, and then click **Delegate Management Permissions**. You must also add the user to the Local Administrators group on the namespace server. |
| Add a namespace server to a domain-based namespace | Domain Admins group in the domain where the namespace is configured | Right-click the domain-based namespace in the console tree, and then click **Delegate Management Permissions**. You must also add the user to the Local Administrators group on the namespace server to be added. |
| Manage a domain-based namespace | Local Administrators group on each namespace server | Right-click the domain-based namespace in the console tree, and then click **Delegate Management Permissions**. |
| Create a stand-alone namespace | Local Administrators group on the namespace server | Add the user to the local Administrators group on the namespace server. |
| Manage a stand-alone namespace* | Local Administrators group on the namespace server | Right-click the stand-alone namespace in the console tree, and then click **Delegate Management Permissions**. |
| Create a replication group or enable DFS Replication on a folder | Domain Admins group in the domain where the namespace is configured | Right-click the **Replication** node in the console tree, and then click **Delegate Management Permissions**. |

* Delegating management permissions to manage a stand-alone namespace does not grant the user the ability to view and manage security using the **Delegation** tab. This issue occurs because the DFS Management snap-in cannot retrieve the discretionary access control lists (DACLs) for the stand-alone namespace from the registry. To enable the snap-in to display delegation information, you must follow the steps in article 314837 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink?linkid=46803).

# Considerations for hosting namespaces on servers running a mix of Windows Server 2003 and Windows 2000 Server

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

It is possible to host namespaces on domain controllers and member servers running a mix of Windows 2000 Server, Windows Server 2003 R2, and Windows Server 2003 without Service Pack 1 (SP1), but some functionality is disabled or available inconsistently, depending on the operating systems on the servers. Some examples of mixed-mode behavior are as follows:

- If domain controllers or namespace servers are running Windows Server 2003 without SP1 or without Windows Server 2003 R2, they cannot provide referrals that support target priority or client failback.

- If domain controllers or namespace servers are running Windows 2000 Server, they cannot provide referrals that support target server priority or client failback; nor can they order targets by lowest cost in referrals. Additional configuration is required to enable these namespace servers and domain controllers to detect the site of each target server in the namespace. For details, see Update the static site table on namespace servers running Windows 2000 Server.

- If the DFS Management snap-in connects to a namespace server that is not running Windows Server 2003 with SP1 or R2 versions of Windows Server 2003, none of the new configuration settings (such as client failback or target priority) can be enabled. Renaming or moving namespace folders will not work, and delegation will not be effective.

# Getting Started With Namespaces

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**How to...**

- Deploy a namespace for publishing content
- Increase the availability of a namespace

# Deploy a namespace for publishing content

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

DFS Namespaces and DFS Replication can be used to publish documents, software, and line-of-business data to users throughout an organization. Although DFS Replication alone is sufficient to distribute data, you can use DFS Namespaces to configure the namespace so that a folder in the namespace is hosted by multiple servers, each of which holds a replica of the published content in that folder. This increases data availability and distributes the client load across servers.

When browsing a folder in the namespace, users are not aware that the folder is hosted by multiple servers. When a user opens the folder, the client computer is automatically referred to a server in its own site; if no same-site servers are available, you can configure the namespace to refer the client to a server that has the lowest connection cost as defined in Active Directory. In addition, using a DFS Namespaces enhancement known as target priority, you can specify the priority of servers so that a specific server is always placed first or last in the list of servers (known as a referral) the client receives when accessing a folder with targets in the namespace.

To configure a namespace for publication, perform the following procedures as specified:

1. Create a namespace
2. Create a folder in a namespace
3. Add folder targets
4. Set the ordering method for targets in referrals
5. Set target priority to override referral ordering (Optional)
6. Enable client failback (Optional)
7. Replicate folder targets using DFS Replication (Optional)

# Increase the availability of a namespace

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

To ensure that the namespace and its folders are still available if a server fails, you can add multiple namespace servers (for domain-based namespaces) and multiple folder targets for each folder. You can optionally use DFS Replication to keep the contents of the folder targets synchronized.

The procedures for increasing the availability of a namespace are as follows:

1. Add namespace servers to a domain-based namespace
2. Add folder targets
3. Replicate folder targets using DFS Replication (Optional)

| **Note** |
| --- |
| To increase the availability of a stand-alone namespace, you must use the Cluster Administrator snap-in to create a stand-alone namespace on a server cluster. |

# Creating and Managing Namespaces

Updated: August 22, 2005

# Increasing the Availability of a Namespace

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**How to...**

- Add namespace servers to a domain-based namespace
- Add folder targets
- Replicate folder targets using DFS Replication

# Add namespace servers to a domain-based namespace

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can increase the availability of a domain-based namespace by specifying additional namespace servers to host the namespace.

**To add a namespace server to a domain-based namespace**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, right-click a domain-based namespace, and then click **Add Namespace Server**.
3. Enter the path to another server or click **Browse** to locate a server.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. You must also be a member of the local Administrators group on the servers to be added to the namespace.
- This procedure is not applicable for stand-alone namespaces because stand-alone namespaces can only support a single namespace server. To increase the availability of a stand-alone namespace, you must use the Cluster Administrator snap-in to create the namespace on a server cluster.

# Add folder targets

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

A folder target is a Universal Naming Convention (UNC) path of a shared folder or another namespace that is associated with a folder in a namespace. Adding multiple folder targets increases the availability of the folder in the namespace.

**To add a folder target**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, right-click a folder, and then click **Add Folder Target**.
3. Type the path to the folder target or click **Browse** to locate the folder target.
4. If the folder is replicated using DFS Replication, you can specify whether to add the new folder target to the replication group.

**Note**

- To perform this procedure, you must be a member of the Local Administrators group on each server that hosts the namespace, or you must have been delegated the ability to manage an existing namespace.

**See Also**
**Concepts**
Security requirements for creating and managing namespaces

# Replicate folder targets using DFS Replication

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can use DFS Replication to keep the contents of folder targets in sync so that users see the same files regardless of which folder target the client computer is referred to.

**To replicate folder targets using DFS Replication**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, right-click a folder that has two or more folder targets, and then click **Replicate Folder**.
3. Follow the instructions in the Replicate Folder Wizard.

**Important**

- Replication does not begin immediately. The topology and DFS Replication settings must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain these settings. The amount of time this takes depends on Active Directory replication latency and the long polling interval (60 minutes) on each member.

**Note**

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority.

# Optimizing a Namespace

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**How to...**

- Rename or move a folder
- Enable or disable referrals to a folder target
- Change the amount of time that clients cache referrals
- Set the ordering method for targets in referrals
- Set target priority to override referral ordering
- Enable client failback
- Optimize namespace polling

# Rename or move a folder

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

### To rename a folder

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, right-click a folder, and then click **Rename Folder**.
3. Type the new name in the **New Name** field.

### To move a folder

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, right-click a folder, and then click **Move Folder**.
3. Enter the folder path in the **New location** field or click **Browse** to locate a folder.

### Notes

- To perform this procedure, you must be a member of the Local Administrators group on each server that hosts the namespace, or you must have been delegated the ability to manage an existing namespace.
- You can also drag and drop folders in the console tree.

# Enable or disable referrals to a folder target

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

A referral is an ordered list of targets that a client computer receives from a domain controller or namespace server when the user accesses a namespace root or folder with targets in the namespace. After the client receives the referral, the client attempts to access the first target in the list; if the target is not available, the client attempts to access the next target.

By disabling a folder target's referral, you can prevent the client from ever being directed to that folder target when accessing the folder in the namespace.

**To enable or disable referrals to a folder target**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, click a folder with targets, and then click the **Folder Targets** tab in the details pane.
3. Right-click the folder target, and then click one of the following options:
   - To enable the referral, select **Enable Folder Target**.
   - To disable the referral, select **Disable Folder Target**.

**Note**

- To perform this procedure, you must be a member of the Local Administrators group on each server that hosts the namespace, or you must have been delegated the ability to manage an existing namespace.

# Change the amount of time that clients cache referrals

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

A referral is an ordered list of targets that a client computer receives from a domain controller or namespace server when the user accesses a namespace root or folder with targets in the namespace. You can adjust how long clients cache a referral before requesting a new one.

**To change the amount of time that clients cache namespace root referrals**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, right-click a namespace, and then click **Properties**.
3. On the **Referrals** tab, in the **Cache duration (in seconds)** box, type the amount of time (in seconds) that clients cache namespace root referrals. The default setting is 300 seconds or five minutes.

**To change the amount of time that clients cache folder referrals**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, right-click a folder that has targets, and then click **Properties**.
3. On the **Referrals** tab, in the **Cache duration (in seconds)** box, type the amount of time (in seconds) that clients cache folder referrals in the **Cache duration (in seconds)** box. The default setting is 1800 seconds or 30 minutes.

**Note**

- To perform this procedure, you must be a member of the Local Administrators group on each server that hosts the namespace, or you must have been delegated the ability to manage an existing namespace.

# Set the ordering method for targets in referrals

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

A referral is an ordered list of targets that a client computer receives from a domain controller or namespace server when the user accesses a namespace root or folder with targets in the namespace. After the client receives the referral, the client attempts to access the first target in the list; if the target is not available, the client attempts to access the next target.

Targets in the client's site are always listed first in a referral. Targets outside of the client's site are listed according to the ordering method. The ordering methods are described in Referral properties.

Use the following procedure to set the ordering method on the namespace root.

**To set the ordering method for targets in namespace root referrals**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, right-click a namespace, and then click **Properties**.
3. On the **Referrals** tab, select an ordering method.

Folders with targets inherit the ordering method from the namespace root. You can override the ordering method by using the following procedure.

**To set the ordering method for targets in folder referrals**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, right-click a folder with targets, and then click **Properties**.
3. On the **Referrals** tab, select the **Exclude targets outside of the client's site** check box.

**Note**

- To perform this procedure, you must be a member of the Local Administrators group on each server that hosts the namespace, or you must have been delegated the ability to manage an existing namespace.

# Set target priority to override referral ordering

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

A referral is an ordered list of targets that a client computer receives from a domain controller or namespace server when the user accesses a namespace root or folder with targets in the namespace. Each target in a referral is ordered according to the ordering method for the namespace root or folder. To refine how targets are ordered, you can set priority on individual targets. For example, you can specify that the target is first among all targets, last among all targets, or first (or last) among all targets of equal cost.

To set target priority on a root target for a domain-based namespace, use the following procedure.

**To set target priority on a root target for a domain-based namespace**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, click the namespace whose root targets you want to set priority on.
3. In the details pane, on the **Namespace Servers** tab, right-click the root target whose priority you want to change, and then click **Properties**.
4. On the **Advanced** tab, click **Override referral ordering**, and then click the priority you want.

To set target priority on a folder target, use the following procedure.

**To set target priority on a folder target**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, click the folder whose targets you want to set priority on.
3. In the details pane, on the **Folder Targets** tab, right-click the folder target whose priority you want to change, and then click **Properties**.
4. On the **Advanced** tab, click **Override referral ordering**, and then click the priority you want.

**Note**

- To perform this procedure, you must be a member of the Local Administrators group on each server that hosts the namespace, or you must have been delegated the ability to manage an existing namespace.

# Enable client failback

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

A referral is an ordered list of targets that a client computer receives from a domain controller or namespace server when the user accesses a namespace root or folder with targets in the namespace. If a target becomes unavailable, you can configure clients to fail back to the target after it is restored.

**To enable client failback for a namespace root**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, right-click a namespace, and then click **Properties**.
3. On the **Referrals** tab, click the **Clients fail back to preferred targets** check box.

Folders with targets inherit client failback settings from the namespace root. If client failback is disabled on the namespace root, you can use the following procedure to enable client failback on a folder with targets.

**To enable client failback for a folder with targets**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, right-click a folder with targets, and then click **Properties**.
3. On the **Referrals** tab, click the **Clients fail back to preferred targets** check box.

**Notes**

- To perform this procedure, you must be a member of the Local Administrators group on each server that hosts the namespace, or you must have been delegated the ability to manage an existing namespace.
- For failback to work, client computers must run the operating systems and hotfixes described in Referral properties.

# Optimize namespace polling

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

To maintain a consistent domain-based namespace across namespace servers, it is necessary for namespace servers to periodically poll Active Directory to obtain the most current namespace data. You can use this procedure to optimize how this polling occurs.

**To optimize namespace polling**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Namespaces** node, right-click a namespace, and then click **Properties**.
3. On he **Advanced** tab, select whether the namespace will be optimized for consistency or scalability.

**Note**

- To perform this procedure, you must be a member of the Local Administrators group on each server that hosts the namespace, or you must have been delegated the ability to manage an existing namespace.

**See Also**
**Concepts**
Security requirements for creating and managing namespaces
Delegate management permissions for an existing namespace

# Managing Namespaces Hosted on Multiple Server Operating Systems

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**How to...**

- Update the static site table on namespace servers running Windows 2000 Server

# Update the static site table on namespace servers running Windows 2000 Server

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

If you want referrals from namespace servers and domain controllers running Microsoft Windows 2000 Server operating systems to be ordered according to site information, you can use the /UpdateWin2kStaticSiteTable parameter in Dfsutil.exe to update the static site information for all root targets and folder targets in the namespace object in Active Directory.

**To update the static site table**

1. Install Dfsutil.exe, which is part of the Windows Support Tools. You can install the Windows Support Tools by running Suptools.msi in the \Support\Tools folder on your Windows Server 2003 R2 operating system CD.
2. At the command prompt, type the following command:

   **Dfsutil /root:<Namespacepath> /UpdateWin2kStaticSiteTable**

   For example, to update the namespace \\Contoso\Public, type:

   **Dfsutil /root:\\Contoso\Public /UpdateWin2kStaticSiteTable**

**Notes**

- This procedure applies only to domain-based namespaces.
- Using this parameter increases the size of the namespace object in Active Directory, possibly making it exceed the recommended 5-MB size limit.
- This command must be run each time a target server's site information is changed, such as after the target is moved to another site or after the target's site name changes.

# Namespace Properties

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

This section covers:

- Referral properties
- Polling properties
- Target priority

# Referral properties

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The following options are available when you view the properties of a namespace root or folder with targets.

**Amount of time clients cache referrals**

**When this option is available:** Available when the DFS Management snap-in connects to a namespace server that is running a version of one of the following operating systems: Windows Server 2003 R2, Windows Server 2003 with Service Pack 1 (SP1), Windows Server 2003, and Windows 2000 Server.

**Supported namespace types:** Domain-based; stand-alone.

**Supported namespace server operating systems:** Windows Server 2003 and Windows 2000 Server.

**Supported clients:** All supported namespace clients.

**Where configured:** Namespace properties, Referrals tab; Folder properties, Referrals tab.

For clients that are not running Windows XP with Service Pack 2 (SP2) or Windows Server 2003 with SP1, the cache duration determines the earliest time that a client computer will request a new referral if the existing cached referral expires before it is accessed again. Clients that use a cached referral will renew the cache duration value of the referral each time a file or folder is accessed using the referral and, thus, use the referral indefinitely until the client's referral cache is cleared or the client is restarted.

This behavior is different for clients running Windows XP with SP2 or Windows Server 2003 with SP1. Specifically, the cache duration is not renewed each time a client accesses a target using a cached referral. Instead, the referral expires after the cache duration value lapses.

One benefit of this change is that namespace clients running Windows XP with SP2 or Windows Server 2003 with SP1 will more quickly discover changes to namespaces and namespace folders. For example, if the folder targets of a folder named Current are changed daily, namespace clients without Windows XP with SP2 or Windows Server 2003 with SP1 would refresh the duration value each time they access the Current folder, causing them to continue to reference stale folder targets well beyond the duration value associated with the initial referral request.

To change the amount of time that clients cache referrals, see Change the amount of time that clients cache referrals.

**Ordering methods for targets in referrals**

**When this option is available:** Availablewhen the DFS Management snap-in connects to a namespace server that is running a version of one of the following operating systems: Windows Server 2003 R2 or Windows Server 2003 with SP1.

**Supported namespace types:** Domain-based; stand-alone.

**Supported namespace server operating systems:** Windows Server 2003; namespace servers running Windows 2000 Server cannot provide referrals based on lowest cost.

**Supported clients:** All supported namespace clients.

**Where configured:** Namespace properties, Referrals tab; Folder properties, Referrals tab.

When a client computer attempts to access a namespace, a domain controller or namespace server provides a referral to the client. The referral contains a list of target servers that are sorted according to the currently configured ordering method. When a client accesses the namespace root or a folder with targets in the namespace, the client attempts to access the first target at the top of the referral; the client moves to the next target if the prior target was not available.

The three ordering methods are:

**Random order**

In this method, targets are ordered as follows:

1. Targets in the same Active Directory site as the client are listed in random order at the top of the referral.

2. Next, targets outside of the client's site are listed in random order.

If no same-site target servers are available, the client computer is referred to a random target server no matter how expensive the connection is or how distant the target is.

**Lowest cost**

In this method, targets are ordered as follows:

1. Targets in the same site as the client are listed in random order at the top of the referral.

2. Next, targets outside of the client's site are listed in order of lowest cost to highest cost. Referrals with the same cost are grouped together and within each group the targets are listed in random order.

| **Note** |
| --- |
| Site link costs are not shown in the DFS Management snap-in. To view site link costs, use the Active Directory Sites and Services snap-in. |

**Exclude targets outside of the client's site**

In this method, the referral contains only the targets that are in the same site as the client. These same-site targets are listed in random order. If no same-site targets exist, the client does not receive a referral and cannot access that portion of the namespace.

| **Note** |
| --- |
| Targets that have target priority set to "First among all targets" or "Last among all targets" are still listed in the referral, even if the ordering method is set to **Exclude targets outside of the client's site**. |

To change the ordering method, see Set the ordering method for targets in referrals.

**Clients failback to preferred targets**

**When this option is available:** Availablewhen the DFS Management snap-in connects to a namespace server that is running a version of one of the following operating systems: Windows Server 2003 R2 or Windows Server 2003 with SP1.

**Supported namespace types:** Domain-based; stand-alone.

**Supported namespace server operating systems:** Windows Server 2003 with SP1.

**Supported clients:** Windows XP with SP2 and the Windows XP client failback hotfix; Windows Server 2003 with SP1 and the Windows Server 2003 client failback hotfix. These hotfixes are described in article 898900 in the Microsoft Knowledge Base on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=53202).

**Where configured:** Namespace properties, Referrals tab; Folder properties, Referrals tab.

Client failover in DFS Namespaces is the process in which a client attempts to access another target in a referral after one of the targets becomes unavailable due to a server or network failure, or due to the target being removed from the namespace. After failover, the client might access a non-optimal target, such as a target with a high site link cost with respect to the client, and the client will continue to access the remote server even after the local server is restored. If you want clients to fail back to a preferred local server when it is restored, select the **Clients fail back to preferred targets**check box.

| **Note** |
| --- |
| When a preferred local server is available, all new file accesses will be to the local server. Files that are currently open will be accessed from the non-preferred server until that file is closed. |

To enable client failback, see Enable client failback.

# Polling properties

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**When this option is available:** Available when the DFS Management snap-in connects to a namespace server that is running a version of Windows Server 2003 R2 or Windows Server 2003 with Service Pack 1 (SP1).

**Supported namespace types:** Domain-based only.

**Where configured:** Namespace properties, Advanced tab.

To maintain a consistent domain-based namespace across namespace servers, it is necessary for namespace servers to periodically poll Active Directory to obtain the most current namespace data.

You can optimize how this polling occurs by choosing one of the following options:

**Optimize for consistency**
**Supported namespace server operating systems:** Windows Server 2003 and Windows 2000 Server.

In this mode, which is enabled by default, the Distributed File System service attempts to keep the domain-based namespace highly consistent on all namespace servers. This consistency is achieved as follows:

- Namespace servers running Windows Server 2003 and Windows 2000 Server poll the primary domain controller (PDC) emulator every hour by default.

- Namespace servers running Windows Server 2003 poll the PDC emulator after the namespace changes to obtain the updated namespace data without needing to wait for Active Directory replication to replicate the updated namespace object to all domain controllers. However, this process can cause an increased load on the PDC emulator in namespaces that have more than 16 namespace servers and in namespaces that change frequently.

This mode is recommended only for domain-based namespaces that are hosted by fewer than 16 namespace servers. For namespaces hosted by more than 16 namespace servers, we recommend choosing the **Optimize for scalability** option.

**Optimize for scalability**
**Supported namespace server operating systems:** Windows Server 2003.

This mode, also known as root scalability mode, allows organizations to use more than the recommended 16 namespace servers for hosting a domain-based namespace in consistency mode. When root scalability mode is enabled, namespace servers do not send change notification messages to other namespaces servers when the namespace changes, nor do they poll the PDC emulator every hour. Instead, they poll their closest domain controller every hour to discover updates to the namespace.

Root scalability mode reduces network traffic to the PDC emulator at the expense of faster updates to all namespaces servers. Updates are still made to the namespace object in Active Directory on the PDC emulator, but namespace servers do not discover those changes until the updated namespace object replicates (using Active Directory replication) to the closest domain controller for each namespace server. After root scalability mode is enabled, clients might have an inconsistent view of the namespace until the most up-to-date version of the namespace object is replicated to all domain controllers and the namespaces servers poll a domain controller to discover the changes.

| **Note** |
| --- |
| Namespace servers running Windows 2000 Server continue to poll the PDC emulator every hour by default, even if this option is selected. |

To change the polling method, see Optimize namespace polling.

# Target priority

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**When this option is available:** Availablewhen the DFS Management snap-in connects to a namespace server that is running a version of Windows Server 2003 with Service Pack 1 (SP1) or Windows Server 2003 R2.

**Supported namespace types:** Domain-based (folder targets and root targets); stand-alone (folder targets only).

**Supported namespace server operating systems:** Windows Server 2003 with SP1 and Windows Server 2003 R2.

**Supported clients:** All supported namespace clients.

**Where configured:** Namespace server properties, Advanced tab; Folder Target properties, Advanced tab.

By assigning target priority for individual root targets or folder targets, you can specify whether a target server appears first or last in a referral. Assigning target priority is useful in many scenarios, such as "hot standby" scenarios where one server is considered the server of last resort. In this scenario, you can specify that the standby server always appears last in referrals, and clients will fail over to this server only if all the other servers fail or become unavailable due to network outages. If multiple servers are configured for always first (or last), then those servers will be sorted based on the overall prioritization (random or lowest cost).

To change target priority, see Set target priority to override referral ordering.

# Introduction to DFS Replication

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

DFS Replication, the successor to the File Replication service (FRS) introduced in Windows 2000 Server operating systems, is a new, state-based, multimaster replication engine that supports replication scheduling and bandwidth throttling. DFS Replication uses a new compression algorithm known as remote differential compression (RDC). RDC is a "diff-over-the wire" client-server protocol that can be used to efficiently update files over a limited-bandwidth network. RDC detects insertions, removals, and re-arrangements of data in files, enabling DFS Replication to replicate only the changed file blocks when files are updated.

| **Note** |
| --- |
| For more current information about DFS Replication, see DFS Namespaces and DFS Replication Overview. |

DFS Replication uses many sophisticated processes to keep data synchronized on multiple servers. Before you begin using DFS Replication, it is helpful to understand the following concepts.

- DFS Replication is a multimaster replication engine. Any change that occurs on one member is replicated to all other members of the replication group.
- DFS Replication detects changes on the volume by monitoring the update sequence number (USN) journal, and DFS Replication replicates changes only after the file is closed.
- DFS Replication uses a staging folder to stage a file before sending or receiving it. For more information about staging folders, see Staging folders and Conflict and Deleted folders.
- DFS Replication uses a version vector exchange protocol to determine which files need to be synchronized. The protocol sends less than 1 kilobyte (KB) per file across the network to synchronize the metadata associated with changed files on the sending and receiving members.
- When a file is changed, only the changed blocks are replicated, not the entire file. The RDC protocol determines the changed file blocks. Using default settings, RDC works for any type of file larger than 64 KB, transferring only a fraction of the file over the network.
- DFS Replication uses a conflict resolution heuristic of last writer wins for files that are in conflict (that is, a file that is updated at multiple servers simultaneously) and earliest creator wins for name conflicts. Files and folders that lose the conflict resolution are moved to a folder known as the Conflict and Deleted folder. You can also configure the service to move deleted files to the Conflict and Deleted folder for retrieval should the file or folder be deleted. For more information, see Staging folders and Conflict and Deleted folders.
- DFS Replication is self-healing and can automatically recover from USN journal wraps, USN journal loss, or loss of the DFS Replication database.
- DFS Replication uses a Windows Management Instrumentation (WMI) provider that provides interfaces to obtain configuration and monitoring information from the DFS Replication service.

# Replication groups and replicated folders

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Replication groups and replicated folders are two important components of DFS Replication. They are illustrated in the following figure.

As this figure shows, a *replication group* is a set of servers, known as *members*, that participates in the replication of one or more replicated folders. A *replicated folder* is a folder that is kept synchronized on each member. In the figure, there are two replicated folders, Projects and Proposals. As data changes in each replicated folder, the changes are replicated across connections between the members of the replication group. The connections between all members form the replication topology.

Creating multiple replicated folders in a single replication group simplifies the process of deploying replicated folders because the topology, schedule, and bandwidth throttling for the replication group are applied to each replicated folder. To deploy additional replicated folders, you can use Dfsradmin.exe or a brief wizard to define the local path and permissions for the new replicated folder. Each replicated folder also has its own settings, such as file and subfolder filters, so that you can filter out different files and subfolders for each replicated folder.

The replicated folders stored on each member can be located on different volumes in the member, and the replicated folders do not need to be shared folders or part of a namespace, though the DFS Management snap-in makes it easy to share replicated folders and optionally publish them in an existing namespace.

# Security requirements for setting up and managing DFS Replication

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The following table describes the groups that can perform basic DFS Replication tasks by default and the method for delegating the ability to perform these tasks.

| Task | Users or Groups That Can Perform This Task By Default | Delegation Method |
|---|---|---|
| Create a replication group or enable DFS Replication on a folder that has folder targets | Domain Admins group in the domain where the replication group will be created. | Right-click the **Replication** node in the console tree, and then click **Delegate Management Permissions**. |
| Administer a replication group | Domain Admins group in the domain where the replication group is configured, or the creator of the replication group. | Right-click the replication group in the console tree, and then click **Delegate Management Permissions**. |
| Add a server to a replication group[1, 2] | If the server is a member server, the user must be a member of the local Administrators group of the server to add.<br>If the server is a domain controller, the user must be a member of the Domain Admins group in the domain where the server is located. | Add the user to local Administrators group of the member server to add, or add the user to the Domain Admins group of the domain controller to add. |

[1]Assumes that the user has been delegated the ability to administer the replication group.

[2]The server to be added must be online.

If you plan to delegate the ability to create and administer replication groups, note the following two important considerations:

- If you delegate to a user or group the ability to create replication groups, and you later remove the user or group from the delegation list, there is no change to the security settings on existing replication groups.

- If you delegate to a user or group the ability to administer a specific replication group, and you later remove the user or group from the delegation list, there is no change to the security settings on any existing configuration data. For example, if the user who is being removed had created a connection in the replication group, then the user would still have permissions to edit that connection because the user is the owner of the Active Directory object that contains the configuration information for the connection.

Microsoft Web site

# DFS Replication requirements

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Before you can deploy DFS Replication, you must configure servers as follows:

- The Active Directory schema must be updated to include the new DFS Replication objects.

  To upgrade the schema, on the schema operations master, run **adprep.exe /forestprep**. The Adprep.exe command-line tool is available in the Cmpnents\R2\Adprep folder on the second Windows Server 2003 R2 installation CD.

- The servers that will participate in DFS Replication must run a Windows Server 2003 R2 operating system. After you install Windows Server 2003 R2, you must install the DFS Replication service on each server that will take part in replication, and you must install the DFS Management snap-in on one server to manage replication. For installation instructions, see Installing the DFS Management Snap-in and DFS Replication Service.

- Antivirus software must be compatible with DFS Replication; contact your antivirus software vendor to check for compatibility.

- Servers in a replication group must be in the same forest. You cannot enable replication across servers in different forests.

- Replicated folders must be stored on NTFS volumes.

- On server clusters, replicated folders must be located in the local storage of a node because the DFS Replication service is not designed to work in a coordinated way with cluster components, and the service will not fail over to another node.

# DFS Replication scalability guidelines

Updated: May 5, 2010

Applies To: Windows Server 2003 R2

DFS Replication is a highly scalable replication engine that was built to efficiently replicate large sets of content over wide area networks. The following list provides a set of scalability guidelines that have been tested by Microsoft for Windows Server 2003 R2.

| **Note** |
| --- |
| For Windows Server 2008 R2 and Windows Server 2008, there is no longer a limit to the number of replication groups, replicated folders, connections, or replication group members. For more information, see the What are the supported limits of DFS Replication? topic in the DFS Replication: Frequently Asked Questions (FAQ). |

- Each server can be a member of up to 256 replication groups.
- Each replication group can contain up to 256 replicated folders.
- Each server can have up to 256 connections (for example, 128 incoming connections and 128 outgoing connections).
- On each server, the number of replication groups multiplied by the number of replicated folders multiplied by the number of simultaneously active connections must be kept to 1024 or fewer.
- A replication group can contain up to 256 members.
- A volume can contain up to 8 million replicated files, and a server can contain up to 1 terabyte of replicated files.
- The maximum tested file size is 64 gigabytes.

| **Note** |
| --- |
| You can successfully deploy configurations that exceed any or all of these tested limits. However, it is important to test large configurations and verify that there is adequate space in the staging folders before using them in production environments. In addition, you might experience increased latency during replication. See the following Web pages for additional information: Understanding DFS Replication "Limits" (http://go.microsoft.com/fwlink/?LinkId=70576); More on DFS Replication Limits (http://go.microsoft.com/fwlink/?LinkId=70575). Also see Staging folders and Conflict and Deleted folders. |

# What to expect during initial replication

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

When you first set up replication, you must choose a primary member. Choose the member that has the most up-to-date files that you want replicated to all other members of the replication group, because the primary member's content is considered "authoritative." This means that during initial replication, the primary member's files will always win the conflict resolution that occurs when the receiving members have files that are older or newer compared to the same files on the primary member.

The following concepts will help you better understand the initial replication process:

- Initial replication does not begin immediately. The topology and DFS Replication settings must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain these settings. The amount of time this takes depends on Active Directory replication latency and the long polling interval (60 minutes) on each member.

- Initial replication always occurs between the primary member and the receiving replication partners of the primary member. After a member has received all files from the primary member, then that member will replicate files to its receiving partners as well. In this way, replication for a new replicated folder starts from the primary member and then progresses out to the other members of the replication group.

- When receiving files from the primary member during initial replication, the receiving members that contain files that are not present on the primary member move those files to their respective DfsrPrivate\PreExisting folder. If a file is identical to a file on the primary member, the file is not replicated. If the version of a file on the receiving member is different from the primary member’s version, the receiving member's version is moved to the Conflict and Deleted folder and remote differential compression (RDC) can be used to download only the changed blocks.

- To determine whether files are identical on the primary member and receiving member, DFS Replication compares the files using a hash algorithm. If the files are identical, only minimal metadata is transferred.

- After the initialization of the replicated folder, the "primary member" designation is removed. (Initialization takes place after all files that exist before DFS Replication picks up the configuration are added to the DFS Replication database.) That member is then treated like any other member and its files are no longer considered authoritative over other members that have completed initial replication. Any member that has completed initial replication is considered authoritative over members that have not completed initial replication.

# Getting Started With DFS Replication

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

This section covers:

- Publish data using DFS Replication
- Collect data for backup purposes using DFS Replication

# Publish data using DFS Replication

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

To publish data using DFS Replication, create a replication group and choose a hub-and-spoke topology with either one or two hub servers (for redundancy). In this topology, you can add data to the hub server, and the data replicates out to the spoke servers. Use the following procedure to create a replication group:

- Create a replication group

To customize the replication group, use the following procedures as appropriate:

- Edit the replication group schedule
- Create or edit a custom connection schedule
- Enable or disable replicating a replicated folder on a specific member
- Enable or disable RDC for a specific connection
- Edit the replication filters for a replicated folder
- Edit the quota size of the staging folder and Conflict and Deleted folder

After you configure the replication group, you can create a namespace to enable clients to fail over to the hub server if the branch server fails or otherwise becomes unavailable. You can also configure the namespace so that clients fail back to the branch server after it is restored.

To configure a namespace for publication, use the following procedures in the order specified:

1. Publish a replicated folder in an existing namespace
2. Set the ordering method for targets in referrals
3. Enable client failback

# Collect data for backup purposes using DFS Replication

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

To collect data for backup or other purposes, use the New Replication Group Wizard to set up a replication group for data collection. This option sets up a two-way replication between two servers, such as a branch server and a hub server. Administrators at the hub office can use backup software to back up the branch server's data from a hub server, eliminating the often error-prone process of having end users performing the backups at branch offices that are not staffed by trained information technology (IT) personnel.

| **Important** |
| --- |
| The data collection topology allows data to replicate from the hub server to the branch server. If you do not want changes made at the hub server to replicate to the branch server, set up shared folder permissions to prevent data from changing on the hub server, or disable the hub-to-branch connection after you set up the replication group. |

| **Important** |
| --- |
| Using DFS Replication for data collection is not a replacement for performing regular backups. |

Use the following procedure to create a replication group for data collection purposes:

- Create a replication group

To customize the replication group, use the following procedures as appropriate:

- Edit the replication group schedule
- Enable or disable replication for a specific connection
- Edit the replication filters for a replicated folder
- Edit the quota size of the staging folder and Conflict and Deleted folder

After you configure the replication group, you can create a namespace to simplify the way users access the published data and increase the availability of the data.

To configure a namespace for data collection, perform the following procedures in the order specified:

1. Publish a replicated folder in an existing namespace
2. Set the ordering method for targets in referrals
3. Set target priority to override referral ordering (Optional)
4. Enable client failback (Optional)

# Configuring and Managing DFS Replication

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

This section covers:

- Deploying DFS Replication
- Managing DFS Replication

# Deploying DFS Replication

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**How to...**

- Create a replication group
- Add a replicated folder to a replication group
- Add a member to a replication group
- Create a connection
- Create a topology
- Delegate the ability to create replication groups
- Delegate the ability to manage an existing replication group

# Create a replication group

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

### To create a replication group

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, right-click the **Replication** node, and then click **New Replication Group**.
3. Follow the instructions in the New Replication Group Wizard.

### Important

- When you create a new replication group, replication does not begin immediately. The topology and DFS Replication settings must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain these settings. The amount of time this takes depends on Active Directory replication latency and each member's long polling interval (60 minutes).

### Notes

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority to create replication groups and be a member of the local Administrators group on each member.

- To check the status of replication, or to troubleshoot replication, create a diagnostic report. For more information, see Create a diagnostic report for DFS Replication.

# Add a replicated folder to a replication group

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

### To create a replicated folder

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, right-click a replication group, and then click **New Replicated Folders**.
3. Follow the instructions in the New Replicated Folders Wizard.

### Important

- Replication of the new replicated folder does not begin immediately. The new DFS Replication settings must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain these settings. The amount of time this takes depends on Active Directory replication latency and the long polling interval (60 minutes) on each member.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority for the replication group and be a member of the local Administrators group on each member. If you are the creator of the replication group, you can also perform this procedure if you are a member of the local Administrators group on each member.

- To check the status of replication, or to troubleshoot replication, create a diagnostic report. For more information, see Create a diagnostic report for DFS Replication.

# Add a member to a replication group

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To add a member to a replication group**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, right-click a replication group, and then click **New Member**.
3. Follow the instructions in the New Member Wizard.

**Important**

- Replication does not begin immediately on the new member. The DFS Replication settings for the new member must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain these settings. The amount of time this takes depends on Active Directory replication latency, the short polling interval (5 minutes) on the new member, and the long polling interval (60 minutes) on existing members.

**Notes**

- Security requirements for performing this task are described in Security requirements for setting up and managing DFS Replication.
- To check the status of replication, or to troubleshoot replication, create a diagnostic report. For more information, see Create a diagnostic report for DFS Replication.

# Create a connection

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To create a connection**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, right-click the replication group that you want to create a new connection in, and then click **New Connection**.
3. Select the sending and receiving members, and select the schedule to use for the connection.
4. To create a second connection for two-way replication between the sending and receiving members, select **Create a second connection in the opposite direction**.

**Important**

- Replication does not begin immediately on the new connection. The new connection settings must be replicated to all domain controllers, and the sending and receiving members must poll their closest domain controller to obtain these settings. The amount of time this takes depends on Active Directory replication latency and the long polling interval (60 minutes) on each member.

**Note**

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the ability to manage an existing replication group. If you are the creator of the replication group, you can also perform this procedure.

# Create a topology

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

### To create a topology

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, right-click the replication group to create a new topology for, and then click **New Topology**.
3. Follow the instructions in the New Topology Wizard.

### Important

- Replication in the new topology does not begin immediately. The topology and DFS Replication settings must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain these settings. The amount of time this takes depends on Active Directory replication latency and the long polling interval (60 minutes) on each member.

### Note

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the ability to manage an existing replication group. If you are the creator of the replication group, you can also perform this procedure.

# Managing DFS Replication

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**How to...**

- Edit the replication group schedule
- Create or edit a custom connection schedule
- Enable or disable replication for a specific connection
- Enable or disable replicating a replicated folder on a specific member
- Enable or disable RDC for a specific connection
- Enable or disable topology verification
- Repair a disconnected topology
- Edit the replication filters for a replicated folder
- Edit the quota size of the staging folder and Conflict and Deleted folder
- Share a replicated folder
- Publish a replicated folder in an existing namespace
- Create a diagnostic report for DFS Replication

# Edit the replication group schedule

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To edit the replication group schedule**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, right-click the replication group whose schedule you want to edit, and then click **Edit Replication Group Schedule**.

**Important**

- Schedule changes are not applied immediately. The new schedule must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain the changes. The amount of time this takes depends on Active Directory replication latency and the long polling interval (60 minutes) on each member.

**Note**

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the ability to manage an existing replication group. If you are the creator of the replication group, you can also perform this procedure.

# Create or edit a custom connection schedule

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To create or edit a custom connection schedule**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, click the replication group that contains the connection you want to edit.
3. In the details pane, click the **Connections** tab.
4. Right-click the connection, click **Properties**, and then click the **Schedule** tab.
5. To specify a custom schedule, select **Custom connection schedule**, and then click **Edit Schedule** to edit the schedule that applies only to that connection.

**Important**

- Schedule changes are not applied immediately. The new schedule must be replicated to all domain controllers, and the sending and receiving members for the connection must poll their closest domain controller to obtain the changes. The amount of time this takes depends on Active Directory replication latency and the long polling interval (60 minutes) on each member.

**Note**

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the ability to manage an existing replication group. If you are the creator of the replication group, you can also perform this procedure.

# Enable or disable replication for a specific connection

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

### To enable or disable replication for a specific connection

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, click the replication group that contains the connection you want to edit.
3. In the details pane, click the **Connections** tab.
4. Do one of the following:
   - To disable a connection, right-click the connection, and then click **Disable**.
   - To enable a connection, right-click the connection, and then click **Enable**.

### Important

- Connection changes are not applied immediately. The new connection settings must be replicated to all domain controllers, and the sending and receiving members must poll their closest domain controller to obtain the changes. The amount of time this takes depends on Active Directory replication latency and the long polling interval (60 minutes) on each member.

### Note

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the ability to manage an existing replication group. If you are the creator of the replication group, you can also perform this procedure.

# Enable or disable replicating a replicated folder on a specific member

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To enable or disable replicating a replicated folder to a specific member**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, click the replication group that contains the membership you want to enable or disable.
3. In the details pane, click the **Memberships** tab.
4. Select the replicated folder on the specific member, and then do one of the following:
   - To disable the replicated folder on the member, right-click the replicated folder, and then click **Disable**.
   - To enable the replicated folder on the member, right-click the replicated folder, and then click **Enable**.

**Important**

- Before you use this procedure, it is important to understand the ramifications of enabling and disabling memberships. After a disabled membership is enabled, the member must complete an initial replication of the replicated folder. Initial replication will cause about 1 KB of data to be transferred for each file or folder in the replicated folder, and any updated or new files present on the member will be moved to the DfsrPrivate\PreExisting folder on the member and be replaced with authoritative files from another member.
- If all memberships are disabled for any replicated folder, then the first member that is enabled will automatically be made the primary member. If the discretionary access control list (DACL) on the local path for this member contains any inherited access-control entries (ACE), these ACEs will be converted to explicit ACEs with the same permissions so that all members will end up with the same DACL on the replicated folder root.
- Membership changes are not applied immediately. The membership changes must be replicated to all domain controllers, and the member must poll its closest domain controller to obtain the changes. The amount of time this takes depends on Active Directory replication latency and the short polling interval (5 minutes) on the member.

**Note**

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the ability to manage an existing replication group. If you are the creator of the replication group, you can also perform this procedure.

# Enable or disable RDC for a specific connection

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Remote differential compression (RDC) is a "diff-over-the-wire" protocol that can be used to efficiently update files over a limited-bandwidth network. RDC detects insertions, removals, re-arrangements of data in files, enabling DFS Replication to replicate only the changes when files are updated.

Because disabling RDC can help conserve disk input/output (I/O) and CPU resources, you might want to disable RDC on a connection if the sending and receiving members are in a local area network (LAN), and bandwidth use is not a concern. However, in a LAN environment where bandwidth is contended, RDC can be beneficial when transferring large files.

**To enable or disable RDC for a specific connection**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, click the replication group that contains the connection you want to edit.
3. In the details pane, click the **Connections** tab.
4. Right-click the connection, click **Properties**, and then on the **General** tab, select or clear the **Use remote differential compression (RDC)** check box.

**Important**

- Changes to RDC settings are not applied immediately. The RDC changes must be replicated to all domain controllers, and the sending and receiving members must poll their closest domain controller to obtain the changes. The amount of time this takes depends on Active Directory replication latency and the long polling interval (60 minutes) on each member.

**Note**

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the ability to manage an existing replication group. If you are the creator of the replication group, you can also perform this procedure.

# Enable or disable topology verification

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Topology verification checks whether the topology is fully connected. You can view the status of the topology by selecting a replication group, clicking the **Connections** tab in the details pane, and viewing the status that appears in the details pane.

**To enable or disable topology validation**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, right-click the **Replication** node, and then do one of the following:
    - To disable topology verification, click **Disable Topology Verification**.
    - To enable topology verification, click **Enable Topology Verification**.

**Note**

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the ability to manage an existing replication group. If you are the creator of the replication group, you can also perform this procedure.

# Repair a disconnected topology

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To repair a disconnected topology**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, click the replication group that contains the disconnected topology.
3. In the details pane, on the **Connections** tab, click the error message at the top of the tab to open the Disconnected Topology dialog box.
4. To view disconnected members, select a replicated folder from the **Replicated folder** list, and then expand the **Disconnected Members**.
5. Click **Close**.
6. Repair the topology by performing any of the following procedures, as appropriate:
   - Create a connection
   - Edit the replication group schedule
   - Create or edit a custom connection schedule
   - Enable or disable replication for a specific connection
   - Enable or disable replicating a replicated folder on a specific member

**Note**

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the ability to manage an existing replication group. If you are the creator of the replication group, you can also perform this procedure.

# Edit the replication filters for a replicated folder

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To edit the replication filters for a replicated folder**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, click the replication group that contains the replicated folder whose filters you want to edit.
3. In the details pane, on the **Replicated Folders** tab, right-click a replicated folder, and then click **Properties**.
4. On the **General** tab, edit the existing filters or add new filters.

**Important**

- Filter changes are not applied immediately. The updated filters must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain the changes. The amount of time this takes depends on Active Directory replication latency and the long polling interval (60 minutes) on each member.

**Note**

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the ability to manage an existing replication group. If you are the creator of the replication group, you can also perform this procedure.

# Edit the quota size of the staging folder and Conflict and Deleted folder

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can edit the quota of the staging folder and Conflict and Deleted folder on a per-replicated folder, per-member basis.

**To edit the quota size of the staging folder and Conflict and Deleted folder**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, click the replication group that contains the replicated folder whose quotas you want to edit.
3. In the details pane, on the **Memberships** tab, right-click the replicated folder on the member whose quota you want to edit, and then click **Properties**.
4. On the **Advanced** tab, adjust the quotas as necessary.

**Important**

- Changes to staging folder quotas and Conflict and Deleted folder quotas are not applied immediately. The updated quotas must be replicated to all domain controllers, and the member must poll its closest domain controller to obtain the changes. The amount of time this takes depends on Active Directory replication latency and the short polling interval (5 minutes) on the member.

**Note**

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the ability to manage an existing replication group. If you are the creator of the replication group, you can also perform this procedure.

# Share a replicated folder

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To share a replicated folder**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, click the replication group that contains the replicated folder you want to share.
3. In the details pane, on the **Replicated Folders** tab, right-click the replicated folder you want to share, and then click **Share and Publish in Namespace**.
4. In the Share and Publish Replicated Folder Wizard, select the **Share the replicated folder** option, and then follow the steps in the wizard.

**Note**

- To perform this procedure, you must be a member of the local Administrators group on each server where the replicated folder is shared.

# Publish a replicated folder in an existing namespace

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To publish a replicated folder**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, click the replication group that contains the replicated folder you want to share.
3. In the details pane, on the **Replicated Folders** tab, right-click the replicated folder you want to share, and then click **Share and Publish in Namespace**.
4. In the Share and Publish Replicated Folder Wizard, select the **Share and publish the replicated folder in a namespace** option, and then follow the steps in the wizard.

**Notes**

- To perform this procedure, you must meet the security requirements for managing DFS Replication and namespaces. If folders will be shared as part of the Share and Publish Replicated Folder Wizard, you must also be a member of the local Administrators group on the servers where each folder is shared.

- If you do not have an existing namespace, you can create one in the **Namespace Path** page in the Share and Publish Replicated Folder Wizard. To create the namespace, click **Browse** in the **Namespace Path** page, and then click **New Namespace**.

# Create a diagnostic report for DFS Replication

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To create a diagnostic report for DFS Replication**

1. Click **Start**, point to **Administrative Tools**, and then click **DFS Management**.
2. In the console tree, under the **Replication** node, right-click the replication group that you want to create a diagnostic report for, and then click **Create Diagnostic Report**.
3. Follow the instructions in the Diagnostic Report Wizard.

**Notes**

- To create a diagnostic report, you must be a member of the local Administrators group on each server that you prepare a report for.

- The amount of time necessary to generate a diagnostic report will vary based on a number of factors, including: DFS Replication health; the number of replicated folders; available server resources (for example, CPU, memory, and so forth); WAN availability (connectivity, bandwidth, and latency); and the chosen reporting options (backlog and file system enumeration). Because of the potential delay in creating diagnostic reports, we recommend creating diagnostic reports for no more than 50 servers at a time.

# DFS Replication Properties

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

This section covers:

- Replication schedules and bandwidth
- Replication topologies
- Staging folders and Conflict and Deleted folders
- File and subfolder filters

# Replication schedules and bandwidth

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The following sections describe options for configuring replication schedules and bandwidth usage in DFS Replication.

**Replication schedules**
The replication schedule determines the days and times at which replication occurs. You can configure the schedule at 15-minute intervals 24 hours a day, seven days a week.

There are two types of schedules:

- **Replication group schedule**. This schedule applies to all connections in the replication group except connections that have a custom connection schedule. You can edit the replication group schedule by viewing the properties of the replication group.

- **Custom connection schedule**. This is a unique schedule that is applied to an individual connection. You can edit the custom schedule by viewing the properties of a connection.

Because members can exist in different time zones, it is important to understand how the schedule is affected by time zones, and whether daylight savings time is in effect. Replication is always initiated by the receiving member; therefore, the schedule reflects the time at which a receiving member initiates replication with a sending member. The receiving members can interpret the schedule in one of the following ways:

- **Universal Coordinated Time (UTC)**. This option causes the receiving member to treat the schedule as an absolute clock. For example, a schedule that begins at 0800 UTC is the same for any location, regardless of time zone or whether daylight savings time is in effect for a receiving member. For example, assume that you set replication to begin at 0800 UTC. A receiving member in Eastern Standard Time would begin replicating at 3:00 A.M. local time (UTC - 5), and a receiving member in Rome would begin replicating at 9:00 A.M. local time (UTC + 1). Note that the UTC offset shifts when daylight savings time is in effect for a particular location.

- **Local time of receiving member**. This option causes the receiving member to use its local time to start and stop replication. Local time is determined by the time zone and daylight savings time status of the receiving member. For example, a schedule that begins at 8:00 A.M. will cause every receiving member to begin replicating when the local time is 8:00 A.M. Note that daylight savings time does not cause the schedule to shift. If replication starts at 9 A.M. before daylight savings time, replication will still start at 9 A.M. when daylight savings time is in effect.

When the schedule is open, replication occurs as files are changed, created, or deleted. When the schedule closes, replication stops, regardless of whether all changed or new files have replicated.

| **Important** |
| --- |
| Schedule changes are not applied immediately. The new schedule must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain the changes. The amount of time this takes depends on Active Directory replication latency and the long polling interval (60 minutes) on each member. |

**Bandwidth usage**
You can configure a different bandwidth usage for each interval of the schedule. The bandwidth setting is an absolute value, not a percentage of available bandwidth. The bandwidth used is not kept at the specified bandwidth setting for every one-second interval. Instead, the bandwidth used can occur in bursts at any given second, but over a period of time, the average bandwidth used is equal to the bandwidth setting.

Microsoft Web site

# Replication topologies

Updated: September 2, 2009

Applies To: Windows Server 2003 R2

The replication topology consists of the logical connections that DFS Replication uses to replicate files among servers. When you set up a replication group, you can choose from three topologies:

- **Hub and spoke**. This topology requires three or more members; otherwise this option is unavailable. For each spoke member, you can choose a required hub member and an optional second hub member for redundancy. This optional hub ensures that a spoke member can still replicate if one of the hub members is unavailable. If you specify two hub members, the hub members will have a full-mesh topology between them.

- **Full mesh**. In this topology, every member replicates with all other members of the replication group. This topology works well when there are ten or fewer members in the replication group. We recommend against using a full mesh topology if you have more than ten members in the replication group.

- **No topology**. Choose this option if you want to create connections yourself after you finish the New Replication Group Wizard or the Replicate Folder Wizard. No replication will take place until you create the connections.

When choosing a topology, keep in mind that two one-way connections are created between the members you choose. These two connections allow data to flow in both directions. For example, in a hub and spoke topology, data will flow from the hub members to the spoke members and from the spoke members to the hub members.

# Staging folders and Conflict and Deleted folders

Updated: February 25, 2010

Applies To: Windows Server 2003 R2

**Staging folders**

DFS Replication uses staging folders to act as caches for new and changed files to be replicated from sending members to receiving members. The sending member begins staging a file when it receives a request from the receiving member. The process involves reading the file from the replicated folder and building a compressed representation of the file in the staging folder. This is the *staged file*. After being constructed, the staged file is sent to the receiving member; if remote differential compression [RDC] is used, only a fraction of the staging file might be replicated. The receiving member downloads the data and builds the file in its staging folder. After the file has completed downloading on the receiving member, DFS Replication decompresses the file and installs it into the replicated folder.

Each replicated folder has its own staging folder, which by default is located under the local path of the replicated folder in the DfsrPrivate\Staging folder. The default size of each staging folder is 4,096 MB. This is not a hard limit, however. It is only a quota that is used to govern cleanup and excessive usage based on high and low watermarks (90 percent and 60 percent of staging folder size, respectively). For example, when the staging folder reaches 90 percent of the configured quota the oldest staged files are purged until the staging folder reaches 60 percent of the configured quota.

It is important to note that the staging folder quota does not determine the largest file that can be replicated. In other words, it is possible to replicate a file that is larger than the configured quota of a staging folder. The large file is placed in the staging folder, and the staging folder cleanup process is triggered when the file is finished staging and space usage is at or above the high watermark. If the cleanup fails because the large file is still in the process of being replicated to receiving members, the cleanup process will be retried later and eventually the large file will be purged from the staging folder.

Although you can adjust the size of each staging folder, you must take the following factors into account while doing so:

- For good operational performance, increasing the quota size of a staging folder is recommended when you have multiple large files that change frequently. We also recommend that you increase the staging folder quota on hub members that have many replication partners.

- The size of each staging folder on a member is cumulative per volume. For example, if you have three replicated folders on a member on the same volume, it is possible for DFS Replication to use 12 GB or more for staging purposes. However, staging space is not preallocated; disk space is only used when staged files are present.

  | **Note** |
  | --- |
  | In this example, staging cleanup might not be triggered when the staging files occupy 10.8 GB (0.9*4 GB*3), because staging space is distributed across the three replicated folders. If free disk space is a concern, you might need to configure the staging quota to be lower than the default quota when several replicated folders share staging space on the same volume. This ensures that staging cleanup is triggered. |

- If the size of a staging folder is below 90 percent of configured capacity (the high watermark), then staged files are kept in the folder and can be used in case new members are added.

- Staged files are purged (based on a "least recently used" algorithm) when a staging folder reaches 90 percent of the configured quota (the high watermark). Files are purged until the staging size falls below the low watermark (default is 60 percent) of the configured quota.

- If a staging folder quota is configured to be too small, DFS Replication might consume additional CPU and disk resources to regenerate the staged files. Replication might also slow down because the lack of staging space can effectively limit the number of concurrent transfers with partners.

- For the initial replication of existing data on the primary member, it is important that you size the staging folder quota large enough so that if multiple large files are blocked in staging due to partners not being able to download the files, the remaining files can continue replicating. To properly size the staging folder for initial replication, you must take into account the size of the files to be replicated. At a minimum, the staging folder quota for servers running Windows Server 2003 R2 should be at least the size of the nine largest files in the replicated folder. To improve performance, set

the size of the staging folder quota as close as possible to the size of the replicated folder.

**Tip**

To determine the size of the largest files in a replicated folder, you can either use Windows Explorer (sort by size and add the nine largest file sizes to get the minimum staging folder size), or, from a Windows PowerShell™ command prompt, use this Windows PowerShell command where <*replicatedfolderpath*> is the path to the replicated folder:

```
Get-ChildItem <replicatedfolderpath> -recurse | Sort-Object length -descending  | select-object -first 9
| ft name,length -wrap -auto
```

To install Windows PowerShell on a server running Windows Server 2003, see Windows PowerShell 1.0 English-Language Installation Package for Windows Server 2003 (KB926139) in the Microsoft Download Center (http://go.microsoft.com/fwlink/?LinkId=184089).

- During normal operation, if the event that indicates the staging quota is over its configured size (event ID 4208 in the DFS Replication event log) is logged multiple times in a day, increase the staging quota by 20 percent.

**Conflict and Deleted folders**

DFS Replication uses a "last-writer wins" method for determining which version of a file to keep when a file is modified on two or more members. The losing file is stored in the Conflict and Deleted folder on the member that resolves the conflict. This member might not be the member where the changes originated.

Each replicated folder has its own Conflict and Deleted folder, which is located under the local path of the replicated folder in the DfsrPrivate\ConflictandDeleted folder. The quota size of the Conflict and Deleted folder is 660 MB by default. Like the staging folder, the Conflict and Deleted folder has high and low watermarks (90 percent and 60 percent of Conflict and Deleted folder quota, respectively) that govern cleanup and excessive usage of the folder. And like the staging folder, the size of each Conflict and Deleted folder on a member is cumulative per volume.

The files in the Conflict and Deleted folder are renamed and are accessible only by members of the local Administrators group. The access control lists (ACLs) on the conflict files are preserved to help ensure security. You can view a log of conflict files, as well as their original file names, by viewing the ConflictandDeletedManifest.xml file in the DfsrPrivate folder.

The Conflict and Deleted folder can also be used to store files that are deleted from replicated folders. You can configure this option by viewing the properties of a membership. Deleted files are treated like conflict files in that they are purged when the Conflict and Deleted folder reaches 90 percent of the configured quota. They are also renamed and listed in the ConflictandDeletedManifest.xml file.

# File and subfolder filters

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can configure file and subfolder filters to prevent files and subfolders from replicating. Both types of filters are set on a per-replicated folder basis. You exclude subfolders by specifying their name or by using the asterisk (*) wildcard. You exclude files by specifying their name or by using the asterisk (*) wildcard to specify file names and extensions.

By default, no subfolders are excluded. The default file filters exclude the following files from replication:

- File names starting with a tilde (~) character
- Files with .bak or .tmp extensions

Regardless of which filters are set, the following types files are always excluded from replication:

- NTFS mounted drives.
- Files encrypted by using encrypting file system (EFS).
- Any reparse points except those associated with DFS Namespaces. If a file has a reparse point used for Hierarchical Storage Management (HSM) or Single Instance Store (SIS), DFS Replication replicates the underlying file but not the reparse point.
- Files on which the temporary attribute has been set.

When creating filters, note the following restrictions:

- You cannot create file or subfolder filters by specifying a full path, such as C:\Replicatedfolder\Temp or C:\Replicatedfolder\file.dat.
- You cannot specify a comma in a filter because commas are used as delimiters.

| **Important** |
| --- |
| Filter changes are not applied immediately. The updated filters must be replicated to all domain controllers, and each member in the replication group must poll its closest domain controller to obtain the changes. The amount of time this takes depends on Active Directory replication latency and the long polling interval (60 minutes) on each member. |

It is also important to understand what happens when filters are created and removed.

- **When a filter is created**. After a member detects a new filter, the member scans its database and removes any file records of files that match the filter. Because the files are no longer listed in the database, any future changes to the files are ignored.
- **When a filter is removed**. After a member detects that a filter has been removed, the member scans the file system, adds records for all files that match the removed filter, and replicates the files.

# Active Directory Federation Services (ADFS)

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Active Directory Federation Services (ADFS) is based on the emerging, industry-supported Web Services Architecture, which is defined in WS-* specifications. ADFS helps you use single sign-on (SS0) to authenticate users to multiple, related Web applications over the life of a single online session. ADFS accomplishes this by securely sharing digital identity and entitlement rights across security and enterprise boundaries.

- For help with specific tasks, see ADFS How To.
- For general background information, see ADFS Concepts.
- For problem-solving instructions, see ADFS troubleshooting.

# ADFS How To

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

- Deploy ADFS
- Complete the Add Resource Partner Wizard
- Complete the Add Account Partner Wizard
- Complete the Add Account Store Wizard
- Complete the Add Applications Wizard
- Configure the Account Store Priority
- Manage ADFS

# Deploy ADFS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

For information about how to deploy Active Directory Federation Services (ADFS), look for ADFS planning and deployment content on the Windows Server 2003 R2 Roadmap page (http://go.microsoft.com/fwlink/?LinkId=45560) of the Microsoft Windows Server 2003 TechCenter Web site.

# Complete the Add Resource Partner Wizard

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can use the Add Resource Partner Wizard to add a new resource partner manually or by importing a policy file. Use this wizard to add a resource partner that will provide a Web application to users who have accounts in your account store (Active Directory or Active Directory Application Mode (ADAM)).

**Add a resource partner manually**
You can use the following procedure to add a resource partner manually.

**To add a resource partner manually**

1. Click **Start**, point to **Administrative Tools**, and then click **Active Directory Federation Services**.
2. In the console tree, double-click **Federation Service**, **Trust Policy**, and **Partner Organizations**.
3. In the console tree, right-click **Resource Partners**, point to **New**, and then click **Resource Partner**.
4. On the **Welcome to the Add Resource Partner Wizard** page, click **Next**.
5. On the **Import Policy File** page, ensure that **No** is selected, and then click **Next**.
6. On the **Resource Partner Details** page, do the following, and then click **Next**:
   - In **Display name**, type the name of the resource partner.
   - In **Federation Service URI**, type the Uniform Resource Identifier (URI) for the resource partner.
   - In **Federation Service endpoint URL**, type the Uniform Resource Locator (URL) of the Federation Service.
7. On the **Federation Scenario** page, do one of the following, and then click **Next**:
   - If you are establishing a federated trust with another organization or you do not want to use an existing forest trust, click **Federated Web SSO**.
   - If you are establishing a federated trust within the same organization when both sides already share a forest trust, click **Federated Web SSO with Forest Trust**.
8. On the **Resource Partner Identity Claims** page, select one or more identity claims to share with the resource partner, and then click **Next**:
   - If the resource partner requires user principal name (UPN) claims to make authorization decisions, select the **UPN Claim** check box.

| **Note** |
| --- |
| If you selected the **Federated Web SSO with Forest Trust** scenario, the **UPN Claim** option is selected and not configurable. This is because UPN claims are required for this scenario. |

   - If the resource partner requires e-mail claims to make authorization decisions, select the **E-mail Claim** check box.
   - If the resource partner requires common name claims to make authorization decisions, select the **Common Name Claim** check box.
9. If you selected **UPN Claim** as an identity claim, on the **Select UPN Suffix** page, do one of the following, and then click

**Next**:

- To pass all UPN suffixes through without replacing them, click **Pass all UPN suffixes through unchanged**.
- To replace all UPN suffixes with a different suffix, click **Replace all UPN suffixes with the following**, and then type the suffix that you want to use to replace all UPN suffixes.

10. If you selected **E-mail Claim** as an identity claim, on the **Select E-mail Suffix** page, do one of the following, and then click **Next**:
    - To pass all e-mail suffixes without replacing them, click **Pass all E-mail suffixes through unchanged**.
    - To replace all e-mail suffixes with a different suffix, click **Replace all E-mail suffixes with**, and then type the suffix that you want to use to replace all e-mail suffixes.

| **Note** |
| --- |
| Common name claims require no additional information. |

11. On the **Enable this Resource Partner** page, if you do not want to enable the resource partner now, clear the **Enable this resource partner** check box, and then click **Next**.
12. To add the new resource partner and close the wizard, click **Finish**.

**Add a resource partner by importing a policy file**

You can use the following procedure to add a resource partner by importing a policy file.

**To add a resource partner by importing a policy file**

1. Click **Start**, point to **Administrative Tools**, and then click **Active Directory Federation Services**.
2. In the console tree, double-click **Federation Service**, **Trust Policy**, and **Partner Organizations**.
3. Right-click **Resource Partners**, point to **New**, and then click **Resource Partner**.
4. On the **Welcome to the Add Resource Partner Wizard** page, click **Next**.
5. On the **Import Policy File** page, do the following, and then click **Next**:
    - Click **Yes**.
    - In **Partner interoperability policy file**, browse to or type the location of the resource partner policy file.
6. On the **Federation Scenario** page, do one of the following, and then click **Next**:
    - If you are establishing a federated trust with another organization or you do not want to use an existing forest trust, click **Federated Web SSO**.
    - If you are establishing a federated trust within the same organization when both sides already share a forest trust, click **Federated Web SSO with Forest Trust**.
7. On the **Resource Partner Identity Claims** page, select one or more identity claims that the account partner will provide to the resource partner, and then click **Next**:
    - If the resource partner requires UPN claims to make authorization decisions, select the **UPN Claim** check box.

| **Note** |
| --- |

| |
|---|
| If you selected the **Federated Web SSO with Forest Trust** scenario, the **UPN Claim** option is selected and not configurable. This is because UPN claims are required for this scenario. |

- If the resource partner requires e-mail claims to make authorization decisions, select the **E-mail Claim** check box.
- If the resource partner requires common name claims to make authorization decisions, select the **Common Name Claim** check box.

8. If you selected **UPN Claim** as an identity claim, on the **Select UPN Suffix** page, select one of the following, and then click **Next**.
   - To pass all UPN suffixes through without replacing them, click **Pass all UPN suffixes through unchanged**.
   - To replace all UPN suffixes with a different suffix, click **Replace all UPN domain suffixes with the following**, type the suffix that you want to use to replace all UPN suffixes, and then click **Add**.
9. If you selected **E-mail Claim** as an identity claim, on the **Select E-mail Suffix** page, do one of the following, and then click **Next**:
   - To pass all e-mail suffixes without replacing them, click **Pass all e-mail suffixes through unchanged**.
   - To replace all UPN suffixes with a different suffix, click **Replace all E-mail suffixes with**, and then type the suffix that you want to use to replace all e-mail suffixes.

| **Note** |
|---|
| Common name claims require no additional information. |

10. On the **Enable this Resource Partner** page, if you do not want to enable the resource partner now, clear the **Enable this resource partner** check box, and then click **Next**.
11. To add the new resource partner and close the wizard, click **Finish**.

# Complete the Add Account Partner Wizard

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can use the Add Account Partner Wizard to add a new account partner manually or by importing a policy file. This will allow user accounts in the account partner to access Web applications that are protected by this Federation Service.

**Add an account partner manually**

You can use the following procedure to add an account partner manually.

**To add an account partner manually**

1. Click **Start**, point to **Administrative Tools**, and then click **Active Directory Federation Services**.
2. In the console tree, double-click **Federation Service**, **Trust Policy**, and **Partner Organizations**.
3. Right-click **Account Partners**, point to **New**, and then click **Account Partner**.
4. On the **Welcome to the Add Account Partner Wizard** page, click **Next**.
5. On the **Import Policy File** page, click **No**, and then click **Next**.
6. On the **Account Partner Details** page, do the following, and then click **Next**
   - In **Display name**, type the display name of the account partner.
   - In **Federation Service URI**, type the Uniform Resource Identifier (URI) of the Federation Service.
   - In **Federation Service endpoint URL**, type the Uniform Resource Locator (URL) of the Federation Service.
7. On the **Account Partner Verification Certificate** page, type the path to the verification certificate, or browse to it, and then click **Next**.
8. On the **Federation Scenario** page, do one of the following, and then click **Next**:
   - If you are establishing a federated trust with another organization or you do not want to use an existing forest trust, click **Federated Web SSO**, and then go to step 10.
   - If you are establishing a federated trust within the same organization when both sides already share a forest trust, click **Federated Web SSO with Forest Trust**.
9. On the **Federated Web SSO with Forest Trust** page, do one of the following, and then click **Next**:
   - To accept users in all domains that are trusted by the account partner, click **All Active Directory domains and forests**. Any user that can authenticate to the account partner will be accepted.
   - To accept user accounts that are located in some of the domains that are trusted by the account partner, click **The following Active Directory domains and forests**. Then, in **New, trusted Active Directory domain or forest**, type the name of a domain or forest, and then click **Add**. Only users from the specified domains will be accepted.
10. On the **Account Partner Identity Claims** page, select one or more identity claims to share with the resource partner, and then click **Next**:
    - If the resource partner requires user principal name (UPN) claims to make authorization decisions, select the **UPN Claim** check box.

**Important**

| |
|---|
| When UPN claims or e-mail claims are used to make authorization decisions, it is essential that each account partner use a unique UPN suffix or e-mail suffix. If two account partners use the same UPN suffix or e-mail suffix, it may not be possible to uniquely identify users. This condition might allow a user from one account partner to receive the permissions that are intended for a user in another account partner. This condition might also introduce a significant security weakness because an administrator could intentionally create user accounts to impersonate users from one of your other account partners. |

| **Note** |
|---|
| If you selected the **Federated Web SSO with Forest Trust** scenario, the **UPN Claim** option is selected and not configurable. This is because UPN claims are required for this scenario. |

- If the resource partner requires e-mail claims to make authorization decisions, select the **E-mail Claim** check box.
- If the resource partner requires common name claims to make authorization decisions, select the **Common Name Claim** check box.

11. If you selected **UPN Claim** as an identity claim, on the **Accepted UPN Suffixes** page, click **All UPN suffixes** (this option is available only if you selected the **Federation Web SSO with Forest Trust** option), or type the accepted suffix, click **Add**, and then click **Next**.
12. If you selected **E-mail Claim** as an identity claim, on the **Accepted E-mail Suffixes** page, click **All E-mail suffixes** (this option is available only if you selected the **Federation Web SSO with Forest Trust** option), or type the accepted suffix, click **Add**, and then click **Next**.

| **Note** |
|---|
| Common name claims require no additional information. |

13. On the **Enable this Account Partner** page, if you do not want to enable the account partner now, clear the **Enable this account partner** check box, and then click **Next**.
14. To add the new account partner and close the wizard, click **Finish**.

**Add an account partner by importing a policy file**

You can use the following procedure to add an account partner by importing a policy file.

**To add an account partner by importing a policy file**

1. Click **Start**, point to **Administrative Tools**, and then click **Active Directory Federation Services**.
2. In the console tree, double-click **Federation Service**, **Trust Policy**, and **Partner Organizations**.
3. Right-click **Account Partners**, point to **New**, and then click **Account Partner**.
4. On the **Welcome to the Add Account Partner Wizard** page, click **Next**.
5. On the **Import Policy File** page, do the following, and then click **Next**:
   - Click **Yes**.
   - In **Partner interoperability policy file**, browse to or type the location of the account partner policy file.
6. On the **Federation Scenario** page, do one of the following, and then click **Next**:
   - If you are establishing a federated trust with another organization or you do not want to use an existing forest trust, click **Federated Web SSO**, and then go to step 8.
   - If you are establishing a federated trust within the same organization when both sides already share a forest trust,

click **Federated Web SSO with Forest Trust**.

7. On the **Federation Web SSO with Forest Trust** page, do one of the following, and then click **Next**:

   - To accept users in all domains that are trusted by the account partner, click **All Active Directory domains and forests**. Any user that can authenticate to the account partner will be accepted.

   - To accept user accounts that are located in some of the domains that are trusted by the account partner, click **The following Active Directory domains and forests**. Then, in **New, trusted Active Directory domain or forest**, type the name of the domain or forest, and then click **Add**. Only users from the specified domains will be accepted.

8. On the **Account Partner Identity Claims** page, select one or more identity claims that this partner will provide, and then click **Next**:

   - If the resource partner requires UPN claims to make authorization decisions, select the **UPN Claim** check box.

| **Important** |
| --- |
| When UPN claims or e-mail claims are used to make authorization decisions, it is essential that each account partner use a unique UPN suffix or e-mail suffix. If two account partners use the same UPN suffix or e-mail suffix, it may not be possible to uniquely identify users. This condition might allow a user from one account partner to receive the permissions that are intended for a user in another account partner. This condition might also introduce a significant security weakness because an administrator could intentionally create user accounts to impersonate users from one of your other account partners. |

| **Note** |
| --- |
| If you selected the **Federated Web SSO with Forest Trust** scenario, the **UPN Claim** option is selected and not configurable. This is because UPN claims are required for this scenario. |

   - If the resource partner requires e-mail claims to make authorization decisions, select the **E-mail Claim** check box.

   - If the resource partner requires common name claims to make authorization decisions, select the **Common Name Claim** check box.

9. If you selected **UPN Claim** as an identity claim, on the **Accepted UPN Suffixes** page, click **All UPN suffixes** (this option is available only if you selected the **Federation Web SSO with Forest Trust** option), or type the accepted suffixes, click **Add**, and then click **Next**.

10. If you selected **E-mail Claim** as an identity claim, on the **Accepted E-mail Suffixes** page, click **All E-mail suffixes** (this option is available only if you selected the **Federation Web SSO with Forest Trust** option), or type the accepted suffix, click **Add**, and then click **Next**.

| **Note** |
| --- |
| Common name claims require no additional information. |

11. On the **Enable this Account Partner** page, if you do not want to enable the account partner now, clear the **Enable this account partner** check box, and then click **Next**.

12. To add the new account partner and close the wizard, click **Finish**.

**Rename an imported account partner**

You can use the following procedure to rename an imported account partner.

**To rename an imported account partner**

1. Click **Start**, point to **Administrative Tools**, and then click **Active Directory Federation Services**.

2. In the console tree, double-click **Federation Service**, **Trust Policy**, **Partner Organizations**, and **Account Partners**.
3. Right-click the account partner, and then click **Rename**.
4. Type a new name for account partner.

# Complete the Add Account Store Wizard

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can use the Add Account Store Wizard to add new Active Directory account stores and Active Directory Application Mode (ADAM) account stores to a Federation Service trust policy. New account stores are added to the end of the account store lists by default. Account stores are used to authenticate users and provide user identity information to Active Directory Federation Services.

**Create an Active Directory account store**

You can use the following procedure to create an Active Directory account store.

**To create an Active Directory account store**

1. Click **Start**, point to **Administrative Tools**, and then click **Active Directory Federation Services**.
2. In the console tree, double-click **Federation Service**, **Trust Policy**, and **My Organization**.
3. Right-click **Account Stores**, point to **New**, and then click **Account Store**.
4. On the **Welcome to the Add Account Store Wizard** page, click **Next**.
5. On the **Account Store Type** page, click **Active Directory**, and then click **Next**.

   | **Note** |
   | --- |
   | You can have only one Active Directory store that is associated with a Federation Service. If the **Active Directory** option is not available, it is because an Active Directory store has already been created for this Federation Service. |

6. If you do not want to enable this account store now, on the **Enable this Account Store** page, clear the **Enable this account store** check box, and then click **Next**.
7. To add the new account store and close the wizard, click **Finish**.

**Create an ADAM account store**

You can use the following procedure to create an ADAM account store.

**To create an ADAM account store**

1. Click **Start**, point to **Administrative Tools**, and then click **Active Directory Federation Services**.
2. In the console tree, double-click **Federation Service**, **Trust Policy**, and **My Organization**.
3. Right-click **Account Stores**, point to **New**, and then click **Account Store**.
4. On the **Welcome to the Add Account Store Wizard** page, click **Next**.
5. On the **Account Store Type** page, click **Active Directory Application Mode (ADAM)**, and then click **Next**.
6. On the **ADAM Store Details** page, do the following, and then click **Next**:
   - In **Account store display name**, type the friendly name of the account store.
   - In **Account store URI**, type the Uniform Resource Identifier (URI) for the ADAM account store.
7. On the **ADAM Server Settings** page, do the following, and then click **Next**:
   - In **ADAM server name or IP address**, type the name or Internet Protocol (IP) address of the ADAM server.
   - In **Port number**, type the TCP/IP port number for the account service.
   - In **LDAP search base distinguished name**, type the distinguished name, for example, DC=adatum,DC=com.

- In **User name LDAP attribute**, type the name of the user name attribute, for example, **userPrincipalName**.

8. On the **Identity Claims** page , select one or more identity claims that will be provided by the account store, and then click **Next**:
   - If the account store provides UPN identity claims, select the **User Principal Name (UPN)** check box, and then type the Lightweight Directory Access Protocol (LDAP) attribute name.
   - If the account store provides e-mail identity claims, select the **E-mail** check box, and then type the LDAP attribute name.
   - If the account store provides common name identity claims, select the **Common name** check box, and then type the LDAP attribute name.
9. If you do not want to enable this account store now, on the **Enable this Account Store** page, clear the **Enable this account store** check box, and then click **Next**.
10. To add the new account store and close the wizard, click **Finish**.

**Related Information**

# Complete the Add Applications Wizard

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can use the Add Application Wizard to add either a claims-aware application or a Windows NT token–based application to the Federation Service trust policy.

**Add a claims-aware application**

You can use the following procedure to add a claims-aware application to the Federation Service trust policy.

**To add a claims-aware application**

1. Click **Start**, point to **Administrative Tools**, and then click **Active Directory Federation Services**.
2. In the console tree, double-click **Federation Service**, **Trust Policy**, and **My Organization**.
3. Right-click **Applications**, point to **New**, and then click **Application**.
4. On the **Welcome to the Add Application Wizard** page, click **Next**.
5. On the **Application Type** page, click **Claims-aware application**, and then click **Next**.
6. On the **Application Details** page, do the following, and then click **Next**:
   - In **Application display name**, type the name of the application.
   - In **Application URL**, type the Uniform Resource Locator (URL) of the application.

| **Important** |
| --- |
| This URL must match the return URL that is configured on the ADFS Web Agent for this application. |

7. On the **Accepted Identity Claims** page, select each identity claim type that the application will use to make authorization decisions, and then click **Next**:
   - If the application requires user principal name (UPN) identity claims to make authorization decisions, select the **User principal name (UPN)** check box.
   - If the application requires e-mail identity claims to make authorization decisions, select the **E-mail** check box.
   - If the application requires common name identity claims to make authorization decisions, select the **Common name** check box.
8. If you do not want to enable the claims-aware application now, on the **Enable this Application** page, clear the **Enable this application** check box, and then click **Next**.
9. To add the new claims-aware application and close the wizard, click **Finish**.

**Add a Windows NT token–based application**

You can use the following procedure to add a Windows NT token–based application to the Federation Service trust policy.

**To add a Windows NT token–based application**

1. Click **Start**, point to **Administrative Tools**, and then click **Active Directory Federation Services**.
2. In the console tree, double-click **Federation Service**, **Trust Policy**, and **My Organization**.
3. Right-click **Applications**, point to **New**, and then click **Application**.
4. On the **Welcome to the Add Application Wizard** page, click **Next**.

5. On the **Application Type** page, click **Windows NT token–based application**, and then click **Next**.
6. On the **Application Details** page, do the following, and then click **Next**:
   - In **Application display name**, type the name of the application.
   - In **Application URL**, type the Uniform Resource Locator (URL) of the application.

| **Important** |
| --- |
| This URL must match the return URL that is configured on the ADFS Web Agent for this application. |

7. On the **Accepted Identity Claim** page, select each identity claim type that the application will use to make authorization decisions, and then click **Next**:
   - If the application requires user principal name (UPN) identity claims to make authorization decisions, click **User principal name (UPN)**.
   - If the application requires e-mail identity claims to make authorization decisions, click **E-mail**.
8. If you do not want to enable the Windows NT token–based application now, on the **Enable this Application** page, clear the **Enable this application** check box, and then click **Next**.
9. To add the new Windows NT token–based application and close the wizard, click **Finish**.

# Configure the Account Store Priority

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

When you add more than one account store, account store priority determines the order in which account stores will be used by Active Directory Federation Services (ADFS). ADFS will attempt to authenticate users beginning with the first account store. Only if authentication fails for a user will ADFS attempt to authenticate the user with the next account store in the list. ADFS will attempt to authenticate a user until the user is successfully authenticated or until all account stores have been attempted. ADFS will stop attempting additional account stores as soon as one account store successfully authenticates a user.

User identity attributes that are provided by account stores are not cumulative. ADFS is aware only of user identity attributes that are provided by the account store that is used to authenticate the user.

**Configure the account store priority**
You can use the following procedure to configure the account store priority.

**To configure the account store priority**

1. Click **Start**, point to **Administrative Tools**, and then click **Active Directory Federation Services**.
2. In the console tree, double-click **Federation Service**, **Trust Policy**, and **My Organization**.
3. Right-click **Account Stores**, and then click **Store Priority**.
4. In the **Account Store Prioritization** dialog box, select an account store, use the **Up** and **Down** buttons to move the account store in the priority list, and then click **OK**.

# Introduction to ADFS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

ADFS is a component in Microsoft® Windows Server™ 2003 R2 that provides Web single-sign-on (SSO) technologies to authenticate a user to multiple Web applications over the life of a single online session. ADFS accomplishes this by securely sharing digital identity and entitlement rights, or "Claims," across security and enterprise boundaries.

ADFS is not:

- A database or repository for employee or customer identity data.
- An extension of the Active Directory™ directory service schema.
- A type of Windows domain or forest trust.

ADFS in Windows Server 2003 R2 supports the WS-Federation Passive Requestor Profile (WS-F PRP).

**Key features of ADFS**

The following are some of the key features of ADFS in Windows Server 2003 R2:

- Federation and Web SSO

  When an organization uses the Active Directory™ directory service, it currently experiences the benefit of SSO functionality through Windows-integrated authentication within the organization's security or enterprise boundaries. ADFS extends this functionality to Internet-facing applications, which enables customers, partners, and suppliers to have a similar, streamlined, Web SSO user experience when they access the organization's Web-based applications. Furthermore, federation servers can be deployed in multiple organizations to facilitate business-to-business (B2B) federated transactions between partner organizations. For more information about ADFS federation, see Federation scenarios.

- Web Services (WS)-* interoperability

  ADFS provides a federated identity management solution that interoperates with other security products that support the WS-* Web Services Architecture. ADFS does this by employing the federation specification of WS-*, called WS-Federation. The WS-Federation specification makes it possible for environments that do not use the Windows identity model to federate with Windows environments. For more information about WS-* specifications, see ADFS resources.

- Extensible architecture

  ADFS provides an extensible architecture that supports the Security Assertion Markup Language (SAML) token type and Kerberos authentication (in the Federated Web SSO with Forest Trust scenario). ADFS can also perform claim mapping, for example, modifying claims using custom business logic as a variable in an access request. Organizations can use this extensibility to modify ADFS to coexist with their current security infrastructure and business policies. For more information about modifying claims, see Claim mapping.

**Extending Active Directory to the Internet**

Active Directory serves as a primary identity and authentication service in many organizations. With Windows Server 2003 Active Directory, forest trusts can be created between two or more Windows Server 2003 forests to provide access to resources that are located in different business units or organizations. For more information about forest trusts, see How Domain and Forest Trusts Work on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35356).

However, there are scenarios in which forest trusts are not a viable option. For example, access across organizations may need to be limited to only a small subset of individuals, not every member of a forest.

By employing ADFS, organizations can extend their existing Active Directory infrastructures to provide access to resources that are offered by trusted partners across the Internet. These trusted partners can include external third parties or other

departments or subsidiaries in the same organization.

ADFS is tightly integrated with Active Directory. ADFS retrieves user attributes from Active Directory, and it authenticates users against Active Directory. ADFS also uses Windows Integrated Authentication.

ADFS works with both Active Directory and Active Directory Application Mode (ADAM). Specifically, ADFS works with both enterprise-wide deployments of Active Directory or instances of ADAM. When it works with Active Directory, ADFS can take advantage of the strong authentication technologies in Active Directory, including Kerberos, X.509 digital certificates, and smart cards. When it works with ADAM, ADFS uses Lightweight Directory Access Protocol (LDAP) Bind as a means to authenticate users. For more information about how ADFS works with Active Directory and ADAM, see Account stores.

ADFS supports distributed authentication and authorization over the Internet. ADFS can be integrated into an organization's or department’s existing access management solution to translate the terms that are used in the organization into claims that are agreed on as part of a federation. ADFS can create, secure, and verify the claims that move between organizations. It can also audit and monitor the activity between organizations and departments to help ensure secure transactions.

# ADFS server roles

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Active Directory Federation Services (ADFS) can operate only when the servers running Windows Server 2003 R2 are configured appropriately. Depending on the environment in your organization, specific ADFS server roles must be deployed. The following sections describe the server roles that can be used to provide an ADFS federated identity management solution.

**Federation server**
Federation servers host the Federation Service component of ADFS. They are used to route authentication requests that are made from user accounts in other organizations (in Federated Web Single-Sign-On (SSO) scenarios) or from clients that can be located anywhere on the Internet (in the Web SSO scenario). For more information about the different ADFS scenarios, see Federation scenarios.

Federation servers also host a security token service that issues tokens that are based on the credentials (for example, user name and password) that are presented to it. After the credentials are verified (by the user logging on), Claims for the user are collected through examination of the attributes for the user that are stored in Active Directory or Active Directory Application Mode (ADAM).

In Federated Web SSO scenarios, claims can then be modified by claim mappings for a specific resource partner. The claims are built into a token that is sent to a federation server in the resource partner. After a federation server in the resource partner receives the claims as incoming claims, it maps them into their organization claims. The organization claims are then built into a new token that is sent to the ADFS Web Agent.

The role that a federation server plays in either of the Federated Web SSO scenarios (Federated Web SSO or Federated Web SSO with Forest Trust) can depend on whether your organization is designated as the account partner or the resource partner:

- Federation servers in the account partner are used to log on local user accounts in either an Active Directory store or an Active Directory Application Mode (ADAM) store. Federation servers also issue initial security tokens that the local user accounts can use to access Web-based applications that are hosted in the resource partner. In addition, federation servers in the account partner issue cookies to users to maintain login status. These cookies include claims for those users. These cookies enable SSO capabilities so that users do not have to enter credentials each time that they visit different Web-based applications in the resource partner.

- Federation servers at the resource partner validate the security tokens that are issued by the federation servers at the account partner. Federation servers at the resource partner also issue security tokens that are meant for the Web-based applications in the resource partner. In addition, federation servers in the resource partner issue cookies to the user accounts, which come from the account partner. These cookies enable SSO capabilities so that users do not have to log in again at their federation servers in the account partner when users attempt to access different Web-based applications at the resource partner.

For more information about the account and resource partners, see Partner organizations.

**Federation server proxy**
Federation server proxies host the Federation Service Proxy component of ADFS. Federation server proxies can be deployed in an organization's perimeter network (also known as a demilitarized zone, extranet, or screened subnet) to forward requests to federation servers that are not accessible from the Internet.

| **Note** |
| --- |
| Although you can deploy separate servers to host the Federation Service Proxy component, it is not necessary to deploy a separate server to act as a federation server proxy in the intranet forest of either the account partner or the resource partner. A federation server performs this role automatically. |

The role that a federation server proxy plays in your organization can depend on whether your organization is the account partner or the resource partner:

- Federation server proxies at the account partner act as proxies for user logons to federation servers that are located in the intranet. Federation server proxies also act as proxies for security tokens that are issued by the account partner

federation server for both its own tokens and those tokens that are destined for resource partners.

- Federation service proxies in the resource partner act as proxies for user security tokens, which are issued from federation servers in both the account partner and the resource partner, to Web-based applications in the resource partner.

**Web server**

In ADFS, Web servers in the resource forest host the ADFS Web Agent component to provide secure access to the Web applications that are hosted on those Web servers. The ADFS Web Agent manages security tokens and authentication cookies that are sent to a Web server. The Web server requires a relationship with a Federation Service so that all authentication tokens come from that Federation Service.

The ADFS Web Agent supports two types of applications: claims-aware applications and Windows NT token–based applications. For information about these types of applications, see Controlling Access to Web-based Applications.

# Federation scenarios

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Active Directory Federation Services (ADFS) supports federated identity scenarios that use Web Services Federation (WS-Federation), WS-Federation Passive Requestor Profile (WS-F PRP), and WS-Federation Passive Requestor Interoperability Profile specifications. The ADFS solution helps administrators deal with federated identity management challenges by making it possible for organizations to securely share a user's identity information over Federation trusts. The following three descriptions of deployment scenarios illustrate how you can use ADFS server roles to federate identities, depending on the needs of your organization.

**Federated Web SSO**

The ADFS Federated Web Single-Sign-On (SSO) scenario involves secure communication that often spans multiple firewalls, perimeter networks, and name resolution servers, in addition to the entire Internet routing infrastructure. Communication over a federated Web SSO environment can help foster more efficient and secure online transactions between organizations that are joined by federation trust relationships.

As shown in the following illustration, a federation trust relationship can be established between two businesses. In this scenario, federation servers route authentication requests from user accounts in Tailspin Toys to Web-based applications that are located in the network of Online Retailer.

Federation servers authenticate requests from trusted partners based on the credentials of the partners. Representations of the credentials are exchanged in the form of security tokens.

For enhanced security, federation server proxies can be used to relay requests to federation servers that are not directly accessible from the Internet.

**Federated Web SSO with Forest Trust**

The ADFS Federated Web SSO with Forest Trust scenario involves two Active Directory forests in a single organization, as shown in the following illustration. One of the forests is located in the organization's perimeter network (also known as a demilitarized zone, extranet, or screened subnet). The other forest is located in the internal network. A one-way, forest trust is established so that the forest in the perimeter network trusts the forest in the internal network. Federation servers are deployed in both networks. A federation trust is established so that accounts in the internal forest can be used to access a Web-based application in the perimeter network, whether the accounts access the site from the intranet forest or from the Internet.

**A. Datum Corp.**

In this scenario, external users, such as customers, can access the Web application by authenticating to the external account federation server, which is located in the perimeter network. External users have user accounts in the perimeter-network Active Directory forest. Internal users, such as employees, can also access the Web application by authenticating to the internal account federation server, which is located in the internal network. Internal users have accounts in the internal Active Directory forest.

If the Web-based application is a Windows NT token-based application, the ADFS Web Agent that is running on the Web application server intercepts requests and creates Windows NT security tokens, which are required by the Web application to make authorization decisions. For external users, this is possible because the Web server that hosts the Windows NT token-based application is joined to the domain in the external forest. For internal users, this is enabled through the forest trust relationship that exists between the perimeter forest and the internal forest.

If the Web-based application is a claims-aware application, the ADFS Web Agent that is running on the Web application server does not have to create Windows NT security tokens for the user. The ADFS Web agent can expose the claims that come across, which allows the application to make authorization decisions based on the contents of the security token that is provided by the account federation server. As a result when it deploys claims-aware applications, the Web server does not have to be joined to the domain, and the external-forest-to-internal-forest trust is not required.

**Web SSO**

In the ADFS Web SSO scenario, users must authenticate only once to access multiple Web-based applications. In this scenario all users are external, and no federation trust exists. Because the Web servers must be Internet accessible and also joined to the Active Directory domain, they are connected to two networks; that is, they are multihomed. The first network is Internet facing (the perimeter network) to provide the needed connectivity. The second network contains the Active Directory forest (the protected network), which is not directly Internet accessible. The federation server proxy is also multihomed to provide the necessary connectivity to the federation server and the Internet. In this scenario, placing the federation server on a network that is not directly accessible from the Internet greatly reduces the risk to the federation server.

# Partner organizations

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

When you plan for cross-organizational (federation-based) collaboration using Active Directory Federation Services (ADFS), you first determine whether your organization will host a Web resource to be accessed by other organizations across the Internet — or the reverse. This determination affects how you deploy ADFS, and it is fundamental in the planning of your ADFS infrastructure.

For Federation scenarios such as Federated Web Single Sign-On (SSO) and Federated Web SSO with Forest Trust (but not the Web SSO scenario), ADFS uses terms such as "account partner" and "resource partner" to help differentiate the organization that hosts the accounts (the account partner) from the organization that hosts the Web-based resources (the resource partner). The term "Federation trusts" is used in ADFS to characterize the one-way, nontransitive relationship that is established between the account partner and the resource partner.

The following sections explain some of the concepts that are related to account partners and resource partners.

**Account partner**

An account partner represents the organization in the federation trust relationship that physically stores user accounts in either an Active Directory store or an Active Directory Application Mode (ADAM) store. The account partner is responsible for collecting and authenticating a user's credentials, building up claims for that user, and packaging the claims into security tokens. These tokens can then be presented across a federation trust to access Web-based resources that are located in the resource partner organization.

In other words, an account partner represents the organization for whose users the account-side Federation Service issues security tokens. The Federation Service in the account partner organization authenticates local users and creates security tokens that are used by the resource partner in making authorization decisions.

In relation to Active Directory, the account partner in ADFS is conceptually equivalent to a single Active Directory forest whose accounts need access to resources that are physically located in another forest. Accounts in this example forest can access resources in the resource forest only when an external trust or forest trust relationship exists between the two forests and the resources to which the users are trying to gain access have been set with the proper authorization permissions.

| **Note** |
| --- |
| This analogy is meant strictly to emphasize how the relationship between account and partner organizations in ADFS is similar, in concept, to the relationship between an account forest and a resource forest in Active Directory. External trusts and forest trusts are not required for ADFS to function. |

**Producing claims that go to the resource partner**

A claim is a statement that a server makes (for example, name, identity, key, group, privilege, or capability) about a client. An account partner produces claims that the resource partner Federation Service consumes. The following list describes the different types of claims that can be configured in the account partner:

- UPN claim

  When you configure the account partner, you can specify a list of user principal name (UPN) domains and suffixes that may be accepted from the account partner. If a UPN identity is received whose domain part is not in the list, the request is rejected.

- E-mail claim

  When you configure the account partner, you can specify a list of e-mail domains and suffixes that may be accepted from the account partner. As with the UPN claim, if an e-mail identity is received whose domain part is not in the list, the request is rejected.

- Common name claim

  When you configure the account partner, you can specify whether common name claims can be received from the account partner. This type of claim may not be mapped; it is simply passed through if it is enabled.

- Group claims

  When you configure the account partner, you can specify a set of incoming group claims that may be accepted from the partner. You can then associate each possible incoming group with an organization group claim. Note that this creates a group mapping. If an incoming group is encountered that has no mapping, it is discarded.

- Custom claims

  When you configure the account partner, you can specify a set of incoming names of custom claims that are accepted from the partner. You can then map each possible incoming name to an organization custom claim. Note that this creates a name mapping. If an incoming custom claim is encountered that has no mapping, it is discarded.

**Resource partner**

A resource partner is the second organizational partner in the federation trust relationship. A resource partner is where the Web servers that host one or more Web-based applications (the resources) reside. The resource partner trusts the account partner to authenticate users. Therefore, to make authorization decisions, the resource partner consumes the claims that are packaged in security tokens coming from users in the account partner.

In other words, a resource partner represents the organization whose Web servers are protected by the resource-side Federation Service. The Federation Service at the resource partner uses the security tokens that are produced by the account partner to make authorization decisions for Web servers that are located in the resource partner.

To function as an ADFS resource, Web servers in the resource partner organization must have the ADFS Web Agent component of ADFS installed. Web servers that function as an ADFS resource can host either claims-aware applications or Windows NT token-based applications. For more information about the two types of applications, see Controlling Access to Web-based Applications.

| **Note** |
| --- |
| If the application that is hosted on the Web server is a Windows NT token–based application, a resource account may be required for the Active Directory forest in the resource partner organization. |

In relation to Active Directory, the resource partner is conceptually equivalent to a single forest whose resources are made available over an external trust or forest trust relationship to accounts that are physically stored in another forest.

| **Note** |
| --- |
| This analogy is meant strictly to emphasize how the relationship between account and partner organizations in ADFS is similar, in concept, to the relationship between an account forest and a resource forest in Active Directory. External trusts and forest trusts are not required for ADFS to function. |

**Consuming claims that come from the account partner**

A resource partner consumes claims that the account partner Federation Service produces and packages in security tokens. The following list describes how claims can be sent to the resource partner:

- UPN claim

  When you configure the resource partner, you can specify whether a UPN claim is to be sent to the resource partner. You can also specify a suffix mapping so that any suffix is mapped into a specified outgoing suffix. For example, julianp@sales.tailspintoys.com can be mapped to julianp@tailspintoys.com. Note that only one outgoing suffix may be specified.

- E-mail claim

  When you configure the resource partner, you can specify whether an e-mail claim is to be sent to the resource partner. You can also specify a suffix mapping so that any suffix is mapped into a specified suffix. For example, vernettep@sales.tailspintoys.com can be mapped to vernettep@tailspintoys.com. Note that only one outgoing suffix may be specified.

- Common name claim

  When you configure the resource partner, you can specify whether common name claims can be sent to the resource partner. This type of claim may not be mapped; it is simply passed through to the resource partner if it is enabled.

- Group claims

  When you configure the resource partner, you can specify a set of outgoing group claims that will be accepted by the resource partner. You can then associate each possible outgoing group claim to organization group claims. Note that this creates a set of group mappings. Organization group claims that do not match an outgoing group claim are not created.

- Custom claims

  When you configure the resource partner, you can specify a set of outgoing custom claims that are accepted by the resource partner. You can map each possible outgoing custom claim to a custom claim. Note that this creates a set of name mappings. Organization custom claims that do not match an outgoing custom claim are not created.

#### Enhanced identity privacy

**Enhanced identity privacy** is an optional setting that can be configured on a resource partner in the trust policy. If the **Enhanced identity privacy** option is enabled, this setting hashes the user-name portion of outgoing UPN claims and e-mail claims. It substitutes the common name with a random value.

The purpose of this feature is to prevent:

- The resource partner from correlating identity claims to personally identifiable user information.

- Collusion between partners in correlating identity claims to personally identifiable user information. This setting creates a unique hash per partner so that identity claim values are different across different trusting realm partners but consistent across sessions for a single partner.

- Simple dictionary attacks against the hash by salting the user value with data that is in the trust policy — data that is not known by the resource partners.

#### How enhanced identity privacy works

If the **Enable enhanced identity privacy** setting is enabled, the user's identity is transformed by the account Federation Service before it is sent to the resource realm. The account Federation Service does this by hashing a combination of the privacy key (for salting), the resource partner Uniform Resource Identifier (URI), and the identity claim itself. Therefore, the resulting transformed identity will be the same when the following values are the same:

- Privacy key

- Resource partner URI

- Identity claim (UPN or e-mail)

The hashing algorithm is case sensitive. Therefore, the hashed results are different if the case of the URI or the user-name portion of the UPN claim or e-mail claim is different.

# Federation trusts

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can use Active Directory Federation Services (ADFS) to enable efficient and secure online transactions between Partner organizations that are joined by federation trust relationships. In other words, a federation trust is the embodiment of a business-level agreement or partnership between two organizations.

As shown in the following illustration, you can establish federation trust relationships between two partner organizations when both of the organizations deploy at least one ADFS federation server and they configure their Federation Service settings appropriately. The one-way arrow signifies the direction of the trust, which — like the direction of Windows trusts — always points to the account side of the forest. This means that authentication flows from the account partner organization to the resource partner organization.

| Note |
| --- |
| No communication occurs over the network between the account Federation Service and the resource Federation Service. |

After you create the federation trust, users who are located in the account partner organization can send authentication requests successfully through the federation trust to the Web server in the resource partner organization. A federation trust is created when the account partner organization and the resource partner organization both install the Federation Service component of ADFS and they both use the Active Directory Federation Services snap-in to configure the account partner and resource partner appropriately.

If one side of a federation trust (either the account partner or the resource partner) is not configured or if it is configured incorrectly by the administrator for either organization, the federation trust will not be created successfully. For detailed guidance about how to create federation trusts, look for ADFS step-by-step or deployment content on the Windows Server 2003 R2 page (http://go.microsoft.com/fwlink/?LinkId=45560) of the Microsoft Windows Server 2003 TechCenter Web site.

| Note |
| --- |
| Federation trusts are not used in the Web Single-Sign-On (SSO) scenario. For more information about the Web SSO scenario, see Federation scenarios. |

# ADFS requirements

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Active Directory Federation Services (ADFS) has the following hardware and software requirements.

**Hardware requirements**

- Processor speed: 133 MHz for x86-based computers
- Recommended minimum RAM: 256 MB
- Free disk space for setup: 10 MB

**Software requirements**

ADFS relies on server functionality that is built into the Windows Server 2003 R2 operating system. The Federation Service, Federation Service Proxy, and ADFS Web Agent components cannot run on earlier operating systems. This section describes the software requirements for each ADFS component. It also describes the overall software configurations that are necessary for ADFS in your network environment.

| **Note** |
| --- |
| The Federation Service and Federation Service Proxy components cannot coexist on the same computer, and they can be installed only on computers running Windows Server 2003 R2, Enterprise Edition, or Windows Server 2003 R2, Datacenter Edition. |

**Federation Service**

Computers running the Federation Service must have the following software installed:

- Windows Server 2003 R2, Enterprise Edition, or Windows Server 2003 R2, Datacenter Edition
- Internet Information Services (IIS)
- Microsoft ASP.NET 2.0
- Microsoft .NET Framework 2.0
- A default Web site that is configured with Transport Layer Security and Secure Sockets Layer (TLS/SSL)
- A certificate for the Federation Service

| **Note** |
| --- |
| This certificate is used for signing tokens. It must be a digital signing X.509 certificate. |

**Active Directory and ADAM account store requirements**

ADFS requires the presence of user accounts in Active Directory or Active Directory Application Mode (ADAM) for the account Federation Service. Active Directory domain controllers or computers hosting the account stores must have the following software installed:

- Windows Server 2003

Or

- Windows Server 2003 R2

Or

- Windows 2000 with Service Pack 4 (SP4) with critical updates

ADFS does not require schema changes or functional-level modifications to Active Directory. To ensure that ADAM works with ADFS, install the version of ADAM that comes with Windows Server 2003 R2.

**Federation Service Proxy**
Computers running the Federation Service Proxy must have the following software installed:

- Windows Server 2003 R2, Enterprise Edition, or Windows Server 2003 R2, Datacenter Edition
- IIS
- ASP.NET 2.0
- Microsoft .NET Framework 2.0
- A default Web site configured with TLS/SSL

**ADFS Web Agent**
Computers running the ADFS Web Agent must have the following software installed:

- Windows Server 2003 R2, Standard Edition; Windows Server 2003 R2, Enterprise Edition; or Windows Server 2003 R2, Datacenter Edition
- IIS
- ASP.NET 2.0
- Microsoft .NET Framework 2.0
- After the ADFS Web Agent installation is complete, at least one Web site in IIS must be configured with TLS/SSL so that federated users can access Web-based applications that are hosted on the Web server.

**Trusted certification authorities**
Because both TLS/SSL and token signing rely on digital certificates, certification authorities (CAs) are an important part of ADFS. Public CAs, such as VeriSign, Inc., represent a mutually trusted third party that allows the identity of the bearer of a certificate to be identified. You can use enterprise CAs, such as Microsoft Certificate Services, for providing token signing and other internal certificate services.

If a client is presented with a server's authentication certificate, the client computer verifies that the CA that issued the certificate is in the client's list of trusted CAs and that the CA has not revoked that certificate. This verification ensures that the client has reached the intended server. When a certificate is used for verifying signed tokens, the client uses the certificate to verify that the token was issued by the correct federation server and that the token has not been tampered with.

**TCP/IP network connectivity**
For ADFS to function, TCP/IP network connectivity must exist between the client; a domain controller; and the computers that host the Federation Service, the Federation Service Proxy (when it is used), and the ADFS Web Agent.

**DNS**
For the purpose of authenticating users in the intranet, internal Domain Name System (DNS) servers in the intranet forest must be configured to return the canonical name (CNAME) of the internal server that is running the Federation Service. For best results, do not use Hosts files with DNS.

**Web browser**
Although any current Web browser with JScript enabled should work as an ADFS client, only Internet Explorer 6, Internet Explorer 5 or 5.5, Mozilla Firefox, and Safari on Apple Macintosh have been tested by Microsoft. For performance reasons, it is highly recommended that JScript be enabled. Cookies must be enabled, or at least trusted, for the federation servers and Web applications that are being accessed.

# Terminology used in ADFS

Updated: March 27, 2008

Applies To: Windows Server 2003 R2

Active Directory Federation Services (ADFS) uses terminology from several different technologies, including certificate services, Internet Information Services (IIS), Active Directory, Active Directory Application Mode (ADAM), and Web Services (WS-*). The following table describes these terms.

| Term | Description |
|---|---|
| account partner | A federation partner that is trusted by the Federation Service to provide security tokens. The account partner issues these tokens to its users (that is, users in the account partner realm) so that they can access Web-based applications in the resource partner. |
| Active Directory Federation Services (ADFS) | A Windows Server 2003 R2 component that provides Web single-sign-on (SSO) technologies to authenticate a user to multiple Web applications over the life of a single online session. ADFS accomplishes this by securely sharing digital identity and entitlement rights across security and enterprise boundaries. ADFS in Windows Server 2003 R2 supports the WS-Federation Passive Requestor Profile (WS-F PRP). |
| claim | A statement that an issuer makes (for example, name, identity, key, group, privilege, or capability) about a client. |
| claim mapping | The act of mapping, removing or filtering, or passing claims between various claim sets. |
| claims-aware application | A Microsoft ASP.NET application that performs authorization based on the claims that are present in an ADFS security token. |
| client account partner discovery Web page | The Web page that is used to interact with the user to determine which account partner the user belongs to when ADFS cannot automatically determine which of the account partners should authenticate the user. |
| client logoff Web page | When ADFS performs a logoff operation, a Web page that is executed to provide visual feedback to the user that the logoff has occurred. |
| client logon Web page | When ADFS collects client credentials, a Web page that is executed to perform the user interaction. The client logon Web page may use any necessary business logic to determine the type of credentials to collect. |
| federation | A pair of realms or domains that have established a federation trust. |
| Federation Service | A security token service that is built into Windows Server 2003 R2. The Federation Service provides tokens in response to requests for security tokens. |
| Federation Service Proxy | A proxy to the Federation Service in the perimeter network (also known as a demilitarized zone, extranet, or screened subnet). The Federation Service Proxy uses WS-F PRP protocols to collect user credential information from browser clients and Web applications and send the information to the Federation Service on their behalf. |
| organization claims | Claims in intermediate or normalized form within an organization's namespace. |
| passive client | A Hypertext Transfer Protocol (HTTP) browser, capable of broadly supported HTTP, that can make use of cookies. ADFS in Windows Server 2003 R2 supports only passive clients, and it adheres to the WS-F PRP specification. |

| | |
|---|---|
| resource partner | A federation partner that trusts the Federation Service to issue claims-based security tokens. The resource partner contains published Web-based applications that users in the account partner can access. |
| security token | A cryptographically signed data unit that expresses one or more claims. |
| security token service (STS) | A Web service that issues security tokens. An STS makes assertions based on evidence that it trusts, to whoever trusts it (or to specific recipients). To communicate trust, a service requires proof, such as a signature to prove knowledge of a security token or set of security tokens. A service itself can generate tokens or it can rely on a separate STS to issue a security token with its own trust statement. This forms the basis of trust brokering. In ADFS, the Federation Service is an STS. |
| server farm | In ADFS, a collection of load-balanced federation servers, federation server proxies, or Web servers hosting the ADFS Web Agent. |
| single sign-on (SSO) | An optimization of the authentication sequence to remove the burden of repeated logon actions by an end user. |
| token-signing certificate | An X509 certificate whose associated public/private key pair is used to provide integrity for security tokens. |
| Uniform Resource Identifier (URI) | A compact string of characters that identifies an abstract resource or physical resource. URIs are explained in RFC 2396 (http://go.microsoft.com/fwlink/?LinkId=48289). In ADFS, URIs are used to uniquely identify partners and account stores. |
| Web Services (WS-*) | The specifications for a Web Services Architecture that is based on industry standards such as Simple Object Access Protocol (SOAP); XML; Web Service Description Language (WSDL); and Universal Description, Discovery, and Integration (UDDI). WS-* provides a foundation for delivering complete, interoperable business solutions for the extended enterprise, including the ability to manage federated identity and security.<br><br>The Web services model is based on the idea that enterprise systems are written in different languages, with different programming models, which run on and are accessed from many different types of devices. Web services are a means of building distributed systems that can connect and interact with one another easily and efficiently across the Internet, regardless of what language they are written in or what platform they run on. |
| Web Services Security (WS-Security) | A series of specifications that describes how to attach signature and encryption headers to SOAP messages. In addition, WS-Security describes how to attach security tokens, including binary security tokens such as X.509 certificates and Kerberos tickets, to messages. In ADFS, WS-Security is used when Kerberos signs security tokens. |
| Windows NT token–based application | A Windows application that relies on a Windows NT token to perform authorization of users. |
| WS-Federation | A specification that defines a model and set of messages for brokering trust and the federation of identity and authentication information across different trust realms.<br><br>The WS-Federation specification identifies two sources of identity and authentication requests across trust realms: active requestors, such as SOAP-enabled applications, and passive requestors, which are defined as HTTP browsers capable of supporting broadly supported HTTP, for example, HTTP 1.1. |

| | |
|---|---|
| WS-Federation Passive Requestor Profile (WS-F PRP) | An implementation of the WS-Federation specification that proposes a standard protocol for how passive clients (such as Web browsers) apply the federation framework. Within this protocol, Web service requestors are expected to understand the new security mechanisms and be capable of interacting with Web service providers. |

# Understanding ADFS Components

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Understanding ADFS Components**

- Federation Service
- Federation Service Proxy
- ADFS Web Agent
- Active Directory Federation Services snap-in
- Active Directory Federation Services Proxy snap-in

# Federation Service

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The Federation Service is a component of Active Directory Federation Services (ADFS) that can be installed independently from other ADFS components. The Federation Service functions as a security token service. The act of installing the Federation Service component on a computer makes that computer a federation server. It also makes the Active Directory Federation Services snap-in available in the **Administrative Tools** menu on that computer.

The Federation Service is designed to use Active Directory to provide tokens in response to requests for security tokens. This enables Active Directory domains and forests to function as:

- Identity providers that can federate with compliant account partners and resource partners. As an identity provider, the Federation Service can project Active Directory identities across the Internet to interact with applications at compliant service providers.

- Service providers that can federate with compliant account partners and resource partners. As a service provider, the Federation Service can allow identities from other organizations to access a partner's Windows-based and ASP.NET-based applications.

- Security token providers for applications that are compliant with the WS-Federation Passive Requestor Profile (WS-F PRP) specification.

As an account partner, the Federation Service allows Active Directory users to access resources at partner organizations. In response to a request from a resource partner, the Federation Service collects and verifies user credentials against Active Directory or Active Directory Application Mode (ADAM). The Federation Service can then populate a set of organization claims based on the Lightweight Directory Access Protocol (LDAP) attributes of the user account. The organization claims are then mapped to appropriate claims for the resource partner and packaged into a security token that is signed by the Federation Service's token-signing certificate. The resultant security token is posted as the response to the resource partner's original request. The resource partner then uses the token to allow access for the user.

As a resource partner, the Federation Service plays the opposite role. When a user attempts to access an ADFS-protected application, the Federation Service determines which account partner should authenticate the user. It then sends an authentication request to that partner. When the user returns with a security token, the Federation Service verifies that the token has been correctly signed by the partner. It then extracts the claims from the token. The claims are mapped to organization claims, and the filtering policy for the specific application is applied. The filtered organization claims are packaged into a security token that is either signed by the Federation Service's token-signing certificate or protected by a Kerberos session key for the Web application. The resultant security token is posted back to the original application Uniform Resource Locator (URL). The application then uses the token to allow access for the user.

ADFS uses the WS-F PRP protocol to carry Claims in security tokens that are issued by the Federation Service to the Web application. For more information about the WS-F PRP specification, see ADFS resources.

These claims are populated initially from Account stores, either Active Directory or ADAM account stores. The Federation Service issues tokens based on the credentials that are presented. After the credentials are verified using the account store, the claims for the user are generated according to the rules of the trust policy. The obtained inbound claims are mapped into outbound claims that are appropriate for a resource partner. The resulting claim mappings are added to a security token that is issued to the resource partner. For more information, see Claim mapping.

After the token is verified, an authentication cookie is issued and written to the client browser. Each time that the client needs to be authenticated, this cookie is used by the Federation Service so that the client does not have to enter credentials again, thereby enabling single sign-on (SSO). For more information, see Cookies used by ADFS.

**Federation Service Web pages**

The Federation Service provides a Web page that prompts the user to select an appropriate account partner to which the user can authenticate. The Federation Service also provides a Web page that prompts for the user's credentials, such as a user name and password for forms-based authentication. A Web page is also provided that supports Windows Integrated Authentication.

Behind the Web pages, the Federation Service provides a Microsoft ASP.NET Web service that processes requests from the client or the federation server proxy. The federation server proxy is located in the perimeter network. It acts as an intermediary

between an Internet client and a Federation Service in the intranet. For more information about the role of the federation server proxy, see ADFS server roles.

There are two basic types of requests to which the Federation Service responds:

- Requests to issue security tokens
- Requests to retrieve trust policy data

**Account partner discovery**

Account partner discovery is the process by which a client can identify what account partner it prefers for authentication in the event that more than a single account partner is configured. The Federation Server presents this choice to the client browser as a drop box containing the account partner names as they are configured in the trust policy.

One mechanism that you can use to avoid account partner discovery is to include the **`whr`** parameter in the query string for the resource being accessed, for example,

`https://webserver/testapp/testpage.aspx?whr=urn:federation:<`*accountpartner*`>`, where <*accountpartner*> indicates the account partner realm of the client.

When the **`whr`** parameter is used, the Web server removes the parameter and writes a cookie to the client browser to remember this setting for future requests. Then, the request proceeds in the same way as if it had not been provided.

# Federation Service Proxy

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The Federation Service Proxy is a component of Active Directory Federation Services (ADFS) in Windows Server 2003 R2 that can be installed independently from other ADFS components. The Federation Service Proxy functions as a proxy in a perimeter network (also known as a demilitarized zone, extranet, or screened subnet) for the Federation Service. The act of installing the Federation Service Proxy component on a computer makes that computer a federation server proxy. It also makes the Active Directory Federation Services Proxy snap-in available on that computer in the **Administrative Tools** menu.

A federation server proxy participates in the WS-Federation Passive Requestor Profile (WS-F PRP) protocol by communicating with a protected Federation Service on the client's behalf. When the federation server proxy is protecting an account partner, it collects user credential information from browser clients. When the federation server proxy is protecting a resource partner, it relays requests by and for Web applications to the Federation Service.

The federation server proxy also stores Hypertext Transfer Protocol (HTTP) cookies on clients when necessary to facilitate single sign-on (SSO). For more information, see Cookies used by ADFS. The federation server proxy writes all three types of cookies: authentication cookies, account partner cookies, and sign-out cookies. For more information about the federation server proxy role, see ADFS server roles.

# ADFS Web Agent

Updated: August 17, 2006

Applies To: Windows Server 2003 R2

The Active Directory Federation Services (ADFS) Web Agent is a component of ADFS. It is used to consume security tokens and either allow or deny a user access to a Web application. To accomplish this, the Web server requires a relationship with a resource Federation Service so that it can direct the user to the Federation Service as needed.

The ADFS Web Agent can be used for two different types of applications:

- Claims-aware applications: A Microsoft ASP.NET application that is written to published ADFS objects that allow the querying of ADFS security token Claims. The application makes authorization decisions based on these claims. Security token failures for this type of application result in the client seeing an "Access Denied" message and events in the Federation Service event log. For more information, see Claims-aware applications.

- Windows NT token–based applications: An application that uses Windows-based authorization mechanisms. The ADFS Web Agent supports conversion from an ADFS security token to an impersonation-level Windows NT access token. For more information, see Windows NT token-based applications.

The Web server also stores Hypertext Transfer Protocol (HTTP) cookies on clients where necessary to facilitate single sign-on (SSO). The ADFS Web Agent comprises two separate components:

- ADFS Web Agent ISAPI Extension

- ADFS Web Agent Authentication Service

**ADFS Web Agent ISAPI Extension**

The ADFS Web Agent ISAPI Extension is an Internet Server Application Programming Interface (ISAPI) extension that you can use to configure information in the Internet Information Services (IIS) metabase. In IIS Manager you can use the **ADFS Web Agent** tabs on the **Web Sites** and **Default Web Sites** property pages to administer policy and certificates that verify the ADFS security token and cookies.

The ADFS Web Agent properties in the following table are inheritable. These properties are required on an IIS resource if the ISAPI extension is going to support the WS-Federation Passive Requestor Profile (WS-F PRP) protocol.

| Properties | Description |
|---|---|
| Federation Service URL | The Uniform Resource Locator (URL) of the Federation Service. This URL is required so that it may be queried for trust information. |
| Cookie path | The path that is specified when the authentication cookie is written. |
| Cookie domain | The domain for which the cookie is valid. |
| Return URL | The URL that the token from the Federation Service comes back to after authentication at the Federation Service. This URL should match the Audience element of the token. The checking against the Audience element is performed by the Windows service. |

**Optional debug trace logging configuration**

Optional debug trace logging is configured for the ISAPI extension through the registry **DWORD** value in the following path: **HKLM\Software\Microsoft\ADFS\WebServerAgent\DebugPrintLevel**. If the value is present, a log in the directory that is specified at **HKLM\Software\Microsoft\ADFS\LogFilesPath** with the name ifsext_<*ApplicationPoolName*>.log is produced. A notification on the registry key **HKLM\Software\Microsoft\ADFS\WebServerAgent** is registered by the extension so that a change in the debug level may be made without restarting the IIS worker process. The following flag values are used to control the verbosity of the log file:

- Error – 0x1
- Warning – 0x2
- Trace - 0x4

**ADFS Web Agent Authentication Service**

The ADFS Web Agent Authentication Service validates incoming tokens and cookies. It runs as Local System to generate a token by using either Service-for-User (S4U) or the ADFS authentication package. However, the IIS application pool is not required to run as Local System.

The ADFS Web Agent Authentication Service has interfaces that may be called only with local remote procedure call (LRPC), not RPC. This service returns an impersonation Windows NT access token if it is given an ADFS security token or an ADFS cookie.

# Active Directory Federation Services snap-in

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The Active Directory Federation Services (ADFS) Microsoft Management Console (MMC) snap-in is installed when you install the Federation Service component in **Add or Remove Programs** in Windows Server 2003 R2, Enterprise Edition. You can use the ADFS snap-in to:

- Configure the Federation Service or federation server farm.
- Manage the trust policy that is associated with your Federation Service:
  - Administer Active Directory or Active Directory Application Mode (ADAM) Account stores.
  - Manage account partners and resource partners that will trust your Partner organizations.
  - Manage the applications that are going to be protected by ADFS.
  - Manage Claims, Certificates used by federation servers, and ADFS-protected Web applications.

Settings that you configure in the ADFS snap-in are stored partly in the Web.config file, which is located in the Federation Service virtual directory, and partly in the trust policy file. You can edit the Web.config file directly and push it out to different servers, or you can use the ADFS snap-in to modify the settings.

The trust policy file should not be edited manually. Instead, edit the trust policy file by using the ADFS snap-in, or edit it programmatically by using the ADFS object model.

| **Note** |
| --- |
| Scripting support is provided in the ADFS object model. |

When you open the ADFS snap-in, the snap-in reads the Web.config file from the Federation Service virtual directory and notes the location of the trust policy file. The snap-in then presents a console tree hierarchy representing the Federation Service and all aspects of the trust policy, including organization claims, partners, account stores, and applications. Each item in this console tree hierarchy has context-menu options that you can use to view, modify, add, and delete trust policy entities.

**Federation Service node**

The **Federation Service** node in the console tree of the ADFS snap-in represents the local Federation Service that is assigned to the federation server on which you are viewing the snap-in. You control the local federation server configuration through this node in the ADFS snap-in. The local federation server configuration is different from the trust policy configuration in that the trust policy configuration is shared among all the federation servers in the federation server farm. The local configuration is stored in the Web.config file, and it includes the following items:

- The friendly name for the Federation Service
- The path to the trust policy file
- The local certificate to be used for signing tokens
- The Microsoft ASP.NET Web pages
- The debug logging level

# Active Directory Federation Services Proxy snap-in

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The Active Directory Federation Services (ADFS) Proxy Microsoft Management Console (MMC) snap-in is installed when you install the Federation Service Proxy component in **Add or Remove Programs** in Windows Server 2003 R2, Enterprise Edition. You can use the ADFS Proxy snap-in to:

- Configure the Federation Service that this Federation Service Proxy is acting as a proxy for.
- Determine how to collect user credential information from browser clients and Web applications.

The settings in the ADFS Proxy snap-in are stored in the Web.config file in the Federation Service Proxy virtual directory.

**Federation Service Proxy node**

The **Federation Service Proxy** node in the snap-in's console tree hierarchy represents the current Federation Service Proxy settings. You control the local federation server proxy configuration through this node in the ADFS Proxy snap-in. The actual client authentication certificate with the private key is present in the local computer personal certificate store.

ADFS distinguishes between the local configuration for a federation server proxy and the trust policy configuration that is shared among all servers in the federation server farm. The local proxy configuration is stored in the Web.config file, and it includes the following items:

- The Federation Service Uniform Resource Locator (URL)
- The client authentication certificate to be used by the federation server proxy for Transport Layer Security and Secure Sockets Layer (TLS/SSL) communication with the Federation Service
- Microsoft ASP.NET Web pages

# Understanding ADFS Authentication and Authorization

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Understanding ADFS Authentication and Authorization**

- Account stores
- Cookies used by ADFS
- Controlling Access to Web-based Applications
- Understanding Claims

# Account stores

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Active Directory Federation Services (ADFS) uses account stores to log on users and extract security claims for those users. You can configure multiple account stores for a single Federation Service and define their priority. The Federation Service uses Lightweight Directory Access Protocol (LDAP) to communicate with account stores.

ADFS supports two types of account stores: Active Directory account stores and Active Directory Application Mode (ADAM) account stores.

**Active Directory account stores**
ADFS is tightly integrated with Active Directory. ADFS retrieves user attributes and authenticates users against Active Directory. ADFS also uses Windows Integrated Authentication and security tokens that Active Directory creates.

For a user to log on to Active Directory, a user name must be in the user principal name (UPN) format (user@adatum.com) or in the Security Accounts Manager (SAM) account name format (adatum\user). After the user is logged on and impersonated, user security IDs (SIDs) are enumerated from the access token. The SIDs are then mapped to organization group Claims.

E-mail claims, common name claims, and custom claims can be extracted from user object attributes that are defined in Active Directory when the Federation Service account is used to perform an LDAP search of an object.

The Federation Service account must have access to the user object. If the user object resides in a domain different from the domain where the Federation Service account resides, the former domain must have an Active Directory domain trust in place to the latter domain.

There is no direct way of determining whether any given user name exists in Active Directory and in all directories that are trusted (either directly or transitively) by Active Directory. Active Directory returns an authoritative failure only if the logon attempt fails as a result of policy restrictions. Examples of policy restriction failures include the following:

- The account is disabled.
- The account password has expired.
- The account is not allowed to log on to this computer.
- The account has logon time restrictions and is not allowed to log on at this time.

Otherwise, Active Directory account store logon failures are always nonauthoritative, and the next-priority account store is tried. For more information about account store logon failures, see ADFS troubleshooting.

The following is the list of configuration items for the Active Directory account store:

- A setting indicating whether this entry is enabled
- The display name for the trusted Active Directory account store
- Optional: A list of SIDs that map to particular organization group claims
- Optional: Configuration defining how to extract organization claims from user object attributes in Active Directory:
    - E-mail identity claim or common name identity claim
    - Custom organization claim

The name of a user object attribute defines the claim name when a custom claim is built.

**ADAM account stores**

ADAM provides data storage and retrieval for directory-enabled applications, without the dependencies that are required for Active Directory. ADAM provides much of the same functionality as Active Directory, but it does not require the deployment of domains or domain controllers. Similar to the way in which ADFS uses Active Directory account store information, ADFS also retrieves user attributes and authenticates users with ADAM.

| **Note** |
| --- |
| ADFS cannot authenticate ADAM accounts that use parentheses as part of the account name. Accounts that have an open parenthesis in the user name will cause an LDAP search failure as a result of the user name forming an invalid LDAP filter. |

Security claims are obtained when the Federation Service account is used to perform an LDAP search of the object. This is a two-step process:

- First, the user object is found by means of a search for the object whose configured attribute is equal to the supplied user name. The Federation Service account uses Kerberos or NTLM encryption to protect this communication.

  | **Note** |
  | --- |
  | This process requires the ADAM server to be joined to a domain that trusts the domain that the Federation Service is a member of. |

- Next, the user credentials are validated by binding to the found user object with the supplied password using LDAP. If Transport Layer Security and Secure Sockets Layer (TLS/SSL) are configured for the ADAM account store properties in the trust policy, the user credentials are protected.

  | **Important** |
  | --- |
  | It is strongly recommended that the traffic between the ADAM server and the federation server be protected by TLS/SSL or other means, such as Internet Protocol security (IPsec). |

If more than one object is returned from the LDAP query with the supplied user name, this is considered an authentication failure. For more information about authentication failures, see ADFS troubleshooting.

Because the presence of the user object is always determined, if the user account exists in the ADAM store, the ADAM store logon is authoritative. Therefore, no additional account stores are attempted. The following is the list of configuration items for the ADAM store:

- A setting indicating whether this entry is enabled
- The display name for the trusted ADAM account store
- The ADAM server name
- An LDAP user object attribute containing the user name
- Optional: Port number. If the port number is not specified, it defaults to 389.
- Optional: Search base. If a subtree is specified, searches are performed on the specified subtree. Otherwise, the entire directory tree is searched.
- Optional: Client timeout: the maximum time that Federation Service waits for a response from the ADAM server before timing out the connection. The default is five seconds.
- Optional: Configuration defining how to extract organization claims:
  - UPN/e-mail/common name identity claim: The name of a defined user object attribute whose value is extracted as the UPN/e-mail/common name claim value

- Group organization claim: The name of a user object attribute and its value that, if present, results in the particular group claim

- Custom organization claim: The name of a defined user object attribute whose value is extracted as the particular custom claim value

If this configuration is absent, the directory is used only to log on the user — without extracting claims.

**Determining the priority order of user logon requests**
When a logon request is made to either Active Directory or ADAM through an ADFS client, it is passed immediately to the specified account store. However, if the account store Uniform Resource Identifier (URI) is not specified, each of the stores is tried in priority order to log on the user. The authentication result is returned if:

- There is only one store configured, and credential verification information is returned.

- The store URI was specified in the logon request, and credential verification information is returned.

- The result of authentication by one of the stores was authoritative.

- Authentication by one of the stores was successful.

**Disabling account stores**
Each account store can be marked as enabled or disabled. If an account store is disabled, it does not participate in any account-store-related operations. Cookies with claims that originate from an account store that is currently disabled are discarded or deleted, and the client is directed to the logon page.

# Cookies used by ADFS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Active Directory Federation Services (ADFS) uses the following three types of cookies:

- Authentication cookie
- Account partner cookie
- Sign-out cookie

**Authentication cookie**

Authentication cookies can be issued by both the Federation Service and the ADFS Web Agent. The ADFS Web Agent takes the ADFS security token that it receives and uses that token as the cookie value. The benefit at the Web server is that it does not need keying material. The Federation Service publishes all the information that is necessary to validate its tokens.

At the Federation Service, the security token in a cookie holds the organization Claims for the client. The organization claims may be mapped to outgoing claims for a particular resource. The ADFS Web Agent can also authenticate and use cookies that are issued by the Federation Service. The Web server receives a cookie when the client comes to the Web server. Then, the ADFS Web Agent can authenticate this cookie and use the claims that it contains. For more information about how the Federation Service uses tokens, claims, and authentication cookies, see Federation Service.

The authentication cookie facilitates single sign-on (SSO). After the Federation Service validates the client once, the authentication cookie is written to the client. The Federation Service produces and consumes the contents of the authentication cookie, and they are opaque to federation server proxies. Further authentication takes place through use of the cookie rather than through repeated collection of the client credentials. For more information about the federation server proxies, see ADFS server roles.

The following illustration shows the contents of an authentication cookie and the ADFS components that use the authentication cookie. The ADFS Web Agent comprises both the ADFS Web Agent Authentication Service and the ADFS Web Agent ISAPI Extension.

The authentication cookie is always a session cookie. The authentication cookie is signed but not encrypted, which is one reason why use of Transport Layer Security and Secure Sockets Layer (TLS/SSL) in ADFS is mandatory.

**Account partner cookie**

The account partner cookie facilitates SSO. After interactive account partner membership discovery occurs, if the account partner cookie has a valid token, the cookie is written to the client. Further interactions use the information in this cookie rather

than prompting the client for account partner membership information again. The account partner cookie is set as a result of the account partner discovery process. For more information about account partner discovery, see Federation Service.

The account partner cookie is a long-lived, persistent cookie. It is neither signed nor encrypted.

**Sign-out cookie**

The sign-out cookie facilitates sign-off. Whenever the Federation Service issues a token, the token's resource partner or target server is added to the sign-out cookie. When it receives a sign-off request, the Federation Service or Federation Service Proxy sends requests to each of the token target servers asking them to clean up any authentication artifacts, such as cached cookies, that the resource partner or Web server may have written to the client. In the case of a resource partner, it sends a cleanup request to any application Web servers that the client has used.

The sign-out cookie is always a session cookie. It is neither signed nor encrypted.

# Controlling Access to Web-based Applications

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Controlling Access to Web-based Applications**

- Claims-aware applications
- Windows NT token-based applications

# Claims-aware applications

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Claims are statements (for example, name, identity, key, group, privilege, or capability) made about users — and understood by both partners in an Active Directory Federation Services (ADFS) federation — that are used for authorization purposes in an application. A claims-aware application is a Microsoft ASP.NET application that has been written using the ADFS library. This type of application is fully capable of using ADFS Claims to make authorization decisions directly. A claims-aware application accepts claims that the Federation Service sends in ADFS security tokens. For more information about how the Federation Service uses security tokens and claims, see Federation Service.

Claim mapping is the act of mapping, removing or filtering, or passing inbound claims into outbound claims. Claim mapping does not occur when claims are sent to an application. Instead, only the organization claims that are specified by the Federation Service administrator are sent to the application. (Organization claims are claims in intermediate or normalized form within an organization's namespace.)

By default, no organization claims that are marked as auditable are sent. All nonauditable claims are sent. Therefore, the Federation Service administrator will opt in for auditable claims to be sent to the application and will opt out for nonauditable claims.

The following list describes the organization claims that can be used by claims-aware applications:

- Identity claims (UPN/e-mail/common name)

  When you configure the application, you specify which of these identity claims will be sent to the application. No mapping or filtering is performed.

- Group claims

  When you configure the application, you specify the organization group claims that will be sent to the application. Organization group claims that are not designated to be sent to the application will be discarded.

- Custom claims

  When you configure the application, you specify the organization custom claims that will be sent to the application. Organization custom claims that are not designated to be sent to the application will be discarded.

**Claims-aware authorization**

Claims-aware authorization consists of a Hypertext Transfer Protocol (HTTP) module and objects for querying the claims that are carried in the ADFS security token. Claims-aware authorization is supported only for Microsoft ASP.NET applications.

The HTTP module processes ADFS protocol messages based on configuration settings in the Web application's Web.config file. The Web pages perform authentication and authorization tasks. The HTTP module also authenticates cookies and obtains claims from the cookies.

# Windows NT token-based applications

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

A Windows NT token–based application is an Internet Information Services (IIS) application that has been written to use traditional Windows native authorization mechanisms. This type of application is not prepared to consume Active Directory Federation Services (ADFS) Claims.

Windows NT token–based applications may be used only by Windows users from the local realm or any realm that is trusted by the local realm — that is, only by users who can log on to the computer with Windows NT token–based authentication techniques.

| **Note** |
| --- |
| In federation scenarios, this means that resource accounts may be required. |

The ADFS security token that is sent to Windows NT token–based applications contains an e-mail claim for the user. It may also contain custom claims with the security IDs (SIDs) of the user account. The Web server generates a Windows impersonation-level access token. An impersonation-level access token captures the security information for a client process, thereby allowing a service to "impersonate" the client process in security operations.

For Windows NT token–based Web applications, the following process order determines how a Windows NT token is created:

1. If the Security Assertion Markup Language (SAML) token contains SIDs in the SAML advice element, the SIDs are used to generate the Windows NT token.

2. If the SAML token does not contain SIDs and instead contains a user principal name (UPN) identity claim, the UPN claim is used to generate the Windows NT token.

3. If the SAML token does not contain SIDs and the UPN identity claim in the e-mail identity claim is present, it is interpreted as a UPN and it is used to generate the Windows NT token.

This behavior is irrespective of whether the UPN or e-mail identity claim is specified as the identity claim that is used to generate the Windows NT token when the trust policy entry for the Web application is created in the Federation Service.

**Traditional Windows-based authorization**

Support for converting an ADFS security token into an impersonation-level Windows NT access token requires a number of components:

- Internet Server Application Programming Interface (ISAPI) extension: This component checks for ADFS cookies, checks for ADFS security tokens from the Federation Service, performs the appropriate protocol redirects, and writes the necessary Cookies used by ADFS to make ADFS work.

- ADFS authentication package: The ADFS authentication package generates an impersonation-level access token, given a UPN for a domain account. The package requires that the caller have the Trusted Computing Base (TCB) privilege.

- **ADFS Web Agent** tabs in IIS Manager: You can use the ADFS Web Agent tabs to administer policy and certificates for verifying the ADFS security token and cookies.

- ADFS Web Agent Authentication Service: The ADFS Web Agent Authentication Service runs as Local System to generate a token by either using Service-for-User (S4U) or using the ADFS authentication package. However, the IIS application pool is not required to run as Local System. The ADFS Web Agent Authentication Service has interfaces that may be called only with local remote procedure call (LRPC), not remote procedure call (RPC). The service returns an impersonation-level Windows NT access token if it is given an ADFS security token or ADFS cookie.

- ADFS Web Agent ISAPI Filter: Certain traditional IIS Web applications use an ISAPI filter that may modify incoming data, such as Uniform Resource Locators (URLs). If this is the case, the ADFS Web Agent ISAPI Filter must be enabled and configured as the highest priority filter. This filter is not enabled by default.

# Understanding Claims

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Understanding Claims**

- Claims
- Claim mapping

# Claims

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Claims are statements (for example, name, identity, key, group, privilege, or capability) made about users — and understood by both partners in an Active Directory Federation Service (ADFS) federation — that are used for authorization purposes in an application.

The Federation Service brokers trust between many disparate entities. It is designed to allow the trusted exchange of arbitrary claims containing arbitrary values. These claims are then used by the receiving party to make authorization decisions.

There are three ways that claims flow through the Federation Service:

- From the account store to the account Federation Service to the resource partner
- From the account partner to the resource Federation Service to the application resource
- From the account store to a Federation Service to the application resource

The Federation Service can be configured to act in all three of these roles. Therefore, one single Federation Service may facilitate all three communication flows.

There are three types of claims that are supported by the Federation Service: identity claims, group claims, and custom claims. The following table describes each of these claim types in more detail.

| **Claim type** | **Description** |
|---|---|
| Identity | UPN, e-mail, and common name in ADFS are referred to as identity claim types.<br>• UPN — Indicates a Kerberos-style user principal name (UPN), for example: user@realm. Only one claim may be the UPN type. Even if multiple UPN values must be communicated, only one may be of the UPN type. Additional UPNs may be configured as custom claim types.<br>• E-mail — Indicates RFC 2822–style e-mail names of the form user@domain. Only one claim may be the e-mail type. Even if multiple e-mail values must be communicated, only one may be of e-mail type. Additional e-mails may be configured as custom claim types.<br>• Common name — Indicates an arbitrary string that is used for personalization. Examples include John Smith or Tailspin Toys Employee. Only one claim may have the common name type. It is important to note that there is no mechanism for guaranteeing the uniqueness of the common name claim. Therefore, use caution when using this claim type for authorization decisions. |
| Group | Indicates membership in a group or role. Administrators define individual claims that have the group type “Group claims.” For example, you might define the following set of group claims: [Developer, Tester, Program Manager]. Each group claim is a separate unit of administration for claim population and mapping. It is useful to think of the value of a group claim as a Boolean value indicating membership. |
| Custom | Indicates a claim that contains custom information about a user, for example, an employee ID number. |

If more than one of the three identity claim types is present in a token, the identity claims are prioritized in the following order:

1. UPN
2. E-mail

3. Common name

At least one of these identity claim types must be present for a token to be issued.

**Auditing claims**
Some group claims and custom claims may be designated as auditable. When auditing is enabled, the audit allows the name of the claim to be exposed in the security event log, but the value of the claim is omitted. An example of an auditable claim is Social Security Number. The claim name Social Security Number is exposed, but the actual number value that is stored in that claim is not exposed. The claim value is not audited when the claim is produced or mapped.

| **Note** |
| --- |
| Identity claim types are always auditable. |

**Claim producers and consumers**
The way claims are used depends on the claim producer or consumer. Claims are either inbound or outbound. ADFS supports the following claim producers and consumers:

- Active Directory account stores
- ADAM account stores
- Account partners
- Resource partners
- Claims-aware applications
- Windows NT token–based applications

**Active Directory account store**
The Active Directory account store is a claim producer that represents authentication for the Federation Service. Specifically, the Federation Service may log on users from its domain, from domains that are directly trusted by its domain, from domains in the same forest as its domain, and from domains in forests that have forest trusts with the domain's forest.

The Active Directory account store is available only if the Federation Service is joined to a domain.

- UPN claim: When you configure the Active Directory account store, the UPN claim is enabled automatically.
- E-mail claim: When you configure the Active Directory account store, you can specify what Lightweight Directory Access Protocol (LDAP) user attributes, if any, contain the user's e-mail address.
- Common name claim: When you configure the Active Directory account store, you can specify what LDAP user attributes, if any, contain the user's common name.
- Group claims: you can assign Windows users and groups directly to the organization group claims using the object picker.
- Custom claims: When you configure the Active Directory account store , you can specify what LDAP user attributes contain claim values and then assign each attribute name to an organization custom claim.

**ADAM account store**
The ADAM account store is a claim producer that represents authentication for the Federation Service.

- UPN claim: When you configure the ADAM account store, you can specify the LDAP user attribute, if any, containing the user's UPN.

- E-mail claim: When you configure the ADAM account store, you can specify the LDAP user attribute, if any, containing the user's e-mail address.

- Common name claim: When you configure the ADAM account store, you can specify the LDAP user attribute, if any, containing the user's common name.

You must assign at least one identity claim type to the ADAM account store for the Federation Service to allow that store to be enabled.

- Group claims: When you configure the ADAM account store, you can specify the LDAP user attribute containing the user's LDAP groups or any other attribute that could function as a group, such as Title (if groups are based on job role), and then assign each possible LDAP group to an organization group.

- Custom claims: When you configure the ADAM account store, you can specify the LDAP user attributes containing claim values. You then assign each attribute name to an organization custom claim.

# Claim mapping

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Active Directory Federation Services (ADFS) uses the WS-Federation Passive Requestor Protocol (WS-F PRP) that carries Claims in security tokens that are issued by the Federation Service. The claims are populated initially from Account stores, either Active Directory account stores or Active Directory Application Mode (ADAM) account stores.

In addition, the Federation Service can map those claims when they go out to a federation partner or when they come in from a federation partner. Claim mapping is the act of mapping, removing or filtering, or passing inbound claims into outbound claims. Claim mapping may be different for each federation partner. Defining the population and mapping of these claims is important for the configuration of the federation. Claim mappings use string comparisons that are case sensitive. The following illustration shows the claim mapping process.

**Organization claim sets**
All incoming claims are mapped into organization claims. Organization claims are claims in intermediate or normalized form within an organization's namespace. All internal Federation Service actions are performed on the organization claim set. Organizational claims are consumed by resource applications.

With organization claims, mappings do not have to be administered individually between any two organizations that need to communicate. Each organization defines a single mapping either to or from its organization claims. This reduces the administrative complexity of ADFS. For example, if the federation has:

- **x** account partners
- **y** resource applications

The federation has **x** + **y** claim mappings. This is reduced from a potential **x** × **y** claim mappings. As a concrete example, if a Federation Service has:

- 3 account partners
- 7 resource applications

The federation needs only 10 claim mappings, as compared to 21 claim mappings, when mapping occurs directly from the incoming claims to the outgoing claims.

**E-mail**
E-mail claim types always map to e-mail claim types. As part of this mapping, on the account Federation Service, the domain suffix may be mapped to a constant value. On the resource Federation Service, the domain suffix may be filtered against a list of constant values.

The following example describes an ADFS federation between two organizations, Tailspin Toys and Adventure Works. In this example, Tailspin Toys is the account partner, and Adventure Works is the resource partner.

- Tailspin Toys, acting as an account Federation Service, maps the e-mail organization claim to the outgoing e-mail claim for Adventure Works. As part of that mapping, it maps all e-mail suffixes to tailspintoys.com. Given the organization e-mail claim (e-mail=jsmith@sales.tailspintoys.com), the outgoing e-mail claim is (e-mail=jsmith@tailspintoys.com).

- Adventure Works, acting as a resource Federation Service, maps the incoming Tailspin Toys e-mail claim to the e-mail organization claim, and, as part of that mapping, it filters the suffix list against tailspintoys.com. Therefore, an incoming Tailspin Toys e-mail claim (email=jsmith@tailspintoys.com) is accepted, but an incoming Tailspin Toys e-mail claim (e-mail=jsmith@adventure-works.com) is rejected.

**UPN**
User principal name (UPN) claim types always map to UPN claim types. They are subject to suffix mappings and filtering in the same way that e-mail claims are. However, because Active Directory allows UPNs without the @ symbol, the account Federation Service attaches the @ symbol, followed by the suffix if there is a UPN suffix mapping defined. Otherwise, if any suffix is passed through, the Federation Service passes the UPN as is, without the @ symbol. On the resource side, if any UPN suffix is allowed, the UPN without the @ symbol is accepted. Otherwise, if a specific UPN suffix is allowed, the UPN without the @ symbol is rejected.

**Common name**
Common name claim types always map to common name claim types. They are subject to no additional rules.

**Custom**
Custom claim types always map to other custom claim types. For example, given an incoming claim set of (UPN, Custom=[EmployeeNumber, TaxPayerID]) and an organization claim set of (UPN, Custom=[Employee, SSN]), you can create mappings from EmployeeNumber to Employee and from TaxPayerID to SSN.

**Group**
Group claim types always map to other group claim types. For example, given an incoming claim set of (UPN, Group=[One, Two, Three]) and an organization claim set of (UPN, Group=[X,Y,Z]), you can create mappings from One to Y, from Two to X, and from Three to Z.

**Group-to-UPN mapping**
In addition to the standard mappings described in the previous sections, you may also use a special group-to-UPN claim mapping. The group-to-UPN claim mapping is supported only on the resource Federation Service when claims are incoming from an account partner. In this case, UPN claim types do not map to UPN claim types. Instead, you provide an ordered list of group-to-UPN claim mappings.

For example, the group-to-UPN list might be:

1. Dev to developers@internal.tailspintoys.com

2. Test to testers@internal.tailspintoys.com

3. PM to progmgrs@internal.tailspintoys.com

Given an incoming claim set of (Common name=John Smith, Group=[Dev]) the organization claim set contains (Common name=John Smith, UPN=developers@internal.tailspintoys.com). Remember that the list is ordered. Therefore, a claim set of (Common name=John Smith, Group=[Dev,PM]) results in (Common name=John Smith, UPN=developers@internal.tailspintoys.com). Also, if the incoming claim has a UPN, the UPN is overwritten. This special mapping rule specifically supports group-based resource accounts that access legacy resources. The order of the group-to-UPN mappings is specified in the trust policy for the Federation Service.

# Understanding Certificates Used by ADFS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Understanding Certificates Used by ADFS**

- Certificates used by federation servers
- Certificates used by federation server proxies
- Certificates used by Web servers

# Certificates used by federation servers

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Token-signing certificates**

Each federation server uses a token-signing certificate to digitally sign all security tokens that it produces. Because each security token is digitally signed by the account partner, the resource partner can verify that the security token was in fact issued by the account partner and that it was not modified. This helps prevent attackers from forging or modifying security tokens to gain unauthorized access to resources.

Digital signatures on security tokens are also used within the account partner when more than one federation server is used. In this situation the digital signatures verify the origin and integrity of security tokens that are issued by other federation servers within the account partner. The digital signatures are verified with verification certificates.

| **Note** |
| --- |
| Each token-signing certificate contains a private key that is associated with the certificate. |

**Verification certificates**

Verification certificates are used to verify that a security token was issued by a valid federation server and that it was not modified. Verification certificates are actually the token-signing certificates of other federation servers.

To verify that a security token was issued by a given federation server and not modified, the federation server must have a verification certificate for the federation server that issued the security token. For example, if federation server A issues a security token and sends the security token to federation server B, federation server B must have a verification certificate (federation server A's token-signing certificate) for federation server A.

| **Note** |
| --- |
| Unlike a token-signing certificate, a verification certificate does not contain the private key that is associated with the certificate. |

**SSL server authentication certificates**

The federation server uses Secure Sockets Layer (SSL) server authentication certificates to secure Web services traffic for communication with Web clients or the federation server proxy. These certificates are requested and installed through the Internet Information Services (IIS) snap-in.

For more information about certificates, see Public Key Infrastructure for Windows Server 2003 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=19936).

# Certificates used by federation server proxies

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**SSL client authentication certificates**
Each federation server proxy uses a Secure Sockets Layer (SSL) client authentication certificate to authenticate to the Federation Service. Any certificate with client authentication extended key usage (EKU) can be used as a federation server proxy client authentication certificate. A copy of the federation server proxy client authentication certificate is stored on both the federation server proxy and in the trust policy of the federation server. However, only the federation server proxy stores the private key that is associated with the federation server proxy client authentication certificate.

**SSL server authentication certificates**
The federation server proxy uses SSL server authentication certificates to secure Web services traffic for communication with Web clients. These certificates are requested and installed through the Internet Information Services (IIS) snap-in.

For more information about certificates, see Public Key Infrastructure for Windows Server 2003 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=19936).

# Certificates used by Web servers

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Each Web server that hosts the ADFS Web Agent uses Secure Sockets Layer (SSL) server authentication certificates to securely communicate with Web clients. These certificates are requested and installed through the Internet Information Services (IIS) snap-in.

For more information about certificates, see Public Key Infrastructure for Windows Server 2003 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=19936).

# ADFS resources

Updated: September 13, 2007

Applies To: Windows Server 2003 R2

You can find detailed documentation about Active Directory Federation Services (ADFS) on the ADFS home page (http://go.microsoft.com/fwlink/?LinkId=79542).

For more information about ADFS or other ADFS-related information, see the following Web resources:

- Web Services and Other Distributed Technologies Developer Center on the MSDN Web site (http://go.microsoft.com/fwlink/?LinkId=44189)
- Web Services Protocol Workshops on the MSDN Web site (http://go.microsoft.com/fwlink/?LinkId=44190)
- Web Services Specifications on the MSDN Web site (http://go.microsoft.com/fwlink/?LinkId=44191)
- Web Services Interoperability Organization (WS-I) (http://go.microsoft.com/fwlink/?LinkId=34328)

# ADFS troubleshooting

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Setup issues**
**You receive an Internet Explorer error page with the message "This page cannot be displayed" "Cannot find server or DNS Error."**
There are a few things that can cause this problem:

- Verify that Windows Firewall is turned off.
- Verify that all the Federation Services and application Web servers have a server authentication certificate issued to the default Web site.
- If there is an external account partner Federation Service Proxy involved, verify that the correct Federation Service host name was used during installation.
- If you are using a Windows NT token-based application, verify that the Federation Service Uniform Resource Locator (URL) on the **ADFS Web Agent** tab of **Web Sites Properties** is configured correctly.

**When you try to connect to the application, you get an Internet Explorer error page with the message "This page cannot be found" "HTTP Error 404 – File or directory not found."**
This issue might be caused by the following configuration problems:

- Verify that the Web application is properly configured in Internet Information Services (IIS).
- Verify that the Web application URL is properly named in the Active Directory Federation Services Snap-in.
- Verify that Microsoft ASP.NET is installed on the application Web server and in the Federation Service.
- If you are connecting to a Windows NT token–based application that uses ASP and you receive the 404 error after supplying your credentials, in the IIS Manager console tree, click the local computer, click **Web Service Extensions**, and then verify that **Active Server Pages** is set to **Allowed**.

**After setting up a Windows NT token–based application, you attempt to connect to it but you are not prompted to choose a host realm and login credentials.**
Verify that the virtual directory of the Windows NT token–based application is set up to use the lfsext.dll Internet Server Application Programming Interface (ISAPI) extension.

**Where are the ADFSSetup.log, ADFSOCM.log, and ADFSMSI.log files located?**
They are located in %SYSTEMROOT%\.

**Enable logging**
**Registry settings to enable logging on the account federation server**
The account federation server uses an authentication package for mapping client certificates. To enable logging for the account federation server authentication package, perform the following tasks in order:

1. If it is not already installed, install the Federation Service component of Active Directory Federation Services (ADFS).
2. Set the following registry key:
   **[HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\WebSso\Parameters]**

   **"DebugLevel"=dword:ffffffff**

**Registry settings to enable logging on the Web server for the:**
**ADFS Web Agent Authentication Package**
The ADFS Web Agent authentication package is used by Windows NT token-based applications for generating tokens when Service-for-User (S4U) is not available.

**[HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\WebSso\Parameters]**

**"DebugLevel"=dword:ffffffff**

**ADFS Web Agent ISAPI Extension**
The ADFS Web Agent ISAPI Extension handles the protocols that are used by ADFS to authenticate requests.

**[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ADFS\WebServerAgent]**

**"DebugPrintLevel"=dword:ffffffff**

**ADFS Web Agent Authentication Service**
The ADFS Web Agent Authentication Service validates incoming tokens and cookies.

**[HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\IFSSVC\Parameters]**

**"DebugPrintLevel"=dword:ffffffff**

**Where are these logs located?**
They are located in %SYSTEMDRIVE%\ADFS\logs.

**Configuration issues**
The following section covers some of the known issues with ADFS configuration.

**Condition: server error**
**Error:** The token request for application with URL https://... cannot be fulfilled because the URL does not identify any known trusting application

**Solution:** This error is returned by the resource Federation Service when the application URL does not identify any known application. Make sure that the application has been added to the trust policy for the Federation Service. For more information about how to do this, see Complete the Add Applications Wizard.

For a claims-aware application, verify that the return URL is typed correctly in the application's web.config file and that it matches the application URL that is specified in the trust policy of the Federation Service.

For a Windows NT token-based application, verify that the return URL is typed correctly on the **ADFS Web Agent** tab of IIS and that it matches the application URL in the trust policy of the Federation Service.

**Condition: validation error**
**Error:** Validation of viewstate MAC failed. If this application is hosted by a Web farm or cluster, ensure that **<**machineKey**>** configuration specifies the same validationKey and validation algorithm.

**AutoGenerate** cannot be used in a cluster. An unhandled exception occurred during the execution of the current Web request. Review the stack trace for more information about the error and where it originated in the code.

Or

**Error:** An unhandled exception was generated during the execution of the current web request. Information regarding the origin and location of the exception can be identified using the exception stack trace below.

**Solution:** Using a text editor, add the following setting to the Web.config file on the computer hosting either the Federation Service, Federation Service Proxy, or ADFS Web Agent that will be farmed:

```
<system.web>

<machineKey>

<machineKey validationKey="specify key for the appropriate algorithm"

decryptionKey="specify key"

validation="SHA1|MD5|3DES"/>
```

Or

**Solution:** Add the following element in the <system.web> section of the Web.config file on the computers hosting the Federation Service, Federation Service Proxy, or ADFS Web Agent that are set up in the farm:

```
<pages enableViewStateMac="false"/>
```

**Condition: The account Federation Service is configured with the wrong cookie path.**

Behavior: The Federation Service tries to authenticate the user each time, and no sign-on occurs. The event logs on the federation server show that the user has been authenticated successfully. However, the user never sees the login succeed.

**Solution:** To resolve this issue, correct the cookie path that is specified in the trust policy.

The cookie path must match a prefix of the request Uniform Resource Identifier (URI). It is important to note that some browsers treat "/path" or "/path1/samp" as a prefix match of "/path1/sample" while others do not allow matches that consume only parts of the individual words. These strict implementations accept only a subset of those matches that are allowed by the first implementation, for example, "/path1" or "/path1/sample".

**Condition: A Windows NT token–based application cannot create a Windows access token for the user using the security token from the resource Federation Service as a result of one of the following conditions:**

- The only identity claim is the common name claim.
- Services-for-User (S4U) fails because there is no resource account corresponding to the user principal name (UPN).

**Behavior:** The Web application returns an anonymous user token.

**Condition: The UPN name for forms authentication with the user@domain NetBIOS name can be different from the UPN for integrated authentication and Transport Layer Security / Secure Sockets Layer (TLS/SSL) client authentication.**
**Behavior:** In the case of integrated and TLS/SSL client authentication, the UPN is always the explicit UPN that is configured in Active Directory for the user object. However, for forms authentication, the UPN can be whatever the user enters in the user name field. Therefore, the UPN can be in the form:

username@netbiosname of domain or username@domaindnsname

**Condition: The Web server application should not be configured with any URLs that are not Secure Hypertext Transfer Protocol (HTTPS).**
**Behavior:** If the application contains links that are not HTTPS, the browser will not send the browser authentication cookies for those URLs. Single sign-on (SSO) is not possible because the ADFS cookies are secure cookies. In cases where the Web server is hosting only Windows NT token–based applications, the Web server will redirect to the HTTPS URL. Therefore, this behavior may not be noticed in most cases.

**Condition: If the Federation Service or Web server is running on a domain controller, APPIDENTITY should be provided with the Write permission to the Temporary ASP.NET files directory.**
(%windir%\Microsoft.NET\Framework\v1.1.4322\Temporary ASP.NET files)

APPIDENTITY refers to the identity of the application pool with which the Federation Service or Federation Service Proxy is configured to run.

**Condition: The Federation Service log file gets filled, and the Federation Service starts to fail all requests.**
**Solution:** Increase the log size of the Federation Service log to something large, such as 16 megabytes (MB).

**Condition: A forest trust is created between an extranet forest and an intranet forest, and a user has successfully authenticated as an intranet domain user to the extranet forest. However, the user cannot authenticate as a user from a domain that is a child domain of the intranet forest.**
**Cause:** The Federation Service maintains a cache of forest trust information that is refreshed every eight hours.

**Solution:** Recycle the Federation Service application pool. This ensures that no authentication requests are dropped.

**Duplicate group or custom claim names**
As a best practice, do not create duplicate group or custom claims using case-insensitive names. For example, do not create an organization group claim using the names “Smith” and “smith”. If similar claim names are typed but they have case-sensitive differences, ADFS will treat those claims differently.

**Active Directory node in the ADFS snap-in:**
**Extracting multiple Active Directory users to a single organizational group claim displays ‘*’ under the account store data field in the details pane.**
**Solution:** This is by design. To verify the list of added Active Directory users, open the properties dialog box for the organizational group claim.

**Account Partners node in the ADFS snap-in:**
**Object picker under the Groups tab in the UPN claim mapping dialog box returns a selected user’s UPN as NULL in the UPN edit field.**
**Solution:** This is expected behavior. If the selected user is not assigned with a UPN explicitly, the object picker returns NULL, and the UPN field shows a blank value. Type the UPN manually in the field.

**Applications node in the ADFS snap-in:**
**A common name claim for a Windows NT token-based application cannot be enabled in the Add Applications Wizard.**
**Solution:** The user cannot enable a common name identity claim for a Windows NT token–based application in the Add Applications Wizard. This can be fixed in the properties dialog box for the common name identity claim in the Added Applications details pane.

**ADAM issues**
**After user accounts are created in Active Directory Application Mode (ADAM) and the trust policy is configured with information about the ADAM store, the Federation Service is not able to validate users in the ADAM store.**
**Solution**: Use caution while creating user accounts using the ADAM ADSI Edit snap-in. Always create a user account with a password. If you create a user account without a password, use ADSI Edit to reset the password for the user account. Most importantly, check the value of the **msDS-UserAccountDisabled** property of the user account. This property should not have the value **True**. The value should be either **False** or **Not set**. If the value of **msDS-UserAccountDisabled** property is **True**, it means that the user account is disabled and the Federation Service cannot validate credentials for this ADAM user account.

**You have enabled an ADAM account store, but the Federation Service is not able to retrieve any claims.**
If the Federation Service is running as Local System, you must add the machine account of the computer hosting the Federation Service to the Readers group in the ADAM store.

If the Federation Service is running as Network Service, you must add the domain account to the Readers group in the ADAM store.

# Active Directory Application Mode (ADAM)

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Active Directory®Application Mode**

# ADAM How To...

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**How to ...**

- Install or Remove ADAM
- Create or Remove an ADAM Instance
- Manage an ADAM Instance
- Manage Replication, Sites, and Configuration Sets
- Manage Schemas and Directory Partitions
- Manage Users and Groups
- Manage Access Control
- Monitor and Maintain ADAM
- Synchronize Data from Active Directory to an ADAM Instance

# Install or Remove ADAM

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Install or remove ADAM**

- Install ADAM
- Remove ADAM

# Install ADAM

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To install ADAM**

1. Open **Add or Remove Programs** from **Control Panel**.
2. Click **Add/Remove Windows Components**.
3. Click **Active Directory Services** under **Components**, and then click **Details**.
4. Select the **Active Directory Application Mode (ADAM**) check box under **Subcomponents of Active Directory Services**, and then click **OK**.
5. Click **Next** on the **Windows Components** page.
6. Review the message that appears. Based on the contents of message, do one of the following:
   - Click **Finish** if the message, "You have successfully completed the ADAM Setup Wizard" appears.
   - If an error message appears, make a note of the error, click **Finish**, and then review the Active Directory Application Mode (ADAM) event messages in **Event Viewer**.

## Notes

- To open **Add or Remove Programs**, click **Start**, click **Control Panel**, and then click **Add or Remove Programs**.
- If an error occurs in the Active Directory Application Mode Setup Wizard before the **Completing the Active Directory Application Mode Setup Wizard** page, first review the error message that describes the cause of the problem. Then, click **Start**, click **Run**, and type the following:

  **%windir%\Debug\adamsetup.log**

# Remove ADAM

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To remove ADAM**

1. Open **Add or Remove Programs** from **Control Panel**.
2. Click **Add/Remove Windows Components**.
3. Click **Active Directory Services** under **Components**, and then click **Details**.
4. Clear the **Active Directory Application Mode (ADAM)** check box under **Sub Components of Active Directory Services**, and then click **Next**.

**Notes**

- To open **Add or Remove Programs**, click **Start**, click **Control Panel**, and then click **Add or Remove Programs**.
- You can sort programs in **Add or Remove Programs** by selecting different options in **Sort by**.
- You might be prompted to restart the computer after removing **Active Directory Application Mode (ADAM)**. If you choose not to restart the computer, future installations of ADAM might fail.
- It is not possible to remove ADAM if there is an ADAM instance running on the computer.

# Create or Remove an ADAM Instance

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Create or Remove an ADAM Instance**

- Use the ADAM Setup Wizard
- Perform an unattended install of an ADAM instance
- Install an ADAM replica from media
- Remove an ADAM instance
- Perform an unattended removal of an ADAM instance

# Use the ADAM Setup Wizard

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Use the ADAM Setup Wizard**

- Starting the ADAM Setup Wizard
- Selecting a setup option
- Specifying an instance name
- Specifying communication ports
- Selecting an application directory partition option
- Specifying file locations
- Selecting a service account
- Selecting an administrator account
- Importing LDIF files during setup
- Reviewing ADAM Setup Wizard selections
- Finishing the installation

# Starting the ADAM Setup Wizard

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To start the ADAM Setup Wizard**

1. Click **Start**, point to **All Programs**, point to **ADAM**, and then click **Create an ADAM instance**.
2. On the **Welcome to the Active Directory Application Mode Setup Wizard** page, click **Next**.

**Note**

- You can use the ADAM Setup Wizard to install a new, unique ADAM instance or to install a replica ADAM instance.

**See Also**
**Concepts**
Adaminstall
Install an ADAM replica from media

# Selecting a setup option

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

On the **Setup Options** page, you must choose whether to install a unique Active Directory Application Mode (ADAM) instance or join an existing configuration set.

**To select a setup option**

- On the **Setup Options** page, do one of the following, and then click **Next**:
  - Click **A unique instance**.
  - Click **A replica of an existing instance**.

### Notes

- The following table summarizes the two choices presented on this page.

| Setup option | Result |
|---|---|
| A unique instance | If you choose to install a unique ADAM instance, the ADAM instance that you install will not be a part of any existing configuration set, and it will not have any replication partners. The ADAM Setup Wizard will create new, default copies of the configuration and schema directory partitions for the new ADAM instance that you are creating. Any schema extensions that you have added to any other ADAM instance will not be available in this new ADAM instance. |
| A replica of an existing instance | If you choose to install a replica of an existing ADAM instance, the ADAM instance that you are installing will contain replicated copies of the configuration and schema directory partitions (including any schema extensions) from the instance from which you choose to replicate. In addition, you have an opportunity in the ADAM Setup Wizard to selectively replicate any application directory partitions that exist in the source configuration set. You must specify a running ADAM instance as the source from which to replicate. To speed up the replication process for the new instance, you can use a restored copy of a previously backed up ADAM instance as the data source. |

- An ADAM instance consists of a single copy of the ADAM directory service, along with its associated directory store, assigned Lightweight Directory Access Protocol (LDAP) and Secure Sockets Layer (SSL) ports, and application event log. You can run multiple ADAM instances simultaneously on a single computer. For more ADAM terminology, see Related Topics.
- You can only join an ADAM instance to a configuration set during ADAM installation.

Understanding ADAM replication and configuration sets
Install an ADAM replica from media

# Specifying an instance name

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

On the **Instance Name** page, you must provide an easily recognizable name for the Active Directory Application Mode (ADAM) instance that you are installing. This name is used on the local computer to uniquely identify this ADAM instance.

The name that you specify appears in the following places:

- Event Viewer
- Services snap-in
- Add or Remove Programs

**To specify an instance name**

- On the **Instance Name** page, type a name for the ADAM instance that you are installing, and then click **Next**.

### Notes

- The Active Directory Application Mode Setup Wizard presents a default instance name of instance*X*, where *X* equals 1 for the first ADAM instance that is installed on the computer, 2 for the second ADAM instance that is installed on the computer, and so on.
- The name that you specify must meet the following requirements:
  - It must be unique with respect to other ADAM instances running on the same computer.
  - It must be no longer than 44 characters.
  - It must use characters only from the ranges of a through z, A through Z, or 0 through 9.
  - The name "ntds" cannot be used.
- The instance name that you specify is used to construct the service name, the service display name, and the service description, as follows:

| Name supplied during setup | Service name | Service display name | Service description |
|---|---|---|---|
| instance1 | ADAM_instance1 | instance1 | Blank (No default description is provided.) |

- You can modify the service display name, as well as the service description, after installation. For more information, see Related Topics.

**See Also**
**Concepts**
View or modify the service display name of an ADAM instance
View or modify the service description of an ADAM instance
Start, stop, pause, resume, or restart an ADAM instance

# Specifying communication ports

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

On the **Ports** page, you can specify the communications ports that the Active Directory Application Mode (ADAM) instance will use to communicate with directory-enabled applications. Directory-enabled applications locate an ADAM instance by using a combination of the name of the computer on which the ADAM instance is running and a communication port number. An ADAM instance can communicate using Lightweight Directory Access Protocol (LDAP) or Secure Sockets Layer (SSL). You must provide a port number for each.

If you are not sure what communication port numbers to use, accept the default values.

**To specify communication ports**

1. On the **Ports** page, type a port number in **LDAP port number**.
2. Type a port number in **SSL port number**, and then click **Next**.

### Notes

- By default, ADAM uses the default communication port numbers of 389 and 636 for LDAP and SSL, respectively. If either of these ports is already in use on the destination computer, ADAM specifies the first available port, starting at 50000.
- If you plan to run ADAM and Active Directory concurrently on the same computer, you must assign ports other than 389 and 636 to ADAM. Active Directory requires the use of ports 389 and 636 (as well as ports 3268 and 3269, if the domain controller running Active Directory is configured as a global catalog).
- For more information about how directory-enabled applications can locate a given ADAM instance, see Related Topics.
- For information about changing the communication ports of an ADAM instance, see Related Topics.

**See Also**
**Concepts**
Modify the communication ports used by an ADAM instance

Administering an ADAM instance

# Selecting an application directory partition option

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

On the **Application Directory Partition** page, you can create a new application directory partition during setup for Active Directory Application Mode (ADAM). An application directory partition holds data that is specific to one or more directory-enabled applications. The ADAM Setup Wizard does not require that you create an application directory partition. You can also create application directory partitions at any time after ADAM installation.

**To select an application directory partition option**

- On the **Application Directory Partition** page, do one of the following, and then click **Next**:
  - Click **No, do not create an application directory partition**.
  - Click **Yes, create an application directory partition**, and then specify a distinguished name for the new partition. ADAM supports both X.500-style and Domain Name System (DNS)-style distinguished names. You can use any of the distinguished name attribute types in the following table when specifying an application partition in ADAM. You must include at least one attribute in the distinguished name that you specify.

| Distinguished name attribute | Type |
|---|---|
| C | Country/region |
| CN | Container |
| DC | Domain component |
| L | Locality |
| O | Organization |
| OU | Organizational unit |

For example:

CN=Partition1,DC=Woodgrove,DC=COM

**Important**

- If you want to add organizational unit (OU) containers in your application directory partition, limit the distinguished name that you specify to the following object classes: OU, C, O, and DC. By default, OUs can only be added under these object classes. For example, you can add an OU to o=Microsoft,c=US. You cannot add an OU to cn=test,o=Microsoft,c=US.

**Note**

- You can also create application directory partitions after ADAM installation. For more information, see Related Topics.

**See Also**

# Specifying file locations

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

On the **File Locations** page, you can view and change the default installation directories for Active Directory Application Mode (ADAM) data (.dit) files and recovery (.log) files.

By default, ADAM data files and recovery files are installed on the destination computer in the following directory:

\%ProgramFiles%\Microsoft ADAM*instancename*\data

where *instancename* equals the ADAM instance name that you specified on the **Instance Name** page.

By default, ADAM program files and administration tools are installed in the following directory:

\%windir%\ADAM

**To specify install file locations for ADAM data or recovery files**

- On the **File Locations** page, do one of the following:
  - Click **Next** to accept the default file locations.
  - Type new file locations in **Data files** or **Data recovery files**, and then click **Next**.

### Notes

- If the directory paths that you specify do not already exist, the ADAM Setup Wizard creates them for you.
- The ADAM Setup Wizard does not accept environmental variables in file location paths.

# Selecting a service account

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

On the **Service Account Selection** page in the ADAM Setup Wizard, you must select a service account for use by the Active Directory Application Mode (ADAM) instance. The account that you select determines the security context in which the ADAM instance runs. Changing the service account after installation may require some additional configuration.

In most cases, the ADAM Setup Wizard defaults to the Network Service account as the service account. The Network Service account is a special, built-in account, with authority similar to that of an authenticated user account. The name of the account is NT AUTHORITY\NetworkService. The Network Service account has limited access to the local computer and authenticated access (as the computer account) to network resources. This limited access helps safeguard your system if individual services or processes are compromised. Services that run as the Network Service account access network resources using the credentials of the computer account.

For more information about selecting a service account and ADAM service account requirements, see Selecting an ADAM service account.

**To select a service account**

- On the **Service Account Selection** page, do one of the following, and then click **Next**:
  - Click **Network service account**.
  - Click **This account**, click **Browse**, and then select a local or domain account.

### Notes

- On Windows XP Professional, workstation and domain user accounts that are used as the ADAM service account must be members of the local Administrators group.
- When you install ADAM on Windows XP Professional computers that are joined to a workgroup, you must edit the **forceguest** registry key to allow users to bind to ADAM successfully. For more information, see Enable binding to ADAM instances running on Windows XP Professional computers joined to a workgroup.
- For additional considerations when running ADAM on Windows XP Professional, see Running ADAM on Windows XP Professional.
- To enable auditing for an ADAM instance running under a service account other than the Network Service account, you must grant the **Generate security audits** right to the account that is used as the ADAM service account.
- To enable a workstation or domain user account as a service account, you must grant the **Log on as a service** right to the account that is used as the ADAM service account. For more information, see Add the Log on as a service right to an account.

# Selecting an administrator account

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

On the **ADAM Administrators** page, you must select a user or group to become the default administrator for this Active Directory Application Mode (ADAM) instance. This user or group that you select will have full administrative control of the ADAM instance.

By default, the ADAM Setup Wizard specifies the currently logged on user. You can change this selection to any local or domain account or group on your network.

**To select an administrator account**

- On the **ADAM Administrators** page, do one of the following, and then click **Next**:
  - Click **Currently logged on user**.
  - Click **This account**, click **Browse**, and then select a local or domain account or group.

### Notes

- If you specify a group to become the ADAM administrator, every member of that group will have administrative control of the ADAM instance.
- The user or group that you select automatically becomes a member of the Administrators group in the configuration directory partition of the ADAM instance. For more information about users and groups in ADAM, see Related Topics.
- Do not specify built-in groups or built-in accounts, such as DOMAIN\Administrators. Instead, if you want to specify a group, specify a domain group, such as *domainname*\Domain Admins, where *domainname* represents the name of your domain.

# Importing LDIF files during setup

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

On the **Import LDIF Files** page, you can specify that the optional ms-InetOrgPerson.ldf, ms-User.ldf, ms-UserProxy.ldf, and MS-AZMan.ldf LDAP Data Interchange Format (LDIF) files be imported. Together, these files contain several user class schema definitions, along with objects for use with Windows Authorization Manager, that can be imported into the schema of the new ADAM instance that is currently being installed.

**To import LDIF files during setup**

- On the **Import LDIF Files** page, do one of the following, and then click **Next**:
  - If you do not want to import or use the optional user class schema definitions, click **Do not import LDIF files for this instance of ADAM**.
  - If you want to use the optional user class schema definitions or Windows Authorization Manager with your ADAM instance, click **Import the selected LDIF files for this instance of ADAM**; in **Available files**, click one or more of the LDAP Data Interchange Format (LDIF) files to import; and then click **Add**.

### Notes

- The following table describes each of the optional .ldf files.

| .ldf file | User classes | Import this file if ... |
|---|---|---|
| MS-User.LDF | • **Person**<br>• **Organizational-Person**<br>• **User** | You want to create user objects in the ADAM directory, but you do not want to create users of the **InetOrgPerson** class (as defined in RFC 2798). |
| MS-InetOrgPerson.LDF | • **Person**<br>• **Organizational-Person**<br>• **User**<br>• **inetOrgPerson** | You want to create user objects in the ADAM directory, and you want to create users of the **InetOrgPerson** class (as defined in RFC 2798). |
| MS-UserProxy.LDF | • **User-Proxy** | You want to create proxy objects in ADAM for use in bind redirection. For more information about proxy objects and bind redirection, see Understanding ADAM bind redirection. |
| MS-AZMan.LDF | • Not applicable | You want to use Windows Authorization Manager with ADAM. For information about role-based authorization in Windows Server 2003, see "Dynamic Groups in Windows Server 2003 Authorization Manager" at the Microsoft MSDN Web site. |

- If you choose not to import these LDIF files during setup, you can import them at a later time, using the **ldifde** command-line tool. For more information, see Related Topics.
- This wizard page appears only during the installation of a unique ADAM instance and not during the installation of a

replica ADAM instance.

- You must be logged on as an account that is specified as the ADAM administrator to import these schema class definitions into the ADAM schema.

# Reviewing ADAM Setup Wizard selections

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

On the **Ready to Install** page, you can review the ADAM setup options that you have selected.

**To review or change your selections in the ADAM Setup Wizard**

1. In the **Selections** box, use the scroll bar to review your selections.
2. To change any of your selections:
   a. Click **Back** until you reach the wizard page that contains the setting that you want to change.
   b. After making the change, click **Next** until you reach the **Ready to Install** page again.
3. To make any additional changes, repeat step 2.
4. Click **Next**.

**Note**

- After you click **Next**, the ADAM Setup Wizard automatically begins copying files and configuring the new ADAM instance.

# Finishing the installation

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

If the Active Directory Application Mode Setup Wizard completes successfully, the **Completing the Active Directory Application Mode Setup Wizard** page displays the message "You have successfully completed the ADAM Setup Wizard." If the Active Directory Application Mode Setup Wizard does not complete successfully, an error message appears.

Errors can occur either during the setup process or during directory service initialization.

**To finish the installation**

- Review the message that appears. Based on the contents of message, do one of the following:
  - If "You have successfully completed the ADAM Setup Wizard" appears, click **Finish**.
  - If an error message appears, make a note of the error, click **Finish**, and then review the Active Directory Application Mode (ADAM) event messages in **Event Viewer**.

### Notes

- If an error occurs in the Active Directory Application Mode Setup Wizard before the **Completing the Active Directory Application Mode Setup Wizard** page, first review the error message that describes the cause of the problem. Then, click **Start**, click **Run**, and type either of the following:

  **%windir%\Debug\adamsetup.log**

  **%windir%\Debug\adamuninstall.log**

  These files contain information that can help you troubleshoot the cause of the ADAM setup failure.

- For both installs and uninstalls, ADAM uses a registry key to return error codes and messages back to the caller (for example, an .msi package). ADAM Setup creates this registry key and associated values only if errors or warnings occur. This registry key is **HKLM\Software\Microsoft\Windows\CurrentVersion\ADAM_Installer_Results**, and it includes the possible values in the following table.

| Key | Contents |
|---|---|
| **ADAMInstallErrorCode** | The numeric error code that caused the installer to fail |
| **ADAMInstallErrorMessage** | A message that is associated with the install error code |
| **ADAMInstallWarnings** | Messages that are associated with the install warnings |
| **ADAMUninstallErrorCode** | The numeric error code that caused the uninstall to fail |
| **ADAMUninstallErrorMessage** | A message that is associated with the uninstall error code |
| **ADAMUninstallWarnings** | Messages that are associated with the uninstall warnings |

# Perform an unattended install of an ADAM instance

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

In addition to using the Active Directory Application Mode Setup Wizard, you can install Active Directory Application Mode (ADAM) without user intervention. An unattended ADAM installation requires an answer file (Answer.txt) that contains a set of preconfigured installation options.

**To perform an unattended install of an ADAM instance**

1. Using any text editor, create a new text file. (As an option, you can copy and paste the sample answer file below into your answer file.)
2. Specify the installation parameters, as described in the table below.
3. Save your answer file.
4. At a command prompt (or in a batch or script file), change to the drive and directory that contains the ADAM setup files, and then type the following command:

   **Adamsetup /c:"adaminstall.exe /answer:** *drive:\pathname\filename.txt* **"**

   where *drive:\pathname\filename.txt* represents the drive, path, and file name of your answer file. (The double quotation marks in the command are required.)

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- The following table describes the parameters that can be used in an ADAM answer file. These parameters are not case sensitive. In other words, you can specify either **InstallType** or **installtype** in your answer file. However, case is preserved on the values that you specify for the **instancename** and **servicepassword** parameters.

| Parameter | Possible values | Default behavior if the parameter is not present in the answer file |
|---|---|---|
| **InstallType**<br>Valid for all installations.<br>Optional. | **Unique** — Creates a unique instance of ADAM.<br>**Replica** — Creates an instance of ADAM by replicating all or part of an existing ADAM instance, either over the network or from restored backup media.<br>When values are also specified in the answer file for the **ReplicationDataSourcePath** and **ReplicationLogSourcePath** parameters, and when **InstallType** is set to **Replica**, ADAM setup installs an ADAM replica instance from restored backup media. If values for those parameters are not present, ADAM setup installs an ADAM replica instance over the network. For more information about installation from media, see Install an ADAM replica from media.<br>**Tools** — Installs ADAM tools only.<br>Any other value — Returns "Invalid installation type specified in InstallType" error message. | Same behavior as **Unique** |

| | | |
|---|---|---|
| **ShowOrHideProgressGUI**<br>Valid for all installations.<br>Optional. | **Show** — ADAM setup displays progress information during installation.<br>**Hide** — ADAM setup does not display progress information during installation. | Same behavior as **Hide** |
| **InstanceName**<br>Valid for all installations.<br>Optional. | An ADAM instance name must meet the following requirements:<br>• It must be unique with respect to other ADAM instances running on the same computer.<br>• It must be no longer than 44 characters.<br>• It must use characters only from the ranges of a through z, A through Z, or 0 through 9. | The instance will be named Instance*n*, where *n* is the lowest number greater than 0 and Instance*n* is unique on the local computer. |
| **ApplicationPartitionsToReplicate**<br>Valid only for replica installations.<br>Optional. | Specify the distinguished names of the application partitions to replicate from the source ADAM instance.<br>The following example specifies three application partitions to replicate:<br>ApplicationPartitionsToReplicate = "CN=my,O=partition" "DC=partition2" "CN=embed qu\"ote in DN"<br>To replicate all application partitions from the source ADAM instance, specify "*" as the value. Any value that is specified for **ApplicationPartitionsToReplicate** is ignored if **InstallType** is not set to **Replica**. | No application partitions are replicated. |
| **ReplicationDataSourcePath**<br>Valid only for replica installations.<br>When a value for this parameter is present, ADAM setup attempts an installation from media. If the value for this parameter is not valid, ADAM setup writes an error to the setup log. | Specify the directory path to a restored instance of ADAM data. Any value that is specified for **ReplicationDataSourcePath** is ignored if **InstallType** is not set to **Replica** or if a value is not also specified for **ReplicationLogSourcePath**. | Application data is replicated over the network, rather than from a restored backup of an ADAM instance. If a value is specified for this parameter, but not for **ReplicationLogSourcePath**, an error occurs. |
| **ReplicationLogSourcePath**<br>Valid only for replica installations.<br>When a value for this parameter is present, ADAM setup attempts an installation from media. If the value for this parameter is not valid, ADAM setup writes an error to the setup log. | Specify the directory path to the log file for a restored instance of ADAM. Any value that is specified for **ReplicationLogSourcePath** is ignored if **InstallType** is not set to **Replica** or if a value is not also specified for **ReplicationDataSourcePath**. | Application data is replicated over the network, rather than from a restored backup of an ADAM instance. If a value is specified for this parameter, but not for **ReplicationDataSourcePath**, an error occurs. |
| **LocalLDAPPortToListenOn**<br>Required for all installations. | 389 or any unused port number between 1025 and 65535, inclusive.<br>Any other value — Returns "Invalid local LDAP port specified." | Defaults to 389. Or, if 389 is not available, defaults to the first available port equal to or greater than 50000. |

| | | |
|---|---|---|
| **LocalSSLPortToListenOn**<br>Required for all installations. | 636 or any unused port number between 1025 and 65535, inclusive.<br>Any other value — Returns "Invalid local SSL port specified." | Defaults to 636. Or, if 636 is not available, defaults to the first available port equal to or greater than 50000. |
| **SourceServer**<br>Required for replica installations. | A valid DNS name or network basic input/output system (NetBIOS) name.<br>Any other value — If the installation type is replica, returns "Invalid syntax for replication source server," else do nothing. | If the installation type is replica, returns "Replication source server not specified," else do nothing. |
| **SourceLDAPPort**<br>Required for replica installations. | Either 389 or a number between 1025 and 65535.<br>Any other value — If the installation type is replica, returns "Invalid replication source port specified," else do nothing. | If the installation type is replica, returns "Replication source port not specified," else do nothing. |
| **NewApplicationPartitionToCreate**<br>Valid for installations of new, unique ADAM instances.<br>Optional. | A valid distinguished name — Creates an application partition with the specified name.<br>"" (empty string) — No new application partition will be created.<br>Any other value — If the installation type is unique, returns "Invalid application partition syntax in NewApplicationPartitionToCreate," else do nothing. | Same behavior as "" |
| **DataFilesPath**<br>Valid for all installations.<br>Optional. | A syntactically correct path name, which may include unresolved environment variables that do not contain existing ADAM files.<br>Any other value — Returns "Invalid path in DataFilesPath." | Store data files in Program Files\Microsoft ADAM*instancename*\data. |
| **LogFilesPath**<br>Valid for all installations.<br>Optional. | A syntactically correct path name, which may include unresolved environment variables that do not contain existing ADAM files.<br>Any other value — Returns "Invalid path in LogFilesPath." | Stores log files in Program Files\Microsoft ADAM*instancename*\data |
| **ServiceAccount**<br>Valid for all installations.<br>Optional. | A valid DNS domain name, followed by a backslash and the account or group name.<br>A valid NetBIOS domain name, followed by a backslash and the account name.<br>A valid user principal name (UPN).<br>A valid account name only. (This is generally not recommended, because resolving an account name that is not accompanied by a domain name requires additional processing.)<br>Any other value — Returns "Invalid user specified in ServiceAccount." | This instance of ADAM will run under the Network Service account. |

| | | |
|---|---|---|
| **AddPermissionsToServiceAccount**<br>Valid for all installations.<br>Optional. | **Yes** — ADAM setup attempts to add the **Log on as a service** right to the account that is specified as the service account.<br>Any other value — ADAM setup does not attempt to add the **Log on as a service** right to the account that is specified as the service account. | ADAM setup does not attempt to add the **Log on as a service** right to the account that is specified as the service account. |
| **ServicePassword**<br>Valid for all installations.<br>Required, unless **ServiceAccount** is the Network Service account. | Any string of characters, including the empty string. | If **ServiceAccount** is the Network Service account, do nothing; otherwise, returns "No password specified in ServicePassword." |
| **Administrator**<br>Valid for all installations.<br>Optional. | A valid DNS domain name, followed by a backslash and the account name.<br>Do not specify built-in groups or built-in accounts, such as DOMAIN\Administrators. Instead, if you want to specify a group, specify a domain group, such as *domainname*\Domain Admins, where *domainname* represents the name of your domain.<br>A valid NetBIOS domain name, followed by a backslash and the account name.<br>A valid UPN.<br>A valid account name only. (This is generally not recommended, because resolving an account name that is not accompanied by a domain name requires additional processing.)<br>Any other value — Returns "Invalid user specified in Administrator." | The currently logged on user will have administrator permissions on this instance of ADAM. |
| **ShowInAddRemovePrograms**<br>Valid for all installations.<br>Optional. | **Show** — Lists the ADAM instance in **Add or Remove Programs**.<br>**Hide** — Does not list the ADAM instance in **Add or Remove Programs** | The installed ADAM instance is shown in **Add or Remove Programs**. |
| **ImportLDIFFiles** | The optional .ldf files (ms-User.ldf, ms-InetOrgPerson.ldf, ms-UserProxy.ldf, and ms-azman.ldf) that you want to import into the ADAM schema. The file names must be enclosed in double quotation marks, delimited with a space (" "). | None of the optional .ldf files are imported. |
| **SourceUserName**<br>**SourcePassword**<br>Valid for replica installations.<br>Optional. | The user name and password of an account that has administrative rights for an existing configuration set. Use these parameters when installing a replica that is being joined to the configuration set. | The replica is joined to the configuration set using the credentials of the logged on user. |

- The following represents a sample answer file for use with **adaminstall**.

```
[ADAMInstall]

; The following line specifies to install a unique ADAM instance.
```

```
InstallType=Unique

; The following line specifies the name to be assigned to the new instance.
InstanceName=MyFirstInstance

; The following line specifies the communications port to use for LDAP.
LocalLDAPPortToListenOn=389

; The following line specifies an application partition to create
NewApplicationPartitionToCreate="o=microsoft,c=us"

; The following line specifies the directory to use for ADAM data files.
DataFilesPath=C:\Program Files\Microsoft ADAM\instance1\data

; The following line specifies the directory to use for ADAM log files.
LogFilesPath=C:\Program Files\Microsoft ADAM\instance1\data

; The following line specifies the .ldf files to import into the ADAM schema.
ImportLDIFFiles="ms-inetorgperson.ldf" "ms-user.ldf"
```

- For both installs and uninstalls, ADAM uses a registry key to return error codes and messages back to the caller, for example, an .msi package. ADAM Setup creates this registry key and associated values only if errors or warnings occur. This registry key is **HKLM\Software\Microsoft\Windows\CurrentVersion\ADAM_Installer_Results**, and it includes the possible values in the following table.

| Key | Contents |
|---|---|
| **ADAMInstallErrorCode** | The numeric error code that caused the installer to fail |
| **ADAMInstallErrorMessage** | A message that is associated with the install error code |
| **ADAMInstallWarnings** | Messages that are associated with the install warnings |
| **ADAMUninstallErrorCode** | The numeric error code that caused the uninstall to fail |
| **ADAMUninstallErrorMessage** | A message that is associated with the uninstall error code |
| **ADAMUninstallWarnings** | Messages that are associated with the uninstall warnings |

# Install an ADAM replica from media

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Install an ADAM replica from media**
When you install an Active Directory Application Mode (ADAM) replica from media, you use a restored backup of an ADAM instance as the data source, rather than another ADAM instance.

- Using the Active Directory Application Mode Setup Wizard
- Using ADAM unattended install

**Using the Active Directory Application Mode Setup Wizard**
**To install an ADAM replica from media**

1. Restore a backup copy of the ADAM instance from which you want to install to an alternate location. (Do not restore the backup to the original location of the ADAM instance.)
2. At a command prompt, type the following:

   *d:\path* **adaminstall /adv**

   where *d:\path* represents the location of Adaminstall.exe.
3. Follow the steps in the Active Directory Application Mode Setup Wizard.

### Notes

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To view Help for any given wizard page, click **Help** in the Active Directory Application Mode Setup Wizard.
- You can install an ADAM replica only from media created by restoring a backup copy of an ADAM instance. For information about restoring an ADAM instance, see Related Topics.
- When you restore an ADAM instance for use in a replica installation from media, you must restore the files to an alternate location, rather than to the original location from which they were backed up. If the replica that you are creating uses a different service account than the service account that the original instance uses, you must assign permission to read all the directories and files in the alternate location to the service account of the replica instance before you run Adaminstall.exe.
- After you restore ADAM files from a backup to an alternate location, the Adamntds.dit file and Edb*.log files will be nested in the specified alternate location. For example, if you specify c:\restore_dir as the restore location for the ADAM files, Adamntds.dit and the Edb*.log files will be located at c:\restore_dir\Program Files\Microsoft ADAM*instancename*\data, where *instancename* represents the ADAM instance that was restored.
- For information about how to back up an ADAM instance, see Related Topics.
- For more information about ADAM unattended installs, see Related Topics.

**Using ADAM unattended install**
**To install an ADAM replica from media**

1. Restore a backup copy of the ADAM replica from which you want to install to an alternate location. (Do not restore the backup to the original location of the ADAM instance.)

2. Create an ADAM unattended install answer file that contains the answer file attributes and values in the following table, in addition to any other answer file parameters that you want to set, as described in Perform an unattended install of an ADAM instance.

| Attribute | Value |
|---|---|
| **InstallType** | **Replica** |
| **ReplicationDataSourcePath** | The directory location to which you restored the ADAM replica data files |
| **ReplicationLogSourcePath** | The directory location to which you restored the ADAM replica log files |
| **ApplicationPartitionsToReplicate** | The application directory partitions (from the restored files) that you want to install. Setting **ApplicationPartitionsToReplicate** equal to ***** installs all application directory partitions that exist in the restored files. Setting a specific value for this parameter installs the specified application directory partitions, along with any application directory partitions that are not part of the restored files but that do exist on other ADAM instances in the configuration set. |

3. At a command prompt (or in a batch or script file), change to the drive and directory that contains the ADAM setup files, and then type the following command:

   **adamsetup /c:"adaminstall.exe /answer:** *drive:\pathname\filename.txt*"

   where *drive:\pathname\filename.txt* represents the drive, path, and file name of your answer file.

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- You can install an ADAM replica only from media created by restoring a backup copy of an ADAM instance. For information about restoring an ADAM instance, see Related Topics.
- When you restore an ADAM instance for use in a replica install from media, you must restore the files to an alternate location, rather than to the original location from which they were backed up.
- After you restore ADAM files from a backup into an alternate location, the Adamntds.dit file and Edb*.log files will be nested in the alternate location that you specified. For example, if you specified **c:\restore_dir** as the restore location for the ADAM files, Adamntds.dit and the Edb*.log files will be located at c:\restore_dir\Program Files\Microsoft ADAM*instancename*\data, where *instancename* represents the ADAM instance that was restored.
- For information about how to back up an ADAM instance, see Related Topics.
- For more information about ADAM unattended installs, see Related Topics.
- For more information about unattended install parameters, see Related Topics.

# Remove an ADAM instance

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To remove an ADAM instance**

1. Open Add or Remove Programs.
2. Click **Change or Remove Programs**, and then click the ADAM instance that you want to remove.
3. Click **Remove**.

**Notes**

- To open Add or Remove Programs, click **Start**, click **Control Panel**, and click **Add or Remove Programs**.
- You can sort programs in **Add or Remove Programs** by selecting different options in **Sort by**.
- It is not necessary to restart the computer after removing an ADAM instance.

# Perform an unattended removal of an ADAM instance

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can remove an ADAM instance without using Add or Remove Programs, by performing an unattended removal of Active Directory Application Mode (ADAM). An unattended removal of ADAM can only be performed under the security context of the ADAM administrator. If you are not currently logged on as the ADAM administrator, the ADAM administrator credentials can be specified through a text answer file.

**To perform an unattended removal of an ADAM instance**

- At a command prompt (or in a batch or script file), type the following command:

  **adamuninstall /i:** *instancename* **/answer:***d:\dirpath\filename*

  where *instancename* represents the name of the ADAM instance to be removed, and *d:\dirpath\filename* represents the drive, path and file name of an optional answer file containing the credentials of the ADAM administrator for the specified instance.

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To pass the credentials of the ADAM administrator to **adamuninstall** from the command line, create a text answer file containing the following syntax:

  **Administrator=***domain\account*

  **AdministratorPassword=***password*

  where *domain\account* represents the domain and account name of the ADAM administrator, and *password* represents the corresponding password.

- The following represents a sample answer file for use with **adamuninstall**:

```
Administrator=cohovineyard\administrator
AdministratorPassword=adminpassword
```

- For both installs and uninstalls, ADAM uses a registry key to return error codes and messages back to the caller, for example, an .msi package. ADAM Setup creates this registry key and associated values only if errors or warnings occur. This registry key is **HKLM\Software\Microsoft\Windows\CurrentVersion\ADAM_Installer_Results**, and it includes the possible values in the following table.

| Key | Contents |
|---|---|
| **ADAMInstallErrorCode** | The numeric error code that caused the installer to fail |
| **ADAMInstallErrorMessage** | A message that is associated with the install error code |
| **ADAMInstallWarnings** | Messages that are associated with the install warnings |
| **ADAMUninstallErrorCode** | The numeric error code that caused the uninstall to fail |

| | |
|---|---|
| **ADAMUninstallErrorMessage** | A message that is associated with the uninstall error code |
| **ADAMUninstallWarnings** | Messages that are associated with the uninstall warnings |

**See Also**
**Concepts**

Adamuninstall

# Manage an ADAM Instance

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Manage an ADAM instance**

- Connect and bind to an ADAM instance using ADAM ADSI Edit
- Connect and bind to an ADAM instance using Ldp.exe
- Browse the directory tree using ADAM ADSI Edit
- Browse the directory tree using Ldp.exe
- List the directory partitions, or naming contexts, of an ADAM instance or configuration set
- List the ADAM instances installed on a computer
- Start, stop, pause, resume, or restart an ADAM instance
- Add the Log on as a service right to an account
- Modify the communication ports used by an ADAM instance
- Modify the service account used by an ADAM instance
- View or modify the service display name of an ADAM instance
- View or modify the service description of an ADAM instance
- Enable binding to ADAM instances running on Windows XP Professional computers joined to a workgroup
- Allow anonymous LDAP binding to an ADAM instance
- Manually register ADAM service principal names in Active Directory
- Manually remove ADAM service principal names from Active Directory

# Connect and bind to an ADAM instance using ADAM ADSI Edit

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To connect and bind to an ADAM instance using ADAM ADSI Edit**

1. Click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
2. In the console tree, click **ADAM ADSI Edit**.
3. On the **Action** menu, click **Connect to**.
4. In **Connection name**, type a name for this connection.
5. In **Server name**, type the DNS name, network basic input/output system (NetBIOS) name, or Internet Protocol (IP) address of the computer on which the ADAM instance is running.
6. In **Port**, type the Lightweight Directory Access Protocol (LDAP) communication port in use by the ADAM instance to which you want to connect.
7. Under **Connect to the following node**, do one of the following:
   - Click **Distinguished name (DN) or naming context**, and then specify the distinguished name to which you want to connect.
   - Click **Well-known naming context**, and then click **Configuration**, **RootDSE**, or **Schema**.
8. Under **Connect using these credentials**, do one of the following:
   - Click **The account of the currently logged on user**.
   - Click **This account**, and then specify the user name and password of the account with which you want to connect.

**Notes**

- To create additional connections to ADAM instances, on the **Action** menu, click **Connect to** for each new connection.
- When you run ADAM on computers running Windows XP Professional, you cannot set or modify the password for any principal in ADAM using ADAM ADSI Edit.
- The default communication port for LDAP is 389.
- ADAM ADSI Edit does not support Secure Sockets Layer (SSL) connections to ADAM.
- To connect to an ADAM instance running on the local computer, type **localhost** as the server name.

# Connect and bind to an ADAM instance using Ldp.exe

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To connect and bind to an ADAM instance using Ldp.exe**

1. Open **Ldp**.
2. On the **Connection** menu, click **Connect**.
3. In **Server**, type the DNS name, network basic input/output system (NetBIOS) name, or Internet Protocol (IP) address of the computer on which the ADAM instance is running.
4. In **Port**, type the Lightweight Directory Access Protocol (LDAP) or Secure Sockets Layer (SSL) communication port number in use by the ADAM instance to which you want to connect, and then click **OK**.
5. On the **Connection** menu, click **Bind**.
6. Do one of the following:
   - To bind using the credentials you logged on with, click **Bind as currently logged on user**.
   - To bind using a domain user account, click **Bind using credentials**,type the user name, password, and domain name (or the computer name, if you are using a local workstation account) of the account that you are using, and then click **OK.**
   - To bind using just a user name and password, click **Simple bind**, type the user name and password of the account that you are using, and then click **OK**.
   - To bind using an advanced method (NTLM, DPA, negotiate, or digest), click **Advanced (***method***)**, click **Advanced**, in **Method**, select the desired method, set other options as needed, and then click **OK**.
7. When you are finished specifying bind options, click **OK**.

### Notes

- To open **Ldp**, click **Start**, point to **All Programs**, point to **ADAM**, click **ADAMTools Command Prompt**, and then type **ldp** at the command prompt.
- The default communication port for LDAP is 389. The default communication port for SSL is 636.
- To connect to an ADAM instance running on the local computer, type **localhost** as the server name.

# Browse the directory tree using ADAM ADSI Edit

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To browse the directory tree using ADAM ADSI Edit**

1. Connect and bind to a directory partition using ADAM ADSI Edit.
2. In the console tree, double-click *connectionname*[*hostname*], where *connectionname* is the name of the connection and *hostname* is the name of the computer on which the directory partition is stored.
3. In the console tree, double-click a directory partition object to view its top-level containers.
4. In the console tree, double-click a top-level container to view the next level of objects in that container.
5. Do one of the following:
   - Continue double-clicking the next lowest container level to continue down a directory tree branch.
   - To view a directory object at the current directory level, in the details pane, double-click the directory object.

## Notes

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- To connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.
- ADAM ADSI Edit does not support Secure Sockets Layer (SSL) connections to ADAM.
- For more information about ADAM ADSI Edit, see Related Topics.

# Browse the directory tree using Ldp.exe

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To browse the directory tree using Ldp.exe**

1. Connect and bind to an ADAM instance using Ldp.exe.
2. On the **View** menu, click **Tree**.
3. In the **Tree View** dialog box, do one of the following:
   - To view all directory partitions on the ADAM instance, click **OK**.
   - To view only a specific directory partition on the ADAM instance, type the distinguished name of the directory partition in **BaseDN**, and then click **OK**.
4. In the console tree, double-click a directory partition object to view its top-level containers.
5. Double-click a top-level container to view the next level of objects in that container.
6. Do one of the following:
   - Continue double-clicking the next lowest container level to continue down a directory tree branch.
   - To view a directory object at the current directory level, double-click the object in the console tree, and then, in the details pane, view object details.

**Notes**

- To open Ldp.exe, click **Start**, point to **All Programs**, point to **ADAM**, click **ADAM Tools Command Prompt**, and then type **ldp** at the command prompt.
- To connect and bind to an ADAM instance using Ldp.exe, see Related Topics.

# List the directory partitions, or naming contexts, of an ADAM instance or configuration set

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To list the directory partitions of an ADAM instance or configuration set**

1. Open an ADAM tools command prompt.
2. At the command prompt, type:

   **dsmgmt**
3. At the **dsmgmt:** prompt, type:

   **partition management**
4. At the **partition management:** prompt, type:

   **connections**
5. At the **server connections:** prompt, type:

   **connect to server** *computername:portnumber*

   where *computername* is the computer on which the ADAM instance is running and *portnumber* is the Lightweight Directory Access Protocol (LDAP) or Secure Sockets Layer (SSL) communications port used by the ADAM instance.
6. At the **server connections:** prompt, type:

   **quit**
7. At the **partition management:** prompt, type:

   **list**
8. After viewing the list of directory partitions, at the **partition management:** prompt, type:

   **quit**

   and then at the **dsmgmt:** prompt, type:

   **quit**

**Note**

- To open an ADAM Tools command prompt, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Tools Command Prompt**.
- For help with **dsmgmt**, type **?** at a **dsmgmt** prompt.

# List the ADAM instances installed on a computer

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To list the ADAM instances installed on a computer**

1. Open an ADAM tools command prompt.
2. At the command prompt, type:

   **dsdbutil**

3. At the **dsdbutil:** prompt, type:

   **list instances**

4. To exit the **dsdbutil** administration tool, at the **dsdbutil:** prompt, type:

   **quit**

## Notes

- To open an ADAM tools command prompt, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Tools Command Prompt**.

- The information about the ADAM instances that are listed by this procedure includes the following: ADAM instance name, Lightweight Directory Access Protocol (LDAP) port, Secure Sockets Layer (SSL) port, installation directory, database file, log file directory, and service state.

# Start, stop, pause, resume, or restart an ADAM instance

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Start, stop, pause, resume, or restart an ADAM instance**

- Using the graphical user interface
- Using the command prompt

**Using the graphical user interface**
**To start, stop, pause, resume, or restart an ADAM instance**

1. Open **Services**.
2. In the details pane, do one of the following:
   - Click the ADAM instance that you want to manage. On the **Action** menu, click **Start**, **Stop**, **Pause**, **Resume**, or **Restart**.
   - Right-click the service, and then click **Start**, **Stop**, **Pause**, **Resume**, or **Restart**.

### Notes

- To open **Services**, click **Start**, click **Run**, type **services.msc**, and then click **OK**.
- By default, an ADAM instance is configured to start automatically.

**Using the command prompt**
**To start, stop, pause, resume, or restart an ADAM instance**

1. Open a Command Prompt.
2. Do one of the following:
   - To start an ADAM instance, type the following at the command prompt:

     **net start** *instance_name*

     where *instance_name* represents the ADAM instance that you want to start.
   - To stop an ADAM instance, type the following at the command prompt:

     **net stop** *instance_name*

     where *instance_name* represents the ADAM instance that you want to stop.

### Notes

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- You cannot pause or resume an ADAM instance from a command prompt.
- By default, an ADAM instance is configured to start automatically.

- For more information about the **net** command, type **net /?** at a command prompt, or see Help and Support Center in Windows Server 2003.

# Add the Log on as a service right to an account

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Add the Log on as a service right to an account**
**To add the "Log on as a service" right to an account on your local computer**

1. Open Local Security Policy.
2. In the console tree, double-click **Local Policies**, and then click **User Rights Assignments**.
3. In the details pane, double-click **Log on as a service**.
4. Click **Add User or Group**, and then add the appropriate account to the list of accounts that possess the **Log on as a service** right.

**To add the "Log on as a service" right to an account for a Group Policy object, when you are on a workstation or server that is joined to a domain**

1. Click **Start**, point to **Run**, type **mmc**, and then click **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**.
3. In **Add/Remove Snap-in**, click **Add**, and then, in **Add Standalone Snap-in**, double-click **Group Policy Object Editor**.
4. In **Select Group Policy Object**, click **Browse**, browse to the Group Policy object (GPO) that you want to modify, click **OK**, and then click **Finish**.
5. Click **Close**, and then click **OK**.
6. In the console tree, click **User Rights Assignment**.

   Where?

   - *GroupPolicyObject* [*ComputerName*] Policy
   - Computer Configuration
   - Windows Settings
   - Security Settings
   - Local Policies
   - User Rights Assignment

7. In the details pane, double-click **Log on as a service**.
8. If the security setting has not yet been defined, select the **Define these policy settings** check box.
9. Click **Add User or Group**, and then add the appropriate account to the list of accounts that possess the **Log on as a service** right.

**To add the "Log on as a service" right to an account for a Group Policy object, when you are on a domain controller or on a computer that has the Windows Server 2003 Administration Tools Pack installed**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the domain or organizational unit (OU) for which you want to edit security settings.
3. Click **Properties**, and then click the **Group Policy** tab.

4. In **Group Policy Object Links**, click the Group Policy object for the domain or OU for which you want to edit security settings, and then click **Edit**.
5. In the console tree, click **User Rights Assignment**.

   Where?

   - *GroupPolicyObject* [*ComputerName*] Policy
   - Computer Configuration
   - Windows Settings
   - Security Settings
   - Local Policies
   - User Rights Assignment

6. Double-click **Log on as a service** in the details pane.
7. If this security setting has not yet been defined, select the **Define these policy settings** check box.
8. Click **Add User or Group**, and then add the appropriate account to the list of accounts that possess the **Log on as a service** right.

**To add the "Log on as a service" right to an account for only domain controllers, when you are on a domain controller**

1. Open **Domain Controller Security Policy**.
2. In the console tree, click **User Rights Assignment**.

   Where?

   - Security Settings
   - Local Policies
   - User Rights Assignment

3. In the details pane, double-click **Log on as a service**.
4. If this security setting has not yet been defined, select the **Define these policy settings** check box.
5. Click **Add User or Group**, and then add the appropriate account to the list of accounts that possess the **Log on as a service** right.

### Notes

- To open **Local Security Policy**, click **Start**, point to **Control Panel**, point to **Administrative Tools**, and then double-click **Local Security Policy**.
- To open **Domain Controller Security Policy**, click **Start**, point to **All Programs**, point to **Administrative Tools**, and then click **Domain Controller Security Policy**.
- When you change a security setting, that setting will take effect in the next refresh of settings.
- The security settings are refreshed every 90 minutes on a workstation or server and every 5 minutes on a domain controller. The settings are also refreshed every 16 hours, whether or not there are any changes.

# Modify the communication ports used by an ADAM instance

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To modify the communications ports used by an ADAM instance**

1. Open an ADAM tools command prompt.
2. At the command prompt, type:

   **net stop** *instancename*

   where *instancename* represents the service name of the ADAM instance on which you want to change the communication port.
3. At the command prompt, type:

   **dsdbutil**
4. At the **dsdbutil:** prompt, type:

   **activate instance** *instancename*

   where *instancename* represents the service name of the ADAM instance on which you want to modify the communication port.
5. At the **dsdbutil:** prompt, do one of the following:

   - To change the Lightweight Directory Access Protocol (LDAP) communication port, type:

     **LDAP port** *portnumber*

     where *portnumber* represents a communication port (either 389 or in the range of 1025 through 65535) that you want to assign to LDAP.

   - To change the Secure Sockets Layer (SSL) communication port, type:

     **SSL port** *portnumber*

     where *portnumber* represents the communication port (either 636 or in the range of 1025 through 65535) that you want to assign to SSL.

6. To exit **dsdbutil**, at the **dsdbutil:** prompt, type:

   **quit**
7. At the command prompt, type:

   **net start** *instancename*

   to restart the ADAM instance.

**Notes**

- To open an ADAM tools command prompt, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Tools Command Prompt**.
- Allowable communication port numbers in ADAM include 389, 636, and any port number in the range of 1025 through 65535.

**See Also**
**Concepts**

# Modify the service account used by an ADAM instance

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To modify the service account used by an ADAM instance**

1. Open an ADAM tools command prompt.
2. At the command prompt, type:

   **net stop** *instancename*

   where *instancename* represents the service name of the ADAM instance on which you want to change the service account.
3. At the command prompt, type:

   **dsdbutil**
4. At the **dsdbutil:** prompt, type:

   **activate instance** *instancename*

   where *instancename* represents the service name of the ADAM instance on which you want to change the service account.
5. At the **dsdbutil:** prompt, type:

   **change service account** *accountname password*

   where *accountname password* represents the account name and password of the account to be used as the ADAM service account.
6. To exit **dsdbutil**, at the **dsdbutil:** prompt, type:

   **quit**
7. At the command prompt, type:

   **net start** *instancename*

   to restart the ADAM instance.

**Notes**

- To open an ADAM tools command prompt, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Tools Command Prompt**.
- When you specify a workstation or domain user account as the service account, the specified account must possess the **Log on as a service** right. To assign the **Log on as a service** right to an account, you must edit the security setting on the appropriate Group Policy object (GPO). For more information, see Related Topics.
- The service account that you select must have permission to read and write the ADAM data and log files located in %ProgramFiles%\Microsoft ADAM*instancename*.
- The service account that you select may depend on whether the ADAM instance participates in a configuration set and also on the replication security level. For more information, see Related Topics.

# View or modify the service display name of an ADAM instance

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To view or modify the service display name of an ADAM instance**

1. Open Command Prompt.
2. Do one of the following:
   - To view the service display name, type:

     **sc** *servername* **getdisplayname** *servicename*

     where *servername* represents the name of the computer on which the ADAM instance is running, and *servicename* represents the service name of the ADAM instance.

   - To modify the service display name, type:

     **sc** *servername* **config** *servicename* **displayname= "***display_name***"**

     where *servername* represents the name of the computer on which the ADAM instance is running, *servicename* represents the service name of the ADAM instance that you want to modify, and *display_name* represents the new service display name that you want to assign. (A space character (" ") is required after the equal sign (=) and before *display_name*).

### Notes

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- If the ADAM instance is running on the local computer, you can omit the *servername* parameter.
- By default, the ADAM instance name is *instancename*, where *instancename* is the name that you provided during ADAM installation.
- By default, the ADAM service name is ADAM_*instancename*, where *instancename* is the name that you provided during ADAM installation.

# View or modify the service description of an ADAM instance

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To view or modify the service description of an ADAM instance**

1. Open Command Prompt.
2. Do one of the following:
   - To view the service description, type:

     **sc** *servername* **qdescription** *serviceename*

     where *servername* represents the name of the computer on which the ADAM instance is running, and *servicename* represents the service name of the ADAM instance.

   - To modify the service description, type:

     **sc** *servername* **description** *servicename* "*service_description*"

     where *servername* represents the name of the computer on which the ADAM service is running, *servicename* represents the service name of the ADAM instance, and *service_description* represents the new description.

### Notes

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- By default, the ADAM service description is empty.
- By default, the ADAM service name is ADAM_*instancename*, where *instancename* is the name that you provided during ADAM setup.

# Enable binding to ADAM instances running on Windows XP Professional computers joined to a workgroup

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To enable binding to ADAM instances running on Windows XP Professional computers joined to a workgroup**

1. Open Registry Editor.
2. In Registry Editor, navigate to the registry subkey HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa.

   Where?

   - HKEY_LOCAL_MACHINE
   - System
   - CurrentControlSet
   - Control
   - LSA

3. In the details pane, right-click **forceguest**, and then click **Modify**.
4. In **Value data**, type **0**, and then click **OK**.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. You can also use the Last Known Good Configuration startup option if you encounter problems after manual changes have been applied.

**Note**

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.

# Allow anonymous LDAP binding to an ADAM instance

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To allow anonymous LDAP binding to an ADAM instance**

1. Open ADAM ADSI Edit.
2. Connect and bind to the configuration directory partition of the ADAM instance on which you want to allow anonymous Lightweight Directory Access Protocol (LDAP) binding.
3. In the console tree, double-click the configuration directory partition (CN=Configuration,CN={*GUID*}), double-click the services container (CN=Services), double-click the Windows NT container (CN=Windows NT), right-click the directory service container (CN=Directory Service), and then click **Properties**.
4. In **Attributes**, click **dsHeuristics**, and then click **Edit**.
5. In **Value**, modify the value of the seventh character in the attribute (counting from the left) to 2, as follows:

   0000002001001
6. Click **OK** twice.

**Notes**

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- To connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.
- ADAM does not allow anonymous LDAP binding by default.

# Manually register ADAM service principal names in Active Directory

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To manually register ADAM service principal names in Active Directory**

1. Do one of the following:
   - Log on as a member of the Domain Admins group, and then open a command prompt.
   - Using **run as**, open a command prompt as a member of the Domain Admins group.
2. Change the current directory to:

   Program Files\Microsoft ADAM*instancename*\data

   where *instancename* represents the name of the ADAM instance.
3. At the command prompt, type:

   *dnsdomainname*

   where *dnsdomainname* represents the name of the *dnsdomainname*.bat script file that ADAM Setup created for manually registering service principal names (SPNs) in Active Directory. ADAM uses the DNS domain name of the computer on which ADAM is running to name this file.

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- SPN registration does not apply to ADAM instances running on computers that are joined to a workgroup, rather than to a domain.
- If you do not register the SPNs for an ADAM instance running on a computer that is joined to a domain, you can still run the ADAM instance, but you will not be able to run the ADAM instance as part of a configuration set for which the replication security level has been set to 2. For more information about replication security levels, see Related Topics.
- The *dnsdomainname*.bat file appears in the directory approximately one minute after ADAM installation is complete.
- If the *dnsdomainname*.bat file does not appear after approximately one minute, the attempt of ADAM setup to register SPNs for the ADAM instance completed successfully.
- The *dnsdomainname*.bat file contains **repadmin /writespn** commands, similar to the commands in the following table.

```
repadmin.exe /writespn hostname.microsoft.com
ADD "CN=adam,CN=Users,DC=microsoft,DC=com"
E3514235-4B06-11D1-AB04-00C04FC2DCD2-ADAM/netbioshostname:389

repadmin.exe /writespn hostname.microsoft.com
ADD "CN=adam,CN=Users,DC=microsoft,DC=com"
E3514235-4B06-11D1-AB04-00C04FC2DCD2-ADAM/dnshostname:389

repadmin.exe /writespn hostname.microsoft.com
ADD "CN=adam,CN=Users,DC=microsoft,DC=com" ldap/netbioshostname:389
```

```
repadmin.exe /writespn hostname.microsoft.com
ADD "CN=adam,CN=Users,DC=microsoft,DC=com" ldap/dnshostname:389
```

# Manually remove ADAM service principal names from Active Directory

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To manually remove ADAM service principal names from Active Directory**

1. Do one of the following:
   - Log on as a member of the Domain Admins group, and then open ADAM ADSI Edit.
   - Using **run as**, open ADAM ADSI Edit as a member of the Domain Admins group.
2. Connect and bind to the domain directory partition of the Active Directory domain in which the ADAM instance resides.
3. Do one of the following:
   - If the Network Service account is specified as the ADAM service account, navigate to the computer object on the computer on which ADAM is installed.
   - If a domain user account is specified as the ADAM service account, navigate to the domain user object of the domain user account.
4. Right-click the computer object or the domain user object, and then click **Properties**.
5. In **Attributes**, click **ServicePrincipalName**, and then click **Edit**.
6. For each ADAM value that is listed in **Values**, click the value, and then click **Remove**.

**Note**

- If service principal names (SPN) in Active Directory exist for the ADAM instance being uninstalled, and **adamuninstall** cannot remove the SPNs automatically, **adamuninstall** creates a .bat file that can be used to remove the SPNs manually. This .bat file is located at %windir%\Debug*domain-servicename*.bat, where *domain* represents the Active Directory domain in which the ADAM instance resides, and *servicename* represents the service name of the ADAM instance being removed. (By default, the service name of an ADAM instance is ADAM_*instancename*, where *instancename* is the instance name that you provide during ADAM setup.)

# Manage Replication, Sites, and Configuration Sets

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Manage replication, sites, and configuration sets**

- Configure replication frequency within a site
- Configure replication availability on a site link
- Add a site object and servers container
- Move an ADAM instance to a site object
- Add a site link object
- Add a site object to a site link object
- Set the cost on a site link object
- Delete a site object
- Identify or transfer the naming master role
- Modify the replication security level of a configuration set

# Configure replication frequency within a site

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To configure replication frequency within a site**

1. Open ADAM ADSI Edit.
2. Connect and bind to the configuration directory partition of the ADAM instance for which you want to configure the replication schedule.
3. In the console tree, double-click the connection, double-click the configuration partition, double-click the sites container (CN=Sites), and then click the site container in which the instance resides.
4. In the details pane, right-click **CN=NTDS Site Settings**, and then click **Schedule**.
5. In the **Schedule** dialog box, select the block of time that you want to schedule, and then click **None**, **Once per Hour**, **Twice per Hour**, or **Four Times per Hour** as the replication frequency.
6. When you are finished updating the schedule, click **OK**.

**Notes**

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- For information about how to connect and bind to a directory partition on an ADAM instance using ADAM ADSI Edit, see Related Topics.
- The replication frequency schedule ensures that ADAM instances within a site periodically check with one another to determine if any changes have occurred. Regardless of the replication frequency that is specified, ADAM instances continue to replicate changes through update notifications. For more information, see Related Topics.

# Configure replication availability on a site link

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To configure replication availability on a site link**

1. Open ADAM ADSI Edit.
2. Connect and bind to the configuration directory partition of an ADAM instance belonging to the site link for which you want to configure replication availability.
3. In the console tree, click the configuration directory partition, double-click the sites container (CN=Sites), double-click the Inter-site Transports container (CN=Inter-site Transports), and then click the IP container (CN=IP).
4. In the details pane, right-click the site link object (by default, CN=DEFAULTIPSITELINK) for which you want to schedule availability, and then click **Schedule**.
5. In the **Schedule** dialog box, select the block of time that you want to schedule, and then click **Replication Not Available** or **Replication Available**.
6. When you are finished updating the schedule, click **OK**.

## Notes

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- For information about how to connect and bind to the configuration partition of an ADAM instance using ADAM ADSI Edit, see Related Topics.
- By default, replication is always available on a given site link.
- By default, all sites belong to the default site link object (CN=DEFAULTIPSITELINK).

# Add a site object and servers container

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To add a site object and servers container**

1. Open ADAM ADSI Edit.
2. Connect and bind to the configuration directory partition of an ADAM instance in the configuration set for which you want to create a site.
3. In the console tree, double-click the configuration directory partition (CN=Configuration,CN={*GUID*}), right-click the sites container (CN=Sites), point to **New**, and then click **Object**.
4. In **Select a class**, click **site**, and then click **Next**.
5. In **Value**, type a common name (CN) for the new site, and then click **Next**.
6. To set values for additional attributes, click **More attributes**, set any additional attribute values, and then click **Finish**.
7. In the console tree, double-click the sites container (CN=Sites).
8. In the console tree, right-click the new site, point to **New**, and then click **Object**.
9. In **Select a class**, click **serversContainer**, and then click **Next**.
10. In **Value**, type a common name (CN) for the server container, and then click **Next**.
11. To set values for additional attributes, click **More attributes**, and then set any additional attribute values.
12. After setting all desired attributes for the servers container, click **Finish**.

**Notes**

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- For information about how to connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.
- To add ADAM instances to a site, the site must have a servers container into which the ADAM instances can be added.

Move an ADAM instance to a site object
Add a site object to a site link object

# Move an ADAM instance to a site object

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To move an ADAM instance to a site object**

1. Open ADAM ADSI Edit.
2. Connect and bind to the configuration directory partition of an ADAM instance in the configuration set that contains the site object.
3. In the console tree, double-click the connection, double-click the configuration directory partition, and then double-click the sites container (CN=Sites).
4. In the sites container, double-click the site containing the ADAM instance that you want to move, and then double-click the servers container of the site.
5. In the servers container, right-click the ADAM instance that you want to move, and then click **Move**.
6. In the **Move** dialog box, double-click **Sites**, double-click the site to which you want to move the ADAM instance, click the servers container of the site, and then click **OK**.

## Notes

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- For information about how to connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.
- Before you can move an ADAM instance to a site, the site must have a servers container to which you can move the ADAM instance.
- The ADAM instance does not appear in its new location until you right-click the destination servers container and then click **Refresh**.

# Add a site link object

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To add a site link object**

1. Open ADAM ADSI Edit.
2. Connect and bind to the configuration directory partition of an ADAM instance in the configuration set for which you want to create a site link.
3. In the console tree, double-click the configuration directory partition, double-click the sites container (CN=Sites), and then double-click the Inter-Site Transports container (CN=Inter-Site Transports).
4. In the Inter-Site Transports container, right-click the IP container (CN=IP), point to **New**, and then click **Object**.
5. In **Select a class**, click **siteLink**, and then click **Next**.
6. In **Value**, type a name for the common name (CN) of the new site link object, and then click **Next**.
7. In **Value**, type a distinguished name of a site to be placed in the site link object, and then click **Next**.
8. To set more attributes on the site link object, click **More attributes**.
9. To create the new site link object, click **Finish**.

**Notes**

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- For information about how to connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.

# Add a site object to a site link object

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To add a site object to a site link object**

1. Open ADAM ADSI Edit.
2. Connect and bind to the configuration directory partition of an ADAM instance in the configuration set in which the site and the site link reside.
3. In the console tree, double-click the configuration directory partition, double-click the sites container (CN=Sites), and then double-click the Inter-Site Transports container (CN=Inter-Site Transports).
4. In the console tree, click the IP container (CN=IP).
5. In the details pane, right-click the site link to which you want to add a site, and then click **Properties**.
6. In **Attributes**, click **SiteList**, and then click **Edit**.
7. In **Value to add**, type the distinguished name of the site that you want to add to the site link, click **Add**, and then click **OK**.

**Notes**

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- For information about how to connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.

# Set the cost on a site link object

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To set the cost on a site link object**

1. Open ADAM ADSI Edit.
2. Connect and bind to the configuration directory partition of an ADAM instance in the configuration set in which the site link object that you want to modify resides.
3. In the console tree, double-click the configuration directory partition, double-click the sites container (CN=Sites), and then double-click the Inter-Site Transports container (CN=Inter-Site Transports).
4. In the console tree, click the IP container (CN=IP).
5. In the details pane, right-click the site link for which you want to set the cost, and then click **Properties**.
6. In the **Properties** dialog box, in **Attributes**, click **cost**, and then click **Edit**.
7. In **Value**, type a cost for the site link.

**Notes**

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- For information about how to connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.
- The default cost for a site link is 100.
- The cost of a site link represents the relative cost of using the site link for replication. The higher the cost of a site link, the lower the preference in ADAM for using the site link for replication.

# Identify or transfer the naming master role

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To identify or transfer the naming master role**

1. Open an ADAM tools command prompt.
2. At the command prompt, type:

   **dsmgmt**
3. At the **dsmgmt:** command prompt, type:

   **roles**
4. At the **fsmo maintenance:** command prompt, type:

   **connections**
5. At the **server connections:** command prompt, type:

   **connect to server** *servername:portnumber*

   where *servername:portnumber* is the computer name and communications port number of the ADAM instance that you want to use as the new naming master.
6. At the **server connections:** command prompt, type:

   **quit**
7. At the **fsmo maintenance:** command prompt, type:

   **transfer naming master**

**Note**

- To open an ADAM tools command prompt, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Tools Command Prompt**.
- For help with **dsmgmt**, type **?** at a **dsmgmt** prompt.

**See Also**

# Modify the replication security level of a configuration set

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To modify the replication security level of a configuration set**

1. Open ADAM ADSI Edit.
2. Connect and bind to the configuration directory partition of an ADAM instance in the configuration set that you want to modify.
3. In the console tree, double-click the connection.
4. In the console tree, right-click the configuration directory partition, and then click **Properties**.
5. In **Attributes**, click **msDS-ReplAuthenticationMode**, click **Edit**, and then, in the **Value** box, set the appropriate value (2, 1, or 0).

**Notes**

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- For information about how to connect and bind to the configuration directory partition of an ADAM instance using ADAM ADSI Edit, see Related Topics.
- The default replication security level for a new ADAM instance is 1, unless a local workstation user account is specified as the ADAM service account, in which case the replication security level defaults to 0.
- If the replication security level is set to 2, all replicating ADAM instances must register service principal names (SPNs) in Active Directory. For more information, see Related Topics.
- The values for **msDS-ReplAuthenticationMode** and their corresponding replication security levels are described in the following table.

| Replication security level | Value | Description | Default environment |
|---|---|---|---|
| Mutual authentication required | 2 | Kerberos authentication (using SPNs) is required. If Kerberos authentication fails, the ADAM instances will not replicate. | The configuration set is fully contained within an Active Directory domain, forest, or forest trust. |
| Negotiated | 1 | Kerberos authentication (using SPNs) is attempted first. If Kerberos fails, NTLM authentication is attempted. If NTLM fails, the ADAM instances will not replicate. | The configuration set contains Windows NT 4.0 member servers. |
| Negotiated pass-through | 0 | All ADAM instances in the configuration set must use identical service account names and passwords. | The configuration set includes computers that are joined to one or more workgroups or to multiple domains or forests without trust relationships. |

# Manage Schemas and Directory Partitions

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Manage schemas and directory partitions**

- Install the ADAM Schema snap-in
- Import or export directory objects using ldifde
- Import or export directory objects using csvde
- Manually configure the replication authentication method
- Deactivate a schema object class or attribute
- Identify or transfer the schema master role
- Seize the ADAM schema master role
- Add a new schema class or attribute definition in ADAM
- Add an application directory partition
- Delete an application directory partition

# Install the ADAM Schema snap-in

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To install the ADAM Schema snap-in**

1. Click **Start**, click **Run**, type **mmc /a**, and then click **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. In **Available Standalone Snap-ins**, click **ADAM Schema**, click **Add**, click **Close**, and then click **OK**.
4. To save this console, on the **File** menu, click **Save**.
5. In **Save in**, point to the %systemroot%**\system32** directory.
6. In **File name**, type **adamschmmgmt.msc**, and then click **Save**.
7. To create a shortcut on your **Start** menu:
   a. Right-click **Start**, click **Open All Users**, double-click the **Programs** folder, and then double-click the **ADAM** folder.
   b. On the **File** menu, point to **New**, and then click **Shortcut**.
   c. In **Type the location of the item**, type **adamschmmgmt.msc**, and then click **Next**.
   d. In **Type a name for this shortcut**, type **ADAM Schema**, and then click **Finish**.

**Caution**

- Modifying the schema is an advanced operation that is best performed by experienced programmers and system administrators. For detailed information about modifying the schema, see the "Active Directory Programmer's Guide" at the Microsoft MSDN Web site.

# Import or export directory objects using ldifde

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To import or export directory objects using ldifde**

1. Open an ADAM tools command prompt.
2. Do one of the following:
   - To import directory objects, at the command prompt, type:

     **ldifde -i -f** *filename* **-s** *servername:port* **-m -a** *username domain password*

   - To export directory objects, at the command prompt, type:

     **ldifde -e -f** *filename* **-s** *servername:port* **-m -a** *username domain password*

**Notes**

- To open an ADAM tools command prompt, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Tools Command Prompt**.
- The following table contains the parameters in step 2 and other commonly used **ldifde** parameters. For more information about **ldifde** parameters, type **ldifde /?** at a command prompt, or see Related Topics.

| Parameter | Description |
|---|---|
| **-i** | Perform an import. |
| **-e** | Perform an export. |
| **-f** | File to import or export. |
| **-s** | Host name and port of the ADAM instance. |
| **-m** | Ignore (that is, do not import or export) attributes that are only used by Active Directory.<br>You can use this parameter when exporting directory objects from an existing Active Directory forest and importing them into ADAM. |
| **-a** | Account credentials. If they are not provided, **ldifde** uses the credentials of the currently logged on user. |
| **-h** | Allows importing of passwords using simple authentication and security layer (SASL) encryption. |
| **-c** *String1 String2* | Replaces all occurrences of *String1* with *String2*. With ADAM, you can use the constants **#schemaNamingContext** and **#configurationNamingContext** in place of the distinguished names of the schema directory partition and configuration directory partitions when replacing strings in .ldf files. |

- For specific information about importing the user class definitions that are supplied with ADAM, see Related Topics.
- For complete syntax information for the **ldifde** command, see Related Topics.

ADAM Csvde

# Import or export directory objects using csvde

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To import or export directory objects using csvde**

1. Open an ADAM tools command prompt.
2. Do one of the following:
   - To import directory objects, at the command prompt, type:

     **csvde -i -f** *filename* **-s** *servername:port* **-m -a** *username domain password*

   - To export directory objects, at the command prompt, type:

     **csvde -e -f** *filename* **-s** *servername:port* **-m -a** *username domain password*

## Notes

- To open an ADAM tools command prompt, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Tools Command Prompt**.
- The following table contains the parameters in step 2 and other commonly used **csvde** parameters. For more information about **csvde** parameters, type **csvde /?** at a command prompt, or see Related Topics.

| Parameter | Description |
|---|---|
| **-i** | Perform an import. |
| **-e** | Perform an export. |
| **-f** | File to import. |
| **-s** | Host name and port of the ADAM instance. |
| **-m** | Ignore (that is, do not import or export) attributes that are only used by Active Directory.<br>You can use this parameter when exporting directory objects from an existing Active Directory forest and importing them into ADAM. |
| **-a** | Account credentials. If they are not provided, **ldifde** uses the credentials of the currently logged on user. |
| **-h** | Allows importing of passwords using simple authentication security layer (SASL) encryption. |
| **-c** *String1 String2* | Replaces all occurrences of *String1* with *String2*. With ADAM, you can use the constants **#schemaNamingContext** and **#configurationNamingContext** in place of the distinguished names of the schema directory partition and configuration directory partitions when replacing strings within .ldf files. |

# Manually configure the replication authentication method

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To manually configure the replication authentication method**

1. Open ADAM ADSI Edit.
2. Connect and bind to the ADAM instance in the configuration set that you want to configure.
3. In the console tree, double-click the configuration directory partition.
4. In the console tree, right-click the configuration directory partition, and then click **Properties**.
5. In **Attributes**, click **msDS-ReplAuthenticationMode**, click **Edit**, and then do one of the following:
   - To force the use of service accounts for replication authentication between configuration set members, type **1** in the **Value** box, and then click **OK**.
   - To allow ADAM to automatically determine how replication authentication occurs between configuration set members, type **0** in the **Value** box, and then click **OK**.

### Notes

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- For information about how to connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.
- For information about how ADAM configures replication authentication between configuration set members, see Related Topics.

**See Also**

# Deactivate a schema object class or attribute

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To deactivate a schema object class or attribute**

1. Open ADAM Schema.
2. In the console tree, click **ADAM Schema**.
3. On the **Action** menu, click **Change ADAM Server**.
4. In **ADAM server**, specify the DNS name, network basic input/output system (NetBIOS) name, or Internet Protocol (IP) address of the computer on which the ADAM instance that you want to configure is running.
5. In **Port**, type the Lightweight Directory Access Protocol (LDAP) or Secure Sockets Layer (SSL) port number of the ADAM instance to which you want to connect.
6. Under **Connect using these credentials**, do one of the following, and then click **OK**:
   - Click **The account of the currently logged on user**.
   - Click **This account**, and then select or type the user name and password of the account with which you want to connect.
7. Do one of the following, depending on whether you want to deactivate an object class or an attribute:
   - To deactivate an object class, in the console tree, double-click **ADAM Schema**, and then click **Classes**. In the details pane, right-click the class that you want to deactivate, and then click **Properties**.
   - To deactivate an attribute, in the console tree, double-click **ADAM Schema**, and then click **Attributes**. In the details pane, right-click the attribute that you want to deactivate, and then click **Properties**.
8. On the **General** tab, clear the **Class is active** check box or the **Attribute is active** check box, click **Yes** to confirm that you want to deactivate the class or attribute, and then click **OK**.

### Notes

- To open the ADAM Schema snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Schema**.
- If the ADAM Schema snap-in is not installed, see Related Topics.

**See Also**
**Concepts**
Install the ADAM Schema snap-in

# Identify or transfer the schema master role

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To identify or transfer the schema master role**

1. Open ADAM Schema.
2. On the **Action** menu, click **Change ADAM Server**.
3. In **ADAM server**, specify the DNS name, network basic input/output system (NetBIOS) name, or Internet Protocol (IP) address of an ADAM instance in the configuration set for which you want to identify or transfer the schema master role.
4. In **Port**, type the Lightweight Directory Access Protocol (LDAP) port number of the ADAM instance to which you want to connect.
5. Under **Connect using these credentials**, do one of the following, and then click **OK**:
   - Click **The account of the currently logged on user**.
   - Click **This account**, and then select or type the user name and password of the account with which you want to connect.
6. In the console tree, right-click **ADAM Schema**, and then click **Operations Master**.
7. Do one of the following:
   - To identify the current schema master, note the ADAM instance that is listed in **Current Schema Master**.
   - To transfer the schema master role to the currently targeted ADAM instance, click **Change**.

## Notes

- To open the ADAM Schema snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Schema**. If the ADAM Schema snap-in is not installed, see Related Topics.
- Each configuration set has only one schema master. To identify the schema master in a different configuration set, target the appropriate configuration set before clicking **Operations Master**.
- For help with **dsmgmt**, type **?** at a **dsmgmt** prompt.

**See Also**

# Seize the ADAM schema master role

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To seize the schema master role**

1. Open an ADAM tools command prompt.
2. At the command prompt, type:

   **dsmgmt**
3. At the **dsmgmt:** command prompt, type:

   **roles**
4. At the **fsmo maintenance:** command prompt, type:

   **connections**
5. At the **server connections:** command prompt, type:

   **connect to server** *computername:portnumber*

   where *computername:portnumber* is the computer name and communications port number of the ADAM instance that you want to use as the new schema master.
6. At the **server connections:** command prompt, type:

   **quit**
7. At the **fsmo maintenance:** command prompt, type:

   **seize schema master**

**Caution**

- Do not seize the schema master role if you can transfer it instead. Seizing the schema master role is a drastic step that should be considered only if the current operations master will never be available again. For more information about transferring operations master roles, see Related Topics.

**Note**

- To open an ADAM tools command prompt, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Tools Command Prompt**.
- For help with **dsmgmt**, type **?** at a **dsmgmt** prompt.

# Add a new schema class or attribute definition in ADAM

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To add a new schema class or attribute definition**

1. Open ADAM Schema.
2. In the console tree, double-click **ADAM Schema**.
3. Do one of the following:
   - To add a class definition, in the console tree, right-click **Classes**, click **Create Class**, and then provide the requested information.
   - To add an attribute definition, in the console tree, right-click **Attributes**, click **Create Attribute**, and then provide the requested information.

## Notes

- To open the ADAM Schema snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Schema**.
- If the ADAM Schema snap-in is not installed, see Related Topics.

# Add an application directory partition

Updated: March 1, 2013

Applies To: Windows Server 2003 R2

**To add an application directory partition**

1. Connect and bind to an ADAM instance with ADAM Ldp.exe.
2. On the **Browse** menu, click **Add child**.
3. In **Dn**, type a distinguished name for the application partition.
4. Under **Edit entry**, type **ObjectClass** in the **Attribute** box and **container** in the **Values** box, and then click **Enter**.
5. Under **Edit entry**, type **instanceType** in the **Attribute** box and **5** in the **Values** box, and then click **Enter**.
6. Click **Run**.

   After the new application directory partition is added, the following appears in the results pane:

   Added {*distinguished name*}

   where *distinguished name* is the distinguished name that you typed in step 3.
7. Click **Close**.

**Notes**

- To connect and bind to an ADAM instance with Ldp.exe, see Related Topics.
- Application directory partitions can be of any object class, but they must have a value of **5** for the **instanceType** attribute.

**See Also**

# Delete an application directory partition

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To delete an application directory partition**

1. Open ADAM ADSI Edit.
2. Connect and bind to the ADAM instance.
3. Double-click the configuration directory partition (CN=Configuration,CN={*GUID*}).
4. In the console tree, click the partitions container (CN=Partitions).
5. In the details pane, right-click the application directory partition that you want to delete, and then click **Delete**.

### Caution

- The only way to retrieve a deleted application directory partition is to restore the entire ADAM instance from a backup copy that was made before the deletion of the partition.

### Notes

- To start the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- For information about how to connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.

**See Also**

# Manage Users and Groups

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Manage users and groups**

- Import the user classes supplied with ADAM
- Add an ADAM user to the directory
- Add an ADAM group to the directory
- Add or remove members to or from an ADAM group
- Disable or enable an ADAM user
- Set or modify the password of an ADAM user
- Add an organizational unit to the directory
- Allow ADAM users to be created in the configuration partition

# Import the user classes supplied with ADAM

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To import the user classes supplied with ADAM**

1. Open an ADAM tools command prompt.
2. At the command prompt, type:

   **ldifde -i -f** *filename* **-s** *computername:port* [**-b** *username domain password*] **-k -j . -c "CN=Schema,CN=Configuration,DC=X" #schemaNamingContext**

   where *filename* represents the name of one of the .ldf files that is supplied with ADAM (ms-User.ldf, ms-InetOrgPerson.ldf, or ms-UserProxy.ldf), *computername:port* represents the computer name and port number of an ADAM instance, and *username domain password* represents the account with which to run the command.

   You should see results similar to the following:

```
Connecting to "localhost"
Logging in as current user using SSPI
Importing directory from file "ms-user.ldf"
Loading entries.............................
65 entries modified successfully.

The command has completed successfully
```

## Notes

- To open an ADAM tools command prompt, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Tools Command Prompt**.
- The following table contains the parameters in step 2 and other commonly used **ldifde** parameters. For more information about **ldifde** parameters, type **ldifde /?** at a command prompt, or see Related Topics.

| Parameter | Description |
|---|---|
| **-i** | Perform an import. |
| **-f** | File to import or export. |
| **-s** | Host name and port of the ADAM instance. |
| **-b** | Security credentials to use during the operation. |
| **-k** | Continue the operation in the event of errors. |
| **-j** | Create a log file in the specified directory. In this case, the current ("**.**") directory. |
| **-c "CN=Schema,CN=Configuration,DC=X" #schemaNamingContext** | Do not modify this string.<br>The **-c** parameter replaces a specified string in the .ldf file with a different string during import. The distinguished name that is specified in the .ldf file (for example, **CN=Schema,CN=Configuration,DC=X**) is replaced with the distinguished name of the schema directory partition for your particular ADAM instance, as passed by the **#schemaNamingContext** constant. |

| Replace ... | With ... |
| --- | --- |
| *computername:port* | The host name and port number of your ADAM instance. You can use "localhost" for *computername* if you are administering the local computer. |
| *username domain password* | The account, domain, and password of an account being used as an ADAM administrator account. |

- ADAM includes three .ldf files containing user classes that you can import. These files are ms-User.ldf, ms-InetOrgPerson.ldf, and ms-UserProxy.ldf, and they are located in the %windir%\adam directory.
- As an alternative to using **ldifde**, you can import the optional ADAM user classes during ADAM setup. For more information, see Related Topics.
- If you do not specify user credentials using the **-b** parameter, **ldifde** uses the credentials of the currently logged on user.
- For complete syntax information for the **ldifde** command, see Related Topics.

# Add an ADAM user to the directory

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To add an ADAM user to the directory**

1. Open ADAM ADSI Edit.
2. Connect and bind to the ADAM instance and directory partition to which you want to add the user.
3. In the console tree, double-click the directory partition to which you want to add the user.
4. In the console tree, right-click the container to which you want to add a user, point to **New**, and then click **Object**.
5. In **Select a class**, click the class that you want to use (**user**, **inetOrgPerson**, **person**, or **OrganizationalPerson**), and then click **Next**.
6. In **Value**, type a value for the common name (CN) attribute of the new user, and then click **Next**.
7. If you want to set values for additional attributes, click **More attributes**.
8. After setting any additional attributes for the new user, click **Finish**.

**Notes**

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- For information about how to connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.
- By default, an ADAM user account is enabled when the user account is created. However, no initial password is set on an ADAM user account that is created using ADAM ADSI Edit. On ADAM instances running on Windows Server 2003, where local or domain password policy restrictions are in effect, the ADAM user account is disabled by default. Before you can enable the user account, you must set a password for it that meets the password policy restrictions that are in effect. This does not apply to ADAM instances running on Windows XP Professional. For more information, see Related Topics.
- Any object class can be used as a security principal in ADAM, if the object class definition contains the **SecurityPrincipal** static auxiliary class and the **unicodePwd** attribute. For more information, see Related Topics.
- The **user**, **inetOrgPerson**, and **OrganizationalPerson** object classes are not available until you import the ADAM user class definitions into the schema. For more information, see Related Topics.

# Add an ADAM group to the directory

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To add an ADAM group to the directory**

1. Open ADAM ADSI Edit.
2. Connect and bind to the ADAM instance to which you want to add a group.
3. In the console tree, double-click the directory partition to which you want to add the group.
4. In the console tree, right-click the container to which you want to add the group, point to **New**, and then click **Object**.
5. In **Select a class**, click **Group**, and then click **Next**.
6. In **Value**, type a common name (CN) for the new group, and then click **Next**.
7. In **groupType**, type **2147483650** (representing an account group) for the new group, and then click **Next**.
8. If you want to set values for additional attributes, click **More attributes**.
9. After setting all desired attributes for the new group, click **Finish**.

**Notes**

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- When you type a value for the **groupType** attribute, 2147483650 (equivalent to 0x80000002 hexidecimal) represents a group type of "account."
- For information about how to connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.

# Add or remove members to or from an ADAM group

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To add or remove members to or from an ADAM group**

1. Open ADAM ADSI Edit.
2. Connect and bind to the ADAM instance containing the group that you want to modify.
3. In the console tree, double-click the directory partition containing the group that you want to modify.
4. Right-click the group that you want to modify, and then click **Properties**.
5. In **Attributes**, click **Member**, and then click **Edit**.
6. For each ADAM security principal that you want to add to the group, click **Add ADAM account**, type the distinguished name of the new member, and then click **OK**.
7. For each Windows security principal you want to add to the group, click **Add Windows account**, type the account name of the new member, and then click **OK**.
8. For each group member that you want to remove from the group, click the member that you want to remove, and then click **Remove**.
9. After making the changes that you want to the group, click **OK** twice.

### Notes

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- For information about how to connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.

# Disable or enable an ADAM user

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To disable or enable an ADAM user**

1. Open ADAM ADSI Edit.
2. Connect and bind to an ADAM instance.
3. Browse to the ADAM user that you want to disable or enable, right-click that user, and then click **Properties**.
4. In **Attributes**, click **msDS-UserAccountDisabled**, and then click **Edit**.
5. Do one of the following, and then click **OK**:
   - To disable the ADAM user, click **True**.
   - To enable the ADAM user, click either **False** or **Not set**.

## Notes

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- To connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.
- By default, an ADAM user is enabled when the user is created. However, if you assign a new ADAM user a password that does not meet the password policy restrictions in effect on the local server or domain, that ADAM user will be disabled by default. This note does not apply to ADAM instances running on Windows XP Professional. For more information, see Related Topics.
- If the ADAM user that you want to disable or enable is currently logged on to the ADAM instance, that user must log off for the new setting to take effect.

# Set or modify the password of an ADAM user

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Set or modify the password of an ADAM user**

- Using ADAM ADSI Edit
- Using Ldp over an encrypted, non-SSL connection
- Using Ldp over an SSL connection

**Using ADAM ADSI Edit**
**To set or modify the password of an ADAM user**

1. Open ADAM ADSI Edit.
2. Connect and bind to the directory partition containing the ADAM user for whom you want to set or modify the password.

   To complete this task, you can bind to the directory partition as an ADAM user or as a Windows Security principal.

   To bind to the directory partition as an ADAM user, complete the following:

   - Click **Start**, point to **Administrative Tools**, and then click **ADSI Edit**.
   - On the **Action** menu, click **Connect to**. The **Connection Settings** dialog box appears.
   - In **Select or type a domain or server: (Server | Domain[:port])**, type the Domain Name System (DNS) name, NetBIOS name, or IP address of the computer on which the ADAM instance is running, followed by a colon (:) and the LDAP communication port that the ADAM instance to which you want to connect is using.For example, if ADAM is running on the local computer, you can type **localhost:389**.
   - Under **Connection point**, click **Select or type a Distinguished Name or Naming Context**, and then type the name of your directory partition.
   - Click **Advanced**, and then click **Specify Credentials**.
   - Under **Connect using these credentials**, type the DN (distinguished name) and the password of your ADAM user, make sure **Simple bind authentication** checkbox is checked, and then click OK.

     | **Note** |
     | --- |
     | Make sure that your ADAM user is enabled, by setting its MSds-UserAccountDisabled attribute to FALSE. |

   To bind to the directory partition as a Windows security principal, complete the following:

   - Click **Start**, point to **Administrative Tools**, and then click **ADSI Edit**.
   - On the **Action** menu, click **Connect to**. The **Connection Settings** dialog box appears.
   - In **Select or type a domain or server: (Server | Domain[:port])**, type the Domain Name System (DNS) name, NetBIOS name, or IP address of the computer on which the ADAM instance is running, followed by a colon (:) and the LDAP communication port that the ADAM instance to which you want to connect is using.For example, if ADAM is running on the local computer, you can type **localhost:389**.
   - Under **Connection point**, click **Select or type a Distinguished Name or Naming Context**, and then type the

name of your directory partition.

- Click **Advanced**, and then click **Specify Credentials**.
- Under **Connect using these credentials**, type the domain, user name, and password of your Windows principal, and then click OK.

3. Browse to the directory object representing the ADAM user, and then right-click the directory object.
4. Click **Reset password**, and then type a password for the user in **New password** and in **Confirm password**.

**Notes**

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- For information about how to connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.

**Using Ldp over an encrypted, non-SSL connection**
**To set or modify the password of an ADAM user**

1. Open Ldp.
2. On the **Options** menu, click **Connection Options**.
3. In **Option Name**, click **LDAP_OPT_ENCRYPT**.
4. In **Value**, type **1**, click **Set**, and then click **Close**.
5. Connect and bind to the ADAM instance as a Windows security principal, and then view the directory partition containing the ADAM user for whom you want to set a password.

   To connect and bind to the ADAM instance as a Windows security principal, complete the following:

   - On the **Connection** menu, click **Connect**. In **Server**, type the DNS name, NetBIOS name, or IP address of the computer on which the ADAM instance is running, and in **Port**, type the LDAP communication port that the ADAM instance to which you want to connect is using.
   - On the **Connection** menu, click **Bind**.
   - Under **Bind type**, select **Bind with credentials**. Type the name of your Windows security principal in the **User** field, along with the password of this account in the **Password** field, and the domain name that this account belongs to in the **Domain** field, and then click OK.

6. Right-click the ADAM user, and then click **Modify**.
7. In **Attribute**, type **userpassword**, and then in **Value**, type a password for the account.
8. Click **Enter**, and then click **Run**. The details pane displays a message similar to the following:

```
***Call Modify...
ldap_modify_s(ld, 'CN=Mary Baker,O=Microsoft,C=US',[1] attrs);
Modified "CN=Mary Baker,O=Microsoft,C=US".
```

**Notes**

- To open Ldp, click **Start**, point to **All Programs**, point to **ADAM**, click **ADAM Tools Command Prompt**, and then type **ldp** at the command prompt.
- You can also use ADAM ADSI Edit to set or modify passwords: right-click the directory object representing the ADAM security principal in ADAM ADSI Edit, and then click **Reset Password**.

- For information about how to connect and bind to an ADAM instance using Ldp, see Related Topics.

- By default, an ADAM instance running on Windows Server 2003 automatically enforces any local or domain password policies. If you set a password for an ADAM user that does not meet the requirements of the password policy in effect, the user account will be disabled.

- The ADAM user for whom you set or modify the password must use the new password the next time that the user logs on.

- This procedure applies to any object class that is used as a security principal in ADAM. Any object class in ADAM can be used as a security principal, as long as the object class definition contains the **msDS-bindableobject** auxiliary class and the **unicodePwd** attribute. For more information, see Related Topics.

- The **user**, **person**, **inetOrgPerson**, and **OrganizationalPerson** object classes are not available by default in the ADAM schema. You must first import them. For more information, see Related Topics.

**Using Ldp over an SSL connection**
**To set or modify the password of an ADAM user**

1. Install a server certificate on the computer where the ADAM instance is running, and install a matching client certificate on the computer from which you administer the ADAM instance.

2. Open Ldp.

3. Connect and bind to the ADAM instance (selecting **SSL** in the **Connect** dialog box) containing the user for whom you want to set or modify a password. For more information, see Appendix A: Configuring LDAP over SSL Requirements for AD LDS (http://go.microsoft.com/fwlink/?LinkId=160191).

   To complete this procedure, connect and bind to the ADAM instance as an ADAM user by completing the following:

   - On the **Connection** menu, click **Connect**. In **Server**, type the DNS name, NetBIOS name, or IP address of the computer on which the ADAM instance is running, and in **Port**, type the SSL communication port that the ADAM instance to which you want to connect is using.

   - On the **Connection** menu, click **Bind**.

   - Under **Bind type**, select **Simple Bind**, type the DN of your ADAM user in the **User** field, along with the password that you just assigned to this account in the **Password** field, and then click OK.

4. Right-click the ADAM user, and then click **Modify**.

5. In **Attribute**, type **userpassword**, and then in **Value**, type a password for the account.

6. Click **Enter**, and then click **Run**. The details pane displays a message similar to the following:

```
***Call Modify...
ldap_modify_s(ld, 'CN=Mary Baker,OU=Beta
users,O=Microsoft,C=US',[1] attrs);
Modified "CN=Mary Baker,OU=Beta users,O=Microsoft,C=US".
```

### Notes

- To open Ldp, click **Start**, point to **All Programs**, point to **ADAM**, click **ADAM Tools Command Prompt**, and then type **ldp** at the command prompt.

- For information about how to connect and bind to an ADAM instance using Ldp, see Related Topics.

- Establishing Secure Sockets Layer (SSL) connections requires the presence of certificates on the server and clients. For information about installing certificates, see Related Topics.

- By default, an ADAM instance running on Windows Server 2003 automatically enforces any local or domain password policies. If you set a password for an ADAM user that does not meet the requirements of the password policy in effect, the user account will be disabled.

- If the ADAM user is currently logged on, that user must log off for the new password to take effect.

- This procedure applies to any object class that is used as a security principal in ADAM. Any object class in ADAM can be used as a security principal, as long as the object class definition contains the **SecurityPrincipal** static auxiliary class and the **unicodePwd** attribute. For more information, see Related Topics.

- The **user**, **person**, **inetOrgPerson**, and **OrganizationalPerson** object types are not available by default in the ADAM schema. You must first import them. For more information, see Related Topics.

# Add an organizational unit to the directory

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To add an organizational unit to the directory**

1. Open ADAM ADSI Edit.
2. Connect and bind to the directory partition of the ADAM instance to which you want to add an organizational unit (OU).
3. In the console tree, double-click the directory partition, right-click the container to which you want to add the OU, point to **New**, and then click **Object**.
4. In **Select a class**, click **organizationalUnit**, and then click **Next**.
5. In **Value**, type a name for the new OU, and then click **Next**.
6. If you want to set values for additional attributes, click **More attributes**.
7. After you set all desired attributes for the new OU, click **Finish**.

**Notes**

- To open the ADAM ADSI Edit snap-in, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
- To connect and bind to an ADAM instance using ADAM ADSI Edit, see Related Topics.
- By default, OUs can only be added under OU (OU=), country/region (C=), organization (O=) or domain-DNS (DC=) object classes. For example, you can add an OU to o=Microsoft,c=US. You cannot add an OU to cn=test,o=Microsoft,c=US. You can, however, update the schema definition of the OU object class to allow other superiors.

# Allow ADAM users to be created in the configuration partition

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can use this procedure to allow users to be created in the configuration partition so that Active Directory Application Mode (ADAM) users can be ADAM administrators.

**To allow ADAM users to be created in the configuration partition**

1. Click **Start**, point to **Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.
2. Double-click the CN=Configuration,CN=Guid container.
3. Double-click the CN=Services object, and then double-click the CN=**Windows NT** object.
4. Right-click CN=**Directory Service**, and then click **Properties**.
5. In the **Attributes** list, click **msDS-Other-Settings**, and then click **Edit**.
6. In the **Values** list, click each value that contains the text **ADAMAllowADAMSecurityPrincipalsInConfigPartition=0**, and then click **Remove**.
7. In the **Value to add box**, type the following:

   **ADAMAllowADAMSecurityPrincipalsInConfigPartition=1**, and then click **Add**.
8. Click **OK** two times, and then close ADAM ADSI Edit.

# Manage Access Control

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Manage access control**

- View or set permissions on a directory object

# View or set permissions on a directory object

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To view or set permissions on a directory object**

1. Open an ADAM tools command prompt.
2. At the command prompt, do one of the following:
   - To list the effective permissions on a directory object, type:

     **dsacls ***hostname:portnumber\object_dn*

     where *hostname* represents the name of the computer on which the ADAM instance that holds the directory object is running, *portnumber* represents the communications port number on which the ADAM instance communicates, and *object_dn* represents the distinguished name of the directory object.

     Example:

     ```
     dsacls \\localhost:389\O=Microsoft,C=US
     ```

   - To grant permissions on a directory object, type:

     **dsacls ***hostname:portnumber******object_dn* **/G** *user_or_group***:***Permissions*

     where *hostname* represents the name of the computer on which the ADAM instance that holds the directory object is running, *portnumber* represents the communications port number on which the ADAM instance communicates, *object_dn* represents the distinguished name of the directory object, *user_or_group* represents the user or group for whom the permissions apply, and *Permissions* represents the permissions to grant.

     Example:

     ```
     dsacls \\localhost:389\cn=Object1, cn=container1,O=Microsoft,C=US /G
     CN=inetuser1,O=Microsoft,C=US:SD
     ```

   - To deny permissions on a directory object, type:

     **dsacls ***hostname:portnumber******object_dn* **/D** *user_or_group***:***PermissionStatement*

     where *hostname* represents the name of the computer on which the ADAM instance that holds the directory object is running, *portnumber* represents the communications port number on which the ADAM instance communicates, *object_dn* represents the distinguished name of the directory object, *user_or_group* represents the user or group for whom the permissions apply, and *PermissionStatement* represents the permissions to deny.

     Example:

     ```
     dsacls \\localhost:389\cn=Object1, cn=container1,O=Microsoft,C=US /D
     CN=inetuser1,O=Microsoft,C=US:SD
     ```

**Notes**

- To open an ADAM tools command prompt, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Tools Command Prompt**.
- For a complete description of all parameters that apply to **dsacls**, including the setting of inheritance, type **dsacls /?** at the ADAM tools command prompt, or see Related Topics.

- A directory object residing on multiple replicas of a given directory partition possesses the same permissions on all of the replica partitions.

# Monitor and Maintain ADAM

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Monitor and maintain ADAM**

- Back up an ADAM instance to a file or a tape
- Restore an ADAM instance
- View an ADAM event log

# Back up an ADAM instance to a file or a tape

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Back up an ADAM instance to a file or a tape**

- Using the graphical user interface
- Using the command prompt

**Using the graphical user interface**
**To back up an ADAM instance to a file or a tape**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled. You can use this wizard, or you can go to the next step to work in **Advanced Mode**.

2. In the Backup or Restore Wizard, click the link for **Advanced Mode**.
3. Click the **Backup** tab, and then, on the **Job** menu, click **New**.
4. To select the ADAM instance folders that you want to back up, select the check box to the left of the folders. By default, ADAM database and log files are located in %ProgramFiles%\Microsoft ADAM*instancename* where *instancename* equals the ADAM instance name.

   | **Important** |
   | --- |
   | If you cannot select adamntds.dit file for backup, open the registry editor and then delete "ADAM (*instanceName*)Write" key value from the following registry key on the ADAM server:HKEY_LOCAL_MACHINE\CurrentControlSet\Control\BackupRestore\FilesNotToBackup |

5. In **Backup destination**, do one of the following:

   - If you want to back up files and folders to a file, click **File**.
   - If you want to back up files and folders to a tape, select a tape device.

   If no tape drive exists, the **Backup destination** option is unavailable, and it is automatically set to **File**.

6. In **Backup media or file name**, do one of the following:

   - If you are backing up files and folders to a file, type a path and file name for the backup (.bkf) file, or click the **Browse** button to find a file.
   - If you are backing up files and folders to a tape, select the tape that you want to use.

7. To select any other backup options that you want, such as the backup type and the backup log type, on the **Tools** menu, click **Options**.
8. Click **Start Backup**, and then make any changes in the **Backup Job Information** dialog box.
9. If you want to set advanced backup options, such as data verification or hardware compression, click **Advanced**.
10. Click **Start Backup** to start the backup operation.

| **Caution** |
| --- |

| |
|---|
| If you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. |

| **Important** |
|---|
| Before backing up the ADAM folder of an instance, use Services to confirm that the instance is started. To start Services, click **Start**, point to **Administrative Tools**, and then click **Services**. |

**Notes**

- To start Backup, click **Start**, point to **All Programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.
- If Backup does not start in wizard mode by default, you can start the wizard by clicking **Wizard Mode** on the **Welcome** tab.
- Some tape drives may not support hardware compression.
- Backup does not support the use of backup media such as CD-RW (compact disc rewritable), CD-R (compact disc recordable), and DVD-R (digital video disc recordable). To save backups to this type of media, back up to a file, and then copy that file to the CD. You can use Backup to restore from a CD.
- Backup files usually have the file name extension .bkf. You can use any extension you like, but it is highly recommended that you use .bkf, which has file associations that ensure that the backup file is recognizable.
- Backup operators and administrators can back up and restore encrypted files and folders without decrypting the files or folders.

**Using the command prompt**
**To back up an ADAM instance to a file or a tape**

1. Open Command Prompt.
2. To back up to a file or tape, type:

   **ntbackup backup** *@bks file name* **/J** {"*backup job name*"} **/F** {"*file name*"} **/T** {"*tape name*"} **/P** {"*pool name*"} **/G** {"*guid name*"} **/N** {"*media name*"} **/A**

| Value | Description |
|---|---|
| *@bks file name* | The name of the backup selection file (.bks file) to be used for this backup operation. The @ character must precede the name of the backup selection file. A backup selection file contains information about the files and folders that you have selected for backup. You have to create the file using the graphical user interface (GUI) version of Backup. As an alternative, you can supply the path to the drive or file to back up, for example, %ProgramFiles%\Microsoft ADAM\instance1. |
| **/J** {"*backup job name*"} | The job name to be used in the backup report. The job name usually describes the files and folders that you are backing up in the current backup job. |
| **/F** {"*file name*"} | The logical disk path and file name of the backup file. Do not use in conjunction with **/P /G /T**. |
| **/T** {"*tape name*"} | Overwrites or appends to this tape. |
| **/P** {"*pool name*"} | The media pool from which you want to use media. This is usually a subpool of the Backup media pool, such as **4mm DDS**. Do not use in conjunction with **/A /G /F /T** |
| **/G** {"*guid name*"} | Overwrites or appends to this tape. Do not use in conjunction with **/P**. |
| **/N** {"*media name*"} | The new tape name. Do not use in conjunction with **/A**. |

| | |
|---|---|
| **/A** | Performs an append operation. Either **/G** or **/T** must be used in conjunction with this switch. Do not use in conjunction with **/P**. |

For information about additional file and tape backup options, see the Help topic on the **ntbackup** command-line utility in Help and Support Center in Windows Server 2003.

**Examples:**

To back up the files and folders that are listed in the backup selection file C:\adaminstance.bks to file C:\backup.bkf, with the job name "Backup Job 1," type the following at the command line:

**ntbackup backup @C:\adaminstance.bks /j "Backup Job 1" /f "C:\Backup.bkf"**

For a tape backup, to create a backup job named "Backup Job 1" that backs up all the files and folders that are listed in the backup selection file C:\backup.bks to a tape drive, type:

**ntbackup backup @C:\backup.bks /n "Media created 11/5/2003 at 1:25 PM" /d "Set created 11/5/2003 at 1:25 PM" /j "Backup Job 1" /p "4mm DDS"**

**Important**

- Before backing up the ADAM folder of an instance, use Services to confirm that the instance is started. To start Services, click **Start**, point to **Administrative Tools**, and then click **Services**.
- If you do not specify options at the command prompt, the options default to the values that are specified in the Backup application.
- Before you use the command line to perform backup operations, it is recommended that you use the Backup GUI to create the initial backup selection file and settings and a scheduled task. You can then use that scheduled task to view the command syntax. Copy the information from the scheduled task, make any changes that are necessary to create a script or command-line syntax, and then delete the scheduled task if it is not needed.
- Some tape drives may not support hardware compression.

**Notes**

- To view the complete syntax for this command, at a command prompt, type:

  **ntbackup /?**

- If you do not specify the other Backup options, **ntbackup** uses the default values of the Backup program for the backup type, verification setting, logging level, hardware compression, and any other settings.
- Backup files usually have the file name extension .bkf. You can use any extension that you want, but it is highly recommended that you use .bkf, which has file associations that ensure that the backup file is recognizable.
- Backup operators and administrators can back up and restore encrypted files and folders without decrypting the files or folders.

# Restore an ADAM instance

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Restore an ADAM instance**

- Restore ADAM data on an ADAM instance that belongs to a configuration set
- Restore a corrupted database that is preventing the ADAM instance from starting
- Restore an ADAM instance that does not belong to a configuration set
- Restore an ADAM instance that belongs to a configuration set

**Restore ADAM data on an ADAM instance that belongs to a configuration set**
**To authoritatively restore ADAM data on an ADAM instance that belongs to a configuration set**

1. If it is running, stop the ADAM instance for which data will be restored.
2. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled. You can use this wizard, or click the **Advanced Mode** link to work in advanced mode.
3. Click the **Restore and Manage Media** tab.
4. In the details pane, select the ADAM instance that you want to restore by selecting the check box to the left of the folder that represents the ADAM instance that you want to restore.
5. In **Restore files to**, click **Original location**.
6. On the **Tools** menu, click **Options**, click the **Restore** tab, click **Always replace the file on my computer**, and then click **OK**.
7. Click **Start Restore**.
8. After the restore is complete, close Backup.
9. Open an ADAM tools command prompt.
10. At the command prompt, type:

    **dsdbutil**
11. At the **dsdbutil:** prompt, type:

    **activate instance** *instancename*

    where *instancename* represents the service name of the ADAM instance on which you want to restore data.
12. At the **dsdbutil:** prompt, type:

    **authoritative restore**
13. At the **authoritative restore:** prompt, type one of the commands in the following table.

| Command | Meaning |
|---|---|
| **restore database** | Performs authoritative restore of the entire directory database |

| | |
|---|---|
| **restore object** *dn* | Performs authoritative restore of the directory object whose distinguished name is represented by *dn* |
| **restore subtree** *dn* | Performs authoritative restore of the directory subtree whose distinguished name is represented by *dn* |

**Notes**

- To open an ADAM tools command prompt, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Tools Command Prompt**.
- To start Backup, click **Start**, point to **All Programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.
- If Backup does not start in wizard mode by default, you can start the wizard by clicking **Wizard Mode** on the **Welcome** tab.
- For information about stopping an ADAM instance, see Related Topics.
- This procedure can be used if you want the data being restored to authoritatively override existing data in the configuration set.
- For more information about the **authoritative restore** command in **dsdbutil**, at the **authoritative restore:** prompt, type **?**.
- When you restore ADAM instances on Windows XP Professional, you can restore only one ADAM instance at a time.
- If you accidentally start a restore of an ADAM instance over a currently running ADAM instance, it is recommended that you immediately restart the computer, stop the ADAM instance, and then perform the restoration again.

**Restore a corrupted database that is preventing the ADAM instance from starting**
**To restore a corrupted database that is preventing the ADAM instance from starting**

1. If it is running, stop the ADAM instance for which data will be restored.
2. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled. You can use this wizard, or click the **Advanced Mode** link to work in advanced mode.
3. Click the **Restore and Manage Media** tab.
4. In the details pane, select the ADAM instance that you want to restore by selecting the check box to the left of the folder that represents the ADAM instance that you want to restore.
5. In **Restore files to**, click **Original location**.
6. On the **Tools** menu, click **Options**, click the **Restore** tab, click **Always replace the file on my computer**, and then click **OK**.
7. Click **Start Restore**.
8. After the restore is complete, close Backup.
9. Restart the ADAM instance.

**Notes**

- To start Backup, click **Start**, point to **All Programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.
- If Backup does not start in wizard mode by default, you can start the wizard by clicking **Wizard Mode** on the **Welcome** tab.

- If the ADAM instance fails to start after you perform this procedure, perform the appropriate procedure for completely restoring an ADAM instance, depending on whether your ADAM instance belongs to a configuration set or is unique.

- When you restore ADAM instances to Windows XP Professional, you can restore only one ADAM instance at a time.

- If you accidentally start a restore of an ADAM instance over a currently running ADAM instance, it is recommended that you immediately restart the computer, stop the ADAM instance, and then perform the restoration again.

**Restore an ADAM instance that does not belong to a configuration set**
**To completely restore an ADAM instance that does not belong to a configuration set**

1. Using the Active Directory Application Mode Setup Wizard or an ADAM unattended install, create an ADAM instance, specifying the same settings that you used during your original ADAM installation. However, do not create an application directory partition during setup.
2. Stop the ADAM instance you just created, as follows:
   a. Click **Start**, point to **Administrative Tools**, and then click **Services**.
   b. In Services, right-click the ADAM instance, and then click **Stop**.
3. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled. You can use this wizard, or click the **Advanced Mode** link to work in advanced mode.
4. Click the **Restore and Manage Media** tab.
5. In the details pane, select the ADAM instance that you want to restore by selecting the check box to the left of the folder that represents the ADAM instance that you want to restore.
6. In **Restore files to**, click **Original location**.
7. On the **Tools** menu, click **Options**, click the **Restore** tab, click **Always replace the file on my computer**, and then click **OK**.
8. Click **Start Restore**.
9. After the restore is complete, close Backup.
10. Stop the ADAM instance you just created, as follows:
    a. Click **Start**, point to **Administrative Tools**, and then click **Services**.
    b. In Services, right-click the ADAM instance, and then click **Stop**.

**Notes**

- To start Backup, click **Start**, point to **All Programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- If Backup does not start in wizard mode by default, you can start the wizard by clicking **Wizard Mode** on the **Welcome** tab.

- For information about backing up an ADAM instance, see Related Topics.

- When you restore ADAM instances to Windows XP Professional, you can restore only one ADAM instance at a time.

- If you accidentally start a restore of an ADAM instance over a currently running ADAM instance, it is recommended that you immediately restart the computer, stop the ADAM instance, and then perform the restoration again.

**Restore an ADAM instance that belongs to a configuration set**
**To completely restore an ADAM instance that belongs to a configuration set**

1. On one of the remaining ADAM instances in the configuration set, delete the server object that represents the ADAM instance that you want to restore, as follows:

   a. Open an ADAM tools command prompt.

   b. At the command prompt, type **dsmgmt**.

   c. At the **dsmgmt:** prompt, type **metadata cleanup**.

   d. At the **metadata cleanup:** prompt, type **select operation target**.

   e. At the **select operation target:** prompt, type **connections**.

   f. At the **server connections:** prompt, type **connect to server***computername:portnumber*, where *computername:portnumber* represents the ADAM instance to which you are connecting.

   g. At the **server connections:** prompt, type **q**.

   h. At the **select operation target:** prompt, type **list sites**, and identify the number corresponding to the site in which the server object that you want to delete resides.

   i. At the **select operation target:** prompt, type **select site** *n*, where *n* represents the number that is identified in the previous step.

   j. Type **list servers in site**, and identify the full distinguished name (also known as DN) of the server whose server object you want to delete.

   k. At the **select operation target:** prompt, type **q**.

   l. At the **metadata cleanup:** prompt, type **q**.

   m. At the **dsmgmt:** prompt, type **q**.

   n. At the command prompt, type **dsmgmt**.

   o. At the **dsmgmt:** prompt, type **metadata cleanup**.

   p. At the **metadata cleanup:** prompt, type **remove selected server***servername***on***computername:portnumber*

      where *servername* represents the distinguished name of the server object that you want to remove and *computername:portnumber* represents the Domain Name System (DNS) name of the ADAM instance to which you are connecting.

   q. Click **Yes** to confirm the deletion of the server object.

   r. In addition, you must delete the server object from the sites container:

      CN=Servers, CN=*sitename*, CN=Sites, CN=Configuration, CN={*GUID*}

      where *sitename* represents the name of the site in which the server object exists, and *GUID* represents the globally unique identifier (GUID) of the ADAM instance.

2. When you complete the previous steps, install an ADAM replica from media.

**Notes**

- To start Backup, click **Start**, point to **All Programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.
- If Backup does not start in wizard mode by default, you can start the wizard by clicking **Wizard Mode** on the **Welcome** tab.
- For help with **dsmgmt**, type **?** at a **dsmgmt** prompt.
- If you accidentally start a restore of an ADAM instance over a currently running ADAM instance, it is recommended that you immediately restart the computer, stop the ADAM instance, and then perform the restoration again.

# View an ADAM event log

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To view an ADAM event log**

1. Open Event Viewer.
2. In the console tree, click the ADAM log that you want to view.
3. In the details pane, view the list of individual events.
4. If you want to see more details about a specific event, in the details pane, double-click the event.

## Notes

- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.
- To refresh the view in Event Viewer, on the **Action** menu, click **Refresh**. When you open a log, Event Viewer displays the current information for the log. While you view the log, the display is not updated unless you refresh the Event Viewer window. If you switch to another log and then return to the first log, the display for the first log is automatically refreshed. When you refresh the view of an event log, only the view is updated; no changes are made to the log. The **Refresh** command is not available for archived logs, because those files can no longer be updated.
- To enable auditing for an ADAM instance running under a service account other than the Network Service account, you must grant the **Generate security audits** right to the ADAM service account.

# Synchronize Data from Active Directory to an ADAM Instance

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Active Directory to ADAM Synchronizer is a command-line tool that synchronizes data from an Active Directory forest to a configuration set of an ADAM instance.

**To synchronize data from Active Directory to an ADAM instance**

1. Open an ADAM tools command prompt.
2. At the command prompt, type:

   **adamsync /install** *server name*:*port .xml file name*

### Notes

- To open an ADAM tools command prompt, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM Tools Command Prompt**.
- The following table contains the parameters in step 2 and other commonly used **adamsync** parameters. For more information about **adamsync** parameters, type **adamsync /?** at a command prompt, or see Related Topics.

| Parameter | Description |
|---|---|
| **/?** | Displays command-line options. |
| **/l** or **/list** | Displays all available configurations of Active Directory to ADAM Synchronizer. |
| **/d** or **/delete** *configuration_dn* | Deletes the specified configuration. |
| **/i** or **/install** *input_file* | Installs the configuration that is contained in the specified input file. |
| **/download** *configuration_dn output_file* | Creates an output file in XML containing the specified configuration. |
| **/export** *configuration_dn output_file* | Saves the current configuration to the specified output file. |
| **/sync** *configuration_dn* | Synchronizes the specified configuration |
| **/reset** *configuration_dn* | Resets the replication cookie of the specified configuration. |
| **/mai** *configuration_dn* | Configures the specified configuration as the authoritative instance. |
| **/fs** *configuration_dn* | Performs a full replication synchronization for the specified configuration. |
| **/ageall** *configuration_dn* | Performs an aging run for the specified configuration. |
| **/so** *configuration_dn object DN* | Performs a replication synchronization for the specified object in the specified configuration. Use the distinguished name of the object. |
| **/passPrompt** | Prompts for user credentials. |

- For specific information about importing the user class definitions that are supplied with ADAM, see Related Topics.

- For complete syntax information for the **adamsync** command, see Related Topics.
- You must have Read or Dirsync access to the objects or partitions in the Active Directory forest that you want to synchronize.
- You must have full control of an application directory partition on an ADAM instance to run this command.

- ADAM requirements
- Comparing ADAM to Active Directory

# Introducing ADAM

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Introducing ADAM**

For organizations that require flexible support for directory-enabled applications, Microsoft has developed Active Directory Application Mode (ADAM). ADAM is a Lightweight Directory Access Protocol (LDAP) directory service. You can run ADAM on servers running Microsoft® Windows Server™ 2003 and also on clients running Microsoft Windows® XP Professional.

| **Note** |
| --- |
| To run ADAM on clients running Windows XP Professional, you must install the latest service packs and hot fixes. |

ADAM provides data storage and retrieval for directory-enabled applications, without the dependencies that are required for the Active Directory® directory service. ADAM provides much of the same functionality as Active Directory, but it does not require the deployment of domains or domain controllers. You can run multiple instances of ADAM concurrently on a single computer, with an independently managed schema for each ADAM instance.

**What's new in ADAM**

The following features are new to ADAM in Windows Server 2003 R2:

- Users can be created in the configuration partition so that ADAM users can be ADAM administrators. For more information, see Allow ADAM users to be created in the configuration partition.
- Active Directory to ADAM Synchronizer tool. This tool synchronizes objects from Active Directory to an ADAM instance. For more information, see Synchronize Data from Active Directory to an ADAM Instance and Adaminstall.
- ADAM users can bind to an ADAM instance by using digest authentication. This authentication method uses the default credentials of the server applications and eliminates the need to keep a plaintext version of the application's password in memory. Digest bind is supported in Ldp.
- Active Directory Schema Analyzer tool. This tool helps to migrate the Active Directory schema to ADAM. For more information, see ADSchemaAnalyzer.
- Newer version of LDP tool with access control list (ACL) editor. For more information about Ldp, see Ldp.
- ADAM can now chain user password requests in ADAM to the user object in Active Directory so that a password is changed in both directory services. When a user in ADAM who is also a user in Active Directory attempts to change the user password in ADAM, that change is treated the same as a user password change in Active Directory. Both the old and new password must be provided (except for Active Directory administrators, who only need to supply the new password), and the new password must meet any password policies that are set in Active Directory. Active Directory performs all policy checking.

**Microsoft directory technologies**

With the introduction of Active Directory Application Mode, Microsoft provides a choice of directory services. Both ADAM and Active Directory build on the same core Microsoft directory service technologies, but they address different needs within an organization.

**Active Directory.** Active Directory provides directory services for both the Windows network operating system (NOS) and for directory-enabled applications. For the NOS, Active Directory stores critical information about the network infrastructure, users and groups, network services, and so on. In this role, Active Directory must adhere to a single schema throughout an entire forest.

**ADAM.** ADAM provides directory services specifically for directory-enabled applications. ADAM does not require or rely on Active Directory domains or forests. However, in environments where Active Directory exists, ADAM can use Active Directory for the authentication of Windows security principals.

**Notes**

- Directory services (such as ADAM and Active Directory) and relational databases both provide data storage and retrieval, but they differ in their optimization. Directory services are optimized for read processing, while relational databases are optimized for transaction processing. In general, consider implementing a directory service if your application reads data more frequently than it writes data. Consider implementing a relational database if your application writes or modifies data more frequently than it reads data, such as with transactional applications.

- ADAM and Active Directory can run concurrently in the same network. In addition, ADAM can support both domain and workgroup users simultaneously, as shown in the figure below. For a comparison between ADAM and Active Directory, see Comparing ADAM to Active Directory.

**Directory-enabled applications**

A directory-enabled application uses a directory, rather than a database, flat file, or other data storage structure, to hold its data. Many off-the-shelf applications, as well as many custom applications, use a directory-enabled design. Examples of types of applications that often use a directory-enabled design include Customer Relationship Management (CRM) applications, Human Resource (HR) applications, and global address book applications.

For information about developing directory-enabled applications for ADAM, see the ADAM Software Developer's Kit (SDK) and ADAM resources.

# ADAM requirements

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Requirements**
The following requirements apply to Active Directory Application Mode (ADAM).

**Platform requirements**
ADAM requires one the following platforms:

- Microsoft® Windows Server™ 2003, Standard Edition
- Microsoft Windows Server™ 2003, Enterprise Edition
- Microsoft Windows Server™ 2003, Datacenter Edition
- The 64-bit version of Windows Server 2003, Enterprise Edition
- The 64-bit version of Windows Server 2003, Datacenter Edition
- Microsoft Windows® XP Professional Service Pack 1 (SP1)
- Microsoft Windows® XP 64-Bit Edition Service Pack 1 (SP1)

| **Note** |
| --- |
| There are some functional considerations for running ADAM on Windows XP Professional. For more information, see Running ADAM on Windows XP Professional. In addition, you must also install the latest service packs and hot fixes to run ADAM on Windows XP Professional. For more information, see Windows Update at the Microsoft Web site. |

**Workgroup and domain requirements**
ADAM does not require a forest, domain, or domain controller. You can install ADAM on computers that are configured as any of the following:

- Domain controllers
- Domain members
- Stand-alone computers

**Support for LDAP clients**
ADAM supports any Lightweight Directory Access Protocol (LDAP) client that is written to the LDAP v3 technical specification.

**Support for ADSI clients**
ADAM supports Active Directory Service Interfaces (ADSI) for clients running the following:

- Windows XP Professional
- Microsoft Windows® XP Home Edition
- Windows Server 2003 family
- Microsoft Windows® 2000

| Note |
| --- |
| For complete ADSI functionality with Windows XP Professional, you must install hotfix 817583. For more information about this hotfix, see article 817583 in the Microsoft Knowledge Base. |

# Comparing ADAM to Active Directory

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Comparing ADAM to Active Directory**

The following table illustrates the functional differences and similarities between Active Directory Application Mode (ADAM) and Active Directory.

| Feature | ADAM | Active Directory |
|---|---|---|
| Supports multiple schemas per server | Yes | No |
| Supports multiple directory instances per server | Yes | No |
| Runs on Windows XP Professional | Yes | No |
| Runs on member servers | Yes | No |
| Supports X.500 naming for top-level directory partitions | Yes | No |
| Supports installing, starting, and stopping without a reboot | Yes | No |
| Group Policy | No | Yes |
| Global catalog | No | Yes |
| IntelliMirror desktop management | No | Yes |
| Automated software distribution | No | Yes |
| Domain trusts and forest trusts | No | Yes |
| Public key infrastructure (PKI)/X.509 | No | Yes |
| Supports DNS service (SRV) resource records | No | Yes |
| Supports Lightweight Directory Access Protocol (LDAP) application programming interface (API) | Yes | Yes |
| Supports Active Directory Service Interfaces (ADSI) API | Yes | Yes |
| Supports Messaging API (MAPI) | No | Yes |
| Delegated administration | Yes | Yes |
| Multimaster replication | Yes | Yes |
| InetOrgPerson | Yes | Yes |
| LDAP over Secure Sockets Layer (SSL) | Yes | Yes |
| Attribute-level security | Yes | Yes |
| LDAP access control list (ACL) support | Yes | Yes |
| Microsoft Identity Integration Server 2003 compatibility | Yes | Yes |
| Extensible schema | Yes | Yes |
| Supports application directory partitions | Yes | Yes |
| Supports installation of a replica from media | Yes | Yes |

| | | |
|---|---|---|
| Supports 64-bit servers | Yes | Yes |
| Supports concurrent LDAP binding | Yes | Yes |

# Understanding ADAM architecture

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Architecture**

Active Directory Application Mode (ADAM) uses the same architecture—and even the same code base—as Active Directory. ADAM provides a hierarchical data store, a directory service component, and interfaces that clients can use to communicate with the directory service. ADAM can run on any computer running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; Windows Server 2003, Datacenter Edition; or Windows XP Professional. ADAM does not require a domain controller or a DNS server. For information about considerations when running ADAM on Windows XP Professional, see Running ADAM on Windows XP Professional.

The following table lists the basic ADAM components, along with their Active Directory counterparts.

| Component | ADAM | Active Directory | Purpose |
|---|---|---|---|
| Directory data store | Adamntds.dit | Ntds.dit | Provides a hierarchical data store for directory data. |
| Directory service | Dsamain.exe, Adamdsa.dll | Ntdsa.dll (Runs within Lsass.exe) | Processes requests from directory clients and other directory services. |
| Directory service interfaces | Lightweight Directory Access Protocol (LDAP), replication | LDAP, replication, Messaging API (MAPI) | Provide interfaces to the directory service for making directory-related requests. |
| Directory server | Windows Server 2003, Windows XP Professional | Microsoft® Windows® 2000 Server or Windows Server 2003 domain controller | Provides the platform on which the directory service runs. |

The following illustration shows the relationship between the components of ADAM. For information about the ADAM directory data store, see Understanding ADAM data and data stores.

**Directory service**

The ADAM directory service manages the directory data store. It responds to directory requests from directory clients, as well as from other directory services. The ADAM directory service runs in the security context of the account that is specified as the ADAM service account. The ADAM directory service provides all of the following functions:

- Authentication of directory users
- Fulfillment of data requests
- Data synchronization between directory servers (through multimaster replication)
- Data management

**Notes**

- ADAM manages replication by grouping ADAM instances into configuration sets. For more information about ADAM replication, see Understanding ADAM replication and configuration sets.

- The ADAM directory service allows or denies access to clients based on credentials that are provided by the clients. ADAM supports all the same authentication, or binding methods, as Active Directory. For more information about authentication and data security, see Understanding ADAM access control.

- ADAM service account requirements vary, depending on the computer on which ADAM is installed and also on the replication scenario. For more information, see Selecting an ADAM service account.

**ADAM instances**
In ADAM, a service instance (or, simply, *instance*) refers to a single running copy of the ADAM directory service. Unlike Active Directory, multiple copies of the ADAM directory service can run simultaneously on the same computer. Each instance of the ADAM directory service has a separate directory data store, a unique service name, and a unique service description that is assigned during installation. For more information about ADAM instances, see Administering an ADAM instance.

**Directory service interfaces**
ADAM provides directory service interfaces for communication with directory clients and other ADAM instances. ADAM provides a Lightweight Directory Access Protocol (LDAP) interface for clients for authentication and for making directory service requests. ADAM provides a remote procedure call (RPC) interface for replication with other ADAM servers and for administration.

**Service dependencies**
ADAM does not require the DNS service or the File Replication service (FRS). Clients address ADAM directly, using the name or Internet Protocol (IP) address of the computer on which ADAM is running, along with the communication port number used by the ADAM instance. Because ADAM does not require or rely on domains or domain controllers, ADAM replication does not require FRS.

# Understanding ADAM data and data stores

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Data and data stores**

Active Directory Application Mode (ADAM) stores directory data in a hierarchical, file-based directory store. By default, the directory store for a given ADAM instance is located in the following:

%ProgramFiles%\Microsoft ADAM*instancename*\data\adamntds.dit

Each ADAM instance has a separate directory store. Any data operation that you perform in ADAM, including searches, reads, imports, exports, indexing, replication, backups, and restores, uses the ADAM directory store in some way. The directory store is organized into logical directory partitions, also called *naming contexts*.

| **Note** |
| --- |
| Like Active Directory, Active Directory Application Mode uses the Extensible Storage Engine (ESE) to manage its directory store. |

**Directory partitions**

The ADAM directory store is organized into logical directory partitions, or naming contexts. Three different types of directory partitions exist: configuration, schema, and application. Each ADAM directory store must contain a single configuration directory partition and a single schema directory partition, and it can contain zero or more application directory partitions. The following table summarizes these partition types, their contents, and ADAM requirements.

| Partition type | Distinguished name | Required/optional | Contents |
| --- | --- | --- | --- |
| Configuration | CN=Configuration,CN={*GUID*} | Required | ADAM configuration information |
| Schema | CN=Schema,CN=Configuration,CN={*GUID*} | Required | Class and attribute definitions |
| Application | Assigned during partition creation | Optional | Application data |

**Configuration directory partition**

The configuration directory partition holds information about ADAM replication scheduling and replica sets, information that defines the other partitions in the replication set, information about the users and groups in the replica set, and other information.

**Schema directory partition**

The schema directory partition holds the definitions for the type of data that can be held by the directory store. The ADAM directory service relies on the definitions in the schema partition for maintaining data consistency. In addition, applications can refer to the schema partition to determine the type of data that the ADAM instance allows. You can extend the schema to allow ADAM to hold data that is specific to a particular application. For more information about ADAM schemas, see Understanding ADAM schema.

| **Note** |
| --- |
| A common configuration partition and a common schema partition are replicated to ADAM service instances that belong to the same configuration set. For more information about replication, see Understanding ADAM replication and configuration sets. |

**Application directory partitions**

Application directory partitions hold the data that is used by your applications. You can create an application partition during ADAM setup or at any time after installation. Depending on your application, you might extend the schema manually or your application might automatically extend the schema for you. Typically, you manage data in a given application directory partition through your application. After the application directory partition is created, ADAM holds the application partition reference objects in CN=Partitions,CN=Configuration.

# Understanding ADAM schema

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Schema**

An Active Directory Application Mode (ADAM) schema defines, using object classes and attributes, the kinds of objects and data that can be created and stored in an ADAM directory. Each ADAM configuration set has its own independently manageable schema, which is stored in the schema directory partition. In keeping with the ADAM design concepts of simplicity and flexibility, the base (or default) ADAM schema contains only the classes and attributes that are needed to start an ADAM instance. The schema can be extended with new classes and attributes, either by administrators or by the applications themselves. In addition, unneeded schema classes and attributes can be deactivated. As with all objects in the directory, access control lists (ACLs) protect schema objects, so that only authorized users can alter the schema. Every object in an ADAM directory is an instance of an object class that is defined in a schema, as shown in the following illustration.

**Object classes**

An object class represents a category of objects, such as users, printers, or application programs, that share a set of common characteristics. The definition for each object class contains a list of the attributes that can be used to describe instances of the class. For example, the User class has attributes such as **givenName**, **surname**, and **streetAddress**. The list of attributes for a class is divided into those attributes that an object of that class must contain and additional attributes that an object may contain. The definition of each class also lists the classes whose objects can be parents of objects of a given class.

For example, the following table shows the definition for the ADAM user class.

| Attribute | Value |
|---|---|
| **Dn** | CN=User,CN=Schema,CN=Configuration |
| **objectClass** | top; classSchema; |
| **cn** | User; |
| **distinguishedName** | CN=User,CN=Schema,CN=Configuration; |
| **subClassOf** | organizationalPerson; |
| **mayContain** | audio; carLicense; departmentNumber; displayName; employeeNumber; employeeType; givenName; homePostalAddress; jpegPhoto; labeledURI; photo; preferredLanguage; roomNumber; secretary; uid; userPKCS12; userSMIMECertificate; x500uniqueIdentifier; |
| **rDNAttID** | cn; |
| **adminDisplayName** | User; |
| **adminDescription** | User; |
| **objectClassCategory** | 1; |
| **lDAPDisplayName** | user; |

| | |
|---|---|
| **name** | User; |
| **objectGUID** | dac9093a-d2aa-408a-81bb-0fe8179165da; |
| **schemaIDGUID** | bf967aba-0de6-11d0-a285-00aa003049e2; |
| **objectCategory** | CN=Class-Schema,CN=Schema,CN=Configuration; |
| **defaultObjectCategory** | CN=Person,CN=Schema,CN=Configuration; |

**Attributes**

The schema also defines each attribute. The definition for each attribute includes unique identifiers for the attribute, the syntax for the attribute, optional range limits for the attribute values, whether the attribute can have only one value or multiple values, and whether the attribute is indexed. The directory schema defines each attribute exactly once. Each attribute can then be referenced by multiple object classes. For example, the **description** attribute is defined once and then referenced by many object classes.

The following table shows the attribute definition for **telephone number**, a representative schema attribute.

| Attribute | Value |
|---|---|
| **objectClass** | top; attributeSchema; |
| **cn** | Telephone-Number; |
| **distinguishedName** | CN=Telephone-Number,CN=Schema,CN=Configuration; |
| **instanceType** | 0x4 = ( IT_WRITE ); |
| **whenCreated** | 11/12/2002 13 |
| **22** | 14 Pacific Standard Time Pacific Daylight Time; |
| **whenChanged** | 11/12/2002 13 |
| **22** | 14 Pacific Standard Time Pacific Daylight Time; |
| **uSNCreated** | 217; |
| **attributeID** | 2.5.4.20; |
| **attributeSyntax** | 2.5.5.12; |
| **isSingleValued** | TRUE; |
| **rangeLower** | 1; |
| **rangeUpper** | 64; |
| **uSNChanged** | 217; |
| **showInAdvancedViewOnly** | TRUE; |
| **adminDisplayName** | Telephone-Number; |
| **adminDescription** | Telephone-Number; |
| **oMSyntax** | 64; |
| **searchFlags** | 0; |
| **lDAPDisplayName** | telephoneNumber; |
| **name** | Telephone-Number; |

| | |
|---|---|
| **objectGUID** | bf19d7eb-ea0f-4f2d-af67-f439a037d8a4; |
| **schemaIDGUID** | bf967a49-0de6-11d0-a285-00aa003049e2; |
| **attributeSecurityGUID** | 77b5b886-944a-11d1-aebd-0000f80367c1; |
| **systemOnly** | FALSE; |
| **systemFlags** | 0x10 = ( FLAG_SCHEMA_BASE_OBJECT ); |
| **isMemberOfPartialAttributeSet** | TRUE; |
| **objectCategory** | CN=Attribute-Schema,CN=Schema,CN=Configuration; |

**Single-valued and multivalued attributes**

Attributes can be single-valued or multivalued. An instance of a single-valued attribute can contain only a single value. An instance of a multivalued attribute can contain multiple values, which must all use the same syntax. Each value of a multivalued attribute must be unique.

| **Note** |
|---|
| A multivalued attribute stores its values in random order. Therefore, you should not make any directory decisions—programmatic or manual—based on the order of the values in a multivalued attribute. |

**Indexed attributes**

Indexing attributes helps to improve the performance of queries that are based on the indexed attribute. Both single-valued and multivalued attributes can be indexed; classes cannot be indexed. Attributes can be marked for indexing through their schema definition. Indexing an attribute also makes it possible for users to use wildcards (*) as prefixes and suffixes when they specify a search string. When you mark an attribute as indexed, all instances of the attribute are added to the index, not just the instances that are members of a particular class. Indexing attributes, particularly multivalued attributes, can negatively affect replication and object creation time, as well as directory database size. Therefore, you should only index commonly used attributes.

For general information about schemas, see "Active Directory Schema" at the Microsoft MSDN Web site.

# Understanding ADAM replication and configuration sets

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Replication and configuration sets**
Active Directory Application Mode (ADAM) uses replication to provide fault tolerance and load balancing for directory services. ADAM uses a type of replication called multimaster replication. Through replication, ADAM copies directory data updates that are made to a directory partition on one ADAM instance to other ADAM instances that hold copies of the same directory partition. ADAM instances that hold copies of the same directory partition or partitions form a logical grouping called a configuration set.

**Multimaster replication**
Multimaster replication simply means that you can make changes to directory data on any ADAM instance. ADAM replicates these changes to other members of the configuration set automatically. Multimaster replication is characterized by loose data consistency with convergence. When you make changes to data on a given directory partition at one ADAM instance, replicas of that directory partition that are stored on other ADAM instances become inconsistent with the most up-to-date replica of the directory partition (the partition where the changes were made). However, as changes get replicated through the configuration set, all partition replicas once again become identical; that is, they converge to the most recent data.

**Configuration sets**
ADAM instances replicate data based on participation in a configuration set. All ADAM instances that are joined to the same a configuration set must replicate a common configuration directory partition and a common schema directory partition. ADAM instances in a configuration set can also replicate any number of application directory partitions. ADAM instances in a configuration set are not required to replicate all application directory partitions in the configuration set. A single ADAM instance can replicate all—or any subset of—the application directory partitions in its configuration set. An ADAM instance cannot, however, replicate an application directory partition from a different configuration set. For more information about the types of directory partitions in ADAM, see Understanding ADAM data and data stores.

The following illustration shows an example of two ADAM configuration sets, each with two ADAM instances. As shown in the illustration, a single computer can run multiple ADAM instances, each in a different configuration set.

**Note**

An ADAM instance can be joined to a configuration set only during installation of the instance.

**Preventing replication conflicts**
What if two different users make changes to the same data on replicas of the same directory partition on two different ADAM instances? In such a case, each ADAM instance attempts to replicate the changes, creating a conflict. To resolve this conflict, replication partners that receive these conflicting changes examine the attribute data that is contained in the changes, each of which holds a version and a time stamp. ADAM instances accept the change with the higher version and discard the other change. If the versions are identical, ADAM instances accept the change with the more recent time stamp.

If two or more values in a multivalued attribute on an object are updated simultaneously on two different ADAM instances,

only one of the updated values will be replicated. In other words, simultaneous updates to a multivalued attribute that occur on two different ADAM instances are considered in conflict, even if the updates apply to different values within the multivalued attribute. The only exception to this rule is for linked value attributes (such as group memberships), which do allow for simultaneous updates to different values within the linked value attribute.

**Replication topology**

Knowledge Consistency Checker (KCC), a process that runs as part of each ADAM instance, automatically constructs the most efficient topology for replication traffic to follow, based on the network. The KCC regularly recalculates the replication topology to adjust for any network changes that occur in the environment.

| **Note** |
| --- |
| An ADAM configuration set maintains its own replication topology, separate from any Active Directory replication topology that might also exist. Directory partitions cannot be replicated between ADAM instances and Active Directory domain controllers. |

**Ensuring replication security**

To ensure replication security, ADAM authenticates replication partners before replication, and replication authentication always occurs over a secure channel. ADAM uses Security Support Provider Interface (SSPI) to establish the appropriate authentication security level between replication partners. The method used for replication authentication within a configuration set depends on the value of the **msDS-ReplAuthenticationMode** attribute on the configuration directory partition. After replication partners have successfully authenticated, all replication traffic between the two partners is encrypted.

The following table describes the security levels for replication authentication and the corresponding **msDS-ReplAuthenticationMode** attribute value for each security level. The default replication security level for a new, unique ADAM instance is 1, unless a local workstation user account is specified as the ADAM service account. If a local workstation account is specified as the ADAM service account, the replication security level is set to 0.

| **Replication security level** | **Authentication mode** | **Description** | **Supported environments** |
| --- | --- | --- | --- |
| Mutual authentication with Kerberos | 2 | Kerberos authentication, using service principal names (SPNs), required. If Kerberos authentication fails, the ADAM instances will not replicate. | Configuration set must be fully contained in an Active Directory domain, forest, or forest trust. |
| Negotiated | 1 | Kerberos authentication (using SPNs) is attempted first. If Kerberos fails, NTLM authentication is attempted. If NTLM fails, the ADAM instances will not replicate. | Configuration set can contain Microsoft® Windows NT® 4.0 member servers. |
| Negotiated pass-through | 0 | All ADAM instances in the configuration set use an identical account name and password as the ADAM service account. | Configuration set can include computers that are joined to one or more workgroups or that are joined to multiple domains or forests without trust relationships. |

For information about modifying the replication security level of a configuration set, see Modify the replication security level of a configuration set.

To help maintain ADAM replication security, the following best practices are recommended:

- Use the highest level of replication security that your environment can support.
- In Active Directory environments, run ADAM on member servers, rather than on domain controllers, whenever possible.
- If you run ADAM on a domain controller in an Active Directory environment, do not use the Network Service account as the ADAM service account. Instead, use a domain user account that does not have administrative privileges.
- In workgroup and Windows NT 4.0 environments, do not use an account with administrative privileges as an ADAM service account.
- Use separate configuration sets for applications with strict isolation requirements.

For more information about ADAM replication requirements for service accounts, see Selecting an ADAM service account. For more information about service principal names (SPNs) and replication security, see Administering ADAM service principal names.

# Understanding ADAM sites

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Sites**
Active Directory Application Mode (ADAM) uses topology information, which is stored as site objects and site link objects in the configuration directory partition, to build the most efficient replication topology for a configuration set. You can use sites in ADAM to represent the physical structure, or *topology*, of your network. You can use ADAM ADSI Edit to define site objects and site link objects.

**Site objects**
You can create a site object in ADAM to represent each area of your network (typically, a building or a group of buildings) in which all computers are connected by high-speed bandwidth. You can then move the directory objects of ADAM instances that are located in each area of the network into the corresponding site object. By default, the directory objects of each ADAM instance that you create belong to a single default site (CN=Default-First-Site-Name,CN=Sites,CN=Configuration,CN={*GUID*}).

For information about establishing single or multiple sites, see Administering sites.

**Site link objects**
You can use site link objects in the directory to represent low-speed bandwidth connections between the sites on your network. Site link objects help you tune replication on your network; you can use them to determine the relative cost of replication across each site link. By default, the default site (CN=Default-First-Site-Name) belongs to the default site link object (CN=DEFAULTIPSITELINK,CN=IP,CN=Inter-Site Transports,CN=Sites,CN=Configuration,CN={GUID} ). You can add new sites that you create to the default site link object. You can also create additional site link objects to represent each of the actual site links on your network.

**Site link costs**
Each site link object in the directory has an associated cost. You can edit the cost attribute on a site link object to specify the relative cost of replication across that site link. ADAM takes into consideration site link costs when it builds the replication topology. ADAM considers a site link with a higher cost to be less desirable than a site link with a lower cost. When multiple paths for replication are available, ADAM prefers the site link with the lower cost.

For more information about how sites affect replication, see Understanding ADAM sites and replication.

# Understanding ADAM sites and replication

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Sites and replication**
In Active Directory Application Mode (ADAM), the replication topology is the set of physical connections that is used to replicate directory updates among ADAM instances in a configuration set. ADAM builds the most efficient replication topology for a configuration set based on the site or sites in which members of the configuration set reside. ADAM treats replication within a site differently than replication between sites.

**Building the intersite replication topology**
One ADAM server in each site, called the intersite topology generator, is assigned to build the topology. Together, these intersite topology generators build a least-cost spanning tree algorithm that eliminates redundant replication paths between sites. The intersite replication topology is updated regularly to respond to any changes that occur in the network. You can control intersite replication through the information that you provide when you create your site links.

**Determining when intersite replication occurs**
Active Directory preserves bandwidth between sites by minimizing the frequency of replication and by allowing you to schedule the availability of site links for replication. By default, intersite replication across each site link occurs every 180 minutes (3 hours). You can adjust this frequency to match your specific needs. Be aware that increasing this frequency increases the amount of bandwidth that is used by replication. In addition, you can schedule the availability of site links for use by replication. By default, a site link is available to carry replication traffic 24 hours a day, 7 days a week. You can limit this schedule to specific days of the week and times of day. You can, for example, schedule intersite replication so that it only occurs after normal business hours. For more information, see Configure replication availability on a site link.

**Building the intrasite replication topology**
The Knowledge Consistency Checker (KCC) on each ADAM instance automatically builds the most efficient replication topology for intrasite replication, using a bidirectional ring design. This bidirectional ring topology attempts to create at least two connections to each ADAM instance (for fault tolerance) and no more than three hops between any two ADAM instances (to reduce replication latency). To help prevent connections of more than three hops, the topology can include shortcut connections across the ring. The KCC updates the replication topology regularly.

**Determining when intrasite replication occurs**
Intrasite replication is optimized for speed, rather than bandwidth, because bandwidth within a site is assumed to be high-speed. Replication within a site occurs automatically on the basis of change notification. Intrasite replication begins when a directory update occurs. By default, the source ADAM instance waits 15 seconds and then sends an update notification to its closest replication partner. If the source ADAM instance has more than one replication partner, subsequent notifications go out by default at 3-second intervals to each partner. After receiving notification of a change, a partner ADAM instance sends a directory update request to the source ADAM instance. The source ADAM instance responds to the request with a replication operation. The 3-second notification interval prevents the source ADAM instance from being overwhelmed with simultaneous update requests from its replication partners.

If no directory updates have occurred within a given time period, intrasite replication still occurs, based on a scheduled interval. By default, this scheduled interval is once per hour. For information about modifying this time period, see Configure replication frequency within a site.

# Understanding ADAM service publication

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**ADAM service publication**
In Active Directory environments, *service publication* refers to the ability of a service to publish information about itself in the directory and to the ability of clients to discover that information and locate the service. When a computer on which Active Directory Application Mode (ADAM) is running is joined to an Active Directory domain, ADAM attempts to create service connection point (SCP) objects in Active Directory.

**Active Directory and service connection points**
In Active Directory network environments, services can publish information about their existence using **serviceConnectionPoint** objects in the directory. These objects contain binding information that client applications use to find and connect to instances of the service. To access a service, a client does not have to know about specific computers; the objects in Active Directory include this information.

When an ADAM instance is running in an Active Directory environment, it makes a best-effort attempt to publish updated information about itself in Active Directory. This attempt is a "best-effort" attempt because the attempt to create SCPs does not always succeed, and failure to create SCPs does not prevent the ADAM instance from running or accepting client connections.

The attempt to create SCPs succeeds if:

- The computer on which the ADAM service is running is joined to a domain, and
- The ADAM service account possesses Create Child rights on the computer object where the **serviceConnectionPoint** object is to be created.

By default, ADAM runs as NetworkService, and the **serviceConnectionPoint** object is created under the computer object that represents the computer on which ADAM is running. If the SCP object already exists, ADAM updates the object with any new information about the ADAM instance.

A **serviceConnectionPoint** object contains the information in the following table.

| serviceConnectionPoint attribute | Attribute contents |
|---|---|
| **Keywords** | • Windows 2000 Lightweight Directory Access Protocol (LDAP) object identifier (also known as OID)<br>• ADAM LDAP object identifier<br>• Globally unique identifier (GUID) of the **NTDS Settings** object under the computer object of the ADAM instance<br>• Site of the ADAM instance<br>• Instance name of the ADAM instance<br>• Operation master role (schema or naming), if held by the ADAM instance<br>• Distinguished name and GUID of the configuration directory partition of the ADAM instance<br>• Distinguished name and GUIDs of all application directory partitions on the ADAM instance |

| | |
|---|---|
| **serviceBindingInformation** | • LDAP connection point (in the form of ldap:*computername:ldapport*)<br>• Secure Sockets Layer (SSL) connection point (in the form of ldaps:*computername:sslport*) |

| **Note** |
|---|
| The **Keywords** attribute is a multivalued attribute. |

By default, the global catalog in Active Directory contains the contents of the **Keywords** attribute of an SCP object. As a result, a client can locate an object on which an SCP is created, even if the object is located in a different domain than the client.

**Client searches**

Client applications can find ADAM instances by searching the SCP attributes that are contained in the global catalog. For information about performing this search programmatically, see "How Clients Find and Use a Service Connection Point" at the Microsoft MSDN Web site. (Unlike the example shown at the Microsoft MSDN Web site, client applications need to perform only one search to retrieve the information necessary for ADAM binding.) Client applications can search for the ADAM object identifier, configuration partition GUID, ADAM instance GUID, ADAM instance name, or any directory partition. Client applications may also perform load balancing by selecting an ADAM instance at random when a search returns more than one applicable ADAM instance.

**Service publication and discovery without SCPs**

ADAM does not require that SCPs be published to run successfully. ADAM operates successfully with or without SCPs. Examples of environments without SCPs include workgroup environments and ADAM instances running under service accounts that do not possess sufficient privileges to create SCPs. In these cases, client applications can rely on Domain Name System (DNS) to resolve the host name of a computer on which ADAM is running. Note, however, that ADAM instances, unlike domain controllers in Active Directory, do not create service (SRV) records in DNS.

# Understanding ADAM LDAP referrals

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**ADAM LDAP referrals**

In accordance with RFC 2251, Active Directory Application Mode (ADAM) supports the use of referrals. With referrals you can use ADAM to direct LDAP clients to a more appropriate location in response to a query from the client. Also in accordance with RFC 2251, ADAM can return referrals in response to any LDAP operation request, except "unbind" and "abandon" requests, which have no responses. ADAM maintains referral data in **crossRef** objects that are stored in the partitions container of the configuration directory partition.

ADAM creates and maintains **crossRef** objects for all directory partitions in the configuration set, including the configuration and schema partitions. These **crossRef** objects are used to generate referrals in response to queries that request data about objects that exist in the configuration set but that are not contained in the ADAM instance handling the request.

At a minimum, at least one Uniform Resource Locator (URL) must be present in the referral. When possible, ADAM returns at least three referrals, to provide referral redundancy to clients in distributed environments. A referral is not returned for a **singleLevel** or **wholeSubtree** search in which the search scope spans multiple naming contexts and several different servers must be contacted to complete the operation. Instead, continuation references are returned.

If a **crossRef** object with a matching directory partition exists, ADAM uses it for referrals. However, if a **crossRef** object does not exist, but the queried namespace uses DNS-style (DC=) naming, ADAM constructs a DNS name to be used as a referral. If the queried namespace does not use DNS-style naming, a superior reference is used, if one exists. A superior reference can be configured by setting the **superiorDnsRoot** attribute on the configuration partition **crossRef** object. If a superior reference is not configured (it is not configured by default), an operational error is returned.

**Generating referrals from a crossRef object**

If the **dNSRoot** attribute has been set on the **crossRef** object (**dNSRoot** is not set by default), ADAM returns the DNS name as the referral for the queried namespace. (By default, the **dNSRoot** attribute is set to NULL.) Then, the client can chase the referral through registered DNS records for each host that contains the queried namespace.

If the **dNSRoot** attribute is NULL, the referral is generated based on other information about the **crossRef**, as follows:

- ADAM refers to the **msDS-NC-Replica-Locations** attribute to find the **NTDS Settings** objects representing the instances hosting this partition (for example: CN=NTDS Settings,CN=Machine1$instance1,CN=Servers,CN=Default-First-Site-Name,CN=Sites,CN=Configuration,CN={<GUID>}). If more than three ADAM instances host the directory partition, a randomly selected set of three instances is chosen.

- From the **NTDS Settings** object (the authoritative source within the directory for communications port information), ADAM retrieves the **msDS-PortLDAP** attribute for the communications port.

- From the parent (**Server Object**), ADAM retrieves the **dNSHostName** attribute (instance1.machine1.example.com). **dNSHostName** is the authoritative source for the server host name, and it can either be a DNS host name or a host Internet Protocol (IP) address. If the server name changes, this object can be relied on to have the updated information.

- ADAM then constructs the referral based on the server and communications port information. ADAM returns multiple referrals for each request to ensure that the client can pursue the request, even if one or more hosts represented in the referrals cannot be reached. ADAM selects a random number of locations (three by default) and continues to use those defaults for five minutes, after which another three hosts are selected. Both the number of hosts and number of minutes are configurable. If the number of hosts specified is greater than the actual number of instances holding the directory partition, all of the hosts are returned as referrals, and they will continue to be used indefinitely. This information is kept in the crossref cache, and it is refreshed anytime the crossref cache is rebuilt. The crossref cache is automatically rebuilt when **msds-nc-replica-locations** changes, that is, when an ADAM instance is added or removed.

| **Note** |
| --- |
| You can modify the values in the following table on the **msDS-Other-Settings** attribute of the directory service object, or on a **crossRef** object, to configure the referral behavior of an ADAM instance. |

| Value name | Default | Meaning |
| --- | --- | --- |
| **MaxReferrals** | 3 | Maximum number of referrals returned by ADAM |
| **ReferralRefreshInterval** | 5 minutes | Time interval at which referral information is updated |
| **SelfReferralOnly** | 0 | Setting the value to 1 prevents ADAM from providing referral information |

Values that you set on a **crossRef** object take precedence over any values that you set on the directory service object.

**Generating referrals without crossRef objects**

If a **crossRef** does not exist for the search base, ADAM determines the DNS name if the distinguished name that is presented in the request uses DNS-style (DC=) syntax. Otherwise, ADAM uses the **supref** attribute of the configuration directory partition to generate a referral to the **Superior Referral**, if one is configured. This attribute is NULL by default, and it must be configured explicitly. Otherwise, no referrals are generated.

# Understanding ADAM bind redirection

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**ADAM bind redirection**

Active Directory Application Mode (ADAM) bind redirection is designed for use primarily with legacy applications that are unable to authenticate directly against Active Directory but still need to use ADAM as the application data store. Through bind redirection, ADAM can accept a bind request from an application and redirect this bind request to Active Directory, based on the contents of a proxy object. A proxy object in ADAM represents an Active Directory security principal, and it can be augmented to store additional data related to that security principal that is specific to the application. Through bind redirection, applications can take advantage of the identity store of Active Directory without any additional overhead. For example, if an administrator disables an account in Active Directory, that account can no longer be used to bind to ADAM. In addition, applications retain the flexibility of using ADAM as an application data store.

**Proxy objects for bind redirection**

Bind redirection relies on the existence of stub, or *proxy*, objects in ADAM, each of which represents an Active Directory security principal. To implement bind redirection, you first create a proxy object schema definition to store data that is specific to your application. In this definition, you include the **msDS-bindProxy** auxiliary class. The **msds-BindProxy** class possesses a single "must contain" attribute, **ObjectSid**, which holds the security ID (SID) of the associated Active Directory security principal. You can initially populate ADAM with proxy objects representing Active Directory users through a synchronization mechanism, such as Microsoft Identity Integration Server 2003, or through the construction and importation of .ldf files into ADAM.

**Processing bind requests**

When a user sends a bind request to ADAM, ADAM does the following based on the type of request:

For simple bind requests:

- If the object class to which the user requests a bind possesses **msDS-bindableObject** as a static auxiliary class, ADAM processes the bind request directly, generating a security context that is based on the ADAM user's SID.

- If, instead, the object class to which the user requests a bind possesses the **msDS-bindProxy** as an auxiliary class, ADAM redirects the bind request to Active Directory. ADAM then generates a security context that includes the token that is returned by Active Directory in response to the redirection, along with the ADAM groups in which the principal is a member.

For simple authentication and security layer (SASL) bind requests:

- The bind request goes directly to the **AcceptSecurityContext** application programming interface (API) call. ADAM generates a security context that is based on the token that is returned from **AcceptSecurityContext**.

**Designing applications for bind redirection**

Although bind redirection is intended for preexisting, legacy applications, it can also be used with new applications. However, for new and modifiable applications, it is recommended that you write the application to use Windows security principals, rather than proxy objects, for authentication. With this type of design, you can maintain a single sign on (SSO) solution and prevent the duplication of accounts.

**New and modifiable applications**

For applications that are currently in development, and for applications that can be updated, it is recommended that you write your applications to authenticate directly against Active Directory, using Windows security principals. This type of design provides the highest degree of security, because passwords flow directly from the client to Active Directory, rather than through ADAM. ADAM can then be used simply as an application-specific data store. Proxy objects in ADAM can hold application data that is specific to each Windows security principal, and an attribute on the ADAM proxy object can be used to uniquely link each proxy object to a particular Windows security principal. A unique identifier on a Windows security principal, such as a security ID (SID) or a globally unique identifier (GUID), can be used for this linking. If your application is unable to authenticate against Active Directory, and you need to synchronize directory contents between ADAM and Active Directory, you can use a synchronization service, such as Microsoft Identity Integration Server (MIIS). However, this option introduces a delay between the originating update and the synchronization of the update.

**Legacy applications**
In some cases, you may be running already deployed, directory-enabled applications that cannot be modified. In these cases, your application may send a flat string to the directory, expecting the return of a distinguished name string with which to bind. For this scenario, the ADAM proxy object can support a unique distinguished name, and it can also contain a flag indicating that the object represents a security principal in Active Directory. Based on the presence of the flag, when a user attempts to bind to the proxy object, ADAM redirects the bind request to Active Directory, rather than processing the request locally.

**Password security**
Because bind redirection can only be used in conjunction with simple bind requests, any password that is sent to ADAM as part of a bind redirection is sent in a plaintext, unencrypted format. Therefore, it is strongly recommended that you implement bind redirection only when using an encrypted connection, for example, Secure Sockets Layer (SSL), which is the default setting in ADAM.

## Notes

- ADAM should be used to store data that is specific to a particular application, while Active Directory should be used to hold more widely used data.
- Only simple bind requests can be redirected.
- You cannot modify the password of an Active Directory security principal through a bind redirection.
- Bind direction only supports security principals from the forest to which the computer is joined or to a trusted domain or forest.
- If both **msDS-bindProxy** and **msDS-bindableObject** are specified as auxiliary classes on a single object, **msDS-bindableObject** takes precedence.

# Understanding ADAM users and groups

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Users and groups**

Active Directory Application Mode (ADAM) relies on users and groups to provide and control access to directory data. ADAM supports the simultaneous use of both Windows users and ADAM users. ADAM provides four default, role-based groups. You can create additional ADAM groups as necessary. Both Windows users and ADAM users can be members of ADAM groups. To create ADAM users in ADAM, you must first import the user object class definitions that are provided with ADAM, or you can supply your own user object definitions.

**Default groups**

ADAM provides four default, role-based groups: Administrators, Instances, Readers, and Users. These groups reside in the configuration partition and in each application partition, but not in the schema partition. Within a configuration set, ADAM replicates these groups, along with all other directory data.

The following three groups reside in the CN=Roles container of each directory partition:

- Administrators (CN=Administrators, CN=Roles)
- Readers (CN=Readers, CN=Roles)
- Users (CN=Users, CN=Roles)

The following group resides only in the CN=Roles container of the configuration directory partition:

- Instances (CN=Instances, CN=Roles)

The following table lists the default ADAM groups, along with the default members and default access assigned to each group.

| Group | Default members | Default access |
|---|---|---|
| **Administrators**<br><br>(CN=Administrators, CN=Roles) | **Configuration partition:**<br><br>ADAM administrators assigned during ADAM setup<br><br>**Application partitions:**<br><br>Administrators group from the configuration partition | Full access to all partitions |
| **Instances**<br><br>(CN=Instances, CN=Roles) | All instances | |
| **Readers**<br><br>(CN=Readers, CN=Roles) | None | Read access to the partition |
| **Users**<br><br>(CN=Users, CN=Roles) | **Configuration partition:**<br><br>Transitively, all ADAM users<br><br>**Application partitions:**<br><br>Transitively, all ADAM users created in the partition | None |

Groups from the configuration partition can be assigned permissions in any partition of an ADAM instance or configuration set. Groups from an application partition can be assigned permissions only in that application partition. Windows security principals can be assigned permissions in any application partition.

**Security principals**

The term *security principal* refers to any object that has a security identifier (SID) and that can be assigned permissions to directory objects. In ADAM, security principals can reside in ADAM, on a local computer, or in an Active Directory domain.

| **Note** |
| --- |
| You can retrieve an active user's individual and group SIDs by explicitly querying the **tokenGroups** attribute on the **rootDSE**. |

**ADAM security principals**

ADAM does not include any default security principals. However, ADAM does provide importable schema extensions that you can use to create users in ADAM. Users created from these user classes can be used as security principals. In addition, you can make any object class in the ADAM schema a security principal by adding the **msDS-bindableobject** auxiliary class and the **unicodePwd** attribute to the schema definition of an object class. Each ADAM security principal must be assigned an account and password, which ADAM uses for authentication.

For more information about authentication in ADAM, see Understanding ADAM access control. For information about the optional user classes provided with ADAM, see Administering users and groups.

**Windows security principals**

ADAM allows the use of Windows security principals for authentication and access control. Local Windows users and groups, as well as domain users and groups, can be used with ADAM. In addition, you can add Windows security principals membership to ADAM groups as members. By default, the security principal that you specify as the ADAM administrator during ADAM setup becomes a member of the Administrators group in the configuration partition. For Windows security principals, ADAM relies on the Local Security Authority (LSA) on the local computer (for local accounts) or the LSA on a domain controller (for domain accounts) for authentication.

For more information about authentication in ADAM, see Understanding ADAM access control.

# Understanding ADAM access control

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Access control**

The term *access control* describes how a directory service provides and secures access to directory data. Access control in Active Directory Application Mode (ADAM) consists of two parts. First, ADAM authenticates the identity of users requesting access to the directory, allowing only successfully authenticated users into the directory. Second, ADAM uses security descriptors, called access control lists (ACLs), on directory objects to determine to which objects an authenticated user has access.

**Authentication**

Users, or *security principals*, request directory data from ADAM through directory-enabled applications, which in turn make requests to ADAM using Lightweight Directory Access Protocol (LDAP). Before making a request for data, the directory-enabled application must present the user's credentials to ADAM for authentication, or *binding*. This request includes a user name, password, and—depending on the type of bind—a domain name or computer name.

ADAM can accept authentication, or *bind*, requests from both ADAM security principals and Windows (local and domain) security principals. ADAM security principals are authenticated directly by ADAM. Local Windows security principals are authenticated by the local computer. Domain security principals must authenticated by an Active Directory domain controller. The following table summarizes supported authentication methods in ADAM, based on the type of security principal.

| Security principal | Accepted credential formats | Authenticated by |
|---|---|---|
| ADAM | • Distinguished name<br>• Canonical name<br>• **displayName** attribute value<br>• User principal name (UPN) | ADAM instance |
| Workstation account | • Machine name\account | Local Security Authority (LSA) on the local computer |
| Domain account | • Domain name\account<br>• UPN | LSA on a domain controller from the user's domain |

| **Note** |
|---|
| A UPN that is used in ADAM does not require the use of the "@" symbol. |

The possible authentication paths in ADAM are shown in the figure below.

For more information about binding to LDAP directories, see Establishing an LDAP Session (http://go.microsoft.com/fwlink/?LinkId=99557).

**ADAM security principals**

ADAM security principals are users or other objects that are created and reside in the ADAM directory. ADAM security principals can be created based on the importable user classes (including **inetOrgPerson**) that are provided with ADAM. Or, ADAM security principals can be created from any object class in the schema that contains the **SecurityPrincipal** static auxclass and the **unicodePwd** attribute. ADAM assigns each ADAM security principal a unique security ID (SID), which is guaranteed to be unique across all ADAM naming contexts. For more information about ADAM security principals, see Understanding ADAM users and groups.

**ACLs**

Permissions on ADAM directory objects are assigned to users and groups using access control lists (ACLs). An ACL contains a list of users and groups that have been assigned permissions on a directory object, and it also contains the types of permissions (read, write, and so on) that they have been assigned. (Each individual entry in an ACL is called an access control entry (ACE).) If an ACL on a directory object does not explicitly assign permissions to a user, or to any groups that a user is a member of, the user will be denied access to that object.

For the most part, ACLs in ADAM function the same as in Active Directory. ACEs differ between ADAM and Active Directory in that ADAM validates SIDs as they are added to the ACE, while Active Directory allows all user SIDs. ADAM user SIDs are allowed only if one of the following conditions is true:

- The ADAM user is in the same naming context as the object to which the ACE is added.
- The object is in the schema naming context.
- The object is in the configuration naming context.

**Security context**

After a user has been successfully authenticated, ADAM can construct the security context for the authenticated user. This security context specifies the SID of the user, along with a list of all of the groups to which the user belongs.

The security context for an authenticated Windows security principal includes:

- The user's SID
- The user's Windows group memberships
- The user's ADAM group memberships (including those groups in which the user is a direct member and those groups in which the user is a member through recursive group expansion)

The security context for an authenticated ADAM security principal includes:

- The user's SID
- SIDs of each of the following ADAM groups:
    - Everyone
    - AuthUsers
    - Users group from the partition in which the ADAM user resides
    - Users group from the configuration partition
    - Groups in which the user is a member through recursive group expansion

By comparing an authenticated user's security context with the ACL on the directory object to which the user has requested access, ADAM can determine whether to grant the user access to the object.

**Retrieving user SIDs**
You can retrieve an active user's SIDs by explicitly querying the **tokenGroups** attribute on the **rootDSE**. The **tokenGroups** attribute is a multivalued attribute. The first value represents the user's individual SID, with the values following representing the user's ADAM and Windows group SIDs.

For more information about how access control is determined in Active Directory and ADAM, see Controlling Access to Objects in Active Directory Domain Services (http://go.microsoft.com/fwlink/?LinkId=99558).

# ADAM resources

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Resources**

Along with the Active Directory Application Mode Administrator's Guide, these additional resources can help you get the most out of your Active Directory Application Mode (ADAM) deployments.

**Microsoft Web site**

- "Understanding LDAP" (http://go.microsoft.com/fwlink/?LinkId=99559).
- "Active Directory Domain Services" at the Microsoft MSDN Web site.
- "Lightweight Directory Access Protocol" (http://go.microsoft.com/fwlink/?LinkId=99560).
- For information about installing the latest service packs or hot fixes, see Windows Update at the Microsoft Web site. Also, see Using Windows Update.
- For information about binding to Lightweight Directory Access Protocol (LDAP) directories, see "Establishing an LDAP Session" (http://go.microsoft.com/fwlink/?LinkID=99557).
- For information about access in Active Directory—and in ADAM, see "Controlling Access to Active Directory Objects in Active Directory Domain Services" (http://go.microsoft.com/fwlink/?LinkId=99558).
- For information about the Active Directory schema, see "Active Directory Schema" at the Microsoft MSDN Web site.
- For information about developing directory-enabled applications, see "Design Guide for Directory-Enabled Applications" (http://go.microsoft.com/fwlink/?LinkId=99561).
- For information about role-based authorization in Windows Server 2003, see "Dynamic Groups in Windows Server 2003 Authorization Manager" (http://go.microsoft.com/fwlink/?LinkId=99562).
- For information about setting up and using certificate services, see "Certificate Services How To" at the Microsoft TechNet Web site.

**Other Resources**

- RFC 2849: The LDAP Data Interchange Format (LDIF)—Technical Specification at the Internet Engineering Task Force (IETF) FTP site (http://go.microsoft.com/fwlink/?LinkId=63904)
- RFC 3377: Lightweight Directory Access Protocol (v3): Technical Specification at the Internet Engineering Task Force (IETF) FTP site (http://go.microsoft.com/fwlink/?LinkId=63908)

# Administering ADAM

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Administering ADAM**

- Using ADAM administration tools
- Administering computers running ADAM
- Running ADAM on Windows XP Professional
- Administering an ADAM instance
- Administering directory partitions
- Administering sites
- Administering replication and configuration sets
- Administering ADAM service publication
- Administering ADAM service principal names
- Administering the ADAM schema
- Administering users and groups
- Administering access control
- Backing up and restoring ADAM
- Selecting an ADAM service account

# Using ADAM administration tools

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Using ADAM administration tools**

Active Directory Application Mode (ADAM) comes with several administration tools. The ADAM Setup Wizard installs ADAM administration tools when you install a new ADAM instance. In addition, you can use the ADAM Setup Wizard to install the ADAM administration tools only, without installing a new ADAM instance. For more information, see Selecting components to install.

To open a command prompt from which to run ADAM administration tools, click **Start**, click **All Programs**, point to **ADAM**, and then click **ADAM Tools Command Prompt**.

The following table describes ADAM administration tools and their purpose.

| Tool | Purpose |
|---|---|
| ADAM ADSI Edit | Microsoft Management Console (MMC) snap-in for general ADAM administration, including replication scheduling. |
| ADAM Schema | MMC snap-in for administration of the ADAM schema. |
| Adamsetup | Command that launches the ADAM Setup Wizard and, through command-line parameters, that can be used to perform unattended ADAM installs. |
| Csvde | Command-line tool for importing and exporting directory contents, such as schema definitions and directory objects, that are stored as comma-separated value (.csv) files. |
| Dsmgmt | Command-line tool for general ADAM administration. |
| Dsacls | Command-line tool for displaying and changing permissions (access control entries (ACEs)) in the access control list (ACL) of objects in ADAM. |
| Dsdbutil | Command-line tool for managing ADAM database (.dit) files. |
| Dsdiag | Command-line tool for general ADAM monitoring. |
| Ldifde | Command-line tool for importing and exporting directory contents, such as schema definitions and directory objects, that are stored as LDAP Data Interchange Format (LDIF) files. |
| Ldp | Graphical user interface (GUI) tool for general administration of a Lightweight Directory Access Protocol (LDAP) directory service. |
| Repadmin | Command-line tool for monitoring replication. |

For information about how to use the ADAM ADSI Edit snap-in, see Connect and bind to an ADAM instance using ADAM ADSI Edit and Browse the directory tree using ADAM ADSI Edit.

For information about how to use Ldp, see Connect and bind to an ADAM instance using Ldp.exe and Browse the directory tree using Ldp.exe.

For more information about ADAM administration tools, see ADAM Administration Tools.

# Administering computers running ADAM

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Administering computers running ADAM**

Directory clients locate an Active Directory Application Mode (ADAM) instance using the name or Internet Protocol (IP) address of the computer running ADAM and the communications port in use by the ADAM instance. In addition, in Active Directory environments, clients can locate ADAM instances through service connection points (SCPs) that are published in Active Directory. Modifying the computer name, Domain Name System (DNS) name, network basic input/output system (NetBIOS) name, or IP address of a computer on which an ADAM instance is running may affect the directory clients' ability to locate that ADAM instance.

| **Note** |
| --- |
| ADAM can be installed on computers running Windows Server 2003 or Windows XP Professional. For considerations when running ADAM on Windows XP Professional, see Running ADAM on Windows XP Professional. |

**Locating ADAM instances**

For a directory-enabled application to communicate with an ADAM instance, the application must specify the NetBIOS name, DNS name, or IP address of the computer on which ADAM is running. In addition, the application must specify the Lightweight Directory Access Protocol (LDAP) or Secure Sockets Layer (SSL) communication port being used by the ADAM instance. For example, a directory-enabled application referencing an ADAM instance running on a computer with a DNS name of ADAMSrv1.microsoft.com—with a NetBIOS name of ADAMSrv and an IP address of 192.168.0.1 and using communication port 389 for LDAP connections—can address the ADAM instance using one of the following:

- ADAMSrv1.microsoft.com:389
- ADAMSrv:389
- 192.168.0.1:389

**Locating ADAM instances in Active Directory environments**

When you run ADAM in an Active Directory environment, each ADAM instance creates and maintains SCP objects about itself in Active Directory. For more information, see Administering ADAM service publication.

**Server object names**

By default, the relative distinguished name of a server object in ADAM is *servername*$*instancename*, where *servername* represents the computer on which the ADAM instance is running and *instancename* represents the service name of the ADAM instance.

**Modifying settings on a computer running ADAM**

You initially specify the computer name, DNS name, NetBIOS name, and IP address when you set up the computer. You initially specify the communication port numbers used by a given ADAM instance when you install the ADAM instance.

You can change these settings on a computer running ADAM at any time. However, when you update any of these settings, you may also need to reconfigure directory-enabled applications to properly address the ADAM instance. For example, if the host name of the computer on which ADAM is running changes, your directory-enabled application may need to be updated accordingly.

# Running ADAM on Windows XP Professional

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Running ADAM on Windows XP Professional**
In addition to running Active Directory Application Mode (ADAM) on domain controllers, member servers, or workgroup servers running Windows Server 2003, you can also run ADAM on computers running Windows XP Professional. Running ADAM on Windows XP Professional introduces some functional considerations, as described in this topic.

**Using ADAM on Windows XP Professional as a personal data store**
For use on computers running Windows XP Professional, ADAM has been designed primarily as a personal data store. It is recommended that you run ADAM on Windows Server 2003 if you need scalability to support a growing number of simultaneously connected clients or if you intend to use ADAM on a centralized directory server.

**Running ADAM on Windows XP Professional in a workgroup**
When you install ADAM on a computer running Windows XP Professional that is joined to a workgroup, you must set the registry key **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\forceguest** to 0. (The default is 1.) Otherwise, users connecting to ADAM over the network are forced to a security context of Guest, and binds to ADAM fail. For more information, see Enable binding to ADAM instances running on Windows XP Professional computers joined to a workgroup.

**Summary of functional considerations when running ADAM on Windows XP Professional**
The following table summarizes all other functional considerations related to running ADAM on Windows XP Professional.

| ADAM feature | Windows Server 2003 | Windows XP Professional |
|---|---|---|
| Support for multiple processors | Supported. | Not supported. When multiple-processor computers are present, ADAM uses only one process at a time to prevent resource monopolization. |
| Maximum cache value | No limit. | Limited to one half of physical RAM. |
| Data and log file locations | Data and log files can reside on different drives. | Data and log files must reside on the same drive. |
| Password policies | Supported. | Not supported. |
| Auditing | Supported. For more information, see Administering an ADAM instance. | Not supported. |
| ADAM service account requirements | See Selecting an ADAM service account. | See Selecting an ADAM service account. |
| Stopping and restarting an ADAM instance | An ADAM instance can be stopped and then restarted immediately. | If a Lightweight Directory Access Protocol (LDAP) client is connected when you shut down the ADAM instance, you may need to wait as long as two minutes before restarting the ADAM instance. This time is required to allow any existing connections to clear. |
| Backing up ADAM | Multiple ADAM instances running on the same computer can be backed up simultaneously. | For computers running multiple ADAM instances, only one ADAM instance can be backed up at a time. |

| | | |
|---|---|---|
| Full ADSI functionality | No hotfixes are required. | For complete Active Directory Service Interfaces (ADSI) functionality with Windows XP Professional, you must install hotfix 817583. For more information about this hotfix, see article 817583 in the Microsoft Knowledge Base. |

For information about general ADAM requirements, see ADAM requirements.

# Administering an ADAM instance

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Administering an ADAM instance**

Each ADAM instance runs as an independent, and separately administered, service on a computer. You can configure the account under which an ADAM instance runs, stop and restart an ADAM instance, and change the ADAM instance service display name and service description. In addition, you can enable Secure Sockets Layer (SSL) connections in ADAM by installing certificates. In Active Directory environments, each ADAM instance attempts to register a service principal name (SPN) in the directory on the account object that corresponds to the service account on which the ADAM instance is running (or, in the case of the ADAM instance running as the Network Service account, on the computer object corresponding to the computer on which the ADAM instance is running). This SPN is used for replication authentication. Depending on the network environment into which you install ADAM, you may have to create SPNs manually.

For information about tasks related to ADAM instances, see Manage an ADAM Instance. For information about SPNs, see Administering ADAM service principal names.

**ADAM service account**

The service account that is used by an ADAM instance determines the access that the ADAM instance has on the local computer and on other computers in the network. ADAM instances also use the service account to authenticate other ADAM instances in their configuration set, to ensure replication security. You determine the ADAM service account during ADAM installation. For information about ADAM service account requirements, see Selecting an ADAM service account.

To modify the ADAM service account for an ADAM instance, you can use the **change service account** command within the **Dsdbutil** command line tool. For more information, see Dsdbutil.

In addition, you may need to assign the **Log on as a service** right to the account that you specify as the ADAM service account. For more information, see Add the Log on as a service right to an account.

To enable auditing for an ADAM instance for which the service account is something other than the Network Service account, you must assign the **Generate security audits** right to the ADAM service account.

**ADAM instance name**

During setup, you assign a name to the ADAM instance, which is used in the creation of the file directory structure and registry keys for ADAM. In addition, the name that you assign is used to create the service name, service display name, and service description, as shown in the example in the following table.

| Name supplied during setup | Service name | Service display name | Service description |
|---|---|---|---|
| instance1 | ADAM_instance1 | instance1 | Blank (No default description provided.) |

The name that you specify for an ADAM instance during setup must meet the following requirements:

- It must be unique with respect to other ADAM instances running on the same computer.
- It must be no longer than 44 characters.
- It must use characters only from the ranges of a through z, A through Z, or 0 through 9.
- The name "ntds" cannot be used.

The service display name appears in Add or Remove Programs and in the Services snap-in. The service description appears in the Services snap-in. You can modify the service display name and the service description at any time after installation.

For information about modifying the service display name, see View or modify the service display name of an ADAM instance. For information about modifying the service description, see View or modify the service description of an ADAM instance.

**Starting and stopping an ADAM instance**

The service for an ADAM instance can be stopped and restarted independently, without restarting the computer on which ADAM is running. In addition, the service for an ADAM instance can be configured to start either automatically or manually, and it can also be disabled.

For information about stopping and starting ADAM, see Start, stop, pause, resume, or restart an ADAM instance. For information about assigning the **Log on as a service** right, see Add the Log on as a service right to an account.

| **Note** |
| --- |
| When you run ADAM on a computer running Windows XP Professional, you may need to wait up to two minutes after stopping an ADAM instance before restarting the instance. ADAM requires this time to close any existing connections. |

#### Event logs and auditing

Each ADAM instance running on a computer writes events to a separate event log. The ADAM event log, which has a display name that matches the name of the ADAM instance, can be viewed in Event Viewer.

To enable auditing for an ADAM instance running under a service account other than the Network Service account, you must grant the **Generate security audits** right to the ADAM service account.

To enable replication auditing for an ADAM instance, you must modify the registry key:

**HKLM\System\CurrentControlSet\Services\instance_name\Parameters**

where *instance_name* represents the name of the ADAM instance on which you want to audit replication. The following table describes the values in the registry key that control replication auditing. To enable replication auditing, set one or both of the values to 1.

| Registry key value | Data type | Meaning |
| --- | --- | --- |
| **Audit Access in Replication** | DWORD | Provides a summary of the replication operations that are occurring. |
| **Audit Objects in Replication** | DWORD | Audits the changes to individual objects and attributes. |

| **Note** |
| --- |
| ADAM also creates setup and uninstall logs in the *%systemroot%*\debug directory. These log files are called Adamsetup.log and Adamuninstall.log. |

#### Using certificates with ADAM

To enable Secure Sockets Layer (SSL) connections to ADAM, you must have certificates installed on the computer running ADAM and also on the clients connecting to ADAM. You can obtain certificates from a trusted certification authority (CA). Or, for internal use, you can issue certificates from your own internal CA, by installing and using certificate services on Windows 2000 Server or Windows Server 2003.

For information about setting up and using certificate services, see "Certificate Services" on the Microsoft TechNet Web site.

In addition, on computers running Windows XP Professional that need to establish SSL connections to an ADAM instance, you must install the hotfix described in article 817583 in the Microsoft Knowledge Base Web site.

| **Note** |
| --- |
| When using certificates with ADAM, you must assign the ADAM service account read access to the certificates that are installed on the computer where the ADAM instance is running. The certificate store is located in the following directory: Documents and Settings\All Users\Application Data\Microsoft\Crypto\RSA\MachineKeys. |

# Administering directory partitions

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Administering directory partitions**

Three types of directory partition exist in Active Directory Application Mode (ADAM): configuration, schema, and application. Configuration and schema directory partitions are created automatically during installation. Application directory partitions can be created either during or after installation. Every ADAM directory partition has a unique distinguished name. Distinguished names for directory partitions in ADAM support both Domain Naming System (DNS)-style and X.500-style naming. An ADAM instance does not specify a naming context by default, but it can be configured to provide a default naming context to clients. ADAM configuration and schema directory partitions can be viewed and managed using ADAM administration tools, which are installed during ADAM setup. Application directory partitions are typically managed through directory-enabled applications.

For information about tasks related to directory partitions, see Manage Schemas and Directory Partitions. For more information about types of directory partitions, see Understanding ADAM data and data stores.

**Creating directory partitions**

The schema and configuration directory partitions are created automatically during installation of an ADAM instance. (Configuration and schema partitions can only be created during ADAM installation.) If you choose to join the ADAM instance being installed to an existing configuration set, the schema and configuration directory partitions from an ADAM instance in the configuration set are replicated to the new instance. If you install a new ADAM instance, the installation process creates default versions of the schema and configuration directory partitions for you. If you install an ADAM instance from media, the schema and configuration directory partitions for the new ADAM instance are replicas of the directory partitions from the media.

When you install a new ADAM instance, you can also choose to replicate one or more application directory partitions from an existing ADAM instance. Or, you can specify the creation of a new application partition. When you create a new application directory partition during installation, you must specify a unique distinguished name for the partition. The new application directory partition consists only of a partition container object with the distinguished name that you specify.

**Naming directory partitions**

Each ADAM directory partition has its own, unique distinguished name. ADAM supports both DNS-style and X.500-style names for top-level directory partitions, including the distinguished name components that are listed in the following table.

| Distinguished name attribute | Meaning |
|---|---|
| C= | Country/region |
| CN= | Common name |
| DC= | Domain component |
| L= | Location |
| O= | Organization |
| OU= | Organizational unit |

**Specifying a default naming context**

By default, an ADAM instance does not provide a default naming context. You can, however, configure ADAM to provide a default naming context, by specifying a value for the **msDS-defaultNamingContext** attribute on the **NTDSA** object, at:

This **msDS-defaultNamingContext** attribute contains no value by default. If a value is set in the attribute, that value is returned to a client through the **defaultNamingContext** attribute of the **rootDse** object when the **rootDse** object is read.

When a bind is requested on the **rootDSE** object, ADAM returns the value of **defaultNamingContext**, if the **msDS-defaultNamingContext** attribute on the **NTDSA** object is set to the distinguished name of a top-level container of an instantiated naming context. Otherwise, no value is returned.

**Importing and exporting directory objects**

You can use a number of methods to import and export directory objects, both to and from the schema directory partition, as well as to and from application directory partitions. You can use the **ldifde** command-line tool to import and export .ldf files.

You can use the **csvde** command-line tool to import and export .csv (comma-delimited) files. For more information, see Import or export directory objects using ldifde and Import or export directory objects using csvde.

**Administering application directory partitions**

You can create an application directory partition during setup. You can also create application directory partitions at any time after installation, either through ADAM administration tools or through your directory-enabled application. In production environments, you typically manage your application directory partitions and the data that they contain through your directory-enabled applications.

For information about creating application directory partitions, see Add an application directory partition.

# Administering sites

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Administering sites**

You can optimize the replication efficiency and reduce the administrative overhead of your network by establishing sites appropriately. The most effective number of sites depends on the physical design of your network. When you first create a new configuration set for Active Directory Application Mode (ADAM), a single, default site (called Default-First-Site-Name) is created that represents your entire network. A single site can be very efficient for a single location network that is completely connected by high-speed bandwidth. If your network contains multiple geographic locations that communicate over low-speed, wide area network (WAN) connections, establishing multiple sites gives you more detailed control of replication behavior, and it reduces network traffic on the WAN that connects the sites. You can administer site objects and site link objects through ADAM ADSI Edit.

For information about sites, see Understanding ADAM sites. For information about tasks related to sites, see Manage Replication, Sites, and Configuration Sets.

**Bandwidth as an important consideration**

Within a site, bandwidth affects how efficiently replication can work. The frequency with which intrasite replication occurs requires high-speed bandwidth to function most effectively. Before you create a new site, make sure that high-speed bandwidth connects all computers in the site candidate. Any area where domain controllers are connected by 10 megabits per second (Mbps) or more of bandwidth is a good site candidate.

**When to establish a single site**

If you have a single local area network (LAN) consisting of a single location, or if your network consists of a series of closely located locations (as in a campus), in which all locations are connected by a high-speed backbone, using the default site as the single site in replication topology can simplify replication management. In a single-site topology, all replication on your network occurs as intrasite replication, which requires no manual replication configuration. In a single-site design, all ADAM instances also remain very current with respect to directory changes, because directory updates are replicated almost immediately.

**When to establish multiple sites**

When your network consists of multiple geographic locations connected by a WAN, establishing separate sites for each location provides the following benefits:

- Efficient use of WAN bandwidth for replication
- Detailed control of replication behavior

Physically separate network locations typically communicate over WAN connections, which are most often characterized by low-speed bandwidth. By creating a separate site for each physical location on your network, you ensure that ADAM instances communicating over WAN connections use intersite replication, which is specifically designed for efficiency over low-bandwidth connections. When you create a site object, you also need to create a servers container within the site object. To move an ADAM instance to a new site object, you move the ADAM instance into the servers container of the site. For more information, see Add a site object and servers container and Move an ADAM instance to a site object.

Site link objects represent the network links between the sites on your network. When you create a new site object in ADAM, add the site object to a site link object. Until you add the new site to a site link object, any ADAM instances in the site will not be able to replicate to ADAM instances outside the site. You can add a new site object to the default site link object. Or, you can create additional site link objects, giving you more detailed control over the relative cost of replication over different WAN connections on your network.

With multiple sites, you have more detailed control of replication behavior through configurable intersite replication settings. These settings include the relative cost of different replication paths and the availability of connections for use by replication. For more information, see Configure replication availability on a site link and Set the cost on a site link object.

# Administering replication and configuration sets

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Administering replication and configuration sets**
In Active Directory Application Mode (ADAM), replication within a site occurs automatically, and it does not require any configuration beyond the construction of configuration sets. For replication between sites, you can specify a schedule for replication. For example, you may want replication to occur only during the night, when your network is not busy. If the ADAM instance replication partners do not all belong to Active Directory domains, you must use identical local service account names and passwords to enable replication.

### Notes

- You can only join an ADAM instance to a configuration set using the ADAM Setup Wizard or during an unattended ADAM installation. After an ADAM instance is installed, it cannot be joined to a configuration set.
- ADAM does not support replication using Simple Mail Transfer Protocol (SMTP).

**Scheduling replication**
For replication between ADAM instances within a site, you can schedule the amount of time that elapses after the last change notification before a default replication event occurs. For more information, see Configure replication frequency within a site.

For replication between ADAM instances in different sites, you can schedule the availability of the site link that exists between the two sites. For more information, see Configure replication availability on a site link.

For more information about replication within and between sites, see Understanding ADAM sites and replication.

**Authenticating ADAM replication partners**
Considerations for replication authentication in ADAM include the authentication level of the configuration set, which is determined by the domain, forest, or workgroup environment, and the service accounts that are in use by the ADAM instances in the configuration set. For information about authentication levels, see Understanding ADAM replication and configuration sets. For information about service account requirements, see Selecting an ADAM service account.

**Operations master roles**
Each ADAM instance belonging to a given configuration set operates with equal authority. However, certain activities that are performed with a given configuration set should only be performed by a single ADAM instance. These activities include schema management, to prevent conflicting schema changes, and instance naming management, to prevent conflicting directory partition names. The ADAM instances that are responsible for these activities are called, respectively, the schema master and the naming master. ADAM assigns these roles automatically. You can also reassign these roles, as may be required, for example, if an ADAM instance that holds one of the operations master roles stops responding or goes offline. For information about reassigning operations master roles, see Identify or transfer the schema master role and Identify or transfer the naming master role.

**Schema master**
The schema master instance controls all updates and modifications to the schema within a given configuration set. To update the schema, you must be a member of the ADAM Administrators group on the configuration set. You must also be able to connect successfully to the schema master. Each configuration set can contain only one schema master.

**Naming master**
The ADAM instance that holds the naming master role controls the addition and removal of directory partitions, or *naming contexts*, in a given configuration set. Each configuration set can contain only one naming master.

# Administering ADAM service publication

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Administering ADAM service publication**
In Active Directory environments, Active Directory Application Mode (ADAM) uses service connection point (SCP) objects to publish ADAM service information in the Active Directory directory store. Considerations for administering ADAM SCP objects include the following:

- Manually creating SCPs when necessary
- Removing SCP objects when necessary
- Modifying permissions on SCP objects when necessary
- Checking the ADAM event log for SCP errors

**Creating SCPs**
By default in Active Directory environments, the ADAM service creates SCPs in Active Directory when the ADAM service starts. To successfully create SCPs, the ADAM service account must have sufficient rights in Active Directory. If SCP creation fails, ADAM writes an event to the ADAM event log regarding the failure.

### Notes

- The default location for the ADAM SCP object is under the computer object that represents the computer on which ADAM is running. This default location can be altered by specifying a different location on the **SCPPublishingService** object.
- When it is used as the ADAM service account on a computer that is joined to a domain, the Network Service account usually has sufficient rights to create SCPs in Active Directory. However, when it is used on an ADAM instance running on a domain controller, the Network Service account does not have sufficient rights to create SCPs in Active Directory.

**Removing SCPs**
An ADAM instance deletes its SCP from Active Directory when you remove the ADAM instance from the computer. Removing the SCP requires sufficient administrative privileges. If SCP removal fails, client applications may be directed to a nonexistent ADAM instance.

**Modifying SCPs**
An ADAM instance checks and updates, if necessary, its SCP each time the ADAM instance starts. At startup, the ADAM instance searches the global catalog for its own globally unique identifier (GUID) and retrieves the distinguished name of the SCP object. The ADAM instance then binds to that distinguished name and updates the SCP object as necessary. In addition, the ADAM instance reviews the SCP object on an hourly basis by default to confirm its validity, particularly regarding any directory partitions that have been added to or removed from the ADAM instance since the SCP object was last updated.

| **Note** |
| --- |
| You can modify the default time interval at which ADAM reviews the SCP object, by adding a value named **Server information update interval (mins)** to the registry key: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services*instancename*\Parameters, and setting this value to the time interval (in minutes) that you want to use. |

For more information about publishing and using SCPs, see "About Service Publication" on the MSDN Web site at http://go.microsoft.com/fwlink/?LinkId=48288.

**Managing ADAM SCPs**
One efficient way to manage SCPs for ADAM is to create an SCP container for your ADAM configuration set in Active Directory. In this container, place the computer objects of the computers on which ADAM instances are running. In addition, create a group called, for example, "ADAM instances," and assign permissions on the SCP container to the group. Also, delegate control

of the group to the assigned ADAM administrator. Then, each time the ADAM administrator installs a new ADAM instance under a new service account, the ADAM administrator can simply add the new service account to the "ADAM instances" group, and the ADAM instance creates and maintains its SCPs transparently.

**Checking the ADAM event log**

SCP-related errors do not prevent an ADAM instance from functioning properly. ADAM does, however, report SCP-related errors in the ADAM event log so that errors can be resolved. ADAM reports SCP-related errors as follows:

- When an SCP creation or update fails, the ADAM instance reports the error and points to a .ldf file that can be used to manually resolve the problem. Using this .ldf file to create or update the SCPs requires administrator privileges in Active Directory.

- When ADAM fails to remove an SCP object, ADAM reports this failure both in the audit log of the appropriate domain controller and in the ADAM event log.

# Administering ADAM service principal names

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Administering ADAM service principal names**
When they run in an Active Directory domain or forest, Active Directory Application Mode (ADAM) instances attempt to register service principal names (SPNs) in Active Directory for use in Kerberos authentication during replication. Each ADAM instance—the first time that the instance starts—attempts to register values to the **Service-Principal-Name** attribute on the account object that represents the service account in use by the ADAM instance. Or, if the ADAM instance uses the Network Service account as the ADAM service account, the ADAM instance attempts to register values to the **Service-Principal-Name** attribute on the computer object that represents the computer on which the ADAM instance is running. The values that the ADAM instance attempts to register include the following:

- E3514235-4B06-11D1-AB04-00C04FC2DCD2-ADAM/netbiosname:port
- E3514235-4B06-11D1-AB04-00C04FC2DCD2-ADAM/dnshostname:port
- Ldap/netbiosname:port
- Ldap/dnshostname:port

In addition, if the ADAM instance uses a reserved communications port (LDAP_PORT, LDAP_GC_PORT, LDAP_SSL_PORT, or LDAP_SSL_GC_PORT), the instance attempts the following SPN registrations:

- Ldap/netbiosname
- Ldap/dnshostname

Wldap32.dll does not use a port-formatted SPN to establish a connection to an ADAM instance using a reserved port. For example, if ADAM instance1 on machine1 uses port 3268 for LDAP, the SPN that Wldap32.dll creates for the connection is ldap\machine1. However, if ADAM instance2 on machine2 uses port 1026 for LDAP, the SPN that Wldap32.dll creates for the connection is ldap\machine2:1026.

| **Note** |
| --- |
| When multiple ADAM instances are running on a single computer, and two or more of the instances each use a reserved port, those ADAM instances must run under the same ADAM service account for the SPNs to be registered correctly. |

SPN registration attempts occur in the security context of the ADAM service account. If the ADAM service account that you specify is not the Network Service account, or if it is a domain user account that does not belong to the Domain Administrators group, this SPN registration fails. ADAM reports this failure as event ID 2516 in the event log for the ADAM instance. If this failure occurs, ADAM setup also reports event ID 2535, which describes how to register the SPNs for ADAM manually.

To register SPNs for ADAM manually in Active Directory, use the *dnsdomainname*.bat script file that ADAM setup creates in the data directory of the ADAM instance (Program Files\Microsoft ADAM*instancename*\data), where *dnsdomainname* represents the name of the DNS domain in which the ADAM instance resides.

**Notes**

- The *.bat file shows up in the directory about one minute after ADAM installation completes.
- The *.bat file contains **repadmin /writespn** commands, similar to the following:

```
repadmin.exe /writespn hostname.microsoft.com
ADD "CN=adam,CN=Users,DC=microsoft,DC=com"
```

```
E3514235-4B06-11D1-AB04-00C04FC2DCD2-ADAM/netbioshostname:389

repadmin.exe /writespn hostname.microsoft.com
ADD "CN=adam,CN=Users,DC=microsoft,DC=com"
E3514235-4B06-11D1-AB04-00C04FC2DCD2-ADAM/dnshostname:389

repadmin.exe /writespn hostname.microsoft.com
ADD "CN=adam,CN=Users,DC=microsoft,DC=com" ldap/netbioshostname:389

repadmin.exe /writespn hostname.microsoft.com
ADD "CN=adam,CN=Users,DC=microsoft,DC=com" ldap/dnshostname:389
```

This script registers the appropriate SPNs in Active Directory, and it must be run by a member of the Domain Administrators group in the domain.

| **Note** |
| --- |
| When SPNs for ADAM instances in a configuration are registered in Active Directory, ADAM replication authentication uses Kerberos. Otherwise, ADAM uses negotiated replication authentication. For more information about replication authentication, see Understanding ADAM replication and configuration sets. |

**Removing ADAM SPNs from Active Directory**

When you remove an ADAM instance, make sure that its associated SPNs are also removed from Active Directory. These SPNs reside on the computer object of the computer where the ADAM instance is installed (if the Network Service account is specified for the ADAM service account) or on the domain user object (if a domain user account is specified for the ADAM service account).

**Forcing the use of SPNs in an Active Directory environment**

To force the use of SPNs and Kerberos for replication authentication in a a configuration set, you can modify the replication security level of the configuration set to equal 2. For more information, see Modify the replication security level of a configuration set.

| **Caution** |
| --- |
| If you set replication security level equal to 2, and SPNs are not registered or properly configured, replication will fail. |

# Administering the ADAM schema

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Administering the ADAM schema**
You can administer the Active Directory Application Mode (ADAM) schema in a number of ways, including extending the schema with new classes and attributes, deactivating classes and attributes, and reactivating classes and attributes. You can use the ADAM Schema snap-in to administer the ADAM schema.

For information about tasks related to administering the schema, see Manage Schemas and Directory Partitions.

**Extending the schema**
Before you can use ADAM to support a particular directory-enabled application, you may need to modify the ADAM schema with classes and attributes that are required by that application. You can easily modify the ADAM schema by using a number of methods, including:

- Automatically, through a directory-enabled application.
- Semiautomatically, using Ldifde.exe and the importation of .ldf files.
- Programmatically, through Active Directory Service Interfaces (ADSI).
- Manually, through Ldp and the ADAM Schema snap-in.

| **Note** |
| --- |
| Before you can use the ADAM Schema snap-in, you must first install it. For more information, see Install the ADAM Schema snap-in. |

For environments that require the ability to create users in the ADAM directory, ADAM includes an importable .ldf file that contains four user object classes. For information about importing the ADAM user .ldf file, see Import the user classes supplied with ADAM.

**Deactivating classes and attributes**
Before deactivating a class, consider the following:

- You can deactivate a class only if that class is not specified as a **subClassOf**, **auxiliaryClass**, **systemAuxiliaryClass**, **possSuperiors**, or **systemPossSuperiors** of any existing active class.
- You cannot use a defunct class in definitions of new classes, and you cannot add a defunct class to existing class definitions.
- You cannot create objects that are instances of a defunct class or modify existing instances of a defunct class. However, the instances of the defunct class become available again for modification when the defunct class is reactivated.

Before deactivating an attribute, consider the following:

- You can deactivate an attribute only if the attribute is not specified as a **systemMustContain**, **mustContain**, **systemMayContain**, **mayContain**, or **rdnAttId** of any existing active class.
- You cannot use a defunct attribute in definitions of new classes, and you cannot add a defunct attribute to existing class definitions.
- You cannot read, modify, or delete instances of a defunct attribute that are present in existing objects. However, the instances of the defunct attribute become available when the defunct attribute is reactivated.

- To purge the directory of instances of an attribute, you must delete the instances before deactivating the attribute.

# Administering users and groups

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Administering users and groups**

You can administer users and groups in Active Directory Application Mode (ADAM) through the ADAM ADSI Edit snap-in or through your directory-enabled applications. For information about how to perform tasks related to users and groups in ADAM, see Manage Users and Groups.

**ADAM users**

To create users in ADAM, you must first import the optional user classes that are provided with ADAM into the ADAM schema. These user classes are provided in importable .ldf files (ms-User.ldf, ms-InetOrgPerson.ldf, ms-UserProxy.ldf), which you can find in the directory %windir%\adam on the computer where ADAM is installed. The following table describes the contents of each of the optional .ldf files.

| .ldf file | User classes | Import this file if ... |
|---|---|---|
| ms-user.ldf | • **Person**<br>• **Organizational-Person**<br>• **User** | You want to create user objects in the ADAM directory, but you do not want to create users of the **inetOrgPerson** class (as defined in RFC 2798). |
| ms-inetorgperson.ldf | • **Person**<br>• **Organizational-Person**<br>• **User**<br>• **inetOrgPerson** | You want to create user objects in the ADAM directory, and you want to create users of the **inetOrgPerson** class (as defined in RFC 2798). |
| ms-userproxy.ldf | • **User-Proxy** | You want to create proxy objects in ADAM for use in bind redirection. For more information about proxy objects and bind redirection, see Understanding ADAM bind redirection. |

For information about the schema definitions for each of the user object classes, see "Active Directory Schema" on the Microsoft MSDN Web site.

For more information about importing user classes, see Import the user classes supplied with ADAM. For information about creating ADAM users, see Add an ADAM user to the directory.

You can also disable ADAM users. For more information about disabling ADAM users, see Disable or enable an ADAM user.

**Setting and modifying passwords**

You can set and modify passwords for ADAM security principals over Secure Sockets Layer (SSL) connections (using Ldp.exe) or over encrypted, non-SSL connections (using ADAM ADSI Edit or Ldp.exe). To establish an SSL connection to ADAM, you must install certificates on the computer running ADAM and on all the clients. For more information about certificates, see Administering an ADAM instance. To make SSL connections to an ADAM instance, you must use Ldp.exe; ADAM ADSI Edit does not support SSL connections.

For information about setting and modifying passwords, see Set or modify the password of an ADAM user.

| **Note** |
|---|
| On computers running Windows XP Professional that need to establish SSL connections to an ADAM instance, you must install the hotfix described in article 817583 in the Microsoft Knowledge Base. |

By default, an ADAM instance running on Windows Server 2003 automatically enforces any local or domain password policies that exist. If you create a new ADAM user, and if you assign a password to that user that does not meet the requirements of the password policy that is in effect, the user will be disabled.

**Password policy settings and account lockouts**
When ADAM runs on a computer running Windows Server 2003, it supports and enforces the password policy settings and account lockout settings that are provided by Windows Server 2003, including the following:

- Minimum age
- Maximum age
- Complexity
- History
- Too many failed logon attempts
- Disabling and enabling of accounts

If the server on which ADAM is running belongs to a workgroup, the server's local password policy settings and account lockout settings are implemented. If the server on which ADAM is running belongs to a domain, the password policy settings and account lockout settings from Active Directory are implemented. Password policy settings are not enforced on ADAM instances that run on a computer running Windows XP Professional.

You can disable the enforcement of password policy settings in ADAM by setting **ADAMDisablePasswordPolicies**, a value in the attribute **msDS-Other-Settings** on CN=Directory Service,CN=Windows NT,CN=Services,CN=Configuration,CN=GUID, to 1.

For more information about password policy settings and account lockout settings in Windows Server 2003, see Help and Support Center in Windows Server 2003.

**ADAM groups**
In addition to the four role-based groups that are provided by default in each directory partition in ADAM, you can add your own groups. You can add both ADAM users and Windows users to the ADAM groups that you create.

For more information, see Add an ADAM group to the directory and Add or remove members to or from an ADAM group.

| **Note** |
| --- |
| In ADAM, it is possible for an ADAM administrator, or for a user with sufficient access to the Administrators group, to remove member accounts from the ADAM Administrators group, possibly leaving ADAM without any valid administrators. To recover from this scenario, the assigned ADAM administrator, as the owner of the Administrators group, can repopulate the ADAM Administrators group with the appropriate accounts. |

**Organizing ADAM users and groups with organizational units**
To keep your ADAM users and groups organized, you may want to place users and groups in organizational units (OUs). In Active Directory and in ADAM, as well as in other Lightweight Directory Access Protocol (LDAP)-based directories, OUs are the most commonly used method for keeping users and groups organized. For information about creating OUs in ADAM, see Add an organizational unit to the directory.

| **Note** |
| --- |
| By default, OUs can only be added under other OU (OU=), country/region (C=), organization (O=), or domain-DNS (DC=) object classes. For example, you can add an OU to O=Microsoft,C=US. You cannot add an OU to CN=test,O=Microsoft,C=US. You can, however, update the schema definition of the OU object class to allow other superiors. |

# Administering access control

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Administering access control**

You can govern access control in Active Directory Application Mode (ADAM) at the directory partition level by assigning users memberships to the role-based groups that are located on each partition. You can customize access control in ADAM on an object-by-object basis using the **dsacls** command-line tool. Other considerations for administering access control in ADAM include the assignment of permissions to Windows security principals and the best practice of avoiding the assignment of permissions to built-in security principals.

For more information about the **dsacls** command-line tool, see Dsacls.

**Default ACLs**

By default, ADAM provides access control list (ACL) settings on each directory partition. Also by default, all objects on a given partition inherit these default ACLs. To customize access control, you can:

- Modify the default ACLs on the partition objects.
- Set new ACLs on individual objects.
- Change inheritance settings on individual objects.

For a table describing the default access that is provided to each of the default ADAM groups, see Understanding ADAM users and groups.

For information about viewing and setting object permissions, see View or set permissions on a directory object.

| **Note** |
| --- |
| In ADAM, it is possible for an ADAM administrator, or for a user with sufficient access to the Administrators group, to remove member accounts from the ADAM Administrators group, possibly leaving ADAM without any valid administrators. To recover from this scenario, the assigned ADAM administrator, as the owner of the Administrators group, can repopulate the ADAM Administrators group with the appropriate accounts. |

**Custom authorization mechanisms**

Depending on your applications, you may have applications that use a custom authorization scheme. With a custom authorization scheme, ADAM still performs the task of authenticating users, but the directory-enabled application manages its own set of authorization information. Even with a custom authorization scheme in place, ADAM continues to enforce the ACLs on ADAM objects. Therefore, if your application implements its own authorization scheme, you may want to assign more relaxed permissions on all ADAM objects, so that the ADAM permissions do not interfere with your application's authorization scheme. If you do relax permissions in ADAM in this way, be sure to prevent clients from gaining access to ADAM through Lightweight Directory Access Protocol (LDAP), thus bypassing your custom authorization mechanisms.

**Role-based authorization**

With Windows Server 2003, one way that a directory-enabled application can control access to directory objects is through role-based authorization, which is an alternative to ACL-based access control. In this scenario, a directory-enabled application does not expose LDAP but instead controls all access to the directory data. ADAM is used simply as a data store. For more information about role-based authorization in Windows Server 2003, see the Microsoft MSDN Web site.

| **Note** |
| --- |
| Using ADAM as an authorization store requires that you import ms-azman.ldf into the ADAM schema. You can import ms-azman.ldf through the ADAM Setup Wizard during installation or by using the **ldifde** command-line tool. For more information, see Importing LDIF files during setup. |

**Windows security principals**

By default, authenticated Windows security principals in ADAM can only read objects in the schema directory partition. To enable authenticated Windows security principals to read any other objects, you can assign permissions on objects to the well-

known security ID (SID) **authenticated user**. You can assign Read permissions for an entire directory partition by making **authenticated user** a member of the Readers group on that directory partition. Or, you can assign Read permissions on an object-by-object basis, using **dsacls**.

**Best practices for assigning permissions**

Although it is possible to assign permissions on objects to built-in security principals, it is recommended as a best practice that you avoid doing so. Built-in security principals represent user groups that are defined by the security system. These built-in groups take the form BUILTIN*groupname*. For example, the Builtin Administrators group (SID S-1-5-32-544) exists on every computer. If permission assignments for a particular object are made to the Builtin Administrators group, the intent of this assignment cannot always be determined. In other words, ADAM cannot always tell whether a security principal requesting access to an object belongs to the Builtin Administrators group for which a permission assignment is intended.

It is also possible to assign permissions on objects to well-known security principals. Well-known security principals represent special identities that are defined within the security system, including Everyone, Local System, Principal Self, Authenticated User, Creator Owner, and so on. It is generally considered acceptable to assign permissions on objects to any of the following well-known security principals:

- Anonymous Logon (after considering the possible security effects)
- Authenticated Users (S-1-5-11)
- Network (S-1-5-2)
- Interactive (S-1-5-4)
- Creator Owner (S-1-3-0)
- Self (S-1-5-10)

As a best practice, avoid assigning permissions on objects to the following well-known security principals:

- Network Service (S-1-5-20)
- Local Service (S-1-5-19)
- Local System (S-1-5-18)

The assignment of permissions on objects to any other well-known security principal should be made on a case-by-case basis, after considering the needs of the application.

# Backing up and restoring ADAM

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Backing up and restoring ADAM**
Active Directory Application Mode (ADAM) data and log files should be backed up regularly to ensure the continued availability of data to applications and users in the event of a system failure.

**Backing up ADAM**
By default, each instance of ADAM running on an ADAM server stores its database file, Adamntds.dit, and the associated log files in %program files%\Microsoft adam*instancename*\data. These files should be included as part of the regular backup plan of your organization. You can back up the directory stores using Backup or any Windows Logo Program, third-party backup utility. For information about backing up an ADAM instance, see Back up an ADAM instance to a file or a tape.

| **Note** |
| --- |
| You can use a restored backup of an ADAM instance to install an ADAM replica from media. For more information, see Install an ADAM replica from media. |

**Restoring ADAM**
When you restore a database to an existing ADAM instance, you must stop the ADAM instance before you run the restore operation. In addition, it is recommended that you move (or delete) the existing database and log files from the ADAM instance before the restore operation.

**Authoritative restore**
If objects in the directory are inadvertently deleted or modified, and if those objects are replicated in a configuration set, you must authoritatively restore those objects so that the correct version of the objects are replicated. To authoritatively restore directory data, run the **dsdbutil** utility after you have restored the data but before you restart the ADAM instance. With **dsdbutil**, you can mark directory objects for authoritative restore. When an object is marked for authoritative restore, its update sequence number is changed so that the number is higher than any other update sequence number in the configuration set. This ensures that any data you restore is properly replicated throughout the configuration set.

For more information about restoring an ADAM instance, including authoritative restores, see Restore an ADAM instance.

## Notes

- If you restore an ADAM backup over a running ADAM instance, Backup leaves the restored files in a pending state, and it does not write the files to disk until the computer is rebooted. In this situation, any directory changes that are made to the running ADAM instance after Backup is run are lost.

- If you accidentally start a restore of an ADAM instance over a currently running ADAM instance, it is recommended that you immediately restart the computer, stop the ADAM instance, and then perform the restoration again.

# Selecting an ADAM service account

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Selecting an ADAM service account**

On the **Service Account Selection** page of the ADAM Setup Wizard, you must select a service account for use by the Active Directory Application Mode (ADAM) instance. The account that you select determines the security context in which the ADAM instance runs. Changing the service account after installation may require some additional configuration.

| **Note** |
| --- |
| The first ADAM instance in a configuration set determines the default replication authentication method. |

**Service account requirements**

ADAM runs as a service, and it requires a service account. ADAM service account requirements depend on the Windows workgroup or domain environment into which you install ADAM, as well as the computer on which ADAM is running.

For ADAM instances that are joined to a configuration set, the service account is also used to authenticate against other ADAM instances in the configuration set for replication. The type of authentication that is used between replication partners is determined by the environment in which ADAM is running and by the service accounts in use. For more information, see Understanding ADAM replication and configuration sets.

The following table outlines ADAM service account requirements.

| **Security context** | **Service account for first ADAM instance** | **Service account for replica ADAM instances** | **Default replication authentication method**** |
| --- | --- | --- | --- |
| Workgroup | Network Service | Replica ADAM instances not allowed | Not applicable |
| Workstation user | Workstation user | Negotiated pass-through* | Not applicable |
| Windows 2000 domain or forest<br><br>-or-<br><br>Windows Server 2003 domain or forest | Network Service<br><br>-or-<br><br>Domain user | Network Service<br><br>-or-<br><br>Domain user | Negotiated |
| Workstation user | Workstation user | Negotiated pass-through* | Not applicable |
| Domain user | Domain user<br><br>-or-<br><br>Network Service | Negotiated | Not applicable |
| Windows NT 4.0 domain | Workstation user<br><br>Domain user | Workstation user<br><br>Domain user | Negotiated pass-through*<br><br>Negotiated |

*When a workstation user account is used on the first ADAM instance in a configuration set, all subsequent ADAM instances in the same configuration set must use an identical local workstation account name and password as the ADAM service account.

**When the Network Service account is used as the ADAM service account, the replication authentication mode is set to Negotiated by default.

**Notes**

- The Network Service account is a special, built-in account, with authority similar to that of an authenticated user account. The name of the account is NT AUTHORITY\NetworkService. The Network Service account has limited access to the local computer and authenticated access (as the computer account) to network resources. This limited access helps safeguard

your system if individual services or processes are compromised. Services that run as the Network Service account access network resources using the credentials of the computer account.

- To enable auditing for an ADAM instance running under a service account other than the Network Service account, you must grant the **Generate security audits** right to the account that is used as the ADAM service account.

- To enable a workstation or domain user account as a service account, you must grant the **Log on as a service** right to the account that is used as the ADAM service account. For more information, see Add the Log on as a service right to an account.

- The account that is used as the ADAM service account must be able to create, read, and modify files in the directory %ProgramFiles%\Microsoft ADAM*instancename*\data.

For more information, see Understanding ADAM architecture.

# ADAM troubleshooting and frequently asked questions (FAQs)

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Troubleshooting and frequently asked questions (FAQs)**

| |
|---|
| **The installation or removal of Active Directory Application Mode (ADAM) fails to complete successfully.**<br><br>If no screen message appears and ADAM setup fails to complete successfully, you can view the setup log at:<br><br>• %windir%\Debug\adamsetup.log<br><br>If no screen message appears and ADAM removal fails to complete successfully, you can view the uninstall log at:<br><br>• %windir%\Debug\adamuninstall.log |
| **A directory-enabled application cannot find an ADAM instance.**<br><br>Be sure to reference the correct communications port number (that is, 389 or 636) when specifying an ADAM instance. |
| **The ADAM service will not start.**<br><br>If the service account that is specified for ADAM is a workstation or a domain user account, make sure that the account possesses the **Run as a service** right. |
| **In an attempt to connect to an ADAM instance using the ADAM Schema snap-in, the following error message appears: "The schema FSMO holder could not be found. Schema modifications can only be made on the schema FSMO holder."**<br><br>You can only modify the schema on the ADAM instance that holds the schema master role. To determine the holder of the schema master role for a configuration set, see Identify or transfer the schema master role. |
| **How do I set or modify the password of an ADAM user?**<br><br>For information about modifying passwords, see Set or modify the password of an ADAM user. |
| **I can't bind to an ADAM instance that runs on a computer running Windows XP Professional.**<br><br>When the computer that runs ADAM is joined to a workgroup, you must set the registry key **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\forceguest** to 0. (The default is 1.) Otherwise, users connecting to ADAM over the network are forced to a security context of Guest, and binds to ADAM fail. For more information, see Enable binding to ADAM instances running on Windows XP Professional computers joined to a workgroup.<br><br>For information about other functional considerations when running ADAM on Windows XP Professional, see Running ADAM on Windows XP Professional. |
| **I can't connect to an ADAM instance over an SSL connection.**<br><br>To enable SSL connections, you must first install certificates on the computer running ADAM and on all client computers. For information about setting up and using certificate services, see "Certificate Services" on the Microsoft TechNet Web site.<br><br>On computers running Windows XP Professional that need to establish SSL connections to an ADAM instance, you must install the hotfix that is described in article 817583 in the Microsoft Knowledge Base Web site.<br><br>For information about other functional considerations when running ADAM on Windows XP Professional, see Running ADAM on Windows XP Professional. |

**I can't create an organizational unit (OU) in my application directory partition.**

OUs can only be created under the following objects:

- OU (ou=)
- country/region (c=)
- organization (o=)
- domain (dc=)

For example, you can create an OU in an application partition named O=Microsoft,C=US, but you cannot create an OU in an application partition named l=Microsoft,C=US.

**I can't locate the security IDs (SIDs) for an ADAM or Windows security principal.**

You can retrieve an active user's individual and group SIDs by explicitly querying the **tokenGroups** attribute on the **rootDSE**.

**Do multivalued attributes in ADAM have a limit to the number of values that they can hold?**

ADAM (as with Active Directory running at Windows Server 2003 forest functional level) places no limits on the number of linked attribute values that a multivalued attribute can hold. For nonlinked values, it is recommended that a multivalued attribute contain no more than 1,500 values.

For information about linked attributes, see "Linked Attributes" on the Microsoft MSDN Web site. For information about **member** as an example of a multivalued attribute in Active Directory, see "Enumerating Groups That Contain Many Members" on the Microsoft MSDN Web site.

**How can ADAM be configured to support anonymous LDAP binds?**

ADAM does not accept anonymous bind requests by default. To enable anonymous LDAP operations in ADAM, you must set the seventh character of the **dsHeuristics** value to 2.

You can find the **dsHeuristics** attribute on the **Directory Service** object in the configuration directory partition (CN=Directory Service,CN=Windows NT,CN=Services,CN=Configuration,CN={*GUID*}).

Modify the attribute to the following value:

0000002001000

In addition, assign permissions so that anonymous users have access to the appropriate objects in the directory. To grant the Read permission on all objects in a given directory partition to anonymous users, you can simply add the built-in security principal Anonymous (from the local computer) to the Readers group on that directory partition.

# ADAM Administration Tools

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**ADAM administration tools**

- ADAM ADSI Edit
- ADAM Csvde
- ADAM Ldifde
- Adaminstall
- Adamsync
- Adamuninstall
- ADSchemaAnalyzer
- Dsacls
- Dsdbutil
- Dsdiag
- Dsmgmt
- Ldp
- Repadmin

# ADAM ADSI Edit

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**ADAM ADSI Edit**
ADAM ADSI Edit runs as a Microsoft Management Console (MMC) snap-in. To start ADAM ADSI Edit, click **Start**, point to **All Programs**, point to **ADAM**, and then click **ADAM ADSI Edit**.

The following sections describe user interface (UI) options in the ADAM ADSI Edit snap-in, depending on the node that you click in the console tree or the command that you click in the **Action** menu.

- ADAM ADSI Edit Node
- Connection Node
- Object Node

**ADAM ADSI Edit Node**
To view the following UI options, in the console tree, click **ADAM ADSI Edit**, and then, on the **Action** menu, click:

**Connect to**
The following dialog box appears:

### Connection Settings

You can use the following options in the **Connection Settings** dialog box to create a connection to a directory partition on an ADAM instance:

**Connection name.** Type a display name for the connection. The connection will be listed in the console tree using the **connection name** that you provide.

**Server name.** The computer name, or DNS host name, of the ADAM instance to which you want to connect.

**Port.** The Lightweight Directory Access Protocol (LDAP) communications port number in use by the ADAM instance to which you want to connect. The default LDAP port is 389.

| **Note** |
| --- |
| ADAM ADSI Edit does not support Secure Sockets Layer (SSL) connections. |

**Distinguished name (DN) or naming context.** Click this option if you want to specify the distinguished name of the directory partition to which you want to connect.

**Well-known naming context.** Click this option if you want to connect to one of the well-known naming contexts, which include **Configuration**, **RootDSE**, and **Schema**.

**The account of the currently logged on user.** Click this option if you want to connect to the ADAM instance using the security context of the account that you are currently using.

**This account.** Click this option if you want to specify a different account to use when connecting to the ADAM instance.

**Refresh**
Updates the information about connections and objects that is displayed in ADAM ADSI Edit.

**Connection node**
To view the following commands, in the console tree, click a connection node for an already established connection, and then, on the **Action** menu, click:

**Remove**
Removes the currently selected connection node from ADAM ADSI Edit. This command only affects the contents of the ADAM ADSI Edit console tree; the command does not delete any objects from the ADAM instance.

**Update Schema Now**
Reloads the schema information from ADAM into the cache of the local computer.

**New**
Creates a new query when you point to **New** and then click **Query**.

**Refresh**
Updates the information about connections and objects that is displayed in ADAM ADSI Edit.

**Object node**
To view the following commands, in the console tree, click a directory object in a directory partition in an ADAM instance, and then, on the **Action** menu, click:

**Move**
Moves the object to another container in ADAM. Opens a dialog box that you can use to select the destination container.

**New Connection from Here**
Creates a new connection and adds the new connection to the console tree.

**New**
Creates a new child object in the selected container when you point to **New** and then click **Object**. Opens a set of chained dialog boxes that begins with the class of the object. If you do not have permission to create an object in the selected container, no classes are listed. After a class is selected, a dialog box opens for each required attribute. In the final dialog box, click **More** to view and edit any optional attributes.

**Delete**
Deletes the selected object from ADAM. A dialog box appears asking you to confirm the deletion. This command does not appear in the menu if you do not have permissions to delete the object from ADAM.

**Rename**
Changes the name of the object in ADAM.

**Refresh**
Updates the information that is displayed in ADAM ADSI Edit about connections and objects.

**Properties**
Opens a dialog box in which you can edit the attribute values of an object.

**Reset Password**
This option is available only for objects that contain a **unicodePwd** attribute. This option provides a dialog box in which the value of the **unicodePwd** attribute can be reset.

# ADAM Csvde

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Csvde**

Imports and exports data from Active Directory using files that store data in the comma-separated value (CSV) format. You can also support batch operations based on the CSV file format standard.

**Syntax**

**csvde** [**-i**] [**-f** *FileName*] [**-s** *ServerName*] [**-c** *String1 String2*] [**-v**] [**-j** *Path*] [**-t** *PortNumber*] [**-d** *BaseDN*] [**-r** *LDAPFilter*] [**-p** *Scope*] [**-l** *LDAPAttributeList*] [**-o** *LDAPAttributeList*] [**-g**] [**-m**] [**-n**] [**-k**] [**-a** *UserDistinguishedName Password*] [**-b** *UserName Domain Password*]

**Parameters**

**-i**
Specifies the import mode. If the import mode is not specified, the default mode is export.

**-f *FileName***
Identifies the import or export file name.

**-s *ServerName***
Specifies the domain controller to perform the import or export operation.

**-c *String1 String2***
Replaces all occurrences of *String1* with *String2*. This is generally used when you are importing data from one domain to another and the distinguished name of the export domain (*String1*) needs to be replaced with the distinguished name of the import domain (*String2*).

**-v**
Sets verbose mode.

**-j *Path***
Sets the log file location. The default is the current path.

**-t *PortNumber***
Specifies a Lightweight Directory Access Protocol (LDAP) port number. The default LDAP port is 389. The global catalog port is 3268.

**-d *BaseDN***
Sets the distinguished name of the search base for data export.

**-r *LDAPFilter***
Creates an LDAP search filter for data export.

**-p *Scope***
Sets the search scope. Search scope options are **Base**, **OneLevel**, or **SubTree**.

**-l *LDAPAttributeList***
Sets the list of attributes to appear in the results of an export query. If this parameter is omitted, all attributes are returned.

**-o *LDAPAttributeList***
Sets the list of attributes to be omitted from the results of an export query. This is typically used when exporting objects from Active Directory and then importing them into another LDAP-compliant directory. If the attributes are not supported by another directory, you can omit the attributes from the result set using this option.

**-g**
Omits paged searches.

**-m**
Omits attributes that cannot be written, such as the **ObjectGUID** and **objectSID** attributes.

**-n**
Omits export of binary values.

**-k**
Ignores errors during the import operation, and continues processing. The following is a complete list of ignored errors: "Object already exists," "Constraint violation," and "Attribute or value already exists."

**-a *UserDistinguishedName Password***
Sets the command to run using the supplied *UserDistinguishedName* and *Password*. By default, the command runs using the credentials of the user who is currently logged on to the network.

**-b *UserName Domain Password***
Sets the command to run as *UserName Domain Password*. By default, the command will run using the credentials of the user who is currently logged on to the network.

**-?**
Displays the command menu.

**Remarks**

- Applications such as Microsoft Excel are capable of reading and saving data in the CSV format. In addition, Microsoft Exchange Server administration tools are also capable of importing and exporting data using the CSV format, as are many other non-Microsoft tools.

  The CSV format consists of one or more lines of data, with each value separated by a comma. The first line (sometimes referred to as the header) of the CSV file must contain the names of each attribute in the same order as the data in any line following the first line.

  Example:

  *CN*,*FirstName*,*SurName*,*Description*

  *FirstUserLogonName*,*1stUserFirstName*,*1stUserSurName*,*Manager*

  *SecondUserLogonName*,*2ndUserFirstName*,*2ndUserSurName*,*President*

- You can use **csvde -r** to create an LDAP search filter for data export. For example, the following filter exports all users with a particular surname: **csvde -r (and(objectClass=***User***)(sn=***SurName***))**

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| Courier font | Code or program output |

# ADAM Ldifde

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Ldifde**

Creates, modifies, and deletes directory objects. You can also use **ldifde** to extend the schema, export user and group information to other applications or services, and populate Active Directory Application Mode (ADAM) with data from other directory services.

**Syntax**

**ldifde** [**-i**] [**-f** *FileName*] [**-s** *ServerName*] [**-c** *String1 String2*] [**-v**] [**-j** *Path*] [**-t** *PortNumber*] [**-d** *BaseDN*] [**-r** *LDAPFilter*] [**-p** *Scope*] [**-l** *LDAPAttributeList*] [**-o** *LDAPAttributeList*] [**-g**] [**-m**] [**-n**] [**-k**] [**-a** *UserDistinguishedName Password*] [**-b** *UserName Domain Password*] [**-?**]

**Parameters**

**-i**
Specifies import mode. If not specified, the default mode is export.

**-f *FileName***
Identifies the import or export file name.

**-s *ServerName***
Specifies the computer on which to perform the import or export operation. By default, **ldifde** will run on the computer on which **ldifde** is installed.

**-c *String1 String2***
Replaces all occurrences of *String1* with *String2*. This is generally used when importing data from one domain to another and the distinguished name of the export domain (*String1*) needs to be replaced with that of the import domain (*String2*).

**-v**
Sets verbose mode.

**-j *Path***
Sets the log file location. The default is the current path.

**-t *PortNumber***
Specifies a Lightweight Directory Access Protocol (LDAP) port number. The default LDAP port is 389. The global catalog port is 3268.

**-d *BaseDN***
Sets the distinguished name of the search base for data export.

**-r *LDAPFilter***
Creates an LDAP search filter for data export. For example, to export all users with a particular surname, you can use the following filter: **-r (and(objectClass=***User***)(sn=***SurName***))**

**-p *Scope***
Sets the search scope. Search scope options are **Base**, **OneLevel**, or **SubTree**.

**-l *LDAPAttributeList***
Sets the list of attributes to return in the results of an export query. If this parameter is omitted, all attributes are returned.

**-o *LDAPAttributeList***
Sets the list of attributes to omit from the results of an export query. This is typically used when exporting objects from Active Directory and then importing them into another LDAP-compliant directory. If attributes are not supported by another directory, you can omit the attributes from the result set using this option.

**-g**
Omits paged searches.

**-m**
Omits attributes that cannot be written, such as the **ObjectGUID** and **objectSID** attributes.

**-n**

Omits export of binary values.

**-k**
Ignores errors during the import operation, and continues processing. The following is a complete list of ignored errors:

- Object is already a member of the group.
- Object class violation (meaning that the specified object class does not exist), if the object being imported has no other attributes.
- Object already exists.
- Constraint violation.
- Attribute or value already exists.
- No such object.

**-a *UserDistinguishedName Password***
Sets the command to run using the supplied *UserDistinguishedName* and *Password*. By default, the command will run using the credentials of the user who is currently logged on to the network. Cannot be used with the **-b** option.

**-b *UserName Domain Password***
Sets the command to run using the supplied *UserName Domain Password*. By default, the command will run using the credentials of the user who is currently logged on to the network. Cannot be used with the **-a** option.

**-?**
Displays the command menu.

**Remarks**

- With the **-c** parameter, you can use the constants **#schemaNamingContext** and **#configurationNamingContext** in place of the distinguished names of the schema directory partition and configuration directory partition.
- When you create the import file to use with the **ldifde** command, use a **changeType** value to define the type of changes the import file will contain. The **changeType** values in the following table are available.

| Value | Description |
|---|---|
| **add** | Specifies that new content is contained in the import file. |
| **modify** | Specifies that existing content has been modified in the import file. |
| **delete** | Specifies that content has been deleted in the import file. |

The following is an example of an LDAP Data Interchange Format (LDIF) import file format using the **add** value:

**DN: CN=***SampleUser***,DC=***DomainName*

**changetype: add**

**CN:** *SampleUser*

**description:** *DescriptionOfFile*

**objectClass:** *User*

**userPrincipalName:** *SampleUser*

**Examples**
To retrieve only the distinguished name, common name, first name, surname, and telephone number of the returned objects, type:

**-l** *DistinguishedName*, **CN,** *GivenName*, **SN,** *Telephone*

To omit the globally unique identifier (GUID) for an object, type:

**-o** *whenCreated*, *whenChanged*, *objectGUID*

**Formatting legend**

| **Format** | **Meaning** |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| Courier font | Code or program output |

# Adaminstall

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Adaminstall**
Performs an unattended installation of Active Directory Application Mode (ADAM) using a preconfigured setup script file.

**Syntax**
**adaminstall** [**/q**] [**/answer:***filename*]

**Parameters**
**/q**
Runs **adamsetup** without displaying progress information on the screen.

**/answer: *filename***
Specifies an unattended ADAM installation, using the answer file that is indicated by *filename*.

**/?**
Displays help at the command prompt.

**Examples**
The following example shows an unattended installation of ADAM using a setup script file called answer.txt:

**adaminstall /answer:** *drive:\pathname***answer.txt**

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| Courier font | Code or program output |

**See Also**
**Concepts**
Perform an unattended install of an ADAM instance
Adamuninstall

# Adamsync

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Adamsync**
Synchronizes objects from Active Directory to an Active Directory Application Mode (ADAM) instance.

**Syntax**
**adamsync** [**/?**] [**/l**] [**/d** *configuration_dn*] [**/i** *input_file*] [**/download** *configuration_dn output_file*] [**/export** *configuration_dn output_file*] [**/sync** *configuration_dn*] [**/reset** *configuration_dn*] [**/mai** *configuration_dn*] [**/fs** *configuration_dn*] [**/ageall** *configuration_dn*] [**/so** *configuration_dn object_dn*] [**/passPrompt**]

**Parameters**

**/?**
Displays command-line options.

**/l or /list**
Displays all available configurations of Active Directory to ADAM Synchronizer.

**/d or /delete *configuration_dn***
Deletes the specified configuration.

**/i or /install *input_file***
Installs the configuration contained in the specified input file.

**/download *configuration_dn output_file***
Creates an output file in XML containing the specified configuration.

**/export *configuration_dn output_file***
Saves the current configuration to the specified output file.

**/sync *configuration_dn***
Synchronizes the specified configuration.

**/reset *configuration_dn***
Resets the replication cookie of the specified configuration.

**/mai *configuration_dn***
Configures the specified configuration as the authoritative instance.

**/fs *configuration_dn***
Performs a full replication synchronization for the specified configuration.

**/ageall *configuration_dn***
Performs an aging run for the specified configuration.

**/so *configuration_dn object_dn***
Performs a replication synchronization for the specified object in the specified configuration. Use the distinguished name of the object.

**/passPrompt**
Prompts for user credentials.

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |

| | |
|---|---|
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| Courier font | Code or program output |

Adaminstall
Remove an ADAM instance

# Adamsync Configuration File XML Reference

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The following topics provide reference information for XML elements that are used in the configuration file for Active Directory to ADAM Synchronizer.

- account-domain
- aging
- attributes
- base-dn
- configuration
- description
- exclude
- frequency
- include
- num-objects
- object-filter
- query
- schedule
- schtasks-cmd
- security-mode
- source-ad-account
- source-ad-name
- source-ad-partition
- source-object-class
- synchronizer-state
- target-dn
- target-object-class
- user-proxy

# account-domain

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains the domain name to use for authentication on the source forest.

**Usage**

```
<account-domain/>
```

**Attributes**
None.

**Child Elements**
None.

**Parent Elements**
<configuration>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

**Remarks**
The <source-ad-account> element and the <account-domain> element combine to create the account domain and name to use for alternate credentials. For example, if the account to use is "fabrikam\jsmith", <account-domain> would contain "fabrikam" and <source-ad-account> would contain "jsmith".

# aging

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains elements that describe how often an aging search is performed and how many objects to search for in the aging run.

**Usage**

```
<aging/>
```

**Attributes**
None.

**Child Elements**
<frequency>

<num-objects>

**Parent Elements**
<schedule>

**Child Element Sequence**
The tree shows the ordering and number of child elements. Child elements in a Sequence must appear in the order given and child elements in a Choice are mutually exclusive. Sequences and Choices can be nested. Element names are followed by the minimum and maximum occurrences.

```
frequency (Minimum = 0; Maximum = 1)
num-objects
```

**Element Information**

| | |
|---|---|
| Can be empty | No |

**Remarks**
An aging search is performed to determine if the objects in ADAM have been deleted from Active Directory. This is accomplished by searching for the ADAM objects in Active Directory because this is the only consistent way to determine if an object has been deleted in Active Directory.

# attributes

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains elements to specify the attributes to include or exclude in a search.

**Usage**

```
<attributes/>
```

**Attributes**
None.

**Child Elements**
<include>

<exclude>

**Parent Elements**
<query>

**Child Element Sequence**
The tree shows the ordering and number of child elements. Child elements in a Sequence must appear in the order given and child elements in a Choice are mutually exclusive. Sequences and Choices can be nested. Element names are followed by the minimum and maximum occurrences.

```
Sequence
    include (Minimum = 0; Maximum = many)
    exclude (Minimum = 0; Maximum = many)
Sequence
```

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

**Remarks**
If this element does not contain any child elements, then all attributes are included in the search.

Attributes can either be included or excluded, but not both. If one or more attributes are included, only those object attributes are included in the search. If one or more attributes are excluded, all attributes are included in the search except those that are specifically excluded.

# base-dn

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains the distinguished name of the base object where the search will begin. The search is performed only on this object and objects that exist below it in the directory tree.

**Usage**

```
<base-dn/>
```

**Attributes**
None.

**Child Elements**
None.

**Parent Elements**
<query>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

# configuration

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The <configuration> element is the root element that contains the configuration data that is required by Active Directory to ADAM Synchronizer.

**Usage**

```
<configuration/>
```

**Attributes**
None.

**Child Elements**
<description>

<security-mode>

<source-ad-name>

<source-ad-partition>

<source-ad-account>

<account-domain>

<target-dn>

<user-proxy>

<query>

<schedule>

<synchronizer-state>

**Parent Elements**
None.

**Child Element Sequence**
The tree shows the ordering and number of child elements. Child elements in a Sequence must appear in the order given and child elements in a Choice are mutually exclusive. Sequences and Choices can be nested. Element names are followed by the minimum and maximum occurrences.

```
description (Minimum = 0; Maximum = 1)
security-mode (Exactly 1)
source-ad-name (Exactly 1)
source-ad-partition (Exactly 1)
source-ad-account (Exactly 1)
account-domain (Minimum = 0; Maximum = 1)
target-dn (Minimum = 0; Maximum = 1)
user-proxy (Minimum = 0; Maximum = 1)
query (Exactly 1)
schedule (Minimum = 0; Maximum = 1)
synchronizer-state
```

**Element Information**

| | |
|---|---|
| Can be empty | No |

# description

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains a string that describes the configuration file. This string can be any length.

**Usage**

```
<description>
```

**Attributes**

None.

**Child Elements**

None.

**Parent Elements**

<configuration>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

# exclude

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains the Lightweight Directory Access Protocol (LDAP) display name of an attribute to exclude in the query during synchronization.

**Usage**

```
<exclude/>
```

**Attributes**
None.

**Child Elements**
None.

**Parent Elements**
<attributes>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

# frequency

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains the number of synchronization runs that will occur before an aging search will be performed. This value must be a positive integer.

**Usage**

```
<frequency/>
```

**Attributes**
None.

**Child Elements**
None.

**Parent Elements**
<aging>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

**Remarks**
Setting this value to "1" will verify the objects on every synchronization run. Setting this value to "2" will verify the objects on every other synchronization run.

# include

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains the LDAP display name of an attribute to include in the query during synchronization.

**Usage**

```
<include/>
```

**Attributes**
None.

**Child Elements**
None.

**Parent Elements**
<attributes>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

# num-objects

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains the number of objects to search for in each aging search.

**Usage**

```
<num-objects/>
```

**Attributes**

None.

**Child Elements**

None.

**Parent Elements**

<aging>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

# object-filter

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains the Lightweight Directory Access Protocol (LDAP) query string.

**Usage**

```
<object-filter/>
```

**Attributes**
None.

**Child Elements**
None.

**Parent Elements**
<query>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

**Remarks**
Characters that are reserved for use by XML, such as "<", ">" and "&" must be properly formatted to prevent the XML from being invalidated. For example, the "&" character is replaced by the "&" string. This is known is a character reference.

# query

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains child elements that describe the query that is used to search Active Directory for objects to synchronize.

**Usage**

```
<query/>
```

**Attributes**
None.

**Child Elements**
<base-dn>

<object-filter>

<attributes>

**Parent Elements**
None.

**Child Element Sequence**
The tree shows the ordering and number of child elements. Child elements in a Sequence must appear in the order given and child elements in a Choice are mutually exclusive. Sequences and Choices can be nested. Element names are followed by the minimum and maximum occurrences.

```
base-dn (Minimum = 1; Maximum = many)
object-filter
attributes (Minimum = 0; Maximum = 1)
```

**Element Information**

| | |
|---|---|
| Can be empty | No |

**Remarks**
All filtering is performed on the client side of the operation, not the server side.

# schedule

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains elements that describe how often to verify deleted objects and changed attribute values in Active Directory.

**Usage**

```
<schedule/>
```

**Attributes**
None.

**Child Elements**
<aging>

<schtasks-cmd>

**Parent Elements**
None.

**Child Element Sequence**
The tree shows the ordering and number of child elements. Child elements in a Sequence must appear in the order given and child elements in a Choice are mutually exclusive. Sequences and Choices can be nested. Element names are followed by the minimum and maximum occurrences.

```
aging (Minimum = 0; Maximum = 1)
schtasks-cmd (Minimum = 0; Maximum = 1)
```

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

# schtasks-cmd

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Reserved for future use.

**Usage**

```
<schtasks-cmd/>
```

**Attributes**
None.

**Child Elements**
None.

**Parent Elements**
None.

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

# security-mode

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Defines the security mode of the synchronization.

**Usage**

```
<security-mode/>
```

**Attributes**
None.

**Child Elements**
None.

**Parent Elements**
<configuration>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

**Remarks**
This element can contain either "partition" or "object". Any other value is invalid.

If this element contains "partition", the user account must have Replicate Directory Changes permissions on the source partition to synchronize objects.

If this element contains "object", the user account requires only readaccess to the objects to be synchronized.

# source-ad-account

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains the account name to use for authentication on the source forest. If this element is empty, the synchronizer will use the credentials of the account that is currently logged on.

**Usage**

```
<source-ad-account/>
```

**Attributes**
None.

**Child Elements**
None.

**Parent Elements**
<configuration>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

**Remarks**
The <source-ad-account> element and the <acocunt-domain> element combine to create the account domain and name to use for alternate credentials. For example, if the account to use is "fabrikam\jsmith", <account-domain> would contain "fabrikam" and <source-ad-account> would contain "jsmith".

Because passwords should never be stored as plain text in an XML file, the ADAM synchronizer will request the password from the user when the configuration is installed. This password will be encrypted and stored by the synchronizer for use when the synchronization is performed.

# source-ad-name

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains the name of the Active Directory forest that is the source of the synchronization.

**Usage**

```
<source-ad-name/>
```

**Attributes**
None.

**Child Elements**
None.

**Parent Elements**
<configuration>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

**Remarks**
If this element contains a fully-qualified distinguished name, it will be resolved using the domain controller locator. If an LDAP bindable name is specified, such as a DNS name, this object will be bound to.

# source-ad-partition

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains the distinguished name of the Active Directory partition that is the source of the synchronization.

**Usage**

```
<source-ad-partition>
```

**Attributes**

None.

**Child Elements**

None.

**Parent Elements**

<configuration>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

# source-object-class

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains the Lightweight Directory Access Protocol (LDAP) display name of the schema class on the source that should be converted when objects of this type are copied to Active Directory Application Mode (ADAM).

**Usage**

```
<source-object-class/>
```

**Attributes**
None.

**Child Elements**
None.

**Parent Elements**
<user-proxy>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

**Remarks**
These elements should be user principals only.

Object classes that are derived from this class are not converted. You must specify a separate <source-object-class> element for each object class to be converted.

# synchronizer-state

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains information that is reserved for use by the synchronizer. You should not modify any information in this element.

**Usage**

```
<synchronizer-state/>
```

**Attributes**

None.

**Child Elements**

None.

**Parent Elements**

<configuration>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

# target-dn

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains the distinguished name of the Active Directory Application Mode (ADAM) partition that is the destination of the synchronization.

**Usage**

```
<target-dn/>
```

**Attributes**
None.

**Child Elements**
None.

**Parent Elements**
<configuration>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

# target-object-class

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains the Lightweight Directory Access Protocol (LDAP) display name of the schema class to which the objects will be converted.

**Usage**

```
<target-object-class/>
```

**Attributes**
None.

**Child Elements**
None.

**Parent Elements**
<user-proxy>

**Element Information**

| | |
|---|---|
| Can be empty | Yes |

**Remarks**
All objects of the classes that are specified by the preceding <source-object-class> elements will be converted to this type during the conversion.

This class should have all the necessary attributes for each <source-object-class> in its schema definition.

# user-proxy

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Contains the list of source object classes that should be converted during the synchronization.

**Usage**

```
<user-proxy/>
```

**Attributes**
None.

**Child Elements**
<source-object-class>

<target-object-class>

**Parent Elements**
<configuration.

**Child Element Sequence**
The tree shows the ordering and number of child elements. Child elements in a Sequence must appear in the order given and child elements in a Choice are mutually exclusive. Sequences and Choices can be nested. Element names are followed by the minimum and maximum occurrences.

```
Sequence
    source-object-class (Minimum = 1; Maximum = many)
    target-object-class (Exactly 1)
Sequence
```

**Element Information**

| | |
|---|---|
| Can be empty | No |

**Remarks**
This element contains one or more <source-object-class> elements, followed by a single <target-object-class> element. All objects of the class specified by the <source-object-class> elements will be converted into the type specified by the <target-object-class> element.

Object classes that are derived from the classes specified by the <source-object-class> elements are not converted. You must specify a separate <source-object-class> element for each object class to be converted.

The <source-object-class> elements should contain only user principles.

If no conversion is needed, it is recommended that you include a single, empty <source-object-class> element in this element.

# Adamuninstall

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Adamuninstall**
Uninstalls an Active Directory Application Mode (ADAM) instance.

**Syntax**
**adamuninstall** [**/q**] [**/answer:***filename*] [**/force**] {**/i:***instancename* | **/tools**}

**Parameters**

**/q**
Runs **adamuninstall** without displaying progress information on the screen.

**/answer: *filename***
Specifies the name of the answer file, represented by *filename*, that contains preconfigured values for ADAM uninstall.

This answer file can be used to specify the account and password of the ADAM administrator, using the following syntax:

**Administrator=***domain\account*

**AdministratorPassword=***password*

where *domain\account* represents the account of the ADAM administrator and *password* represents the corresponding password.

**/force**
Causes **adamuninstall** to ignore any warnings and continue the removal of a given ADAM instance. **Adamuninstall** automatically skips any operations that generate warnings.

**/i: *instancename***
Uninstalls an ADAM instance named *instancename*, and also uninstalls the ADAM administration tools.

**/tools**
Uninstalls the ADAM administration tools only.

**Remarks**

- If service principal names (SPN) in Active Directory exist for the ADAM instance that is being uninstalled, and **adamuninstall** cannot remove the SPNs automatically, **adamuninstall** creates a .bat file that can be used to remove the SPNs manually. This .bat file is located at %windir%\Debug*domain-servicename*.bat, where *domain* represents the Active Directory domain in which the ADAM instance resides, and *servicename* represents the service name of the ADAM instance. (By default, the service name of an ADAM instance is ADAM_*instancename*, where *instancename* is the ADAM instance name that you provide during ADAM setup.)

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| Courier font | Code or program output |

**See Also**

**Concepts**

Perform an unattended install of an ADAM instance

Adaminstall

Remove an ADAM instance

# ADSchemaAnalyzer

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**ADSchemaAnalyzer**

You can use ADSchemaAnalyzer to help migrate the Active Directory schema to ADAM. To start ADSchemaAnalyzer, click **Start**, point to **All Programs**, point to **ADAM**, click **ADAM Tools Command Prompt**, and then at the command prompt type: **adschemaanalyzer**.

The following sections describe commands on the ADSchemaAnalyzer menus:

- File
- Schema
- Tools

**File**

The following table describes commands on the **File** menu.

| Command | Description |
|---|---|
| **Load target schema** | Opens a dialog box that you can use to authenticate to a specified Lightweight Directory Access Protocol (LDAP) server. Type a user name and password of an account that has permissions to the LDAP server. If you do a simple bind with an empty password, you are connected with anonymous credentials. Select the server type to load the target schema from. To select an LDAP Data Interchange Format (LDIF) file to load, click **Load LDIF**. |
| **Load base schema** | Opens a dialog box that you can use to authenticate to a specified LDAP server. Type a user name and password of an account that has permissions to the LDAP server. If you do a simple bind with an empty password, you are connected with anonymous credentials. Select the server type to load the base schema from. To select an LDIF file to load, click **Load LDIF**. |
| **Create LDIF file** | Produces an LDIF file that contains all selected schema elements. |

**Schema**

The following table describes commands on the **Schema** menu.

| Command | Description |
|---|---|
| **Hide present elements** | Hides all elements that are present on the target server. |
| **Show present elements** | Shows all elements that are present on the target server. |
| **Mark all non-present elements as included** | Marks all elements that are not present on the target server as included for export. |

**Tools**

The following table describes commands on the **Tools** menu.

**Options**

Opens a dialog box that you can use to set options for ADSchemaAnalyzer. The following table describes options on the tabs in the **Options** dialog box.

| Tab | Description |
|---|---|

| | |
|---|---|
| **Dependencies graph** | The following are the options on the **Dependencies graph** tab.<br>• **AttributeSecurityGUID (attribute to propset reference)** - Select this option to display attributes that belong to a propset.<br>• **AppliesTo (propset to class reference)** - Select this option to display classes that reference a given attribute or class.<br>• **Show Dependents node** - Select this option to show the Dependents node in the tree for each element. |
| **LDIF generation** | The following are the options on the **LDIF generation** tab.<br>• **Don't update present elements** - Use this option if you do not want to update present elements in the LDIF file.<br>• **Update with references to new elements only** - Use this option to update the LDIF file with references to new elements.<br>• **Update with references to new and present elements** - Use this option to update the LDIF file with references to new and present elements.<br>• **Allowed to write systemPossSureriors and systemAuxClasses as possSuperiors and auxClasses, if schema circular dependencies exist** - Use this option if there are schema circular dependencies and you want to import the schema by writing **systemPossSuperiors** as **possSuperiors** and **systemAuxClasses** as **auxClasses**. |
| **Miscellaneous** | The following are the options on the **Miscellaneous** tab.<br>• **Marking an element as present marks all its subelements as present** - Select this option to mark all subelements as present automatically when you mark an element as present in the tree.<br>• **Debug output** - Select this option to debug the output of the LDIF file. |

Right-click schema elements in the tree to mark them as **Auto**, **Included**, **Excluded**, or **Present**:

- **Auto** automatically marks an element as included or excluded in the export. If an element is marked as **Auto (included)**, you can right-click that element and then click **Why auto included?** to see the reverse dependency tree for the element.

- **Included** marks the element so that it is included in the export. ADSchemaAnalyzer marks all related elements, such as **superclasses**, aux classes, must/may contains, **defaultObjectCategory**, and **possSuperiors**. ADSchemaAnalyzer includes propsets for included attributes and back-links for links.

- **Excluded** marks the element so that it is not included in the export. You can block certain paths in the dependency graph. For example, you might want to import **domainDns**, but not **samAccountDomain** (which is an **auxClass** of **domainDns**). You can exclude a complete element, such as the **samAccountDomain** class, or you can exclude a relationship; for example, you can remove the **auxClass** reference from the **domainDns** class. If you exclude a relationship, any other classes that reference that element continue to include it.

- **Present** means that the element is present on the target server. By default, the top class is marked as present.

# Dsacls

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Dsacls**
Displays and changes permissions (access control entries (ACEs)) in the access control list (ACL) of objects in Active Directory Application Mode (ADAM).

The ACEs that you add by using **dsacls** must be object-specific permissions that override the default partition permissions that are defined in the ADAM schema. Do not add ACEs unless you are well informed about security for ADAM objects.

If you specify an object without additional parameters, **dsacls** displays the ACEs in the ACL.

**Syntax**
**dsacls "**[*****Computer*****]*ObjectDN***"** [**/A**] [**/D** *PermissionStatement* [*PermissionStatement*]...] [**/G** *PermissionStatement* [*PermissionStatement*]...] [**/I:**{**T** | **S** | **P**}] [**/N**] [**/P:**{**Y** | **N**}] [**/R** {*User* | *Group*} [{*User* | *Group*}]...] [**/S** [**/T**]] [**/resetDefaultACL**] [**/resetDefaultSACL**] [**/takeOwnership**] [**/simple**] [**/domain:** *domain*] [**/user:** *username*] [**/passwd:** {*password* | ***** }] [**/?**]

**Parameters**

**"[*Computer*\]*ObjectDN*"**
Identifies the Active Directory object to investigate. Type the distinguished name of the object. To specify an object on a remote computer, type the computer name followed by the distinguished name. This parameter must be enclosed in quotation marks.

Example:

**"CN=Kim Akers,CN=Users,DC=domain,DC=test,DC=microsoft,DC=com"**

or

**"\\Server01\CN=Kim Akers,CN=Users,DC=domain,DC=test,DC=microsoft,DC=com"**

**/A**
Adds ownership and auditing information to the display.

**/D PermissionStatement [*PermissionStatement*]...**
Denies the specified permissions to the user or group.

You can deny permissions to multiple users in each **/D** command.

Example:

**/D Domain1\User1:CCDC Domain1\User2:DC;computer**

**/G PermissionStatement [*PermissionStatement*]...**
Grants specified permissions to the user or group.

You can grant permissions to multiple users in each **/G** command

Example:

**/G Domain1\User1:CCDC Domain1\User2:DC;computer**

**/I:{T | S | P}**
Specifies the objects to which the permissions are applied. This parameter determines whether the permissions are inheritable. **T** is the default.

| Value | Description |
|---|---|
| T | This object and subobjects |
| S | Subobjects only |
| P | Propagate inheritable permissions one level only |

**/N**
Provides that the specified ACE replaces the ACEs in the ACL. By default, the ACE is added to the ACL.

**/P:{Y | N}**
Determines whether the object is protected so that it cannot inherit permissions from its parent objects. If you omit this parameter, the inheritance properties of the object are not changed.

| Value | Description |
|---|---|
| **Y** | The object is protected, and it cannot inherit permissions. |
| **N** | The object is not protected, and it can inherit permissions. |

**Note**

- This parameter changes a property of the object, not of an ACE. To determine whether an ACE is inheritable, use the **/I** parameter.

**/R {*User* | *Group*} [{*User* | *Group*}]...**
Deletes all ACEs for the specified users or groups. *User* can be specified as *User@Domain* or as *Domain\User*. *Group* can be specified as *Group@Domain* or as *Domain\Group*.

You can delete ACEs for multiple users and groups in a single **/R** parameter

Example:

**/R Domain1\User1 Domain1\User2**

**/S**
Restores the security on the object to the default for that object class, as defined in the Active Directory schema.

**/T**
Restores the security on the tree of objects to the default for each object class. This parameter is valid only with the **/S** parameter.

**/resetDefaultDACL**
Restores the DACL on the object to the default setting for the object, based on the schema definition for the object class.

**/resetDefaultSACL**
Restores the SACL on the object to the default setting, based on the schema definition for the object class.

**/takeOwnership**
Assigns object owernship to the account under which Dsacls is running.

**/simple**
Specifies to bind to the directory server using an LDAP simple bind.

**/domain: *domain***
Specifies to bind to the directory server using an account from the domain represented by *domain*.

**/user: *username***
Specifies to bind to the directory server using the account represented by *username*.

**/passwd: *password***
Specifies to bind to the directory server using the password represented by *password*. If no password is specified, the user is prompted for a password.

**/?**
Displays help for **dsacls**.

**Syntax for PermissionStatement**
*PermissionStatement* values use the following format:

{*User* | *Group*}**:***Permissions*[**;**{*ObjectType* | *Property*}][**;***InheritedObjectType*]

**Parameters**
**{*User* | *Group*}**

Specifies the user or group to whom the rights apply. *User* can be specified as a distinguished name, *User@Domain*, or *Domain**User*. *Group* can be specified as a distinguished name, *Group@Domain*, or *Domain**Group*.

***Permissions***

Type one or more of the values in the following tables (without spaces).

**Generic Permissions**

| Value | Description |
|---|---|
| **GR** | Generic Read |
| **GE** | Generic Execute |
| **GW** | Generic Write |
| **GA** | Generic All |

**Specific Permissions**

| Value | Description |
|---|---|
| **SD** | Delete. |
| **DT** | Delete an object and all of its children. |
| **RC** | Read security information. |
| **WD** | Change security information. |
| **WO** | Change owner information. |
| **LC** | List the children of an object. |
| **CC** | Create a child object.<br><br>If {*ObjectType* \| *Property*} is not specified to define a specific child-object type, this applies to all types of child objects; otherwise, it applies to the specified child-object type. |
| **DC** | Delete a child object.<br><br>If {*ObjectType* \| *Property*} is not specified to define a specific child-object type, this applies to all types of child objects; otherwise, it applies to the specified child-object type. |
| **WS** | Write to self object.<br><br>This is meaningful only on Group objects and when {*ObjectType* \| *Property*} is a "member." |
| **RP** | Read property.<br><br>If {*ObjectType* \| *Property*} is not specified to define a specific property, this applies to all properties of the object; otherwise, it applies to the specified property of the object. |
| **WP** | Write property.<br><br>If {*ObjectType* \| *Property*} is not specified to define a specific property, this applies to all properties of the object; otherwise, it applies to the specified property of the object. |
| **CA** | Control access right.<br><br>If {*ObjectType* \| *Property*} is not specified to define the specific extended right for control access, this applies to all meaningful control accesses on the object; otherwise, it applies to the specific extended right for that object. |

| | |
|---|---|
| **LO** | List the object access.<br><br>Can be used to grant list access to a specific object if List Children (**LC**) is not granted to the parent as well. Can also be denied on specific objects to hide those objects if the user/group has **LC** permission on the parent.<br><br>**Note**<br><br>• Active Directory does not enforce this permission by default. Active Directory must be configured to check for this permission. |

**{*ObjectType* | *Property*}**

Limits the permission to the specified object type or property. Type the display name of the object type or the property. If an object type or property is not specified, the permission applies to all object types and properties.

For example, the following command permits the user to create all types of child objects:

**/G Domain\User:CC**

However, the following command permits the user to create only child computer objects:

**/G Domain\User:CC;computer**

***InheritedObjectType***

Limits inheritance of the permission to the specified type of object. Type the display name of the object type. If an object type is not specified, the permission can be inherited by all object types. This parameter is used only when permissions are inheritable.

For example, the following command permits all types of objects to inherit the permission:

**/G Domain\User:CC**

However, the following command permits only user objects to inherit the permission:

**/G Domain\User:CC;;user**

**Examples**

**SDRCWDWO;;user**

Delete, read security information. Change security information and change ownership permissions on objects of the type "user."

**CCDC;group;**

Create child and delete child permissions to create or delete objects of the type "group."

**RPWP;telephonenumber;**

Read property and write property permissions on the telephone number property.

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| Courier font | Code or program output |

# Dsdbutil

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Dsdbutil**
Provides management facilities for Active Directory Application Mode (ADAM). This tool is intended for use by experienced administrators.

| **Note** |
| --- |
| Some **dsdbutil** commands can be used only against ADAM instances that are not currently running. |

The syntax for each command is listed below.

- activate instance
- authoritative restore
- change service account
- files
- LDAP port
- list instances
- popups
- quit
- semantic database analysis
- set DSRM Password
- SSL port

**activate instance**
Specifies the ADAM instance to be managed. At the **dsdbutil:** prompt, type the command using the syntax below. You cannot activate an ADAM instance if that ADAM instance is currently running.

**Syntax**
**activate instance** *instancename*

***Instancename***
Specifies the name of an ADAM instance to be managed.

**authoritative restore**
Restores an ADAM instance to a specific point in time by marking objects in ADAM as being authoritative with respect to their replication partners. At the **authoritative restore:** prompt, type any of the parameters listed under "Syntax."

**Syntax**
{**restore database**|**restore database verinc** *%d*|**restore subtree** *%s*|**restore subtree** *%s* **verinc** *%d*|**restore object** *%s*|**restore object** *%s* **verinc** *%d*}

**Parameters**
**restore database**
Marks all of Adamntds.dit (all directory partitions that are held by the ADAM instance) as authoritative. The schema cannot be authoritatively restored.

**restore database verinc *%d***
Marks all of Adamntds.dit (all directory partitions that are held by the ADAM instance) as authoritative, and increments the version number as follows. If **verinc** is not provided, the version number is increased by the age (in days) of the object being restored, multiplied by 100,000. If **verinc** is provided, the version number is increased by the age (in days) of the object being restored, multiplied by *%d*. Use this option only to authoritatively restore over a previous, incorrect, authoritative restore, such as an authoritative restore completed using a backup that contains incorrect data.

***%d***
A numeric variable, such as the replication delay time period.

**restore subtree *%s***
Marks the subtree and all children of the subtree as being authoritative. The subtree is defined by using the full distinguished name of the object.

**restore subtree *%s* verinc *%d***
Marks the subtree and all children of the subtree as being authoritative, and increments the version number as follows. If **verinc** is not provided, the version number is increased by the age (in days) of the object being restored, multiplied by 100,000. If **verinc** is provided, the version number is increased by the age (in days) of the object being restored, multiplied by *%d*. The subtree is defined by using the full distinguished name of the object. Use this option only to authoritatively restore over a previous, incorrect, authoritative restore, such as an authoritative restore completed using a backup that contains incorrect data.

**restore object *%s***
Marks the object as being authoritative. The object is specified by using the full distinguished name of the object.

**restore object *%s* verinc *%d***
Marks the object as being authoritative, and increments the version number as follows. If **verinc** is not provided, the version number is increased by the age (in days) of the object being restored, multiplied by 100,000. If **verinc** is provided, the version number is increased by the age (in days) of the object being restored, multiplied by *%d*. The object is specified by using the full distinguished name of the object. Use this option only to authoritatively restore over a previous, incorrect, authoritative restore, such as an authoritative restore completed using a backup that contains incorrect data.

***%s***
An alphanumeric variable, such as the name of an ADAM instance.

**Quit**
Takes you back to the previous menu, or exits the utility.

**? or help**
Displays help at the command prompt.

#### change service account
Sets the service account for the ADAM instance. At the **dsdbutil:** prompt, type the command using the syntax listed below.

##### Syntax
**change service account** *account password*

***account***
The account to be used as the new ADAM service account.

***password***
The password for the account to be used as the new ADAM service account.

#### files
Provides commands for managing directory service data and log files. The data file is called Adamntds.dit. At the **files:** prompt, type any of the parameters listed under "Syntax."

##### Syntax
{**compact to** *%s*|**header**|
**info**|**integrity**|**move DB to** *%s*|**move logs to** *%s*|**recover**|**set path backup** *%s*|**set path db** *%s*|**set path logs** *%s*|**set path working dir** *%s*

##### Parameters
**compact to *%s* (where *%s* identifies an *empty target directory*)**
Compacts the existing data file, and writes the compacted file to the specified directory. The directory can be remote; that is, it can be mapped by means of the **net use** command or by similar means. After compaction is complete, archive the old data file, and move the newly compacted file back to the original location of the data file.

**header**
Writes the header of the Adamntds.dit data file to the screen. This command can help you analyze database problems.

**info**
Analyzes and reports the free space for the disks that are installed in the system, reads the registry, and then reports the sizes of the data and log files. The directory service maintains the registry, which identifies the location of the data files, log files, and directory service working directory.

**integrity**
Performs an integrity check on the data file, which can detect any kind of low-level database corruption. It reads every byte of the data file; therefore, it can take a long time to process large databases. Note that you should always run **recover** before performing an integrity check.

**move DB to *%s* (where *%s* identifies a target directory)**
Moves the Adamntds.dit data file to the new directory that is specified by *%s*, and updates the registry so that, upon service restart, the directory service uses the new location.

**move logs to *%s* (where *%s* identifies a target directory)**
Moves the directory service log files to the new directory that is specified by *%s*, and updates the registry so that, upon service restart, the directory service uses the new location.

**recover**
Performs a soft recovery of the database. Soft recovery scans the log files and ensures that all committed transactions in the log files are also reflected in the data file. The **ntbackup** program truncates the log files appropriately. Logs are used to ensure that committed transactions are not lost if the system fails or if there is an unexpected power loss. Essentially, transaction data is written first to a log file and then to the data file. When you restart after failure, you can rerun the log to reproduce the transactions that are committed but that have not been written to the data file.

**set path backup *%s* (where *%s* identifies a target directory)**
Sets the disk-to-disk backup target to the directory that is specified by *%s*. The directory service can be configured to perform an online, disk-to-disk

backup at scheduled intervals.

**set path db *%s* (where *%s* identifies a target directory)**
Updates the part of the registry that identifies the location and file name of the data file. Use this command only to rebuild an ADAM instance that has lost its data file and that is not being restored by means of normal restoration procedures.

**set path logs *%s* (where *%s* identifies a target directory)**
Updates the part of the registry that identifies the location of the log files. Use this command only to rebuild an ADAM instance that has lost its log files and that is not being restored by means of normal restoration procedures.

**set path working dir *%s* (where *%s* identifies a target directory)**
Sets the part of the registry that identifies the directory service's working directory to the directory that is specified by *%s*.

***%s***
An alphanumeric variable, such as a domain or ADAM instance name.

**quit**
Takes you back to the previous menu, or exits the utility.

**? or help**
Displays help at the command prompt.

| **Caution** |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

| **Note** |
| --- |
| Active Directory Application Mode is implemented on top of an indexed sequential access method (ISAM) table manager. This is the same table manager that is used by Microsoft Exchange Server, the file replication service, the security configuration editor, the certificate server, Windows Internet Name Service (WINS), and other Windows components. The version of the database that Windows Server 2003 uses is called extensible storage engine (ESENT). ESENT is a transacted database system that uses log files to support rollback semantics to ensure that transactions are committed to the database. Ideally, data and log files should be located on separate drives to improve performance and support recovery of the data if a disk fails. |

**LDAP port**
Sets the Lightweight Directory Access Protocol (LDAP) communications port for the ADAM instance. At the **dsdbutil:** prompt, type the command using the syntax listed below.

**Syntax**
**LDAP port** *portnumber*

***portnumber***
Specifies the new communications port number to be used for LDAP on the ADAM instance.

**list instances**
Lists information about the ADAM instances installed on the current computer. To run this command, type **list instances** at the **dsdbutil:** prompt. This command does not require or accept any parameters.

**popups**
Enables or disables interactive pop-up messages. To enable interactive pop-up messages, at the **dsdbutil:** prompt, type **popups on**. To disable pop-up messages, at the **dsdbutil:** prompt, type **popups off**.

**quit**
Closes the **dsdbutil** command-line tool.

**semantic database analysis**
Analyzes data with respect to ADAM semantics. At the **semantic database analysis:** prompt, type any of the parameters listed under "Syntax."

**Syntax**
{**get** *%d*|**go**|**verbose** *%s*}

**Parameters**
**get *%d***
Retrieves the record number *%d* from Ntds.dit.

**go**
Starts the semantic analysis of Ntds.dit. A report is generated and written to a file named Dsdit.dmp.*n* in the current directory, where *n* is an integer that is incremented each time that you carry out the command.

**verbose *%s***
Toggles verbose mode on or off.

***%d***
A numeric variable, such as a replication delay time period.

***%s***

An alphanumeric variable, such as a domain or ADAM instance name.

**quit**
Takes you back to the previous menu, or exits the utility.

**? or help**
Displays help at the command prompt.

**Remarks**

- Unlike the file management commands described earlier, which test the integrity of the database with respect to ESENT database semantics, the semantic analysis analyzes data with respect to ADAM semantics. It generates reports on the number of records present, including deleted and phantom records.

| **Note** |
| --- |
| End users should not use this command except, when Microsoft requests them to use it as an aid in fault diagnosis. |

**set DSRM Password**
This command does not apply to ADAM.

**SSL port**
Sets the Secure Sockets Layer (SSL) communications port for the ADAM instance. At the **dsdbutil:** prompt, type the command using the syntax listed below.

**Syntax**
**SSL port** *portnumber*

***portnumber***
Specifies the new communications port number to be used for SSL on the ADAM instance.

**Remarks**

- If the variable has spaces in it, enclose it in parentheses, instead of in quotation marks, as follows:

  **connect to server (***xxx yyy***)**

**Formatting legend**

| Format | Meaning |
| --- | --- |
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| Courier font | Code or program output |

# Dsdiag

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Dsdiag**
Analyzes the state of the Active Directory directory service, or the Active Directory Application Mode (ADAM) directory service, and reports any problems, to assist in troubleshooting. **Dsdiag** provides detailed information about how to identify abnormal behavior in the system.

**Dsdiag** consists of a framework for running tests and a series of tests to verify different functional areas of the system. This framework selects which directory services are tested, according to scope directives from the user.

| **Note** |
| --- |
| Some **Dsdiag** tests apply only to Active Directory. |

- Syntax
- Examples
- Formatting legend

**Syntax**
**dsdiag /s:***adamserver* [**/n:***NamingContext*] [**/u:***Domain\UserName* **/p:{*** | *Password* | **""}**] [{**/a** | **/e**}] [{**/q** | **/v**}] [**/i**] [**/f:***LogFile*] [**/ferr:***ErrLog*] [**/c** [**/skip:***Test*]] [**/test:***Test*][**/d**][**/fix**] [{**/h** | **/?**}]

**Parameters**

**/s: *adamserver***
Uses *adamserver* as the home server. This parameter is required.

**/n: *Partition***
Uses *Partition* as the application directory partition to test. Domains may be specified in network basic input/output system (NetBIOS), Domain Name System (DNS), or distinguished name formats.

**/u: *Domain\UserName* /p:{* | *Password* | ""}**
Uses *Domain\UserName* credentials for binding, with *Password* as the password. Use **""** for an empty or null password, or use ***** to prompt for the password.

**/a**
Tests all the servers on this site.

**/e**
Tests all the servers in the entire enterprise. Overrides **/a**.

**/q**
(Quiet) Prints only error messages.

**/v**
(Verbose) Prints extended information.

**/d**
(Debug) Prints configuration information for the entire enterprise, and displays verbose output information. This parameter can be useful for discovering detailed information about a directory server.

**/i**
Ignores superfluous error messages.

**/fix**
Only affects the *MachineAccount* test. This parameter causes the test to repair the service principal names (SPNs) on the machine account object of the directory server.

**/f: *LogFile***
Redirects all output to *LogFile*. The **/f** parameter operates independently of **/ferr**.

**/ferr: *ErrLog***
Redirects fatal error output to a separate file called *ErrLog*. The **/ferr** parameter operates independently of **/f**.

**/c**
(Comprehensive) Runs all tests except **DcPromo** and **RegisterInDNS**, including nondefault tests. Optionally, this parameter can be used with **/skip** to skip specified tests. The following tests are not run by default:
**TopologyCutoffServersOutboundSecureChannels**

**/skip: *Test***
Skips the specified test. This parameter must be used with **/c**. This parameter should not be run in the same command with **/test**. The only test that cannot be skipped is **Connectivity**.

**/test: *Test***
Runs only this test. The nonskippable test **Connectivity** is also run. This parameter should not be run in the same command with **/skip**.

| **Note** |
| --- |
| All tests except **DcPromo** and **RegisterInDNS** must be run on computers that have been promoted to directory server. |

Valid tests are as follows:

**Connectivity**
Tests whether directory servers are DNS registered, can be pinged, and have Lightweight Directory Access Protocol/remote procedure call (LDAP/RPC) connectivity.

**Replications**
Checks for timely replication and any replication errors between directory servers.

**Topology**
Checks that Knowledge Consistency Checker (KCC) has generated a fully connected topology for all directory servers.

**CutoffServers**
Checks for any servers that are not receiving replications because their partners are not available.

**NCSecDesc**
Checks that the security descriptors on the application directory partition heads have appropriate permissions for replication.

**NetLogons**
Checks that the appropriate logon privileges exist to allow replication to proceed.

**Advertising**
Checks whether each directory server is advertising itself in the roles it should be capable of fulfilling. This test fails if the Net Logon service has stopped or failed to start.

**KnowsOfRoleHolders**
Checks whether the directory server can contact the servers that hold the five operations master (also known as flexible single master operations, or FSMO) roles.

**Intersite**
Checks for failures that would prevent or temporarily hold up intersite replication, and tries to predict how long it will take before the KCC is able to recover.

**Caution**

- Results of this test are often not valid.

**FSMOCheck**
Checks that the directory server can contact a Key Distribution Center (KDC), Time Server, Preferred Time Server, primary directory server (primary domain controller (PDC)), and global catalog server. This test does not test any of the servers for operations master roles.

**RidManager**
Checks whether the RID master is accessible and if it contains the proper information.

**MachineAccount**
Checks whether the machine account is properly registered and the services are advertised.

**Services**
Checks whether the appropriate directory server services are running.

**OutboundSecureChannels**
Checks that secure channels exist from all the directory servers in the domain to the domains that are specified by **/testdomain**. The **/nositerestriction** parameter prevents the test from being limited to the directory servers in the site.

**ObjectsReplicated**
Checks that **Machine Account** and **DSA** objects have replicated. Use **/objectdn:***dn* with **/n:***nc* to specify an additional object to check.

**frssysvol**
Checks that File Replication service (FRS) SYSVOL is ready.

**kccevent**
Checks that KCC is completing without errors.

**systemlog**
Checks that the system is running without errors.

**DcPromo**
This command does not apply to ADAM.

**RegisterInDNS**
This commmand does not apply to ADAM.

**DeadCRTest**
Looks for cross-references that appear to be left over from a failed creation of an application directory partition.

**CheckSDRefDom**
Checks that all application directory partitions have appropriate security descriptor reference domains.

**VerifyReplicas**
Verifies that all application directory partitions are fully instantiated on all replica servers.

**CrossRefValidation**
Verifies the validity of cross-references.

**VerifyReferences**
Verifies that certain system references are intact for the FRS and Replication infrastructure.

**VerifyEnterpriseReferences**
Verifies that certain system references are intact for the FRS and Replication infrastructure across all objects in the enterprise on each directory server.

**{/h | /?}**
Displays a syntax screen at the command prompt.

#### Examples

##### Example 1: A normal ADAM instance

To examine an ADAM instance to verify that it is healthy and functioning properly, type the following at the command prompt:

**dsdiag /s:adam1 /u:cohovineyard\administrator /p:password**

Output similar to the following appears:

```
Directory Service Diagnosis

Performing initial setup:

Done gathering initial info.

Doing initial required tests
```

```
Testing server: Default-First-Site-Name\adam1

# Dsmgmt

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

#### Dsmgmt

Provides management facilities for Active Directory Application Mode (ADAM).

To run **dsmgmt**, at an ADAM tools command prompt, type **dsmgmt**, and then press ENTER. At the **dsmgmt:** prompt, type one of the following commands:

- configurable settings
- ds behavior
- partition management
- LDAP policies
- metadata cleanup
- popups
- quit
- roles
- security account management

#### Configurable settings

Helps to modify the Time to Live (TTL) of dynamic data that is stored in ADAM. To reach the **configurable setting:** prompt, at the **dsmgmt:** prompt, type **configurable settings**, and then press ENTER. Then, at the **configurable setting:** prompt, use the following syntax.

##### Syntax

{**cancel changes**|**connections**|**list**|**set** *%s* **to** *%s*|**show values**}

##### Parameters

**cancel changes**
Cancels the changes that are made but that are not yet committed.

**Connections**
Invokes the **server connections** submenu.

**List**
Lists the names of the supported configurable settings.

**set *%s* to *%s***
Sets the configurable settings *%s1* to the value *%s2*.

**show values**
Displays values of configurable settings.

***%s***
An alphanumeric variable, such as an ADAM instance name.

**Quit**
Takes you back to the previous menu or exits the utility.

**? or help**
Displays help at the command prompt.

#### ds behavior

Enables administrators to specify whether password modifications can be made over unsecured (nonencrypted) connections. By default, password modifications over unsecured connections are not allowed. To view the **ds behavior** command-line options, type **?** at the **ds behavior:** command prompt.

#### partition management

Enables administrators to prepare cross-reference and server objects in the directory. To reach the **partition management:** prompt, at the **dsmgmt:** prompt, type **partition management**, and then press ENTER. Then, at the **partition management:** prompt, use the following syntax.

##### Syntax

{**add nc replica** *%s %s*|**connections**|**create nc** *%s %s*|**create nc** *%s %s %s*|**remove nc replica** *%s %s*|**list**|**list nc information** *%s*|**list nc replicas** *%s*|**precreate** *%s %s*|**delete NC** *%s*|**select operation targe**

##### Parameters

**add nc replica *%s %s***
Adds the ADAM instance *%s2* to the replica set for the application directory partition *%s1*. If *%s2* is not specified, the ADAM instance that you are connected to is used as the default.

**Connections**
Invokes the **Connections** submenu.

**create nc *%s %s***
This command only applies to Active Directory (and not to ADAM).

**create nc *%s %s %s***
This command applies to ADAM (and not to Active Directory). Creates the application directory partition with the distinguished name specified by *%s1*, of an object class specified by *%s2*, on the ADAM instance specified by the *computername:portnumber* specified by *%s3*. If *%s3* is not specified, the currently connected ADAM instance is used.

**remove nc replica *%s %s***
Removes the ADAM instance *%s2* from the replica set for the application directory partition *%s1*. If *%s2* is not specified, the ADAM instance that you are currently connected to is used.

**List**
Lists all the naming contexts (or, directory partitions) that exist in the configuration set.

**list nc information *%s***
Prints out the reference domain and replication delays for the application directory partition.

**list nc replicas *%s***
Prints the list of ADAM instances in the replica set for application directory partition *%s*. Remember that this is the list of ADAM instances that will eventually hold replicas of the application directory partition and that these replicas may not necessarily be fully replicated yet.

**precreate *%s %s***
Creates a cross-reference object for the application directory partition *%s1*, allowing an ADAM instance named *%s2* to hold a replica of that directory partition. The directory partition must be specified by a fully distinguished name, and the ADAM instance must be specified by *computername:portnumber*.

**delete nc *%s***
Removes the application directory partition *%s*. Before you remove a application directory partition, all the replicas must be removed and their removal must replicate back to the naming operations master.

**select operation target**
Invokes the **Select operation target** submenu.

**set nc reference domain *%s %s***
This command does not apply to ADAM.

**set nc replicate notification delay *%s %d %d***
Sets the notification delays for the application directory partition specified by *%s* to %d1 and %d2 for the delay in notifying the first ADAM instance of changes and the delay in notifying subsequent ADAM instances of changes, respectively.

***%s***
An alphanumeric variable, such as an ADAM instance name.

***%d***
A numeric variable, such as a replication delay time period.

**Quit**
Takes you back to the previous menu, or exits the utility.

**? or help**
Displays help at the command prompt.

**LDAP policies**
Sets the Lightweight Directory Access Protocol (LDAP) administration limits for the Default-Query Policy object. To reach the **LDAP policies:** prompt, at the **dsmgmt:** prompt, type **ldap policies**, and then press ENTER. At the **LDAP policies:** prompt, use the following syntax.

**Syntax**
{**cancel changes**|**commit changes**|**connections**|**list**|**set** *%s* **to** *%s*|**show values**}

**Parameters**
**cancel changes**
Cancels any uncommitted modifications of the LDAP administration limits to the default query policy.

**commit changes**
Commits all modifications of the LDAP administration limits to the default query policy.

**Connections**
Invokes the **server connections** submenu.

**List**
Lists all supported LDAP administration limits for the ADAM instance.

**set *%s1* to *%s2***
Sets the value of the LDAP administration limit *%s1* to the value *%s2*.

**show values**
Shows the current and proposed values for the LDAP administration limits.

***%s***
An alphanumeric variable, such as an ADAM instance name.

**Quit**
Takes you back to the previous menu or exits the utility.

**? or help**
Displays help at the command prompt.

**Remarks**

- The following table describes LDAP administration limits, with the default values noted in parentheses.

| Value | Description |
|---|---|
| **InitRecvTimeout** | Initial receive time-out (120 seconds) |
| **MaxConnections** | Maximum number of open connections (5000) |
| **MaxConnIdleTime** | Maximum amount of time a connection can be idle (900 seconds) |
| **MaxActiveQueries** | Maximum number of queries that can be active at one time (20) |
| **MaxNotificationPerConnection** | Maximum number of notifications that a client can request for a given connection (5) |
| **MaxPageSize** | Maximum page size supported for LDAP responses (1000 records) |
| **MaxQueryDuration** | Maximum length of time the ADAM instance can execute a query (120 seconds) |
| **MaxTempTableSize** | Maximum size of temporary storage allocated to execute queries (10,000 records) |
| **MaxResultSetSize** | Maximum size of the LDAP Result Set (262,144 bytes) |
| **MaxPoolThreads** | Maximum number of threads created by the ADAM instance for query execution (4 per processor) |
| **MaxDatagramRecv** | Maximum number of datagrams that can be processed by the ADAM instance simultaneously (1024) |

- To ensure that ADAM instances can support service level guarantees, specify operational limits for a number of LDAP operations. These limits prevent specific operations from adversely affecting the performance of a server, and they also make the server resilient to denial-of-service attacks.

  LDAP policies are implemented by using objects of the class **queryPolicy**. Query Policy objects can be created in the container Query Policies, which is a child of the Directory Service container in the configuration naming context. For example: CN=Query-Policies, CN=Directory Service, CN=Windows NT, CN=Services (configuration directory partition).

  An ADAM instance uses the following three mechanisms to apply LDAP policies:

  - An ADAM instance might refer to a specific LDAP policy. The **nTDSASettings** object includes an optional attribute **queryPolicyObject**, which contains the distinguished name of a Query Policy.

  - In the absence of a specific query policy being applied to an ADAM instance, the ADAM instance applies the Query Policy that has been assigned to the ADAM instance's site. The **ntDSSiteSettings** object includes an optional attribute **queryPolicyObject**, which contains the distinguished name of a Query Policy.

  - In the absence of a specific ADAM instance or a site Query Policy, an ADAM instance uses the default Query Policy that is named Default-Query Policy.

A Query Policy object includes the multivalued attributes **LDAPIPDenyList** and **LDAPAdminLimits**. An administrator can use **dsmgmt** to set the LDAP administration limits (but not for the IP Deny list) for the Default-Query Policy object.

#### metadata cleanup

Cleans up metadata for retired ADAM instances. To reach the **metadata cleanup:** prompt, at the **dsmgmt:** prompt, type **metadata cleanup**, and then press ENTER. At the **metadata cleanup:** prompt, use the following syntax.

##### Syntax

{**connections**|**remove selected domain**|**remove selected naming context**|**remove selected server**|**select operation target**}

##### Parameters

**Connections**
Removes metadata associated with the domain that is selected in the **Select operation target** submenu.

**remove selected domain**
This command does not apply to ADAM.

**remove selected naming context**
Removes directory service objects for the selected naming context.

**remove selected server**
Removes metadata associated with the ADAM instance that is selected in the **Select operation target** submenu.

**select operation target**
Invokes the **Select operation target** submenu.

**Quit**
Takes you back to the previous menu, or exits the utility.

**? or help**
Displays help at the command prompt.

##### Remarks

- Metadata is maintained for each ADAM instance in a configuration set. When an ADAM instance is uninstalled, any metadata about the uninstalled ADAM instance that has been replicated to other ADAM instances is also removed. However, in some cases, metadata for the uninstalled ADAM instance can remain on the other ADAM instances in the configuration set. To remove this stale metadata, connect to an ADAM instance that holds the stale metadata, and select the uninstalled ADAM instance as the operation target.

| **Caution** |
| --- |
| Do not delete the metadata of existing ADAM instances. |

#### popups {on|off}

Enables or disables interactive pop-up messages. To enable interactive pop-up messages, at the **dsmgmt:** prompt, type **popups on**. To disable pop-up messages, at the **dsmgmt:** prompt, type **popups off**.

#### quit

Type **quit** at the **dsmgmt:** prompt to close the **dsmgmt** command-line tool.

#### roles

Transfers and seizes operations master roles. To reach the **roles:** prompt, at the **dsmgmt:** prompt, type **roles**, and then press ENTER. At the **roles:** prompt, use the following syntax.

| **Note** |
| --- |
| Only the naming master and schema master roles apply to ADAM. Commands relating to the PDC, RID, and infrastructure masters do not apply to ADAM. |

##### Syntax

{**connections**|**seize naming master**|**seize infrastructure master**|**seize PDC**|**seize RID master**|**seize schema master**|**select operation target**|**transfer naming master**|**transfer infrastructure master**|

##### Parameters

**connections**
Invokes the **server connections** submenu.

**seize naming master**
Forces the ADAM instance to which you are connected to claim ownership of the naming operations master role without regard to the data that is associated with the role. Use only for recovery purposes.

**seize infrastructure master**
Does not apply to ADAM.

**seize PDC**
Does not apply to ADAM.

**seize RID master**
Does not apply to ADAM.

**seize schema master**
Forces the ADAM instance to which you are connected to claim ownership of the schema operations master role without regard to the data that is associated with the role. Use only for recovery purposes.

**select operation target**
Invokes the **Select operation target** submenu. From within the submenu, you can list the operations master (also known as flexible single master operations, or FSMO) roles that are held by the currently connected server. For a complete list of **select operation target** subcommands, type **?** at the **select operation target:** prompt.

**transfer naming master**
Instructs the ADAM instance to which you are connected to obtain the naming role by means of controlled transfer.

**transfer infrastructure master**
Does not apply to ADAM.

**transfer PDC**
Does not apply to ADAM.

**transfer RID master**
Does not apply to ADAM.

**transfer schema master**
Instructs the ADAM instance to which you are connected to obtain the schema operations master role by means of controlled transfer.

**quit**
Takes you back to the previous menu, or exits the utility.

**? or help**
Displays help at the command prompt.

##### Remarks

- Although ADAM is based on a multimaster administration model, some operations support only a single master. For multimaster operations, conflict resolution ensures that after the system finishes replicating, all replicas agree on the value for a given property on a given object. However, some data, for which adequate conflict resolution is not possible, is key to the operation of the system as a

whole. This data is controlled by individual ADAM instances, called operations masters.

The following two operations master roles apply to ADAM configuration sets.

- **Schema operations master.** There is a single schema operations master role for each ADAM configuration set. This role allows the operations master server to accept schema updates. There are other restrictions on schema updates.

- **Naming master.** There is a single naming master role for an ADAM configuration set. The naming master role allows the owner to define new cross-reference objects that represent directory partitions in the partitions container.

- An operations master role can only be moved by administrative involvement; it is not moved automatically. Additionally, moving a role is controlled by standard access controls. Therefore, an organization should tightly control the location and movement of operations master roles. For example, an organization with a strong information technology (IT) presence might place the schema role on a server in the IT group and configure its access control list (ACL) so that it cannot be moved at all.

  Operations master roles require two forms of management: controlled transfer and seizure.

  Use controlled transfer when you want to move a role from one server to another, perhaps to track a policy change with respect to role location or in anticipation of a server being shut down, moved, or decommissioned.

  Seizure is required when a server that is holding a role fails and you do not intend to restore it. Even in the case of a server that is recovered from a backup, the server does not assume that it owns a role (even if the backup tape says so), because the server cannot determine if the role was legitimately transferred to another server in the time period between when the backup was made and when the server failed and was recovered. The restored server assumes role ownership only if a quorum of existing servers is available during recovery and they all agree that the restored server is still the owner.

  The **roles** submenu in **dsmgmt** is used to perform controlled transfer and recovery of operations master roles. Controlled transfer is simple and safe. Because the source and destination servers are running, the system software guarantees that the operations master role token and its associated data is transferred safely. Operations master role seizure is equally simple but not as safe; you simply tell a particular ADAM instance that it is now the owner of a particular role.

| **Caution** |
| --- |
| Do not make a server a role owner by means of seizure commands if the real role holder exists on the network. Doing this can create irreconcilable conflicts for key system data. If an operations master role owner is temporarily unavailable, do not make another ADAM instance the role owner. This can result in a situation in which two computers function as the role owner, which might cause irreconcilable conflicts for key system data. |

**security account management**

This command does not apply to ADAM.

**Formatting legend**

| **Format** | **Meaning** |
| --- | --- |
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| Courier font | Code or program output |

# Ldp

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Ldp**

The **Ldp** dialog box consists of two panes: the console tree and the details pane. The console tree lists the base object and any child objects. The details pane lists the results of the Lightweight Directory Access Protocol (LDAP) operations. To start Ldp, click **Start**, point to **All Programs**, point to **ADAM**, click **ADAM Tools Command Prompt**, and then type **ldp** at the command prompt.

The following sections describe commands on the Ldp menus:

- Connection
- Browse
- View
- Options
- Utilities

**Connection**

The following table describes commands on the **Connection** menu.

| Command | Description |
|---|---|
| **Connect** | Opens a dialog box that you can use to open a session with a specified LDAP server. A connection must be established with an LDAP server before any other LDAP commands can be run. Type the appropriate port number for the service that you are connecting to. By default, LDAP uses TCP for a connection-oriented session. To use User Datagram Protocol (UDP) for a connectionless session, select the **Connectionless** check box. By default, a successful connection causes the appearance of **RootDSE** information in the details pane. |

| | |
|---|---|
| **Bind** | Opens a dialog box that you can use to authenticate a specified LDAP server. Type a user name and password of an account that has permissions to the LDAP server. If you do a simple bind with an empty password, you will be connected with anonymous credentials. As a shortcut, use the **Bind** command without using the **Connect** command to connect, and then authenticate with the server that you last connected to. Click **Advanced** on the **Bind** dialog box to open the **Bind Options** dialog box and configure authentication method options.<br><br>The following are the options in the **Bind Options** dialog box.<br><br>• **Function Type** - Specifies a category of authentication for Ldp to use when choosing authentication methods.<br><br>• **Generic** - Specifies use of a standard authentication protocol.<br><br>• **Simple** - Specifies use of no authentication protocol and sends the password in plaintext.<br><br>• **Extended** - Not available.<br><br>• **Method** - Specifies the type of authentication that Ldp uses when passing credentials.<br><br>• **Synchronous** - Specifies that the authenticating server must respond immediately to requests. This option works only with simple authentication.<br><br>• **Use auth. Identity** - Allows the use of alternate authentication credentials. All authentication methods except simple require synchronous calls. |
| **Disconnect** | Terminates an open session with a specified LDAP server. Closing Ldp automatically disconnects any open sessions. |
| **New** | Keeps the currently connected session, but clears the details pane. The keyboard shortcut for this action is CTRL+N. |
| **Save** | Saves changes to a previously saved file. |
| **Save as** | Saves the contents of the details pane to a text file. Use the **Open** command to view the contents of this file in the details pane later. |
| **Print** | Prints the contents of the details pane. |

**Browse**

The following sections describe commands on the **Browse** menu:

**Add Child**

Opens a dialog box that you can use to add objects to Active Directory. You must enter the full distinguished name of the object, as well as all the mandatory attributes for the class of object being added.

The following table describes options in the **Add** dialog box.

| Option | Description |
|---|---|
| **Dn** | Type the full distinguished name of the new object. |
| **Attribute** | Type the required or optional attribute. |
| **Values** | Type the values that are associated with the attribute. Separate multiple values for a single attribute with a semicolon. No spaces are required. |
| **Enter** | Adds the entered attribute and values to the **Entry List** box, and clears the **Attribute** and **Values** boxes. Continue entering attributes and values until all required and desired optional attributes are in the **Entry List** box. |
| **Insert file** | Opens a dialog box that you can use to open a text file with the appropriate attributes and values. |

| | |
|---|---|
| **Entry List** | Displays the attributes and values that you enter. |
| **Edit** | Opens a dialog box that you can use to enter changes to the selected entry in the **Entry List** box. |
| **Remove** | Deletes the selected entry from the **Entry List** box. |
| **Extended** | Select this check box if the object being added is part of an extended control. |
| **Synchronous** | If this check box is selected (which is the default), Ldp is required to wait for a response from the destination server before continuing. If you clear this check box, Ldp continues before a response is received. Clear this check box when slow wide area network (WAN) connections are causing Ldp commands to time out. |
| **Run** | Adds the current attributes and values in the Entry List to Active Directory. If Ldp encounters any errors, the object is not added and an error message appears in the details pane. |

**Delete**

This command opens a dialog box that you can use to delete an object from Active Directory. Attributes can be deleted only if they are defined as optional and if they contain no values. To delete an attribute's values, on the **Browse** menu in the **Add** dialog box, click **Edit**.

| Option | Description |
|---|---|
| **DN** | Type the full distinguished name of the new object. |
| **Extended** | Select this check box if the object being modified is part of an extended control. |
| **Synchronous** | If this check box is selected (which is the default), Ldp is required to wait for a response from the destination server before continuing. If you clear this check box, Ldp continues before a response is received. Clear this check box when slow WAN connections are causing Ldp commands to time out. |
| **Recursive (client)** | Deletes all objects in a container, but does not delete the container. |

**Modify**

This command opens a dialog box that you can use to change the attributes of an object that is stored in Active Directory.

The following table describes options in the **Modify** dialog box.

| Option | Description |
|---|---|
| **Dn** | Type the full distinguished name of the new object. |
| **Attribute** | Type the required or optional attribute. |
| **Values** | Type the values that are associated with the attribute. Separate multiple values for a single attribute with a semicolon. No spaces are required. |
| **Insert file** | Opens a dialog box that you can use to open a text file with the appropriate attributes and values. |
| **Enter** | Adds the entered attribute and values to the **Entry List** section of the dialog box, and clears the **Attribute** and **Values** fields. Continue entering attributes and values until all required and desired optional attributes are in the **Entry List** box. |
| **Operation** | **Add**, **Delete**, or **Replace**. To add a new value to an existing attribute, click **Add**. To permanently remove an attribute from the listed object, click **Delete**. Attributes that contain data cannot be deleted. Also, attempting to delete required attributes results in an error. To replace an existing value with another or to change listed values for an existing attribute, click **Replace**. |
| **Entry List** | Displays the existing attributes and values for an object. |
| **Edit** | Opens a dialog box that you can use to make changes to the selected entry in the **Entry List** box. |

| | |
|---|---|
| **Synchronous** | If this check box is selected (which is the default), Ldp is required to wait for a response from the destination server before continuing. If you clear this check box, Ldp continues before a response is received. Clear this check box when slow WAN connections are causing Ldp commands to time out. |
| **Extended** | Select this check box if the object being modified is part of an extended control. |
| **Run** | Sends the edited values in the **Entry List** box to Active Directory. |

**Modify DN**

Opens a dialog box that you can use to change the relative distinguished name of an object. This option is designed to modify leaf objects only. If you rename the container portion of the distinguished name, the object moves to the container that is named.

The following table describes options in the **Modify RDN** dialog box.

| Option | Description |
|---|---|
| **Old Dn** | Type the current distinguished name of the object. |
| **New Dn** | Type the new distinguished name for the object. |
| **Delete Old** | If this check box is selected (which is the default), the old distinguished name is removed from the LDAP directory. |
| **Synchronous** | If this check box is selected (which is the default), Ldp is required to wait for a response from the destination server before continuing. If you clear this check box, Ldp continues before a response is received. Clear this check box when slow WAN connections are causing Ldp commands to time out. |
| **Extended rename** | Select this check box if the object being renamed is part of an extended control. |
| **Run** | Sends the change to Active Directory. |

**Search**

Opens a dialog box that you can use to create a customized search filter and to perform the search on the directory information tree. The search base must be specified as a distinguished name, and the filter must be a valid LDAP filter. Items returned from a search are separated by **>>** characters.

The following table describes options in the **Search** dialog box.

| Option | Description |
|---|---|
| **Base Dn** | Type a distinguished name to specify where the search starts. |
| **Filter** | Type the search criteria, separated by LDAP search filters. Type attributes and values to find an object or set of objects. Note that LDAP search filters are defined in RFC 2254 and in the article 255602 at the Microsoft Knowledge Base. |
| **Scope** | Specifies how many levels the search encompasses. |
| **Base** | Searches the base object only. |
| **One Level** | Searches objects immediately subordinate to the base object, but does not search the base object. |
| **Subtree** | Searches the entire subtree, from the base object down to all child objects. |
| **Options** | Opens the **Search Options** dialog box. You can use these options to apply filters that allow some entries and exclude others from the search and that allow you to control the way the search is processed. |
| **Run** | Sends the search request to Active Directory. |

**Compare**

Opens a dialog box that you can use to compare the value of an attribute of an object with a specified value. The result

returned is either true or false.

The following table describes options in the **Compare** dialog box.

| Option | Description |
|---|---|
| **Dn** | Type the full distinguished name of the object whose values will be compared. |
| **Attribute** | Type the attribute to be compared. |
| **Value** | Type the value that will be compared with the existing value in Active Directory. Separate multiple values for a single attribute with a semicolon. No spaces are required. |
| **Synchronous** | If this check box is selected (which is the default), Ldp is required to wait for a response from the destination server before continuing. If you clear this check box, Ldp continues before a response is received. Clear this check box when slow WAN connections are causing Ldp commands to time out. |
| **Run** | Starts the comparison. |

**Extended Op**

Opens a dialog box that you can use to submit an extended operation to an LDAP directory by specifying an LDAP object identifier (also known as OID) and an applicable value.

The following table describes options in the **Extended Operations** dialog box.

| Option | Description |
|---|---|
| **Oid** | Type the object identifier number. |
| **Data** | Type the value of the object identifier attribute. |
| **Controls** | See **Controls Option** in the **Options** section. |
| **Send** | Submits the extended operation to Active Directory. |

**GetLastError**

Calls the LDAP **GetLastError** function.

**Security**

Opens a dialog box that you can use to submit an extended operation to an LDAP directory by specifying an LDAP object identifier and an applicable value.

The following table describes the **Security Descriptor** dialog box.

| Option | Description |
|---|---|
| **Security Descriptor** | Opens a dialog box that you can use to view access permissions on an object. |

**Replication**

Opens a dialog box that you can use to submit an extended operation to an LDAP directory by specifying an LDAP object identifier and an applicable value.

The following table describes the **Replication Metadata** dialog box.

| Option | Description |
|---|---|
| **Replication/View Metadata** | In **Object DN**, type the distinguished name of the object whose replication metadata you want to view. |

**Process Pending**

Opens a dialog box that shows the list of requests that are not finished processing.

**View**

The following table describes commands on the **View** menu.

| Command | Description |
|---|---|

| | |
|---|---|
| **Tree** | In **BaseDN**, type the distinguished name of the object to use as the base object in the navigation pane. |
| **Enterprise Configuration** | This menu option does not apply to ADAM. |
| **Status Bar** | Shows or hides the status bar, which is located along the bottom of the LDAP window. |

**Options**

The following sections describe the commands on the **Options** menu:

**Search**

The following table describes options in the **Search Options** dialog box.

| Option | Description |
|---|---|
| **Time limit** | Type the number of milliseconds that the search can take on the server. By default, the maximum is 120 seconds. |
| **Size limit** | Type the maximum number of bytes that the search can return. Typing a null value does not place a maximum size on the data that is returned. |
| **Timeout (s)** | Type the number of seconds that Ldp waits for the LDAP server to respond to a search request. |
| **Timeout (ms)** | Type the number of milliseconds that Ldp waits for the LDAP server to respond to a search request. |
| **Page size** | Type the maximum size, in bytes, of each page of returned data. |
| **Attributes** | Specifies which attributes to return in the search. Separate multiple attributes with a semicolon. Use the wildcard character (*****) to indicate all attributes. |
| **Search Call Type** | Specifies a call type to use in the search. If the search will take some time, you can click **Async.** so that you can perform other tasks while waiting for the search to complete. |
| **Attributes Only** | Select this check box to return only attributes of objects. The distinguished name is not returned. |
| **Chase referrals** | Performs a search for objects that are found in external LDAP directories. By default, the objects' trusts of external LDAP directories return only a referral instead of the actual object. |
| **Display Results** | Displays a detailed list of objects that are returned by the search. By default, only a success or failure and the number of objects found appear. |
| **Sort Keys** | Opens the **Sort Keys** dialog box. See the **Sort Keys** section below. |
| **Controls** | Opens the **Controls** dialog box. |

**Pending**

Opens a dialog box that you can use to place filters on the list of processes that have not yet completed.

The following table describes options in the **Pending Options** dialog box.

| Option | Description |
|---|---|
| **All search results** | Specifies that all search results display. |
| **Blocking** | Clear this check box to set a time limit. |
| **Time Limit (sec):** | Type a time limit in seconds. |
| **Time Limit (millisec):** | Type a time limit in milliseconds. |

**General**

The following table describes options in the **General Options** dialog box.

| Option | Description |
| --- | --- |
| **Value Parsing** | Specifies the display format of LDAP data. **Binary** displays the LDAP information in its native numerical format. **String** Converts the LDAP information from its native format to ASCII characters so that it is more readable when displayed. This is the default setting. Values that are too long to be converted are still displayed in binary form. |
| **LDAP Version** | Specifies which version of LDAP the server is using. The default is **version 3**. |
| **DN Processing** | Converts the distinguished names, displayed in component parts, by extending the data types that Ldp returns when performing a command. |
| **Buffer Size** | In **Number of lines**, type the number of returned lines to display per command. In **Chars per line**, type the number of returned characters to display per command. |
| **Auto default NC query** | Specifies that Ldp queries the default naming context when a connection to the LDAP server is made. The default naming context is the **RootDSE**. This setting is used when the distinguished name value in the **View\|Tree** dialog box is left blank. |
| **Virtual List View (VLV)** | Select **Auto VLV browse when** to display a virtual list view whenever the object count is greater than the value that is displayed in **container size is greater than**. The default value is 100. |

**Connection Options**

Opens a dialog box that you can use to change the value of any option.

The following table describes options in the **Connection Options** dialog box.

| Option | Description |
| --- | --- |
| **Option Name** | Type the name of the option whose value will be reset. |
| **Value** | Type the new value for the specified option. |
| **Set** | Sends the information to the LDAP directory. |

**Controls**

In the **Controls** dialog box, enter information to extend the functionality of LDAP.

The **Object Identifier** option must be specified when you implement a control. To obtain a list of object identifiers, view the **supportedControls** property in the **RootDSE** of a domain controller. Individual controls are described in the "Understanding LDAP" white paper at the Microsoft Web site.

### Notes

- Only server controls can be sent to a server. Client controls work only with LDAP application programming interfaces (APIs).
- To view a list of extended LDAP controls, see article 222560 at the Microsoft Knowledge Base.

**Sort Keys**

**Sort Keys** is a type of control that formats the display of search results. To format the display of your search results, in the **Sort Keys** dialog box, type an attribute type.

For more information, search for "sortKeyRequestControl" in the "Understanding LDAP" white paper at the Microsoft Web site.

**TLS**

The following table describes the subcommands for the **TLS** command.

| Option | Description |
| --- | --- |
| **StartTLS** or **StopTLS** | Starts or stops a secure session with the LDAP server that uses Transport Level Security (TLS). |

**Utilities**

The following table describes the commands on the **Utilities** menu.

| Option | Description |
| --- | --- |
| **Large Integer Converter** | To convert long integers into high and low parts, type a value in the **String** box. |
| **SID Lookup** | To determine the *domain\user* that is associated with a given security ID (SID), type a SID into **List of sids**, and then click **OK**. The associated *domain\user* appears in the details pane. |

# Repadmin

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Repadmin**
Performs tasks related to replication, including managing and modifing replication topology, forcing replication events, and displaying replication metadata and up-to-date vectors. **Repadmin** contains several subcommands, which are described below in detail.

### Notes

- Most **repadmin** subcommands apply to both Active Directory Application Mode (ADAM) and Active Directory, except as noted in the description for each subcommand.
- Not all general parameters apply to all subcommands.

**General syntax**
**repadmin** *subcommand* [*dsa*] [**/u:** *UserName*] [**/pw:** {*Password*|*****}] [**/rpc**] [**/ldap**] [**/homeserver:***dsaname*]

**General parameters**
***subcommand***
One of the **repadmin** subcommands described in the "Subcommands" section.

| Value | Description |
|---|---|
| *Dsaname* | One of the following:<br>• *computername*:*portnumber*<br>Specifies an ADAM instance or Active Directory domain controller, using the name of the computer on which the directory service is running and (for ADAM only) the port number used for communication, for example, **adam01:389** or **adam01:636**.<br>• *DNSname*:*portnumber*<br>Specifies an ADAM instance or Active Directory domain controller by Domain Name System (DNS) name of the computer on which the directory service is running and (for ADAM only) the port number used for communication, for example, **adam01.microsoft.com:389** or **adam01.microsoft.com:636**. |
| *dsaguid* | Specifies an ADAM instance or Active Directory domain controller using the globally unique identifier (GUID) of the directory service. When you use "*dsaguid*" against an ADAM configuration set, you must also use the **/homeserver:** parameter. |
| . | **Repadmin** attempts to select a directory server automatically. When you use "." against an ADAM configuration set, you must also use the **/homeserver:** parameter. |
| ***** | **Repadmin** selects all ADAM instances or Active Directory domain controllers in the ADAM configuration set or Active Directory forest. When you use "*" against an ADAM configuration set, you must also use the **/homeserver:** parameter. |
| **site**:*sitename* | Selects all ADAM instances or Active Directory domain controllers in the site called *sitename*, for example, **site:microsoftsite1**. When you use "site:" against an ADAM configuration set, you must also use the **/homeserver:** parameter. |
| **fsmo_dnm:** | Selects the directory server holding the naming operation master role (for ADAM), or the domain naming operation master role (for Active Directory). When you use **fsmo_dnm:** against an ADAM configuration set, you must also use the **/homeserver:** parameter. |

| | |
|---|---|
| **fsmo_schema:** | Selects the directory server holding the schema operation master role. When you use **fsmo_schema:** against an ADAM configuration set, you must also use the **/homeserver:** parameter. |

***dsa* {*dsaname*|*dsaguid*|.|*|site:*sitename*|fsmo_dnm:|fsmo_schema:}**

The *dsa* parameter represents the directory server (ADAM instance or Active Directory domain controller) to be targeted by the **repadmin** subcommand. The *dsa* parameter can be provided in a number of ways, as described in the following table. (Type **repadmin /listhelp** at the command line for additional information about the *dsa* parameter.)

**/u: *UserName***

Specifies the account name to use for binding to the directory. By default, **/u** uses the account name with which the user is currently logged on. You can use any of the following formats to specify an account name: *account name* (for example, **Linda**), *domain\account name* (for example, **widgets\Linda**), or *user principal name (UPN)* (for example, **Linda@cohovineyard.com**)

**/pw: {*Password*|*}**

Specifies the password to use for authentication. If you type *****, you are prompted for a password.

**/rpc**

Forces **repadmin** to communicate using a remote procedure call (RPC) session.

**/ldap**

Forces **repadmin** to communicate using a Lightweight Directory Access Protocol (LDAP) session. If LDAP communication fails, **repadmin** attempts to communicate using RPC. LDAP is the default communication method for **repadmin**.

**/homeserver: *dsaname***

Forces **repadmin** to run against a specific ADAM configuration set or Active Directory forest, determined by the configuration set or forest membership of the directory server that is represented by *dsaname*. *Dsaname* can be specified in the following formats for an ADAM instance: *computername:portnumber* or *DNSname:portnumber Dsaname* can be specified in the following formats for an Active directory domain controller: *computername* or *DNSname*. You must use this parameter when you run **repadmin** against an ADAM configuration set, and *dsaguid*, "*****", "**.**", "**site:***site*", "**fsmo_dnm:**", or "**fsmo_schema:**" are used as the value for the *dsa* parameter.

**Note**

- Not all **repadmin** subcommands require the *dsa* parameter.

**Subcommands**

To view the **repadmin** subcommand syntax, click a **repadmin** subcommand:

- repadmin bind
- repadmin bridgeheads
- repadmin checkprop
- repadmin dsaguid
- repadmin failcache
- repadmin istg
- repadmin kcc
- repadmin latency
- repadmin notifyopt
- repadmin queue
- repadmin replauthmode

- repadmin replicate
- repadmin replsingleobj
- repadmin showattr
- repadmin showcert
- repadmin showchanges
- repadmin showconn
- repadmin showctx
- repadmin showism
- repadmin showmsg
- repadmin showncsig
- repadmin showobjmeta
- repadmin showoutcalls

**repadmin bind**

Connects to and displays the replication features for a directory server.

**Syntax**

**repadmin /bind** [*dsa*] [**/u:** *UserName*] [**/pw:** {*Password*|*****}] [**/rpc**] [**/ldap**]

**Parameters**

**/bind [*dsa*]**

Specifies the directory server for which information will be displayed. For details about the *dsa* parameter, see General parameters.

**Other parameters**

For details about other parameters, see General parameters.

#### repadmin bridgeheads

Lists the directory servers acting as bridgehead servers for a specified site.

##### Syntax

**repadmin /bridgeheads** [*dsa*] [**/verbose**] [**/u:** *UserName*] [**/pw:** {*Password*|*****}] [**/rpc**] [**/ldap**]

##### Parameters

**/bridgeheads *dsa***

Specifies a directory server that is located in the site for which bridgehead servers will be listed. For details about the *dsa* parameter, see General parameters.

**Other parameters**

For details about other parameters, see General parameters.

#### repadmin checkprop

Compares the properties of specified directory servers to determine if they are up to date with each other. The source directory server contains the original information that needs to be checked. The data on the destination directory server is compared to the data on the source directory server.

##### Syntax

**repadmin /checkprop** [*dsa*] *NamingContext OriginatingDCInvocationID OriginatingUSN*

##### Parameters

***Dsa***

Specifies a directory server. For details about the *dsa* parameter, see General parameters.

***NamingContext***

Specifies the distinguished name of the directory partition on the source directory server.

***OriginatingDCInvocationID***

Specifies the unique hexadecimal number that identifies an object on a source directory server. The *InvocationID* can be retrieved by using **showrepl**.

***OriginatingUSN***

Specifies the Update Sequence Number (USN) for the object on the source directory server. The USN is for the object whose *InvocationID* is already listed.

#### repadmin dsaguid

Returns a server name when given a GUID.

##### Syntax

**repadmin /dsaguid** [*dsa*] [*GUID*]

##### Parameters

***Dsa***

Specifies a directory server. For details about the *dsa* parameter, see General parameters.

***GUID***

Specifies the unique hexadecimal number that identifies the directory server. The GUID can be retrieved by using **showrepl**.

#### repadmin failcache

Displays a list of failed replication events that are detected by Knowledge Consistency Checker (KCC).

##### Syntax

**repadmin /failcache** [*dsa*]

##### Parameters

***Dsa***

Specifies a directory server. For details about the *dsa* parameter, see General parameters.

#### repadmin istg

Returns the computer name of the Intersite Topology Generator (ISTG) server for a specified site.

##### Syntax

**repadmin /istg** [*dsa*] [**/verbose**]

##### Parameters

***Dsa***
Specifies a directory server. For details about the *dsa* parameter, see General parameters.

**/verbose**
Lists detailed information.

**repadmin kcc**
Forces KCC to calculate replication topology for a specified directory server. By default, this calculation occurs every 15 minutes.

**Syntax**
**repadmin /kcc** [*dsa*] [**/async**]

**Parameters**
***Dsa***
Specifies a directory server. For details about the *dsa* parameter, see General parameters.

**/async**
Specifies that the operation will be asynchronous. This means that **repadmin** starts the replication event, but it does not expect an immediate response from the destination directory server. Use this parameter to start **kcc** without waiting for it to complete.

**repadmin latency**
Displays the amount of time between replications, using the ISTG Keep Alive time stamp.

### Notes

- This command does not apply to ADAM.
- The ISTG Keep Alive time stamp is not used in forests that are set to Windows Server 2003 forest functional level. Instead, in those environments, use **repadmin /showutdvec /latency**.

**Syntax**
**repadmin /latency** [*dsa*] [**/verbose**]

**Parameters**
***dsa***
Specifies a directory server. For details about the *dsa* parameter, see General parameters.

**/verbose**
Lists detailed information.

**repadmin notifyopt**
Displays or sets the notification timing settings for replication of a specified directory partition.

**Syntax**
**repadmin /notifyopt** [*dsa*] *NamingContext* [**/first:***Value*] [**/subs:***Value*]

**Parameters**
***dsa***
Specifies a directory server. For details about the *dsa* parameter, see General parameters.

***NamingContext***
Specifies the distinguished name of the directory partition on the source directory server.

**/first: *Value***
The number of seconds after a change is made before the directory server notifies its first replication partner that there is a change.

**/subs: *Value***
After the first replication partner is notified of a change, specifies the number of seconds to wait before notifying the next replication partner.

**repadmin queue**
Displays tasks that are waiting in the replication queue.

**Syntax**

**repadmin /queue** [*dsa*]

#### Parameters

***dsa***

Specifies a directory server. For details about the *dsa* parameter, see General parameters.

#### repadmin replauthmode

Modifies or displays the replication authentication mode in use by an ADAM configuration set.

#### Syntax

**repadmin /replauthmode** *dsa* [*newmode*]

#### Parameters

***Dsa***

Specifies a directory server. For details about the *dsa* parameter, see General parameters.

***newmode***

Specifies the replication authentication mode to be used by the configuration set. If this parameter is not specified, the command will display the current replication authentication mode. For information about replication authentication modes in ADAM, see Understanding ADAM replication and configuration sets.

### Other parameters

For details about other parameters, see General parameters.

#### repadmin replicate

Starts synchronization for the specified directory partition between the source and destination directory servers. The source GUID can be determined when viewing the replication partners by using **showrepl**.

### Syntax 1

**repadmin /replicate** *destination_dsa source_dsa* [**/force**] [**/async**] [**/full**] [**/addref**]

### Syntax 2

**repadmin /replicate** *destination_dsa* [**/force**] [**/async**] [**/full**] [**/addref**] **/allsources**

#### Parameters

***destination_dsa***

Specifies the host_name[:port] of the destination directory server with which you want to replicate. This parameter cannot be used with **/allsource**. For details about valid values for this parameter, see *dsa* in General parameters.

***source_dsa***

Specifies the host_name[:port] of the source directory server with which you want to replicate. This parameter cannot be used with **/allsource**. For details about valid values for this parameter, see *dsa* in General parameters.

**/force**

This parameter is used to override the **Disable Replication** option on a directory server. Do not use this parameter unless you are certain that replication has been disabled, and that you want to override this setting.

**/async**

Specifies that the operation will be asynchronous. This means that **repadmin** starts the replication event, but it does not expect an immediate response from the destination directory server. Use this parameter when there are slow links between directory servers.

**/full**

Forces a full replication of all objects from the destination directory server.

**/addref**

Directs the source to check for a notification entry on the source. If the source does not have a notification entry for this destination, one is added.

**/allsources**

A given destination can have multiple sources for the same naming context. Directs the destination to sync with all sources instead of just one. This parameter cannot be used with *source_dsa*.

**/readonly**

This parameter is ignored by the **/replicate** operation.

#### repadmin replsingleobj

Replicates a single object between any two directory servers that have partitions in common. The two directory servers do not have a replication agreement. Replication agreements can be shown by using the **repadmin /showrepl** command.

##### Syntax

**repadmin /replsingleobject** *dsa DsaSourceGUID ObjectDN*

##### Parameters

***dsa***

Specifies the directory server to which the object will be replicated. For details about the *dsa* parameter, see General parameters.

***DsaSourceGUID***

Specifies the unique hexadecimal number that identifies the object that will be replicated. The **objectGUID** can be retrieved by using **showrepl**.

***ObjectDN***

Specifies the distinguished name of the object.

#### repadmin showattr

The **/showattr** operation displays objects and their attributes.

##### Syntax

**repadmin /showattr** *dsa OBJ_LIST* [*OBJ_LIST_OPTIONS*] [**/attr**|**/attrs:** *attribute attribute* ...] [**/allvalues**] [**/long**] [**/nolongblob**] [**/nolongblob**] [**/nolongfriendly**] [**/dumpallblob**]

##### Parameters

***Dsa***

Specifies the directory server to which the object will be replicated. For details about the *dsa* parameter, see General parameters. This is a required parameter.

***OBJ_LIST***

This parameter takes a distinguished name or a special keyword that expands into a distinguished name. The keywords are as follows: **<***DistinguishedName***>** s**pecify the distinguished name of an object**; **Ncobj:config:**; **Ncobj:schema:**; **Ncobj:domain:** This keyword represents the distinguished name of the domain directory partition of the directory server; **Dsaobj:** This keyword represents the NTDS settings object of the directory server; and, **""** Use an empty string to specify the RootDSE.

***OBJ_LIST_OPTIONS***

The OBJ_LIST_OPTION parameter is required to perform a generic LDAP search from the command line. The parameter requires a **BaseDN**, with the ability to use a search modifier option. The valid search modifier options are as follows: **/filter:**<ldap_filter>; **/base**; **/subtree**; and, **/onelevel**. See the LDAP documentation for the LDAP filter syntax.

**/atts:<*attribute, attribute...*>**

Returns only the attributes that are specified. Separate each listed attribute with a comma. By default, returns all attributes.

**/allvalues**

For an attribute, the tool only displays 20 values unless this flag is specified, in which case it shows all values.

**/long**

Displays one value per line.

**/nolongblob**

This parameter is ignored by **/showattr**.

**/nolongfriendly**

This parameter is ignored by **/showattr**.

**/friendlyblob[:*attribute attribute* ...]**

If any attributes are specified, only those attributes that are named are displayed in friendly format. Otherwise, all known BLOBs are formatted.

**/nolongfriendly**

Does not format BLOBs.

**/dumpallblob**

Dumps the BLOB in a default byte-by-byte format if there is not a friendly formatted interpretation available for it.

**/nodumpallblob**
Does not show the BLOB if there is not a formatted interpretation available.

**/attr|/attrs:** ***attribute attribute ...***
The parameters **/attr** or **/attrs:**, if present, specify that only those named attributes are displayed.

| **Note** |
| --- |
| A BLOB in this context means an attribute that is not a simple type, like a string or an integer. A BLOB is a complex structured type that is stored as binary bytes. To make sense of the BLOB, a program must interpret it and format it. A friendly BLOB is a BLOB that the program knows about and can format in an understandable way. The program has a list of BLOBs that it understands. |

**repadmin showcert**
Displays the certificates (used with Simple Mail Transfer Protocol (SMTP)-based replication) that are loaded on a specified directory server.

| **Note** |
| --- |
| This command does not apply to ADAM. |

**Syntax**
**repadmin /showcert** *dsa*

**Parameters**
***dsa***
Specifies the directory server to which the object will be replicated. For details about the *dsa* parameter, see General parameters.

**repadmin showchanges**
Displays changes from a specified directory partition or changes to a specified object. "Syntax 1" saves changes to a directory partition. If this information is saved to a file, the **getchanges** operation can be run again for comparison. "Syntax 2" lists changes to a specified object.

| **Note** |
| --- |
| For this command to run properly, the account under which the command is run must possess the **replication get changes** right on the specified directory partition. |

**Syntax 1**
**repadmin /showchanges** *source_dsa NamingContext* [**/cookie:** *File*] [**/atts:** *attribute,attribute,...*]

**Syntax 2**
**repadmin /showchanges** *dest_dsa SourcedsaObjectGUID NamingContext* [**/verbose**] [**/statistics**] [**/noincremental**] [**/objectsecurity**] [**/ancestors**] [**/atts:** *attribute1,attribute2,...*] [**/filter:** *ldap filter*]

**Parameters**
***dest_dsa***
Specifies the host name of the destination directory server from which to enumerate the host directory servers.

***source_dsa***
Specifies the host name of the directory server that hosts the directory partition whose changes you want to view.

***NamingContext***
Specifies the distinguished name of the directory partition.

**/cookie:** ***File***
Specifies a name for the file to which list changes are saved.

**/atts:** ***attribute1attributes...***
Returns only the attributes specified. Separate each listed attribute with a comma.

***SourcedsaObjectGUID***
Specifies the unique hexadecimal number that identifies the object whose changes will be listed. The **objectGUID** can be retrieved by using the **showrepl** operation.

**/verbose**
Lists detailed information.

**/statistics**
Displays a summary of information about changes, instead of a list of individual changes.

**/noincremental**
Returns changes in value change format, which lists current values for attributes as well what attributes have been added or deleted. If not specified, changes are returned in attribute change format, which shows only the current value of the attribute.

**/objectsecurity**
Overrides the need for the Get Changes right to the directory partition. By default, this right is needed to run the **GetChanges** parameter. However, only changes that the currently logged on user has the rights to view are displayed.

**/ancestors**
Returns changes in USN order.

**/filter: *ldap filter***
Returns only those changes that meet the filter requirements.

| **Note** |
| --- |
| The information from "Syntax 1" can be saved to a file for later comparison. |

#### repadmin showconn
Displays the connection objects for a specified directory server. The default is **local site**.

##### Syntax
**repadmin /showconn** [*dsa*] [*ServerRDN*|*ContainerDN*|*dsa_GUID*] [**/From:***ServerRDN*] [**/intersite**]

##### Parameters
***dsa***
Specifies the directory server to which the object will be replicated. For details about the *dsa* parameter, see General parameters.

***ServerRDN***
Specifies the relative distinguished name of a server.

***ContainerDN***
Specifies the distinguished name of a container.

***dsa_GUID***
Specifies the unique hexadecimal number that identifies the directory server. The GUID can be retrieved by using the **showrepl** operation.

**/From: *ServerRDN***
Displays only the connection objects that exist to the specified server. By default, all connection objects are displayed.

**/intersite**
Displays only those connection objects that are between sites.

#### repadmin showctx
Displays a list of computers that have opened sessions with a specified directory server.

##### Syntax
**repadmin /showctx** [*dsa*] [**/nocache**]

##### Parameters
***dsa***
Specifies the directory server to which the object will be replicated. For details about the *dsa* parameter, see General parameters.

**/nocache**
Specifies that GUIDs are left in hexadecimal form. By default, GUIDs are translated into strings.

#### repadmin showism
Queries the Intersite Messaging Service (ISM) for site routes. This operation cannot be executed remotely.

| Note |
| --- |
| This command does not apply to ADAM. |

**Syntax**

**repadmin /showism** [*TransportDN*] [**/verbose**]

**Parameters**

***TransportDN***

Specifies whether the mail server is using SMTP or RPC to send messages.

**/verbose**

Lists detailed information.

| Note |
| --- |
| This command cannot be run against a remote directory server. |

**repadmin showmsg**

Displays the error message for a given error number.

**Syntax**

**repadmin /showmsg** {*Win32Error*|*DSEventID* **/NTDSMSG**}

**Parameters**

***Win32Error***

Returns a short description of the given Win32 error code.

***DSEventID*** **/NTDSMSG**

Returns the actual event log text for the specified event ID.

**repadmin showncsig**

Each directory server maintains a directory partition signature list. This command displays a list of the removed application partition GUIDs. An application directory partition can be configured to be held or not held on a particular directory server using **dsdbutil** (for ADAM), or **ntdsutil** (for Active Directory).

**Syntax**

**repadmin /showncsig** [*dsa*]

**Parameters**

***dsa***

Specifies the directory server to which the object will be replicated. For details about the *dsa* parameter, see General parameters.

**repadmin showobjmeta**

Displays the replication metadata for a specified object that is stored in the directory, including attribute ID, version number, originating and local USN, and originating server's GUID and Date and Time stamp. By comparing the replication metadata for the same object on different directory servers, an administrator can determine whether replication has taken place.

**Syntax**

**repadmin /showobjmeta** [*dsa*] *ObjectDN* [**/nocache**] [**/linked**]

**Parameters**

***dsa***

Specifies the host name of the directory server to which the object will be replicated. For details about the *dsa* parameter, see General parameters.

***ObjectDN***

Specifies the distinguished name of the object.

**/nocache**

Specifies that GUIDs are left in hexadecimal form. By default, GUIDs are translated into strings.

**/linked**

Displays metadata that is associated with, but not stored with, the specified object.

**repadmin showoutcalls**

Displays calls that have been made by the specified directory server to other directory servers but not yet answered.

**Syntax**

**repadmin/showoutcalls** [*dsa*]

**Parameters**

***dsa***

Specifies the directory server to which the object will be replicated. For details about the *dsa* parameter, see General parameters.

**repadmin showproxy**

Lists cross-domain move proxy objects. When an object is moved from one domain to another, a marker remains in the original domain. This marker is called a proxy.

| **Note** |
| --- |
| This command does not apply to ADAM. |

**Syntax 1**

**repadmin /showproxy** [*dsa*] [*NamingContext*] [**matchstring**]

**Syntax 2**

**repadmin /showproxy** [*dsa*] [*ObjectDN*] [**matchstring**] **/movedobject**

**Parameters**

***dsa***

Specifies the directory server to which the object will be replicated. For details about the *dsa* parameter, see General parameters.

***NamingContext***

Specifies the distinguished name of the directory partition on the source directory server.

***ObjectDN***

Specifies the distinguished name of the object.

**matchstring**

Specifies a filter for the output. Type a string of characters that must be present in the distinguished name to display the object.

**movedobject**

Displays a history of information from the original domain on a moved object after it has reached the new domain.

**repadmin showrepl**

Displays replication information. Inbound replica links are displayed by default. Outbound links can also be shown, as well as connections corresponding to those links. The command also displays errors corresponding to replica links that cannot be created by KCC. This helps the administrator build a visual representation of the replication topology and see the role of each directory server in the replication process.

**Syntax**

**repadmin /showrepl** [*dsa*] [*SourceDCObjectGUID*] [*NamingContext*] [**/verbose**] [**/nocache**] [**/repsto**] [**/conn**] [**/csv**] [**/all**] [**/errorsonly**] [**/intersite**]

**Parameters**

***dsa***

Specifies the host name of the directory server to which the object will be replicated. For details about the *dsa* parameter, see General parameters.

***SourceDCObjectGUID***

Specifies the unique hexadecimal number that identifies the object whose replication events will be listed.

***NamingContext***

Specifies the distinguished name of the directory partition.

**/verbose**

Lists detailed information.

**/nocache**

Specifies that GUIDs are left in hexadecimal form. By default, GUIDs are translated into strings.

**/repsto**
Lists the directory servers that pull replication information from the specified directory partition. To see the outbound neighbors, specify **/repsto** or **/all**.

**/conn**
Displays the connection objects that are associated with each link.

**/csv**
Displays the output of the **repadmin showrepl** operation in a Comma Separated Variable (CSV) format for viewing and analysis in Microsoft Excel. **Repadmin** supports redirection of screen output to a file.

**/all**
Displays all replication partners.

**/errorsonly**
Only shows the partnership if it has an error associated with it.

**/intersite**
Only shows this partnership if the source server belongs to a different site than the site of the server on which the command is being run.

#### repadmin showscp

Displays service connection point (SCP) objects in Active Directory that have been created by ADAM instances. This command must be run against an Active Directory domain controller.

**Syntax**

**repadmin /showscp** [*dsa*]

**Parameters**

***dsa***
Specifies the host name of a directory server that the object will be replicated to. For details about the *dsa* parameter, see General parameters.

### repadmin showsig

Displays the retired invocation IDs on a directory server. A directory server changes its invocation ID when it is restored or when it rehosts an application partition.

**Syntax**

**repadmin /showsig** [*dsa*]

**Parameters**

***dsa***
Specifies the directory server to which the object will be replicated. For details about the *dsa* parameter, see General parameters.

#### repadmin showtime

Converts a directory service time value to string format for both the local and the Universal Time, Coordinated (UTC) time zones.

**Syntax**

**repadmin /showtime** [*DSTimeValue*]

**Parameters**

***DSTimeValue***
Specifies the time value to be converted.

| **Note** |
| --- |
| With parameters omitted, **repadmin /showtime** displays the current system time in both the directory service format and the string format. |

#### repadmin showtrust

Lists all Active Directory domains that are trusted by a specified Active Directory domain.

| Note |
| --- |
| This command does not apply to ADAM. |

**Syntax**

**repadmin /showtrust** [*dsa*]

**Parameters**

***dsa***

Specifies a directory server. For details about the *dsa* parameter, see General parameters.

**repadmin showutdvec**

Displays the highest USN for the specified directory server. This information shows how up to date a replica is with its replication partners.

**Syntax**

**repadmin /showutdvec** *dsa NamingContext* [**/nocache**] [**/latency**]

**Parameters**

***dsa***

Specifies the directory server to which the object will be replicated. For details about the *dsa* parameter, see General parameters.

***NamingContext***

Specifies the distinguished name of the directory partition.

**/nocache**

Specifies that GUIDs are left in hexadecimal form. By default, GUIDs are translated into strings.

**/latency**

Sorts the information by the time required to complete the replication. By default, the information is sorted by USN.

**repadmin showvalue**

Displays the values of the type, last modified time, originating directory server, and distinguished name of a specified object.

**Syntax**

**repadmin /showvalue** [*dsa*] *ObjectDN* [*AttributeName*] [*ValueDN*] [**/nocache**]

**Parameters**

***dsa***

Specifies a directory server. For details about the *dsa* parameter, see General parameters.

***ObjectDN***

Specifies the distinguished name of the object.

***AttributeName***

Specifies a single attribute whose value you want to display.

***ValueDN***

Specifies the distinguished name of the attribute that is displayed.

**/nocache**

Specifies that GUIDs are left in hexadecimal form. By default, GUIDs are translated into strings.

**repadmin syncall**

Synchronizes a specified directory server with all replication partners. This command contains several subcommands, which are described below.

| Note |
| --- |
| By default, if no directory partition is provided in the *namingcontext* parameter, the command performs its operations on the configuration directory partition. |

**Syntax**

**repadmin /syncall** *dsa* [*NamingContext*] [*Flags*]

**Parameters**

***dsa***
Specifies a directory server. For details about the *dsa* parameter, see General parameters.

***NamingContext***
Specifies the distinguished name of the directory partition.

***Flags***
Performs specific actions during the replication, as indicated in the following table.

| Flag | Description |
|---|---|
| **/a** | Abort if any server is unavailable. |
| **/A** | Synchronize all directory partitions that are held on the directory server represented by *dsa*. |
| **/d** | Identify servers by distinguished name (rather than GUID DNS) in messages. |
| **/e** | Synchronize the directory partition across all sites. (The default behavior is to synchronize the directory partition only in the site in which the directory server represented by *dsa* resides.) |
| **/h** | Display help for **repadmin /syncall**. |
| **/i** | Iterate indefinitely. |
| **/l** | Perform **repadmin /showrepl** on each directory server pair in the path, rather than performing synchronization. |
| **/j** | Synchronize adjacent directory servers only. |
| **/p** | Pause for possible user abort after every message. |
| **/P** | Push changes outward from the directory server that is represented by *dsa*. (The default behavior of the command is to pull, rather than to push, changes.) |
| **/q** | Run in quiet mode; suppress callback messages. |
| **/Q** | Run in very quiet mode; report fatal errors only. |
| **/s** | Perform a topology analysis and generate messages, but do not synchronize the directory partition. |
| **/S** | Skip initial directory server response checking, and assume that all directory servers are available. |

**repadmin viewlist**
Displays a list of directory servers.

**Syntax**
**repadmin /viewlist** [*dsa*] [*OBJ_LIST*]

**Parameters**
***dsa***
Specifies a directory server. For details about the *dsa* parameter, see General parameters.

***OBJ_LIST***
Accepts a distinguished name or a special keyword that expands into a distinguished name. The keywords include the following: **Ncobj:config:**; **Ncobj:schema:**; **Ncobj:domain:** This keyword is the domain partition distinguished name of the home server; and, **Dsaobj:** This keyword is the NTDS settings object of the home server.

**repadmin writespn**
Updates the service principal names (SPNs) in Active Directory.

| **Note** |
|---|
| This command does not create SPNs in ADAM. However, ADAM setup may generate scripts that utilize this command for writing SPNs for ADAM instances into Active Directory. For more information, see Administering ADAM service principal names. |

**Syntax**

**repadmin /writespn** [*dsa*] {**add|replace|delete**} *accountDN SPN*

**Parameters**

***dsa***

Specifies a directory server. For details about the *dsa* parameter, see General parameters.

**Formatting legend**

| **Format** | **Meaning** |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| Courier font | Code or program output |

# Glossary

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Symbols | A | B | C | D | E | F | G | H | I | J | K | L | M | N | O | P | Q | R | S | T | U | V | W | X | Y | Z

**Symbols**

**1.2.840.113556.1.4.1851**

The object identifier that is assigned to Active Directory Application Mode (ADAM). You can use this object identifier programmatically to differentiate ADAM from other directory services.

See also: directory service; object identifier

**A**

**Active Directory**

The Windows-based directory service. Active Directory stores information about objects on a network and makes this information available to users and network administrators. Active Directory gives network users access to permitted resources anywhere on the network using a single logon process. It provides network administrators with an intuitive, hierarchical view of the network and a single point of administration for all network objects.

See also: directory service

**Active Directory Application Mode (ADAM)**

A stand-alone directory service that is designed specifically for use with directory-enabled applications. Active Directory Application Mode (ADAM) does not require or depend on Active Directory forests or domains. ADAM stores and replicates only application-related information. ADAM does not store or replicate network operating system (NOS)-related information.

See also: directory service; directory-enabled application

**Active Directory Application Mode (ADAM) instance**

For Active Directory Application Mode (ADAM), a single copy of the ADAM directory service, along with its associated directory store, assigned Lightweight Directory Access Protocol (LDAP) and Secure Sockets Layer (SSL) ports, and application event log. You can run multiple ADAM instances simultaneously on a single computer.

See also: Active Directory Application Mode (ADAM); directory service; Lightweight Directory Access Protocol (LDAP); Secure Sockets Layer (SSL)

**ADAM**

See definition for: Active Directory Application Mode (ADAM)

**ADAM instance**

See definition for: Active Directory Application Mode (ADAM) instance

**authentication**

The process for verifying that an entity or object is who or what it claims to be. Examples include confirming the source and integrity of information, such as verifying a digital signature or verifying the identity of a user or computer.

**authentication protocol**

The protocol by which an entity on a network proves its identity to a remote entity. Typically, identity is proved with the use of a secret key, such as a password, or with a stronger key, such as the key on a smart card. Some authentication protocols also implement mechanisms to share keys between client and server to provide message integrity or privacy.

See also: authentication

**B**

**binding**

A process by which software components and layers are linked together. When a network component is installed, the binding

relationships and dependencies for the components are established. Binding allows components to communicate with each other.

**C**

**configuration set**

For Active Directory Application Mode (ADAM), a set of ADAM instances that share and replicate a common schema partition and a common configuration partition.

See also: Active Directory Application Mode (ADAM); Active Directory Application Mode (ADAM) instance

**D**

**Digest Access protocol**

A lightweight authentication protocol for parties involved in communications that are based on Hypertext Transfer Protocol (HTTP) or Simple Authentication and Security Layer (SASL).

See also: Microsoft Digest; Simple Authentication and Security Layer (SASL)

**directory service**

Both the directory information source and the service that makes the information available and usable. A directory service enables the user to find an object when given any one of its attributes.

See also: Active Directory

**Directory Services Markup Language (DSML)**

An open, extensible, standards-based format for publishing directory service schemas and exchanging directory contents.

See also: directory service

**directory-enabled application**

An application that reads, writes, or modifies data that is stored in a directory service.

See also: directory service

**DLL**

See definition for: dynamic-link library (DLL)

**DSML**

See definition for: Directory Services Markup Language (DSML)

**dynamic-link library (DLL)**

An operating system feature that allows executable routines (generally serving a specific function or set of functions) to be stored separately as files with .dll extensions. These routines are loaded only when needed by the program that calls them.

**E**

There are no glossary terms that begin with this letter.

**F**

There are no glossary terms that begin with this letter.

**G**

**group**

A collection of users, computers, contacts, and other groups. Groups can be used as security or as e-mail distribution collections. Distribution groups are used only for e-mail. Security groups are used both to grant access to resources and as e-mail distribution lists.

**group account**

A collection of user accounts. By making a user account a member of a group, you give the related user all the rights and permissions granted to the group.

See also: group

**group memberships**

The groups to which a user account belongs. Permissions and rights granted to a group are also provided to its members. In most cases, the actions a user can perform in Windows are determined by the group memberships of the user account to which the user is logged on.

See also: group

**H**

**Hypertext Transfer Protocol (HTTP)**

The protocol used to transfer information on the World Wide Web. An HTTP address (one kind of Uniform Resource Locator (URL)) takes the following form: http://www.microsoft.com.

**I**

There are no glossary terms that begin with this letter.

**J**

There are no glossary terms that begin with this letter.

**K**

There are no glossary terms that begin with this letter.

**L**

**LDAP**

See definition for: Lightweight Directory Access Protocol (LDAP)

**Lightweight Directory Access Protocol (LDAP)**

The primary access protocol for Active Directory. LDAP is an industry-standard protocol, established by the Internet Engineering Task Force (IETF), that allows users to query and update information in a directory service. Active Directory supports both LDAP version 2 and LDAP version 3.

See also: Active Directory Application Mode (ADAM); directory service

**M**

**Microsoft Digest**

A security support provider (SSP) that implements the Digest Access protocol. Microsoft Digest provides a simple challenge response mechanism for authenticating clients, and it is intended for use by client/server applications that use communications that are based on Hypertext Transfer Protocol (HTTP) or Simple Authentication and Security Layer (SASL).

See also: authentication; Digest Access protocol; Hypertext Transfer Protocol (HTTP); security support provider (SSP); Simple Authentication and Security Layer (SASL)

**N**

**Network Service account**

A predefined local account that is used to start a service and provide the security context for that service. The name of the account is NT AUTHORITY\NetworkService. The Network Service account has limited access to the local computer and authenticated access (as the computer account) to network resources.

**O**

**object identifier**

A number that identifies an object class or attribute. Object identifiers (OIDs) are organized into an industry-wide global hierarchy. An object identifier is represented as a dotted decimal string, such as 1.2.3.4, with each dot representing a new branch in the hierarchy. National registration authorities issue root object identifiers to individuals or organizations, who manage the hierarchy below their root object identifier.

**P**

There are no glossary terms that begin with this letter.

**Q**

There are no glossary terms that begin with this letter.

**R**

**replica**

In Active Directory replication, one instance of a logical Active Directory partition that is synchronized by means of replication between domain controllers that hold copies of the same directory partition. *Replica* can also refer to an instance of an object or attribute in a distributed directory. In the File Replication service (FRS), a computer that has been included in the configuration of a specific replica set.

See also: Active Directory

**S**
**SASL**

See definition for: Simple Authentication and Security Layer (SASL)

**Secure Sockets Layer (SSL)**

A proposed open standard for establishing a secure communications channel to prevent the interception of critical information, such as credit card numbers. Primarily, it enables secure electronic financial transactions on the World Wide Web, although it is designed to work on other Internet services as well.

**security context**

The security attributes or rules that are currently in effect. For example, the rules that govern what a user can do to a protected object are determined by security information in the user's access token and in the object's security descriptor. Together, the access token and the security descriptor form a security context for the user's actions on the object.

**security ID (SID)**

A data structure of variable length that identifies user, group, and computer accounts. Every account on a network is issued a unique SID when the account is first created. Internal processes in Windows refer to an account's SID rather than the account's user or group name.

See also: group account

**security package**

The software implementation of a security protocol. Security packages are contained in security support provider dynamic-link libraries (DLLs) or in security support provider/authentication package DLLs.

See also: security support provider (SSP)

**security principal**

An account holder that is automatically assigned a security identifier (SID) to control access to resources. A security principal can be a user, group, service, or computer.

See also: group; security ID (SID)

**security protocol**

A specification that defines security-related data objects and rules about how the objects are used to maintain security on a computer system.

**security support provider (SSP)**

A dynamic-link library (DLL) that implements the Security Support Provider Interface (SSPI) by making one or more security packages available to applications. Each security package provides mappings between an application's SSPI function calls and an actual security model's functions. Security packages support security protocols such as Kerberos and NTLM.

See also: dynamic-link library; security package; security protocol; Security Support Provider Interface (SSPI)

**Security Support Provider Interface (SSPI)**

A common interface between transport-level applications, such as Microsoft Remote Procedure Call (RPC), and security support providers (SSPs), such as Windows Distributed Security. SSPI allows a transport application to call one of the SSPs to obtain an authenticated connection. These calls do not require extensive knowledge of the security protocol's details.

See also: security protocol; security support provider

**Service Principal Name (SPN)**

A way of referring to a service principal. SPN structures generally follow Internet Engineering Task Force (IETF) naming conventions, and they often include the name of the computer on which the service is running. SPNs may be used to request Kerberos tickets, and they are required for mutual authentication.

See also: authentication

**SID**

See definition for: security ID (SID)

**Simple Authentication and Security Layer (SASL)**

An open framework, described in Request for Comments (RFC) 2222, for adding authentication support to connection-based protocols.

See also: authentication

**SSL**

See definition for: Secure Sockets Layer (SSL)

**SSP**

See definition for: security support provider (SSP)

# Storage Manager for SANs

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Storage Manager for SANs helps you create and manage logical unit numbers (LUNs) on Fibre Channel and iSCSI disk drive subsystems that support Virtual Disk Service (VDS) in your storage area network (SAN).

A LUN is a logical reference to a portion of a storage subsystem. A LUN can comprise a disk, a section of a disk, a whole disk array, or a section of a disk array in the subsystem. Using LUNs simplifies the management of storage resources in your SAN because they serve as logical identifiers through which you can assign access and control privileges.

- To install and start working with Storage Manager for SANs, see Deploying Storage Manager for SANs.
- For an overview of managing LUNs with Storage Manager for SANs, see Overview of Storage Manager for SANs.
- For a list of steps about how to create a LUN using Storage Manager for SANs, see Checklist: Prepare and Create a LUN.
- For information about the connections between the servers in your SAN and the LUNs that you create using Storage Manager for SANs, see Manage Server Connections.
- To create and manage LUNs, see Manage LUNs.
- To create and manage targets on iSCSI subsystems, see Manage iSCSI Targets.
- For information about Fibre Channel and iSCSI subsystems, see Manage Subsystems.
- For information about disk drives in the Fibre Channel and iSCSI subsystems, see Manage Drives.
- For information about DiskRAID, see DiskRAID.

# Deploying Storage Manager for SANs

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

After you install a Windows Server 2003 R2 operating system, use **Add or Remove Programs** in Control Panel to install the Storage Manager for SANs component.

To install Storage Manager for SANs, you must be logged on under an account that has administrative rights on the local computer and have the installation CD for Windows Server 2003 R2 available.

| **Important** |
| --- |
| You may need to restart your server after the installation of Storage Manager for SANs has completed. You should plan accordingly. |

**To install Storage Manager for SANs**

1. In Control Panel, click **Add or Remove Programs**. Then click **Add/Remove Windows Components**.
2. From the list of components, in the **Windows Components Wizard** dialog box, select **Management and Monitoring Tools**, and click **Details**.
3. From the list of subcomponents, select **Storage Manager for SANs**, and then click **OK**.
4. Click **Next**, and after the configuration of the new component has completed, click **Finish**.

**Opening the Storage Manager for SANs snap-in**

You administer the Storage Manager for SANs component through a Microsoft Management Console (MMC) snap-in. To use Storage Manager for SANs, you must be logged on under an account that has administrative rights.

To open Storage Manager for SANs, in Control Panel, double-click **Administrative Tools**, and then double-click **Storage Manager for SANs**.

Checklist: Prepare and Create a LUN

# Overview of Storage Manager for SANs

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can use Storage Manager for SANs to create and manage logical unit numbers (LUNs) on both Fibre Channel and iSCSI disk storage subsystems that support Virtual Disk Service (VDS).

Because of hardware, protocol, and security differences, LUN configuration and management on Fibre Channel and iSCSI environments is different. This section explains those differences, lists the types of LUNs that can be created, and defines LUNs in the context of partitions and volumes.

**Managing LUNs in a Fibre Channel environment**
In a Fibre Channel environment, LUNs created on a disk storage subsystem are assigned directly to a server or cluster, which accesses the LUN through one or more Fibre Channel host bus adapter (HBA) ports. You only need to identify the server or cluster that will access the LUN, and then select which HBA ports on that server or cluster will be used for LUN traffic.

When a server or cluster is identified, Storage Manager for SANs automatically discovers the available Fibre Channel HBA ports on that server or cluster. You can also add ports manually by typing their World Wide Name (WWN).

**Managing LUNs in an iSCSI environment**
Unlike in a Fibre Channel environment, LUNs created on an iSCSI disk storage subsystem are not only assigned to a server or cluster. For iSCSI, LUNs are first assigned to logical entities called targets.

Targets are created in order to manage the connections between an iSCSI device and the servers that need to access it. A target defines the portals (IP addresses) that can be used to connect to the iSCSI device, as well as the security settings (if any) that the iSCSI device requires in order to authenticate the servers that are requesting access to its resources.

| **Note** |
| --- |
| In most cases, you can create and manage targets yourself. However, some iSCSI storage subsystems only support simple target configurations, where targets are automatically created when you create a LUN. With simple target configurations, you also cannot delete a target or manually assign LUNs to it. LUNs are automatically assigned when they are created. For this type of subsystem, you just need to identify the server or cluster that will access the LUN, and the iSCSI subsystem will enable access from that server or cluster to the LUN. |

To connect to a target, a server in the storage area network (SAN) uses an iSCSI initiator. An iSCSI initiator is a logical entity that enables the server to communicate with the target. The iSCSI initiator first logs on to the target, and only after access is granted by the target, the server can start reading and writing to LUNs assigned to that target. Each iSCSI initiator can have one or more network adapters through which communication is established.

As with Fibre Channel environments, you only need to identify the server or cluster that will access the LUN, and Storage Manager for SANs automatically discovers the iSCSI initiators on that server or cluster, and lists all the available adapters for those initiators. After the iSCSI initiator adapters have been discovered, you can select which adapters will be used for LUN traffic.

For more information, see Microsoft Storage Technologies - iSCSI at the Microsoft Web site.

**Types of LUNs**
Storage Manager for SANs supports the following types of LUNs.

| LUN type | Description |
| --- | --- |
| Simple | Simple LUNs use only one physical drive or one portion of a physical drive. This is the most basic type of LUN. |
| Spanned | Spanned LUNS are simple LUNs that span multiple physical drives. |

| | |
|---|---|
| Striped | Striped LUNs write data across multiple physical drives. Data is divided into blocks and spread among all the drives. Since striping writes data to all disks at the same rate, it provides increased I/O performance by distributing I/O requests across disks. Striped LUNs cannot be extended or mirrored, and do not offer fault tolerance. If one of the disks containing a striped LUN fails, the entire LUN fails.<br><br>Select this type of LUN when improved I/O performance is required. |
| Mirrored | Mirrored LUNs are fault-tolerant LUNs that provide data redundancy by creating identical copies of the LUN on two physical drives. All read and write operations happen concurrently on both drives. If one of the physical disks fails, the data on the failed disk becomes unavailable, but the LUN continues to be available using the unaffected disk.<br><br>Select this type of LUN when fault tolerance is required. |
| Striped with parity | Striped LUNs with parity are fault-tolerant LUNs with data and parity spread intermittently across three or more physical disks. If a portion of a physical disk fails, the data that was on the failed portion is recreated from the remaining data and parity information. This type of LUN provides better read performance than a mirrored LUN, but write performance is reduced by the parity calculation.<br><br>Select this type of LUN when fault tolerance is required and improved read performance is desired. |

**LUNs, partitions and volumes**

A LUN is a logical reference to a portion of a storage subsystem. A LUN can comprise a disk, a section of a disk, a whole disk array, or a section of a disk array in the subsystem. This logical reference, when it is assigned to a server in your SAN, acts as a physical disk drive that the server can read and write to. Using LUNs simplifies the management of storage resources in your SAN, because they serve as logical identifiers through which you can assign access and control privileges.

After a LUN has been assigned to a server, you can create one or more partitions on that LUN. Partitions define how much physical space is allocated for storage. For the operating system to start writing and reading data on partitions, you need to create volumes by formatting the partitions using a file system. Volumes define how much logical space is allocated for storage. They can expand over more than one partition.

# Manage Server Connections

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

With Storage Manager for SANs, you can configure the connections that servers in your SAN will use to access the LUNs that you create on your storage subsystems. Before you assign a LUN to a server or to a cluster, you must first configure the connections on each server that will access the LUN.

The configuration of Fibre Channel connections is different from that of iSCSI connections. This section explains those differences, lists the steps to create each type of connection, offers information about enabling more than one connection from a server or cluster to a LUN (Multipath I/O), and explains how to provide storage for server clusters.

**In this section**

- Add and Configure a Server with Fibre Channel Connections
- Add and Configure a Server with iSCSI Connections
- Define a Server Cluster in Storage Manager for SANs
- Support for Multipath I/O (MPIO)

# Add and Configure a Server with Fibre Channel Connections

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Logical unit numbers (LUNs) created on Fibre Channel storage subsystems are assigned directly to servers with Fibre Channel connections on the SAN. To configure the Fibre Channel connections, you only need to identify the server that will access the LUN, and then select which ports on that server will be enabled for LUN access.

Storage Manager for SANs automatically discovers Fibre Channel ports on a server. You can also add ports manually by entering their World Wide Name (WWN).

**To add and configure a server with Fibre Channel connections**

1. In **LUN Management**, click **Manage Server Connections**.
2. In the **Manage Server Connections** dialog box, click **Add**.
3. In the **Add Server** dialog box, type the name or browse to the server that you want to add and optionally, type a description for it.
4. Click **OK**. The server will now be listed in the **Manage Server Connections** dialog box, with all the ports that were automatically discovered on it listed on the **Fibre Channel Ports** tab.
5. To add a Fibre Channel port manually:
   a. On the **Fibre Channel Ports** tab, click **Add** and enter the WWN of the new port.
   b. Optionally, type a description for the new port.
   c. Click **OK**.
6. To enable Fibre Channel ports for LUN access:
   a. Select a server from the server list.
   b. On the **Fibre Channel Ports** tab, select all the ports that you want to enable on the selected server.

| ⚠**Caution** |
| --- |
| If you enable more than one Fibre Channel port and the server is not configured to use Multipath I/O, data corruption may occur. For more information about Multipath I/O, see Support for Multipath I/O (MPIO). |

7. Click **OK** when you are done configuring the Fibre Channel connections.

# Add and Configure a Server with iSCSI Connections

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Unlike in a Fibre Channel environment, logical unit numbers (LUNs) created on an iSCSI disk storage subsystem are not directly assigned to a server. For iSCSI, LUNs are assigned to logical entities called targets. Servers that require access to a LUN have to connect to the target to which the LUN is assigned. To connect to a target, a server in the storage area network (SAN) uses an iSCSI initiator.

| **Note** |
| --- |
| In most cases, you can create and manage targets yourself. However, some iSCSI storage subsystems only support simple target configurations, where targets are automatically created when you create a LUN. With simple target configurations, you also cannot delete a target or manually assign LUNs to it. LUNs are automatically assigned when they are created. For this type of subsystem, you just need to identify the server or cluster that will access the LUN, and the iSCSI subsystem will enable access from that server or cluster to the LUN. |

To configure the iSCSI connections, you first need to identify the server that will access the LUN and then select which iSCSI initiator adapters will be used for LUN access. iSCSI initiator adapters on a server are automatically discovered by Storage Manager for SANs.

**To add and configure a server with iSCSI connections**

1. In **LUN Management**, click **Manage Server Connections**.
2. In the **Manage Server Connections** dialog box, click **Add**.
3. In the **Add Server** dialog box, type the name or browse to the server that you want to add and optionally, type a description for it.
4. Click **OK**. The server will now be listed in the **Manage Server Connections** dialog box, with all the initiator adapters that were automatically discovered on it listed on the **iSCSI Initiator Adapters** tab.
5. To enable iSCSI initiator adapters for LUN access:
   a. Select a server from the server list.
   b. On the **iSCSI Initiator Adapters** tab, select all the initiator adapters that you want to enable on the selected server.

   | **Caution** |
   | --- |
   | If you enable more than one iSCSI initiator adapter and the server is not configured to use Multipath I/O, data corruption can occur. For more information about Multipath I/O, see Support for Multipath I/O (MPIO). |

6. Click **OK** when you are done configuring the iSCSI connections.

   | **Note** |
   | --- |
   | Optionally, you can change the iSCSI initiator name, by typing a new name for it in the text box provided on the **iSCSI Initiator Adapters** tab. |

# Define a Server Cluster in Storage Manager for SANs

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

With Storage Manager for SANs, you can provide logical unit number (LUN) access to a group of servers (a server cluster) in your storage area network (SAN). Server clusters are created by defining them in Storage Manager for SANs and by enabling clustering services on each individual server in the cluster.

| **Caution** |
| --- |
| To prevent data loss, make sure that each server is a member of only one cluster and that clustering services are running on all cluster nodes. For more information about clustering services, see Clustering Services at the Microsoft Web site. |

After server clusters are created, you can assign LUNs to them in the same way you assign LUNs to individual servers.

**To define a server cluster in Storage Manager for SANs**

1. In **LUN Management**, click **Manage Server Connections**.
2. In the **Manage Server Connections** dialog box, click **Manage Clusters**.
3. In the **Manage Clusters** dialog box, click **Add**.
4. In the **Add New Cluster** dialog box, type a name for the cluster and optionally, type a general description that will help you identify the cluster.
5. From the server list, select all the servers that you want to include in the new cluster.

   | **Note** |
   | --- |
   | To add servers to a cluster you must first add them to the server list in **Manage Server Connections**. For more information see Manage Server Connections. |

6. Click **OK** to create the new cluster.
7. Click **OK** again, to go back to the **Manage Server Connections** dialog box.

The new cluster will now be listed in the **Manage Server Connections** dialog box. To configure the connections of the cluster, configure the Fibre Channel ports or iSCSI initiator adapters of each individual server included in the cluster by selecting the server from the list. All configuration changes you do on individual servers will take effect on the cluster.

| **Caution** |
| --- |
| If you are going to enable more than one connection (Fibre Channel ports and/or iSCSI initiator adapters) on a server in the cluster, and that server is not configured to use Multipath I/O, data corruption can occur. For more information about Multipath I/O, see Support for Multipath I/O (MPIO). |

**See Also**
**Concepts**
Assign a LUN

# Support for Multipath I/O (MPIO)

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Multipathing increases availability by providing multiple paths (path failover) from a server or cluster to a storage subsystem.

If a server in your storage area network (SAN) supports Microsoft Multipath I/O (MPIO), you can enable more than one read/write path to a logical unit number (LUN) by assigning multiple Fibre Channel ports or multiple iSCSI initiator adapters on that server to the same LUN. The same is true when accessing the LUN from a cluster.

| **Caution** |
| --- |
| To prevent data loss, ensure that the server or cluster supports MPIO before enabling access through multiple paths to the same LUN. If the server or cluster does not support MPIO, or if you are not sure, assign only a single Fibre Channel port or iSCSI initiator adapter to each LUN. |

For more information, see Microsoft Storage Technologies - Multipath I/O at the Microsoft Web site.

# Manage LUNs

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Storage Manager for SANs helps you create and manage logical unit numbers (LUNs) on Fibre Channel and iSCSI disk drive subsystems in your storage area network (SAN).

The **LUN Management** node lists all the LUNs created with Storage Manager for SANs and enables you to create new LUNs, extend the size of a LUN, assign and unassign LUNs, and delete LUNs.

**In this section**

Create a LUN

Extend a LUN

Delete a LUN

Assign a LUN

# Create a LUN

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Storage Manager for SANs includes the Create LUN Wizard, which can help you create logical unit numbers (LUNs).

| **Note** |
| --- |
| If you want to use the Create LUN Wizard to assign the LUN that you create to a server or cluster, you must first configure the storage area network (SAN) server connections by using the instructions in Manage Server Connections. |

| **Note** |
| --- |
| If the LUN that you are creating is on an iSCSI subsystem and you want to use the Create LUN Wizard to assign that LUN to an iSCSI target, you must first configure the iSCSI targets in your SAN by using the instructions in Manage iSCSI Targets. |

**To create a LUN**

1. In **LUN Management**, click **Create LUN**.
2. Follow the steps in the **Create LUN Wizard** pages:

| Wizard Page | Details |
| --- | --- |
| **Before You Begin** | Before you create a LUN, verify that the following steps have been completed:<br>• At least one subsystem is listed in the **Subsystems** node.<br>• Storage space is available on at least one of the available subsystems.<br>• If you want to use the wizard to assign the LUN to a server, the SAN server connections have been configured. |
| **Subsystem and Type** | Select the subsystem on which to create the LUN and specify the type of LUN to create:<br>• Fault tolerant LUN types require more disk space than simple LUNs. Therefore, the maximum size of the LUN is smaller than for a simple LUN.<br>• For more information about the different LUN types, see Overview of Storage Manager for SANs. |
| **Size and Name** | Type a name for the new LUN and specify the size of the LUN:<br>• The LUN name can have as many as 63 characters.<br>• Depending on the version of the Virtual Disk Service (VDS) provider that the subsystem is running, you may not be able to type a name for the LUN.<br>• Click the drop-down list to select between megabytes (MB), gigabytes (GB) and terabytes (TB). |
| **Target Access (iSCSI only)** | If iSCSI targets have already been created on the subsystem, you can assign the LUN to one of those targets now. You can also leave it unassigned for later use. |

| | |
|---|---|
| **Server Access** | If you have already configured your server connections, you can assign the LUN to a server or cluster now. You can also leave it unassigned for later use.<br><br>**Note**<br>If you are creating a LUN on an iSCSI subsystem, then this LUN must also be assigned to an iSCSI target. The server or cluster you select on the **Server Access** page will only have access to the LUN after the iSCSI initiator on that server or cluster logs on to the target the LUN has been assigned to. |
| **Create Volume (Fibre Channel only)** | If on the **Server Access** page you chose to assign the LUN to the server you are currently managing with the Storage Manager for SANs snap-in, you can create an NTFS volume for the LUN. If you select to format the volume:<br><br>• As a general rule, leave the **Allocation unit size** option as **Default**. The *allocation unit size* is the smallest amount of disk space that can be allocated to hold a file. Windows picks default sizes based on the size of the volume. These default sizes are selected to reduce the amount of space that is lost and the amount of fragmentation on the volume.<br><br>• The **Quick Format** option speeds the volume creation process on large LUNs. If you want to scan for bad sectors during the formatting process, unselect this option and a full file format will be done.<br><br>**Note**<br>If you prefer, you can select not to format the volume and can use Disk Management to format it later. For more information, see Disk Management at the Microsoft Web site. |
| **Create New LUN** | Before creating the LUN, the wizard lists all the properties you have selected for the new LUN. Click **Create LUN** to start the LUN creation process.<br><br>**Note**<br>Depending on the properties you selected, especially those related to the LUN size and the volume creation options, the LUN creation process may take some time to complete. |

# Extend a LUN

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

If there is storage space available in the subsystems where a logical unit number (LUN) was created, you can extend the size of that LUN.

| **Important** |
| --- |
| Extending a LUN does not automatically extend its file system partition. You must use Disk Manager or a similar tool to extend the file system partition from the server that has access to the LUN. |

**To extend a LUN**

1. In the console tree, click **LUN Management**.
2. In the results pane, select the LUN you want to extend.
3. In the action pane, click **Extend LUN**.
4. In the **Extend LUN** dialog box, type the new size for the LUN and select the units in megabytes (MB), gigabytes (GB) or terabytes (TB).
5. To extend the LUN, click **OK**.

**See Also**
**Concepts**
Manage Subsystems

# Delete a LUN

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

| ⚠Caution |
| --- |
| Deleting a logical unit number (LUN) permanently deletes all data on all volumes on the LUN. This operation cannot be undone. Make sure that you have shut down all applications that access the LUN. |

**To delete a LUN**

1. In the console tree, click **LUN Management**.
2. In the results pane, select the LUN you want to delete.
3. In the action pane, click **Delete LUN**.
4. Select **Check here if you want to delete this LUN**, and then click **OK**.

**See Also**
**Concepts**
Manage LUNs

# Assign a LUN

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

| **Caution** |
| --- |
| If two or more Fibre Channel ports or iSCSI initiator adapters have been enabled on the servers or clusters to which the logical unit number (LUN) will be assigned, and the servers or clusters are not configured to use Multipath I/O, data corruption can occur. For more information about Multipath I/O, see Support for Multipath I/O (MPIO). |

**To assign a LUN**

1. In the console tree, click **LUN Management**.
2. In the results pane, select the LUN you want to assign.
3. In the action pane, click **Assign LUN**.
4. Follow the steps in the **Assign LUN Wizard** pages:

| Wizard Page | Details |
| --- | --- |
| **Target Access (iSCSI only)** | If iSCSI targets have already been created on the subsystem, you can assign the LUN to one of those targets now. You can also leave it unassigned for later use. |
| **Server Access** | If you have already configured your server connections, you can assign the LUN to a server or cluster now. You can also leave it unassigned for later use.<br>**Note**<br>If you are creating a LUN on an iSCSI subsystem, then this LUN must also be assigned to an iSCSI target. The server or cluster you select on the **Server Access** page will only have access to the LUN after the iSCSI initiator on that server or cluster logs on to the target the LUN has been assigned to. |
| **Assign LUN** | Before assigning the LUN, the wizard lists any current assignments for that LUN and confirms the new assignment. To accept the new assignment and close the wizard, click **Assign LUN**.<br>**Note**<br>If a current LUN assignment exists, it will be lost when the new assignment takes place. |

# Manage iSCSI Targets

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Logical unit numbers (LUNs) created on an iSCSI disk storage subsystem are not directly assigned to a server. For iSCSI, LUNs are assigned to logical entities called targets.

Targets are created in order to manage the connections between an iSCSI device and the servers that need to access it. A target defines the portals (IP addresses) that can be used to connect to the iSCSI device, as well as the security settings (if any) that the iSCSI device requires in order to authenticate the servers that are requesting access to its resources.

Servers that require access to a LUN have to connect to the target to which the LUN is assigned. To connect to a target, a server in the storage area network (SAN) uses an iSCSI initiator. An iSCSI initiator is a logical entity that enables the server to communicate with the target. The iSCSI initiator first logs on to the target. The target must grant access before the server can start reading and writing to all LUNs that are assigned to that target.

With Storage Manager for SANs, you can create targets for the iSCSI subsystems in your SAN, configure the security settings for these targets, and start logon sessions with them.

**Note**

In most cases, you can create and manage targets yourself. However, some iSCSI storage subsystems only support simple target configurations, where targets are automatically created when you create a LUN. With simple target configurations, you also cannot delete a target or manually assign LUNs to it. LUNs are automatically assigned when they are created. For this type of subsystem, you just need to identify the server or cluster that will access the LUN, and the iSCSI subsystem will enable access from that server or cluster to the LUN.

**Note**

For more information, see Microsoft Storage Technologies - iSCSI at the Microsoft Web site.

# Create an iSCSI Target

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Targets are created in order to manage the connections between the iSCSI storage subsystems in your storage area network (SAN) and the servers that need to access them. You assign logical unit numbers (LUNs) to a target, and all servers that log on to that target will have access to the LUNs assigned to it.

| **Note** |
| --- |
| In most cases, you can create and manage targets yourself. However, some iSCSI storage subsystems only support simple target configurations, where targets are automatically created when you create a LUN. With simple target configurations, you also cannot delete a target or manually assign LUNs to it. LUNs are automatically assigned when they are created. For this type of subsystem, you just need to identify the server or cluster that will access the LUN, and the iSCSI subsystem will enable access from that server or cluster to the LUN. |

After iSCSI targets have been created, you must configure the iSCSI security settings for each of them. For more information about iSCSI security, see Manage iSCSI Security.

**To create an iSCSI target**

1. In **LUN Management**, click **Manage iSCSI targets**.

2. In the **Manage iSCSI Targets** dialog box, in **Select a subsystem to manage**, select the subsystem you want to create the target for, and then click **Add**.

3. In the **Add Target** dialog box, in **Target Friendly Name**, type a descriptive name for the target that will help you to distinguish it from other targets.

4. In **Select portals to enable for this target**, select the check box next to each IP address that the target should use, and then click **OK**.

# Remove an iSCSI Target

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

| ⚠Caution |
| --- |
| When you remove a target, all initiators currently logged on to that target will no longer be able to access the LUNs that are assigned to that target. This action cannot be undone. |

**To remove an iSCSI target**

1. In **LUN Management**, click **Manage iSCSI Targets**.
2. In the **Manage iSCSI Targets** dialog box, in **Select a subsystem to manage**, select the subsystem for which the target you want to remove was created.
3. In **Targets available on this subsystem**, select the target you want to remove, and then click **Remove**.
4. In the **Remove Target** dialog box, select **Check here if you want to remove this target**, and then click **OK** to remove the target.

Manage iSCSI Targets

# Manage iSCSI Security

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

There are several levels of iSCSI security available with Storage Manager for SANs. The basic level is based on the Challenge Handshake Authentication Protocol (CHAP). CHAP is a protocol that is used to authenticate the peer of a connection and is based upon the peers sharing a *secret* (a security key that is similar to a password). IP security (IPsec) is a protocol that enforces authentication and data encryption at the IP packet layer, which provides an added level of security.

You must choose the security level that best fits the security policies of your organization:

- **One-way CHAP authentication**. With this level of security, only the target authenticates the initiator. The secret is set just for the target and all initiators that want to access that target need to use the same secret to start a logon session with the target.

- **Mutual CHAP authentication**. With this level of security, the target and the initiator authenticate each other. A separate secret is set for each target and for each initiator in the storage area network (SAN).

- **IPsec**. With this level of security, all IP packets sent during data transfers are encrypted and authenticated. A common key is set on all IP portals, allowing all peers to authenticate each other and negotiate packet encryption. For more information, see IPsec at the Microsoft Web site.

| **Caution** |
| --- |
| At a minimum, use one-way CHAP authentication between iSCSI initiators and targets. |

| **Note** |
| --- |
| The level of security that you can set for a storage subsystem depends on the hardware manufacturer. Not all subsystems support all levels of iSCSI security. You should contact your hardware manufacturer to verify what level of security is supported. |

| **Note** |
| --- |
| For more information about iSCSI security and to learn more about iSCSI in general, see Microsoft Storage Technologies - iSCSI at the Microsoft Web site. |

**To manage iSCSI security**

1. In **LUN Management**, click **Manage iSCSI Security**.

2. To configure one-way CHAP authentication, in the **Manage iSCSI Security** dialog box, configure the following settings on the **Targets** tab:

    a. If you want to configure different CHAP secrets for different targets, in the list of targets, select a target that you want to set the CHAP secret for, and click **Set Secret**.

    -Or-

    To use the same CHAP secret for a group of targets, select the targets from the list and click **Set Secret**.

    b. In the **Set Secret** dialog box, type and confirm the target CHAP secret.

    c. Optionally, select **Remember secret on local initiator** if you want to automatically pass the new secret to the local initiator.

d. To set the new secret, click **OK**.

3. To configure mutual CHAP authentication, you must first configure one-way CHAP authentication by following step 2. Then, enter the following configuration on the **Local Initiator** tab:

   a. Type and confirm the CHAP secret for the local initiator.

   b. Under mutual CHAP authentication, the initiator will only be able to log on to targets that know the initiator secret. To share the initiator secret with the targets that the server needs to access, in the list of targets, select each target that you want to authenticate on the initiator.

   c. To set the new secret for the local initiator and to share it with the selected targets, click **Apply Secret**.

4. To configure IPsec, in the **Manage iSCSI Security** dialog box, configure the following settings on the **Portals** tab:

   a. If you want to use different IPsec keys for different portals, in the list of portals, select a portal and click **Set IPsec Key**.

      -Or-

      To use the same IPsec key for a group of portals, select the portals from the list, and click **Set IPsec Key**.

   b. In the **Set IPsec Key** dialog box, type and confirm a new IPsec key.

   c. Optionally, select **Remember the IPsec key on local initiator** if you want to automatically pass the new key to the local initiator.

   d. To set the new IPsec key, click **OK**.

5. When you are done configuring iSCSI security, click **OK**.

Log On to iSCSI Targets

# Log On to iSCSI Targets

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can log on to iSCSI targets using Storage Manager for SANs. This starts a logon session only between the server that is running Storage Manager for SANs and the selected target. Each server that requires access to the logical unit numbers (LUNs) that are assigned to a target must start a separate logon session with that target.

| **Note** |
| --- |
| If you have not yet configured iSCSI security for initiators and targets, you will not be able to log on to a target. For more information about iSCSI security, see Manage iSCSI Security. |

| **Note** |
| --- |
| You can also start a logon session between a server in your storage area network (SAN) and a target, using the local iSCSI initiator interface, if available (this depends on the iSCSI initiator software that is installed on that server). |

**To log on to iSCSI targets**

1. In **LUN Management**, click **Log On to iSCSI Targets**.
2. In the **Log On to iSCSI Targets** dialog box, select the target that you want to establish a logon session with, and click **Log On**.
3. In the **Log On to Target** dialog box, select the type of Challenge Handshake Authentication Protocol (CHAP) authentication to use for the logon session:
   - **Log on using one-way CHAP authentication**
   - **Log on using mutual CHAP authentication**
4. To establish the logon session, click **OK**.

# Manage Subsystems

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Storage subsystems are automatically discovered using the Virtual Disk Service (VDS). Only those subsystems in your storage area network (SAN) that support VDS can be administered using Storage Manager for SANs.

| **Note** |
| --- |
| For more information about VDS, see Virtual Disk Service Technical Reference. |

The **Subsystems** node lists all the storage subsystems currently discovered in your SAN and allows you to change the subsystem name that was returned by VDS.

**In this section**

Rename a Subsystem

# Rename a Subsystem

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

| Note |
| --- |
| Depending on the version of the Virtual Disk Service (VDS) provider that the storage subsystem is running, you may not be able to change the subsystem name. |

**To rename a subsystem**

1. In the console tree, click **Subsystems**.
2. In the results pane, select the subsystem you want to rename.
3. In the action pane, click **Rename Subsystem**.
4. In the **Rename Subsystem** dialog box, type a new name for the subsystem, and then click **OK**.

# Manage Drives

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The **Drives** node lists all the drives in the subsystems that are discovered in your storage area network (SAN). To help identify the drives you are working with, you can make the light on a drive blink.

| **Note** |
| --- |
| The ability to make the drive light blink depends on your hardware. |

**In this section**

Make a Drive Light Blink

# Make a Drive Light Blink

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

| **Note** |
| --- |
| The ability to make a drive light blink depends on your hardware. If your storage subsystem does not support this feature, the **Blink Drive Light** action will not be available. |

**To make a drive light blink**

1. In the console tree, click **Drives**.
2. In the results pane, click the drive whose light you want to blink.
3. In the action pane, click **Blink Drive Light**.
4. In the **Blink Drive LED** dialog box, click **Start**.

Manage Drives

# DiskRAID

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

DiskRAID is a command-line tool that enables you to configure and manage redundant array of independent (or inexpensive) disks (RAID) storage subsystems.

RAID is a method used to standardize and categorize fault-tolerant disk systems. RAID levels provide various mixes of performance, reliability, and cost. RAID is usually used on servers. Some servers provide three of the RAID levels: Level 0 (striping), Level 1 (mirroring), and Level 5 (striping with parity).

A hardware RAID subsystem distinguishes physically addressable storage units from one another by using a Logical Unit Number (LUN). A LUN object must have at least one plex, and can have any number of additional plexes. Each plex contains a copy of the data on the LUN object. Plexes can be added to and removed from a LUN object.

Most DiskRAID commands operate on a specific host bus adapter (HBA) port, initiator adapter, initiator portal, provider, subsystem, controller, port, drive, LUN, target portal, target, or target portal group. You use the SELECT command to select an object. The selected object is said to have focus. Focus simplifies common configuration tasks, such as creating multiple LUNs within the same subsystem.

Windows Server 2003 operating systems include the Virtual Disk Service (VDS), which is a set of application programming interfaces (APIs) that provides a single interface for managing storage. Each hardware vendor writes a VDS hardware provider that translates the general-purpose VDS APIs into specific instructions for their hardware. With this abstraction layer provided by VDS, Windows Server 2003 simplifies storage management, because storage applications no longer need to take into account the specific hardware being targeted. Instead, you can use compatible storage applications, such as DiskRAID, to manage any hardware that has a VDS provider.

**Requirements**

Before you can use DiskRAID to manage your storage subsystems, you must:

- Have a computer running one of the Windows Server 2003 operating systems with Service Pack 1 (SP1) and Windows Server 2003 R2 installed.
- Be a member of the Backup Operators group or Administrators group on the local computer.
- Have at least one registered VDS hardware provider on your computer.

**DiskRAID commands**

To view the command syntax, click a command:

- add
- associate
- automagic
- break
- chap
- create
- delete
- detail
- dissociate

- exit
- extend
- flushcache
- help
- importtarget
- initiator
- invalidatecache
- ipsec
- lbpolicy
- list
- login
- logout
- maintenance
- name
- offline
- online
- recover
- reenumerate
- refresh
- rem
- remove
- replace
- reset
- select
- setflag
- standby
- unmask

**add**

Adds an existing LUN to the currently selected LUN, or adds an iSCSI target portal to the currently selected iSCSI target portal group.

**Syntax**

**add plex lun**=*n* [**noerr**]

**add tpgroup tportal=** *n* [**noerr**]

**Parameters**

**plex lun**=*n*

Specifies the LUN number to add as a plex to the currently selected LUN.

| ⚠**Caution** |
| --- |
| All data on the LUN being added as a plex will be deleted. |

**tpgroup tportal=** *n*

Specifies the iSCSI target portal number to add to the currently selected iSCSI target portal group.

**noerr**

Specifies that any failures that occur while performing this operation will be ignored. This is useful in script mode.

**associate**

Sets the specified list of controller ports as active for the currently selected LUN (other controller ports are made inactive), or adds the specified controller ports to the list of existing active controller ports for the currently selected LUN, or associates the specified iSCSI target for the currently selected LUN.

**Syntax**

**associate controllers** [**add**] *n*[**,***n* [**,**...]]

**associate ports** [**add**] *n*-*m*[**,***n*-*m*[**,**...]]

**associate targets** [**add**] *n*[**,***n* [**,**...]]

**Parameters**

**controllers**

For use with VDS 1.0 providers only. Adds to or replaces the list of controllers that are associated with the currently selected LUN.

**ports**

For use with VDS 1.1 providers only. Adds to or replaces the list of controller ports that are associated with the currently selected LUN.

**targets**

For use with VDS 1.1 providers only. Adds to or replaces the list of iSCSI targets that are associated with the currently selected LUN.

**add**

For VDS 1.0 providers, adds the specified controllers to the existing list of controllers associated with the LUN. If this parameter is not specified, the list of controllers replaces the existing list of controllers associated with this LUN.

For VDS 1.1 providers, adds the specified controller ports to the existing list of controller ports associated with the LUN. If this parameter is not specified, the list of controller ports replaces the existing list of controller ports associated with this LUN.

*n* **[,** *n* **[, ...]]**

For use with the **controllers** or **targets** parameter. Specifies the numbers of the controllers or iSCSI targets to set to active or associate.

*n* **-** *m* **[,** *n* **-** *m* **[,...]]**

For use with the **ports** parameter. Specifies the controller ports to set active using a controller number (*n*) and port number (*m*) pair.

**Example**
The following example shows how to associate and add ports to a LUN that uses a VDS 1.1 provider.

**automagic**
Sets or clears flags that give hints to providers on how to configure a LUN. Used with no parameters, the **automagic** operation displays a list of flags.

**Syntax**
**automagic** {**set** | **clear** | **apply**} **all** *flag*=*value* [*flag*=*value* [...]]

**Parameters**
**set**

Sets the specified flags to the specified values.

**clear**

Clears the specified flags. The **all** keyword clears all the automagic flags.

**apply**

Applies the current flags to the selected LUN.

*flag*

Flags are identified by three-letter acronyms.

| Flag | Description |
|---|---|
| FCR | Fast Crash Recovery Required |
| FTL | Fault Tolerant |
| MSR | Mostly Reads |
| MXD | Maximum Drives 0 |
| MXS | Maximum Size Expected 0B |
| ORA | Optimal Read Alignment0B |
| ORS | Optimal Read Size 0B |
| OSR | Optimize For Sequential Reads- |
| OSW | Optimize For Sequential Writes |
| OWA | Optimal Write Alignment 0B |
| OWS | Optimal Write Size0B |
| RBP | Rebuild Priority 0 |
| RBV | Read Back Verify Enabled |
| RMP | Remap Enabled |
| STS | Stripe Size0 |
| WTC | Write-Through Caching Enabled |
| YNK | Removable |

**break**
Removes the plex from the currently selected LUN. The plex and the data it contained are not retained, and the drive extents

may be reclaimed.

**Syntax**

**break plex**=*plex_number* [**noerr**]

**Parameters**

**plex**

Specifies the number of the plex to remove. The plex and the data it contained will not be retained, and the resources used by this plex will be reclaimed. The data contained on the LUN is not guaranteed to be consistent. If you want to retain this plex, use the Volume Shadow Copy Service (VSS).

**noerr**

Specifies that any failures that occur while performing this operation will be ignored. This is useful in script mode.

**Remarks**

| **Note** |
| --- |
| You must first select a mirrored LUN before using the **break** command. |

| **Caution** |
| --- |
| All data on the plex will be deleted. |

| **Caution** |
| --- |
| All data contained on the original LUN is not guaranteed to be consistent. |

**chap**

Sets the Challenge Handshake Authentication Protocol (CHAP) shared secret so that iSCSI initiators and iSCSI targets can communicate with one another.

**Syntax**

**chap initiator set secret**=[*secret*] [**target**=*target*]

**chap initiator remember secret**=[*secret*] **target**=*target*

**chap target set secret**=[*secret*] [**initiator**=*initiatorname*]

**chap target remember secret**=[*secret*] **initiator**=*initiatorname*

**Parameters**

**initiator set**

Sets the shared secret in the local iSCSI initiator service used for mutual CHAP authentication when the initiator authenticates the target.

**initiator remember**

Communicates the CHAP secret of an iSCSI target to the local iSCSI initiator service so that the initiator service can use the secret in order to authenticate itself to the target during CHAP authentication.

**target set**

Sets the shared secret in the currently selected iSCSI target used for CHAP authentication when the target authenticates the initiator.

**target remember**

Communicates the CHAP secret of an iSCSI initiator to the current in-focus iSCSI target so that the target can use the secret in order to authenticate itself to the initiator during mutual CHAP authentication.

**secret**

Specifies the secret to use. If empty the secret will be cleared.

**target**

Specifies a target in the currently selected subsystem to associate with the secret. This is optional when setting a secret on the initiator and leaving it out indicates that the secret will be used for all targets that do not already have an associated secret.

**initiatorname**

Specifies an initiator iSCSI name to associate with the secret. This is optional when setting a secret on a target and leaving it out indicates that the secret will be used for all initiators that do not already have an associated secret.

#### create

Creates a new LUN or iSCSI target on the currently selected subsystem, or creates a target portal group on the currently selected target. You can view the actual binding using the **DiskRAID list** command.

#### Syntax

**create lun simple** [**size=***n*] [**drives=***n*] [**noerr**]

**create lun stripe** [**size=***n*] [**drives=***n***,** *n* [**,**...]] [**stripesize=***n*] [**noerr**]

**create lun raid** [**size=***n*] [**drives=***n***,** *n* [**,**...]] [**stripesize=***n*] [**noerr**]

**create lun mirror** [**size=***n*] [**drives=***n***,** *n* [**,**...]] [**stripesize=***n*] [**noerr**]

**create lun automagic size=** *n* [**noerr**]

**create target name=** *name* [**iscsiname=***iscsiname*] [**noerr**]

**create tpgroup** [**noerr**]

#### Parameter

**simple**

Creates a simple LUN.

**stripe**

Creates a striped LUN.

**RAID**

Creates a striped LUN with parity.

**mirror**

Creates a mirrored LUN.

**automagic**

Creates a LUN using the *automagic* hints currently in effect. See the **automagic** sub-command for more information.

**size**=

Specifies the total LUN size in megabytes. If the **size=** parameter is not specified, the LUN created will be the largest possible size allowed by all the specified drives.

A provider typically creates a LUN at least as big as the requested size, but the provider may have to round up to the next largest size in some cases. For example, if size is specified as .99 GB and the provider can only allocate GB disk extents, the resulting LUN would be 1 GB.

To specify the size using other units, use one of the following recognized suffixes immediately after the size:

- **B** for byte.
- **KB** for kilobyte.
- **MB** for megabyte.
- **GB** for gigabyte.

- **TB** for terabyte.
- **PB** for petabyte.

**drives**=

Specifies the *drive_number* for the drives to use to create a LUN. If the **size=** parameter is not specified, the LUN created is the largest possible size allowed by all the specified drives. If the **size=** parameter is specified, providers will select drives from the specified drive list to create the LUN. Providers will attempt to use the drives in the order specified when possible.

**stripesize**=

Specifies the size in megabytes for a *stripe* or *RAID* LUN. The stripesize cannot be changed after the LUN is created.

To specify the size using other units, use one of the following recognized suffixes immediately after the size:

- **B** for byte.
- **KB** for kilobyte.
- **MB** for megabyte.
- **GB** for gigabyte.
- **TB** for terabyte.
- **PB** for petabyte.

**target**

Creates a new iSCSI target on the currently selected subsystem.

**name**

Supplies the friendly name for the target.

**iscsiname**

Supplies the iSCSI name for the target and can be omitted to have the provider generate a name.

**tpgroup**

Creates a new iSCSI target portal group on the currently selected target.

**noerr**

Specifies that any failures that occur while performing this operation will be ignored. This is useful in script mode.

**Remarks**

- Either the **size**= or the **drives**= parameter must be specified. They can also be used together.
- The stripe size for a LUN cannot be changed after creation.

**delete**

Deletes the currently selected LUN, iSCSI target (as long as there are not any LUNs associated with the iSCSI target) or iSCSI target portal group.

**Syntax**

**delete lun** [**noerr**]

**delete target** [**noerr**]

**delete tpgroup** [**noerr**]

#### Parameters

**lun**

Deletes the currently selected LUN and all data on it.

**target**

Deletes the currently selected iSCSI target if no LUNs are associated with the target.

**tpgroup**

Deletes the currently selected iSCSI target portal group.

**noerr**

Specifies that any failures that occur while performing this operation will be ignored. This is useful in script mode.

### detail

Displays detailed information about the currently selected object of the specified type.

#### Syntax

**Detail** {**hbaport** | **iadapter** | **iportal** | **provider** | **subsystem** | **controller** | **port** | **drive** | **lun** | **tportal** | **target** | **tpgroup**} [**verbose**]

#### Parameters

**hbaport**

Lists detailed information about the currently selected host bus adapter (HBA) port.

**iadapter**

Lists detailed information about the currently selected iSCSI initiator adapter.

**iportal**

Lists detailed information about the currently selected iSCSI initiator portal.

**provider**

Lists detailed information about the currently selected provider.

**subsystem**

Lists detailed information about the currently selected subsystem.

**controller**

Lists detailed information about the currently selected controller.

**port**

Lists detailed information about the currently selected controller port.

**drive**

Lists detailed information about the currently selected drive, including the occupying LUNs.

**lun**

Lists detailed information about the currently selected LUN, including the contributing drives. The output differs slightly depending on whether the LUN is part of a Fibre Channel or iSCSI subsystem. "If the Unmasked Hosts list contains only an asterisk, this means that the LUN is unmasked to all hosts.

**tportal**

Lists detailed information about the currently selected iSCSI target portal.

**target**

Lists detailed information about the currently selected iSCSI target.

**tpgroup**

Lists detailed information about the currently selected iSCSI target portal group.

**verbose**

For use only with the LUN parameter. Lists additional information, including its plexes.

#### dissociate

Sets specified list of controller ports as inactive for the currently selected LUN (other controller ports are not affected), or dissociates the specified list of iSCSI targets for the currently selected LUN.

#### Syntax

**dissociate controllers** *n*[**,***n*[**,**...]]

**dissociate ports** *n* **-** *m*[**,***n***-***m*[**,**...]]

**dissociate targets** *n*[**,***n*[**,**...]]

#### Parameter

**controllers**

For use with VDS 1.0 providers only. Removes controllers from the list of controllers that are associated with the currently selected LUN.

**ports**

For use with VDS 1.1 providers only. Removes controller ports from the list of controller ports that are associated with the currently selected LUN.

**targets**

For use with VDS 1.1 providers only. Removes targets from the list of iSCSI targets that are associated with the currently selected LUN.

*n*[**,***n*[**,**...]]

For use with the **controllers** or **targets** parameter. Specifies the numbers of the controllers or iSCSI targets to set as inactive or dissociate.

*n* **-** *m*[**,***n***-***m*[**,**...]]

For use with the **ports** parameter. Specifies the controller ports to set as inactive by using a controller number (*n*) and port number (*m*) pair.

#### Example

#### exit

Exits DiskRAID.

#### Syntax

**exit**

#### extend

Extends the currently selected LUN by adding sectors to the end of the LUN. Not all providers support extending LUNs. Does not extend any volumes or file systems contained on the LUN. After you extend the LUN, you should extend the associated on-disk structures using the **DiskPart extend** command.

#### Syntax

**extend lun** [**size**=*LUN_size*] [**drives**=*drive_number*, [*drive_number*, ...]] [**noerr**]

#### Parameters

**size=**

Specifies the size in megabytes to extend the LUN. If the **size=** parameter is not specified, the LUN is extended by the largest possible size allowed by all the specified drives. If the **size=** parameter is specified, providers select drives from the list specified by the **drives=** parameter to create the LUN.

To specify the size using other units, use one of the following recognized suffixes immediately after the size:

- **B** for byte.
- **KB** for kilobyte.
- **MB** for megabyte.
- **GB** for gigabyte.
- **TB** for terabyte
- **PB** for petabyte

**drives=**

Specifies the *drive_number* for the drives to use when creating a LUN. If the **size=** parameter is not specified, the LUN created is the largest possible size allowed by all the specified drives. Providers use the drives in the order specified when possible.

**noerr**

Specifies that any failures that occur while performing this operation should be ignored. This is useful in script mode.

**Remarks**

- Either the *size* or the *drive* parameter must be specified. They can also be used together.

**flushcache**
Clears the cache on the currently selected controller.

**Syntax**
**flushcache controller**

**help**
Displays a list of all DiskRAID commands.

**Syntax**
**help**

**importtarget**
Retrieves or sets the current Volume Shadow Copy Service (VSS) import target that is set for the currently selected subsystem.

**Syntax**
**importtarget subsystem [set target]**

**Parameter**
**set target**

If specified, sets the currently selected target to the VSS import target for the currently selected subsystem. If not specified, the command retrieves the current VSS import target that is set for the currently selected subsystem.

**initiator**
Retrieves information about the local iSCSI initiator.

**Syntax**
**initiator**

**invalidatecache**
Invalidates the cache on the currently selected controller.

**Syntax**
**invalidatecache controller**

**ipsec**

Lists and configures IPsec information about the currently selected iSCSI initiator portal or iSCSI target portal. Also sets the IPsec configuration of all the initiator portals in the local iSCSI initiator service and sets the group pre-shared key used for IPsec in the iSCSI target portals for the currently selected subsystem.

**Syntax**

**ipsec iportal tportal=** *tportal*

**ipsec iportal set key=**[*key*] **tportal=***tportal* [*flag* [*flag* [...]]]

**ipsec iportal set tunnel=** *tunneladdress* **destination=**destinationaddress

**ipsec tportal iportal=** *iportal*

**ipsec tportal set key=**[*key*] {**initiator** | **iportal=***iportal*} [*flag* [*flag* [...]]]

**ipsec tportal set tunnel=** *tunneladdress* **destination=** *destinationaddress*

**ipsec initiator set groupkey=**[*groupkey*]

**ipsec initiator set key=**[*key*] **tportal=***tportal* [*flag* [*flag* [...]]]

**ipsec initiator set tunnel=** *tunneladdress* **destination=** *destinationaddress*

**ipsec subsystem set groupkey=**[*key*]

**Parameters**

**iportal tportal=** *tportal*

Displays the IPsec configuration of the currently selected initiator portal that is associated with the specified target portal on the currently selected subsystem.

**tportal iportal=** *iportal*

Displays the IPsec configuration of the currently selected target portal that is associated with the specified initiator portal on the currently selected initiator adapter.

**iportal set**

Sets the IPsec configuration of the currently selected initiator portal with either the IPsec key and flags, or the IPsec tunnel address.

**tportal set**

Sets the IPsec configuration of the currently selected target portal with either the IPsec key and flags, or the IPsec tunnel address.

**initiator set**

Sets the IPsec configuration of all the initiator portals in the local iSCSI initiator service with the IPsec key and flags, the IPsec tunnel address, or group IPsec key.

**subsystem set**

Sets the group IPsec key of the target portals in the currently selected subsystem.

**key**

Specifies the pre-shared key to be used for IPsec. If not specified, the existing key is cleared.

**tportal**

Specifies the target portal in currently selected subsystem to associate with the key.

**iportal**

Specifies the initiator portal in the currently selected initiator adapter to associate the key with.

**initiator**

Associates the key with all initiator portals in the service.

*flag*

Flags are identified by three letter acronyms:

**IKE**: Enable IPsec/Internet Key Exchange (IKE)

**NMM**: Enable IPsec negotiating through main mode

**NAM**: Enable IPsec negotiating through aggressive mode

**PFS**: Enable perfect forward secrecy

**TRA**: Prefer transport mode

**TUN**: Prefer tunnel mode

**tunneladdress**

Sets the tunnel mode address for the currently selected initiator portal, currently selected target portal, or all initiator portals in the service. Specifies the outer IP address used to create a connection if tunnel mode is used.

**destinationaddress**

Specifies the destination address to associate with the tunnel mode address.

**groupkey**

Specifies the group pre-shared key to be used for IPsec in the local iSCSI initiator service (if **initiator set** is specified) or the currently subsystem (if **subsystem set** is specified). If empty the key will be cleared.

#### lbpolicy

Sets the load balance policy on the currently selected LUN.

#### Syntax

**lbpolicy set lun type=** *type* [**paths=***path***-**{**primary** | *weight*}[**,***path***-**{**primary** | *weight*}[**,**...]]]

**lbpolicy set lun paths=** *path* **-**{**primary** | *weight*}[**,***path***-**{**primary** | *weight*}[**,**...]]

#### Parameters

**type**

Specifies the load balance policy. If the type is not specified, then the **path** parameter must be specified. Type can be one of the following:

**FAILOVER**: Uses one primary path with other paths being backup paths.

**ROUNDROBIN**: Uses all paths in round-robin fashion, which tries each path sequentially.

**SUBSETROUNDROBIN**: Uses all primary paths in round-robin fashion; backup paths are used only if all primary paths fail.

**DYNLQD**: Uses the path with the least number of active requests.

**WEIGHTED**: Uses the path with the least weight (each path must be assigned a weight).

**LEASTBLOCKS**: Uses the path with the least blocks.

**VENDORSPECIFIC**: Uses a vendor-specific policy.

**paths**

Specifies whether a path is **primary** or has a particular *weight*. Any paths not specified are implicitly set as backup. Any paths listed must be one of the currently selected LUN's paths.

#### list

Displays a list of objects of the specified type.

#### Syntax

**List** {**hbaports** | **iadapters** | **iportals** | **providers** | **subsystems** | **controllers** | **ports** | **drives** | **LUNs** | **tportals** | **targets** | **tpgroups**}

#### Parameters

**hbaports**

Lists summary information about all HBA ports known to VDS. The currently selected HBA port is marked by an asterisk (*).

**iadapters**

Lists summary information about all iSCSI initiator adapters known to VDS. The currently selected initiator adapter is marked by an asterisk (*).

**iportals**

Lists summary information about all iSCSI initiator portals in the currently selected initiator adapter. The currently selected initiator portal is marked by an asterisk (*).

**providers**

Lists summary information about each provider known to VDS. The currently selected provider is marked by an asterisk (*).

**subsystems**

Lists summary information about each subsystem in the system. The currently selected subsystem is marked by an asterisk (*).

**controllers**

Lists summary information about each controller in the currently selected subsystem. The currently selected controller is marked by an asterisk (*).

**ports**

Lists summary information about each controller port in the currently selected controller. The currently selected port is marked by an asterisk (*).

**drives**

Lists summary information about each drive in the currently selected subsystem. The currently selected drive is marked by an asterisk (*).

**luns**

Lists summary information about each LUN in the currently selected subsystem. The currently selected LUN is marked by an asterisk (*).

**tportals**

Lists summary information about all iSCSI target portals in the currently selected subsystem. The currently selected target portal is marked by an asterisk (*).

**targets**

Lists summary information about all iSCSI targets in the currently selected subsystem. The currently selected target is marked by an asterisk (*).

**tpgroups**

Lists outputs summary information about all iSCSI target portal groups in the currently selected target. The currently selected portal group is marked by an asterisk (*).

### login

Logs the specified iSCSI initiator adapter into the currently selected iSCSI target.

#### Syntax

**login target iadapter=** *iadapter* [**type=**{**manual** | **persistent** | **boot**}] [**chap=**{**none** | **oneway** | **mutual**}] [**iportal=***iportal*] [**tportal=***tportal*] [*flag* [*flag* [...]]]

#### Parameters

**type**

Specifies the type of login to perform: **manual**, **persistent**, or **boot**. If unspecified, a manual login will be performed.

**manual** - Login manually.

**persistent** - Automatically use the same login when the computer is restarted.

**boot** - *This option is for future development and is not currently used.*

**chap**

Specifies the type of CHAP authentication to use: **none**, **oneway** CHAP, or **mutual** CHAP; if unspecified, no authentication will be used.

**tportal**

Specifies an optional target portal in the currently selected subsystem to use for the log in.

**iportal**

Specifies an optional initiator portal in the specified initiator adapter to use for the log in.

*flag*

Identified by three letter acronyms:

**IPS**: Require IPsec

**EMP**: Enable multipath

**EHD**: Enable header digest

**EDD**: Enable data digest

**logout**
Logs the specified iSCSI initiator adapter out of the currently selected iSCSI target.

**Syntax**
**logout target iadapter=** *iadapter*

**Parameters**
**iadapter**

**Specifies the initiator adapter with a login session to logout from.**

**maintenance**
Performs maintenance operations on the currently selected object of the specified type.

**Syntax**
**maintenance** *object operation* [**count**=*iteration*]

**Parameters**
*object*

Specifies the type of object on which to perform the operation. The *object* type can be a **subsystem**, **controller**, **port, drive** or **LUN**.

*operation*

Specifies the maintenance operation to perform. The *operation* type can be **spinup**, **spindown**, **blink**, **beep** or **ping**. An *operation* must be specified.

**count=**

Specifies the number of times to repeat the *operation*. This is typically used with **blink**, **beep**,or **ping**.

**name**
Sets the friendly name of the currently selected subsystem, LUN, or iSCSI target to the specified name.

**Syntax**
**name** {**subsystem** | **lun** | **target**} [*name*]

**Parameter**

*name*

Specifies a name for the subsystem, LUN, or target. The name must be less than 64 characters in length. If no name is supplied, the existing name, if any, is deleted.

**offline**
Sets the state of the currently selected object of the specified type to **offline**.

**Syntax**
**offline** *object*

**Parameter**
*object*

Specifies the type of object on which to perform this operation. The *object* type can be **subsystem**, **controller**, **drive**, **LUN**, or **tportal**.

**online**
Sets the state of the selected object of the specified type to **online**. If object is **hbaport**, changes the status of the paths to the currently selected HBA port to **online**.

**Syntax**
**online** *object*

**Parameter**
*object*

Specifies the type of object on which to perform this operation. The *object* type can be **hbaport**, **subsystem**, **controller**, **drive**, **LUN**, or **tportal**.

**recover**
Performs operations necessary, such as resynchronization or hot sparing, to repair the currently selected fault-tolerant LUN. For example, RECOVER might cause a hot spare to be bound to a RAID set that has a failed disk or other disk extent reallocation.

**Syntax**
**recover** *lun*

**reenumerate**
Reenumerates objects of the specified type.

**Syntax**
**reenumerate** {**subsystems** | **drives**}

**Parameters**
**subsystems**

Queries the provider to discover any new subsystems that were added in the currently selected provider.

**drives**

Queries the internal I/O buses to discover any new drives that were added in the currently selected subsystem.

**refresh**
Refreshes internal data for the currently selected provider.

**Syntax**
**refresh provider**

**rem**
Used to comment scripts.

**Syntax**
**Rem** *comment*

**remove**
Removes the specified iSCSI target portal from the currently selected target portal group.

**Syntax**

**remove tpgroup tportal=** *tportal* [**noerr**]

**Parameter**
**tpgroup tportal=** *tportal*

Specifies the iSCSI target portal to remove.

**noerr**

Specifies that any failures that occur while performing this operation should be ignored. This is useful in script mode.

**replace**
Replaces the specified drive with the currently selected drive.

**Syntax**
**replace drive**=*drive_number*

**Parameter**
**drive=**

Specifies the *drive_number* for the drive to be replaced.

**Remarks**

- The specified drive may not be the currently selected drive.

**reset**
Resets the currently selected controller or port.

**Syntax**
**Reset** {**controller** | **port**}

**Parameters**
**controller**

Resets the controller.

**port**

Resets the port.

**select**
Displays or changes the currently selected object.

**Syntax**
**Select** {**hbaport** | **iadapter** | **iportal** | **provider** | **subsystem** | **controller** | **port** | **drive** | **lun** | **tportal** | **target** | **tpgroup** } [*n*]

**Parameters**
**object**

Specifies the type of object to select. The *object* type can be **provider**, **subsystem**, **controller**, **drive**, or **LUN**.

**hbaport** [*n*]

Sets the focus to the specified local HBA port. If no HBA port is specified, the command displays the currently selected HBA port (if any). Specifying an invalid HBA port index results in no in-focus HBA port. Selecting an HBA port deselects any selected initiator adapters and initiator portals.

**iadapter** [*n*]

Sets the focus to the specified local iSCSI initiator adapter. If no initiator adapter is specified, the command displays the currently selected initiator adapter (if any). Specifying an invalid initiator adapter index results in no in-focus initiator adapter. Selecting an initiator adapter deselects any selected HBA ports and initiator portals.

**iportal** [*n*]

Sets the focus to the specified local iSCSI initiator portal within the selected iSCSI initiator adapter. If no initiator portal is specified, the command displays the currently selected initiator portal (if any). Specifying an invalid initiator portal index results

in no selected initiator portal.

**provider** [*n*]

Sets the focus to the specified provider. If no provider is specified, the command displays the currently selected provider (if any). Specifying an invalid provider index results in no in-focus provider.

**subsystem** [*n*]

Sets the focus to the specified subsystem. If no subsystem is specified, the command displays the subsystem with focus (if any). Specifying an invalid subsystem index results in no in-focus subsystem. Selecting a subsystem implicitly selects its associated provider.

**controller** [*n*]

Sets the focus to the specified controller within the currently selected subsystem. If no controller is specified, the command displays the currently selected controller (if any). Specifying an invalid controller index results in no in-focus controller. Selecting a controller deselects any selected controller ports, drives, LUNs, target portals, targets, and target portal groups.

**port** [*n*]

Sets the focus to the specified controller port within the currently selected controller. If no port is specified, the command displays the currently selected port (if any). Specifying an invalid port index results in no selected port.

**drive** [*n*]

Sets the focus to the specified drive, or physical spindle, within the currently selected subsystem. If no drive is specified, the command displays the currently selected drive (if any). Specifying an invalid drive index results in no in-focus drive. Selecting a drive deselects any selected controllers, controller ports, LUNs, target portals, targets, and target portal groups.

**lun** [*n*]

Sets the focus to the specified LUN within the currently selected subsystem. If no LUN is specified, the command displays the currently selected LUN (if any). Specifying an invalid LUN index results in no selected LUN. Selecting a LUN deselects any selected controllers, controller ports, drives, target portals, targets, and target portal groups.

**tportal** [*n*]

Sets the focus to the specified iSCSI target portal within the currently selected subsystem. If no target portal is specified, the command displays the currently selected target portal (if any). Specifying an invalid target portal index results in no selected target portal. Selecting a target portal deselects any controllers, controller ports, drives, LUNs, targets, and target portal groups.

**target** [*n*]

Sets the focus to the specified iSCSI target within the currently selected subsystem. If no target is specified, the command displays the currently selected target (if any). Specifying an invalid target index results in no selected target. Selecting a target deselects any controllers, controller ports, drives, LUNs, target portals, and target portal groups.

**tpgroup** [*n*]

Sets the focus to the specified iSCSI target portal group within the currently selected iSCSI target. If no target portal group is specified, the command displays the currently selected target portal group (if any). Specifying an invalid target portal group index results in no in-focus target portal group.

*n*

Specifies the *object number* to select. If the *object number* specified is not valid, any existing selections for objects of the specified type are cleared. If no *object number* is specified, the current object is displayed.

#### setflag

Sets the currently selected drive as a hot spare.

#### Syntax

**setflag drive hotspare**={**true** | **false**}

#### Parameters

**true**

Selects the currently selected drive as a hot spare.

### false

Unselects the currently selected drive as a hot spare.

#### Remarks

- Hot spares cannot be used for ordinary LUN binding operations. They are reserved for fault handling only. The drive must not be currently bound to any existing LUN.

#### standby

Changes the status of the paths to the currently selected host bus adapter (HBA) port to STANDBY.

#### Syntax

**standby hbaport**

#### Parameters

### hbaport

Changes the status of the paths to the currently selected host bus adapter (HBA) port to STANDBY.

#### unmask

Makes the currently selected LUNs accessible from the specified hosts.

#### Syntax

**unmask LUN** {**all** | **none** | [**add**] **wwn**=*hexadecimal_number* [;*hexadecimal_number* [;...]] | [**add**] **initiator=***initiator*[;*initiator*[;...]]} [**uninstall**]

#### Parameters

### all

Specifies that the LUN should be made accessible from all hosts. However, you cannot unmask the LUN to all targets in an iSCSI subsystem.

### none

Specifies that the LUN should not be accessible to any host.

### add

Specifies that the hosts specified must be added to the existing list of hosts that this LUN is accessible from. If this parameter is not specified, the list of hosts supplied replaces the existing list of hosts that this LUN is accessible from.

### WWN=

Specifies a list of hexadecimal numbers representing world-wide names from which the LUN or hosts should be made accessible. To mask/unmask to a specific set of hosts in a Fibre Channel subsystem, you can type a semicolon-separated list of WWN's for the ports on the host machines of interest.

### initiator=

Specifies a list of iSCSI initiators to which the currently selected LUN should be made accessible. To mask/unmask to a specific set of hosts in an iSCSI subsystem, you can type a semicolon-separated list of iSCSI initiator names for the initiators on the host computers of interest.

### uninstall

If specified, uninstalls the disk associated with the LUN on the local system before the LUN is masked.

#### Scripting DiskRAID

DiskRAID may be scripted on any Windows Server 2003 system with an associated VDS hardware provider. To invoke a DiskRAID script, at the command prompt type:

**diskraid /s** *script.txt*

By default, DiskRAID stops processing commands and returns an error code if there is a problem in the script. To continue script execution, include the NOERR parameter on the command. This permits such useful practices as using a single script to delete all the LUNs in a subsystem regardless of the total number of LUNs. Not all commands support the NOERR parameter.

Errors are always returned on command-syntax errors, regardless of whether you included the NOERR parameter,

**DiskRAID error codes:**

| Error Code | Error Description |
|---|---|
| 0 | No error occurred. The entire script ran without failure. |
| 1 | A fatal exception occurred. |
| 2 | The arguments specified on a DiskRAID command line were incorrect. |
| 3 | DiskRAID was unable to open the specified script or output file. |
| 4 | One of the services DiskRAID uses returned a failure. |
| 5 | A command syntax error occurred. The script failed because an object was improperly selected or was invalid for use with that command. |

**Example: Interactively View Status of Subsystem**
If you want to view the status of subsystem 0 on your computer, type the following at the command line:

**diskraid**

Press ENTER. The following is displayed:

```
Microsoft Diskraid version 5.2.xxxx
Copyright (c) 2003 Microsoft Corporation
On computer: COMPUTER_NAME
```

To select subsystem 0, type the following at the DiskRAID prompt:

**select subsystem 0**

Press ENTER. Output similar to the following is displayed:

```
Subsystem 0 is now the selected subsystem.

DISKRAID> list drives

  Drive ###  Status      Health          Size      Free    Bus  Slot  Flags
  ---------  ----------  ------------  --------  --------  ---  ----  -----
  Drive 0    Online      Healthy         107 GB    107 GB    0     1
  Drive 1    Offline     Healthy          29 GB     29 GB    1     0
  Drive 2    Online      Healthy         107 GB    107 GB    0     2
  Drive 3    Not Ready   Healthy          19 GB     19 GB    1     1
```

To exit DiskRAID, type the following at the DiskRAID prompt:

**exit**

Press ENTER. The following output is displayed:

```
Leaving Diskraid
```

# File Server Resource Manager

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

With the increasing demand on storage resources, as organizations rely more heavily on data than ever before, IT administrators face the challenge of overseeing a larger and more complex storage infrastructure, while at the same time, tracking the kind of information available in it. Managing storage resources not only includes data size and availability any more but also the enforcement of company policies and a very good understanding of how existing storage is utilized, allowing for sound strategic planning and proper response to organizational changes.

File Server Resource Manager is a suite of tools that allows administrators to understand, control, and manage the quantity and type of data stored on their servers. By using File Server Resource Manager, administrators can place quotas on folders and volumes, actively screen files, and generate comprehensive storage reports. This set of advanced instruments not only helps the administrator to efficiently monitor existing storage resources but it also aids in the planning and implementation of future policy changes.

- Before working with File Server Resource Manager, to configure general notification and reporting options, see Setting File Server Resource Manager Options.
- To create quotas that set a soft or hard space limit on a volume or folder tree, see Quota Management.
- To create file screening rules that block files from a volume or a folder tree, see File Screening Management.
- To generate storage reports that can be used to monitor disk usage patterns, identify duplicate files and dormant files, track quota usage, and audit file screening, see Storage Reports.
- For problem-solving instructions, see Troubleshooting File Server Resource Manager.

# Deploying File Server Resource Manager

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

After you install Windows Server 2003 R2, use **Add or Remove Programs** in Control Panel to install the File Server Resource Manager component.

To install File Server Resource Manager, you must be logged on under an account that has administrative rights on the local computer and have the installation CD for Windows Server 2003 R2 at hand.

| **Important** |
| --- |
| You may need to reboot your server after the installation of File Server Resource Manager has completed. Please plan accordingly. |

**To install File Server Resource Manager**

1. In Control Panel, click **Add or Remove Programs**. Then click**Add/Remove Windows Components**.
2. From the list of components, in the **Windows Components Wizard** dialog box, select **Management and Monitoring Tools**, and click **Details**.
3. From the list of subcomponents, select **File Server Resource Manager**, and then click **OK**.
4. Click **Next**, and after the configuration of the new component has completed, click **Finish**.

**To open the File Server Resource Manager console**

The File Server Resource Manager component is administered through a Microsoft Management Console (MMC) snap-in console.

- On the **Start** menu, click **All Programs**, click **Administrative Tools**, and then click **File Server Resource Manager**.

# Setting File Server Resource Manager Options

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The general File Server Resource Manager options can be set in the **File Server Resource Manager Options** dialog box. These settings will be used throughout the different nodes and some of them can be modified when configuring specific actions.

**This section covers:**

- Configure E-mail Notifications
- Configure Storage Reports
- Configure Report Repositories
- Configure File Screen Audit

# Configure E-mail Notifications

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

When you create quotas and file screens, you have the option of sending e-mail notifications to users when their quota limit is approaching or after they have attempted to save files that have been blocked. If you want to routinely notify certain administrators of quota and file screening events, you can configure one or more default recipients.

To send these notifications, you must specify the SMTP server to be used for forwarding the e-mail messages.

**To configure e-mail options**

1. In the console tree, right-click **File Server Resource Manager**, and then click **Configure options**. The **File Server Resource Manager Options** dialog box opens.

2. On the **E-mail Notifications** tab, under **SMTP server name or IP address**, type the host name or the IP address of the SMTP server that will forward e-mail notifications.

3. If you want to routinely notify certain administrators of quota or file screening events, under **Default administrator recipients**, type each e-mail address.

   Use the format *account@domain*. Use semicolons to separate multiple accounts.

4. To test your settings, click **Send Test E-mail**.

# Configure Storage Reports

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can configure the default parameters for storage reports. These default parameters are used for the incident reports generated when a quota or file screening event occurs. They are also used for scheduled and on-demand reports, but the default parameters can be changed when defining the specific properties of these.

| **Important** |
| --- |
| When you change the default parameters for a type of report, changes affect all incident reports. |

**To configure the default parameters for storage reports**

1. In the console tree, right-click **File Server Resource Manager**, and then click **Configure options**. The **File Server Resource Manager Options** dialog box opens.

2. On the **Storage Reports** tab, under **Configure default parameters**, select the type of report that you want to modify.

3. Click **Edit Parameters**.

4. Depending on the type of report that you select, different report parameters will be available for editing. Perform all necessary modifications, and then click **OK** to save them as default parameters for that type of report.

5. Repeat steps 2 through 4 for all types of reports that you want to edit.

Storage Reports

# Configure Report Repositories

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

You can specify the location where storage reports will be saved on disk. A default path has been defined, but it can be changed if desired. There are three types of reports:

**Incident reports**
This type of report is automatically generated when a quota or file screening event occurs.

**Scheduled reports**
This type of report is generated when there is a schedule defined in the **Storage Reports** node.

**On-demand reports**
This type of report can be generated manually, in the **Storage Reports** node.

**To change the report repositories locations**

1. In the console tree, right-click **File Server Resource Manager**, and then click **Configure options**. The **File Server Resource Manager Options** dialog box opens.

2. On the **Report Locations** tab, type the path or browse to the location where you want the incident, scheduled, and on-demand reports to be saved.

3. Click **OK**.

**See Also**
**Concepts**
Storage Reports

# Configure File Screen Audit

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

By using File Server Resource Manager, you can record file screening activity in an auditing database. The information saved in this database is used to generate the File Screen Audit Report.

| **Important** |
| --- |
| If the **Record file screening activity in the auditing database** check box is cleared, the File Screen Audit Reports will not contain any information. |

**To configure file screen audit**

1. In the console tree, right-click **File Server Resource Manager**, and then click **Configure options**. The **File Server Resource Manager Options** dialog box opens.

2. On the **File Screen Audit** tab, select the **Record file screening activity in the auditing database** check box.

3. Click **OK**. All file screening activity will now be stored in the auditing database and can be viewed by running a File Screen Audit Report.

**Concepts**
Storage Reports

# Quota Management

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

On the Quota Management node of the File Server Resource Manager Microsoft Management Console (MMC) snap-in, you can perform the following tasks:

- Create quotas to limit the space allowed for a volume or folder and generate notifications when the quota limits are approached or exceeded.
- Generate auto quotas that apply to all existing folders in a volume or folder, as well as to any new subfolders created in the future.
- Define quota templates that can be easily applied to new volumes or folders and that can be used across an organization.

**For Example:**

- You can place a 200 megabytes (MB) limit on the personal folder of each user on a server, with a notification to you and the user when 180 MB of storage has been exceeded.
- A flexible 500 MB quota on a group's shared folder can be set. When this storage limit is reached, all users in the group are notified by e-mail that the storage quota has been temporarily extended to 520 MB, so that they can delete unnecessary files and comply with the preset 500 MB quota policy.
- You can receive a notification when a temporary folder reaches 2 gigabytes (GB) of usage yet not limit that folder's quota because it is necessary for a service running on your server.

**This section covers:**

- Create a quota
- Create a quota template
- Create an auto quota
- Edit quota template properties
- Edit auto quota properties

| **Note** |
| --- |
| To set e-mail notifications and certain reporting capabilities, you must first configure the general File Server Resource Manager options. |

**See Also**
**Concepts**
Setting File Server Resource Manager Options

# Create a quota

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Quotas can be created from a template or individually. The following procedure describes how to create a quota that is based on a template, which we recommend.

| **Note** |
| --- |
| By creating quotas exclusively from templates, you can centrally manage your quotas by updating the templates instead of the individual quotas. Then, you can apply changes to all quotas based on the modified template. This feature simplifies the implementation of storage policy changes by providing one central point where all updates can be made. |

**To create a quota that is based on a template**

1. In **Quota Management**, under **Quota Templates**, select the template on which you will base your new quota. Then, right-click the template, and click **Create quota from template**. This opens the **Create Quota** dialog box.

2. Under **Quota path**, select or type the path to the folder to which the quota will apply. Note that the quota properties will also apply to all of its subfolders.

3. To base the quota on a quota template, select the **Derive properties from this quota template** option, and select the template from the drop-down combo box. Note that each template properties will be displayed under **Summary of quota properties**.

4. Click **Create**.

Create a quota template

# Create a quota template

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

A *quota template* defines a space limit, the type of quota (hard or soft), and a set of notifications to be generated when the quota limit approaches.

| **Note** |
| --- |
| By creating quotas exclusively from templates, you can centrally manage your quotas by updating the templates instead of the individual quotas. This is a feature that simplifies the implementation of storage policy changes by providing one central point where all updates can be made. |

**To create a quota template**

1. In **Quota Management**, right-click **Quota Templates**, and click **Create quota template**. This opens the **Create Quota Template** dialog box.

2. If you want, you can copy the properties of an existing template by selecting it from the drop-down combo box and clicking **Copy**. These properties can be used as a base for the new template, or you can create an entirely new one.

3. To identify the new template, enter a template name and an optional quota label.

4. To configure the space limit for the quota:

   a. Under **Limit**, specify the amount of space to allow.

   b. Specify the type of quota to impose:

      A *hard quota* prevents users from saving files after the space limit is reached, and generates notifications when the volume of data reaches each configured threshold.

      A *soft quota* does not enforce the quota limit, but generates all configured notifications.

   *Notification thresholds* determine what happens when the quota limit approaches. You can send e-mail notifications, log an event, execute a command or a script, or generate reports. By default, no notifications are generated.

5. To configure notifications that will be generated when the quota limit is reached, in the **Notification thresholds** list, highlight the **Limit (100%)** threshold, and click **Edit**. This opens the **Limit Properties** dialog box.

6. To configure e-mail notifications, set the following options on the **E-mail Message** tab:

   - Select the **Send e-mail to the following administrators** check box, and enter the names of the administrative accounts that will receive notifications. Use the format *account@domain*; use semicolons to separate multiple accounts.

   - To contact the person who saved the file that exceeded the quota threshold, select the **Send e-mail to the user who exceeded the threshold** check box.

   - Optionally, edit the default subject line and message body that are provided.

     The text that is in brackets inserts variable information about the quota event that caused the notification. For example, the [Source Io Owner] variable inserts the user name of the user or application that wrote the file to disk. Use the **Insert Variable** button to insert additional variables in the text.

(You can use the **Additional E-mail Headers** button to configure additional headers, including "From," "Cc," "Blind Cc," and "Reply-To.")

7. To log an error to the event log, on the **Event Log** tab, select the **Send warning to event log** check box, and optionally edit the default log entry.

8. To run a command or script, on the **Command** tab, select the **Run this command or script** check box, and type the command or browse to the location where the script is stored. Optionally, enter command arguments, select a working directory for the command or script, or modify the command security setting.

9. To specify that one or more storage reports be generated automatically, on the **Report** tab, select the **Generate reports** check box, and select which reports to generate. You must choose at least one e-mail recipient for the report, either an administrator or the user.

10. After configuring each type of notification that you want to generate, click **OK** to save the threshold.

11. To configure additional notification thresholds, perform these steps:

    a. In the **Notification Thresholds** area, click **Add**.

    b. At the top of the **Add Threshold** dialog box, enter the percentage of the quota limit at which to generate the notifications. The default threshold for the first notification is 85 percent.

    c. Use the **E-Mail Message**, **Event Log**, **Command**, and **Reports** tabs to configure each type of notification that you want to generate, as you did in steps 6 through 10. Then click **OK**.

12. When you complete the quota properties, click **OK** to save the template.

| **Important** |
| --- |
| To send e-mail notifications and to configure the storage reports with parameters appropriate for your server environment, you must first set the general File Server Resource Manager options. |

Edit quota template properties

# Create an auto quota

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

By using auto quotas, you can assign a quota template to a folder and specify that quotas based on that template be automatically generated and applied to the existing subfolders, as well as to any new subfolders created in the future.

For example, you may define an auto quota for folders that are created on demand, for roaming profile users or for new users. Every time a new folder is created, a new quota entry is automatically generated for that folder, using the template defined in the auto quota profile of its parent folder. These automatically generated quota entries can then be viewed in the results pane, under the **Quotas** node, as individually created quotas, which can be edited and modified separately.

**To create an auto quota**

1. In **Quota Management** select the **Quotas** node.
2. Right-click **Quotas** and click **Create quota** or select **Create quota** from the actions pane. This opens the **Create Quota** dialog box.
3. Under **quota path** select or type the path to the folder to which the auto quota will apply. The auto quota will be applied to all subfolders (current and future) in this folder. Once the path is entered, select the **Auto apply template and create quotas on existing and new subfolders option.**
4. Under **Derive properties from this quota template** select the quota template that you wish to apply. You can review the properties of each quota template in the summary list box.
5. Click **Create**.

| **Note** |
| --- |
| You can verify all automatically generated quotas by opening the **Quotas** node. An individual quota for each subfolder will be listed. |

Edit auto quota properties

# Edit quota template properties

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

When making changes to a quota template, you have the option of extending those changes to quotas that were created using the original quota template. You can choose to modify only those quotas that still match the original template or all quotas that were derived from the original template, regardless of any modifications made to the quotas since they were created. This feature simplifies the process of updating the properties of quotas by providing one central point where all changes can be made.

| **Note** |
| --- |
| If you choose to apply the changes to all quotas that were derived from the original template, you will overwrite any custom quota properties that you may have created. |

**To edit quota template properties**

1. In **Quota Templates**, select the template that you want to modify.
2. Right-click the quota template and click **Edit template properties**, or select **Edit template properties** from the actions pane, under **Selected Quota Templates**. This opens the **Quota Template Properties** dialog box.
3. Perform all necessary changes. Optionally, you can copy the properties of a different template and modify them for this one.
4. When you are finished editing the template properties click **OK**. This will open the **Update Quotas Derived from Template** dialog box.
5. Select the type of update you want to apply:
   - If you have quotas that have been modified since they were created using the original template, and you do not want to change them, select **Apply template only to derived quotas that match the original template**. This option will update only those quotas that have not been edited and maintain the original template properties.
   - If you want to modify all existing quotas that were created using the original template, select **Apply template to all derived quotas**.
   - If you want to keep the existing quotas unchanged, select **Do not apply template to derived quotas**.
6. Click **OK**.

# Edit auto quota properties

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

When making changes to an auto quota, you have the option of extending those changes to existing quotas in the auto quota path. You can choose to modify only those quotas that still match the original auto quota, or all quotas in the auto quota path, regardless of any modifications made to the quotas since they were created. This feature simplifies the process of updating the properties of quotas that were derived from an auto quota by providing one central point where all changes can be made.

| **Note** |
| --- |
| If you choose to apply the changes to all quotas in the auto quota path, you will overwrite any custom quota properties that you may have created. |

**To edit an auto quota**

1. In **Quotas**, select the quota that you want to modify.
2. Right-click the Quota entry and click **Edit quota properties** or select **Edit quota properties** from the actions pane, under **Selected Quotas**. This opens the **Edit Auto Apply Quota** dialog box.
3. Under **Derive properties from this quota template** select the new quota template that you want to apply. You can review the properties of each quota template in the summary list box.
4. Click **OK**. This will open the **Update Quotas Derived from Auto Apply Quota** dialog box.
5. Select the type of update you want to apply:
   - If you have quotas that have been modified since they were automatically generated, and you do not want to change them select **Apply auto apply quota only to derived quotas that match the original auto apply quota**. This option will update only those quotas in the Auto Apply Quota Path that have not been edited and maintain the original auto apply quota properties.
   - If you want to modify all existing quotas in the Auto Apply Quota Path, select **Apply auto apply quota to all derived quotas**.
   - If you want to keep the existing quotas unchanged, but make the modified auto quota effective for new folders in the Auto Apply Quota Path, select **Do not apply auto apply quota to derived quotas**.
6. Click **OK**.

# File Screening Management

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

On the File Screening Management node of the File Server Resource Manager MMC snap-in, you can perform the following tasks:

- Create file screens to control the types of files that users can save and to send notifications when users attempt to save blocked files.
- Define file screening templates that can be easily applied to new volumes or folders and that can be used across an organization.
- Create file screening exceptions that extend the flexibility of the file screening rules.

**For example:**

- You could ensure that no music files are stored on personal folders on a server, yet you could allow storage of specific types of media files that support legal rights management or comply with company policies. In the same scenario, you may want to give a vice president in the company special privileges to store any type of files in his personal folder.
- A screening process could be implemented to notify you by e-mail when an executable file is stored on a shared folder, with information including the user that stored the file and the exact location of the file, so that the appropriate precautionary steps can be taken.

**This section covers:**

- Define file groups for screening
- Create a file screen
- Create a file screen exception
- Create a file screen template
- Edit file screen template properties

| **Note** |
| --- |
| To set e-mail notifications and certain reporting capabilities, you must first configure the general File Server Resource Manager options. |

**Concepts**
Setting File Server Resource Manager Options

# Define file groups for screening

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

A *file group* is used to define a namespace for a file screen, file screen exception, or storage report. It consists of a set of file name patterns, which are grouped into files to include and files to exclude:

- **Files to include:** files that belong in the group.
- **Files to exclude:** files that do not belong in the group.

| **Note** |
| --- |
| For convenience, you can maintain file groups while you edit the properties of file screens, file screen exceptions, and file screen templates. Any file group changes that you make from these property sheets are not limited to the current item that you are working on. |

**To create a file group**

1. In **File Screen Management**, right-click **File Groups**, and then click **Create file group**.

   -Or-

   While you edit the properties of a file screen, file screen exception, or file screen template, under **Manage file groups**, click **Create**. This opens the **Create File Group Properties** dialog box.

2. Type a name for the file group.

3. Add files to include and files to exclude:

   - For each set of files that you want to include in the file group, in the **Files to include** box, enter a file name pattern, and click **Add**.

     Standard wildcard rules apply. For example, ***.exe** selects all executable files.

   - For each set of files that you want to exclude from the file group, in **Files to exclude**, add exclusions in the same way.

4. Click **OK**.

# Create a file screen

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

When creating a new file screen, you can choose to save a file screen template based on the custom file screen properties that you define. The advantage of this is that a link is maintained between file screens and the template used to create them, so that in the future, changes to the template can be applied to all file screens that derive from it. This is a feature that simplifies the implementation of storage policy changes by providing one central point where all updates can be made.

**To create a file screen**

1. In **File Screening Management**, right-click **File Screens**, and then click **Create file screen**. This opens the **Create File Screen** dialog box.

2. Under **File screen path**, type or browse to the folder to which the file screen will apply. The file screen will apply to all subfolders of the selected folder.

3. Under **How do you want to configure file screen properties**, select the **Define custom file screen properties** option, and then click **Custom Properties**. This opens the **File Screen Properties** dialog box.

4. If you want to copy properties from an existing template, select the template that you want to use, and click **Copy**. You can edit the properties for the new file screen.

5. Under **Screening type**, select the type of screening to apply:

   - **Active screening** prevents users from saving files that are members of blocked file groups, and generates notifications when users try to save blocked files. (The file screen does not prevent users and applications from accessing files that were saved to the path before the file screen was created, regardless of whether the files are members of blocked file groups.)

   - **Passive screening** sends notifications, but does not prevent users from saving blocked files.

   To specify which files to screen, under **File Groups**, select each file group that you want to include. (To select the check box for the file group, click the file group label twice.)

   If you want to view the members and nonmembers of a file group, highlight the file group, and click **Edit**.

6. To configure e-mail notifications for the file screen, set the following options on the **E-mail Message** tab:

   - To notify administrators when a user or application attempts to save an unauthorized file, select **Send e-mail to the following administrators**, and enter the administrative accounts that will receive notifications. Use the format *account@domain*; use semicolons to separate multiple accounts.

   - To send a notice to the user who attempted to save an unauthorized file, select **Send e-mail to the user who attempted to save an unauthorized file**.

   - Optionally, edit the default subject line and message body.
     The text that is in brackets inserts variable information about the file screen event that caused the notification. For example, the [Source I/O Owner] variable inserts the user name of the user or application that attempted to write the file to disk. To insert additional variables in the text, click **Insert Variable**.

7. If you want to log an error to the event log when a user tries to save a blocked file, on the **Event Log** tab, select the **Send warning to event log** check box, and, optionally, edit the default log entry.

In addition, you can set options on the **Command** tab, to run a command or script when a user attempts a file screen violation, and set options on the **Report** tab, to specify one or more storage reports to be generated automatically.

8. When all file screen properties are complete, click **Create** to save the file screen.

   You will be asked if you want to save a file screen template based on the custom file screen properties you just defined. If you will use the current settings in other file screens, it is recommended that you save a template. The template will be applied to the new file screen. This will enable you to later update the file screen automatically when you update the template.

9. To save a template when you create the file screen, select **Save the custom properties as a template**, enter a name for the template, and click **OK**.

   -Or-

   If you do not want to save a template, select **Save the custom file screen without creating a template**, and click **OK**.

Define file groups for screening
Edit file screen template properties

# Create a file screen exception

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Occasionally, you will need to be able to allow exceptions to file screening. For example, you might want to block video files from a file server, but you need to allow your training group to save the video files for their computer-based training. To allow files that other file screens are blocking, create a *file screen exception*.

A file screen exception is a special type of file screen that overrides any file screening that would otherwise apply to a folder, and all its subfolders, in a designated exception path. That is, it creates an exception to any rules derived from a parent folder.

| **Note** |
| --- |
| You cannot create a file screen exception on a folder for which you already have a file screen. You must assign the exception to a subfolder or make changes to the existing file screen. |

To determine which file types will be allowed with the file screen exception, file groups are assigned.

**To create a file screen exception**

1. In**File Screening Management**, right-click **File Screens**, and then click **Create file screen exception**. This opens the **Create File Screen Exception** dialog box.

2. Under **Exception path**, type or select the path to which the exception will apply. The exception will apply to the folder and all of its subfolders.

3. To determine which files to exclude from file screening, in **File groups**, select each file group that you want to include in the file screen exception.

   If you want to view the members and non-members of a file group, highlight the file group, and click **Edit**.

4. Click **OK**.

**See Also**
**Concepts**
Define file groups for screening

# Create a file screen template

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

A *file screen template* defines a group of file groups to block, the type of screening to perform (active or passive) and a set of notifications to be generated.

| **Note** |
| --- |
| By creating file screens exclusively from templates, you can centrally manage your file screens by updating the templates instead of the individual file screens. When you make changes to a template, you can choose to apply those changes to all file screens that are based on that template or only to those file screens whose properties match those in the template. This feature simplifies the implementation of storage policy changes, by providing one central point where all updates can be made. |

**To create a file screen template**

1. In **File Screening Management**, right-click **File Screen Templates**, and then click **Create file screen template**. This opens the **Create File Screen Template** dialog box.

2. To identify the new template, enter a template name.

3. Specify the screening type:

   An *Active Screening* will completely block users from saving unauthorized files.

   A *Passive Screening* will allow users to save unauthorized files, but will generate the notifications defined for this template.

4. Select the file groups to block. You can also choose to create new file groups or edit existing ones.

5. To configure e-mail notifications, set the following options on the **E-mail Message** tab:

   - Select the **Send e-mail to the following administrators** check box, and type the names of the administrative accounts that will receive notifications. Use the format *account@domain;* use semicolons to separate multiple accounts.

   - To contact the person who saved the file, select the **Send e-mail to the user who attempted to save an unauthorized file** check box.

   - Optionally, edit the default subject line and message body that are provided.

     The text that is in brackets inserts variable information about the quota event that caused the notification. For example, the [Source Io Owner] variable inserts the user name of the user or application that wrote the file to disk. To insert additional variables in the text, click **Insert Variable**.

     (To configure additional headers, click **Additional E-mail Headers**)

6. To log an error to the event log, on the **Event Log** tab, select the **Send warning to event log** check box, and optionally edit the default log entry.

7. To run a command or script when a screening event occurs, on the **Command** tab, select the **Run this command or script** check box, and type the command or browse to the location where the script is stored. Optionally, enter command arguments, select a working directory for the command or script, or modify the command security setting.

8. To specify that one or more storage reports be generated automatically, on the **Report** tab, select the **Generate reports** check box, and select which reports to generate. You must choose at least one e-mail recipient for the report, either an administrator or the user.

9. Click **OK**.

| **Important** |
| --- |
| To send e-mail notifications and to configure the storage reports with parameters appropriate for your server environment, you must first set the general File Server Resource Manager options. |

# Storage Reports

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

On the Storage Reports node of the File Server Resource Manager MMC snap-in, you can perform the following tasks:

- Schedule periodic storage reports that allow you to identify trends in disk usage.
- Monitor attempts to save unauthorized files for all users or a selected group of users.
- Generate storage reports instantly.

**For example:**

- You can schedule a report that will run every Sunday at midnight, generating a list that includes the most recently used files of the previous two days. With this information, you can monitor weekend storage activity and plan server downtime that will have less impact on those users that connect from home over the weekend.
- A report can be run, at any given time, to identify all duplicate files in a volume on a server, so disk space can be quickly reclaimed without losing any data.
- You can run a *File by File Group* report, to identify how storage resources are segmented across different file groups; or a *File by Owner* report, to analyze how individual users are using shared storage resources.

**This section covers:**

- Schedule a set of reports
- Generate reports on demand

| **Note** |
| --- |
| To set e-mail notifications and certain reporting capabilities, you must first configure the general File Server Resource Manager options. |

**See Also**
**Concepts**
Setting File Server Resource Manager Options

# Schedule a set of reports

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

To generate a set of reports on a regular schedule, you schedule a *report task*. The report task specifies which reports to generate and what parameters to use; which volumes and folders to report on; how often to generate the reports; and which file formats to save them in.

| **Note** |
| --- |
| To minimize the impact of report processing on performance, generate multiple reports on the same schedule so that the data is only gathered once. To quickly add reports to existing report tasks, you can use the **Add/remove reports from report task** action. That action allows you to add or remove reports from multiple report tasks, and to edit the report parameters. To change schedules or delivery addresses, you must edit individual report tasks. |

**To schedule a report task**

1. Right-click the **Scheduled Report Tasks** node, and click **Schedule a new report task**. This opens the **Storage Reports Task Properties** dialog box.

2. To select a volume or folder on which to report:

   a. In **Scope**, click **Add**.

   b. Browse to the volume or folder that you want to report on, and click **OK**.

   This adds the selected volume or folder to the list. Add as many paths as you want to include.

3. In **Report data**, select each report that you want to generate. (By default, all reports are generated for a scheduled report task.)

4. To edit the parameters of a report:

   a. Highlight the report label, and click **Edit Parameters**.

   b. In the **Report Parameters** dialog box, edit the parameters as needed, and click **OK**.

5. If you want to deliver copies of the reports to administrators by e-mail, on the **Delivery** tab, click **E-mail report to administrators**, and enter each e-mail account. Use the format *account@domain*; use semicolons to separate multiple accounts.

6. To schedule the reports, on the **Schedule** tab, click **Create Schedule**. Then, in the **Schedule** dialog box, click **New**.

   This opens the **Schedule** dialog box, with a default schedule set for 9:00 A.M. daily, starting on the next day.

7. To change the default schedule:

   a. Under **Schedule Task**, select the interval at which to generate the report.

      You can schedule daily, weekly, or monthly reports, or generate the reports only once.

   b. In the options below this field, enter additional information, as needed, to determine when the reports will be generated.

      These options change based on the interval that you choose. For example, for a weekly report, you can specify how

many weeks between reports and which days of the week to generate reports on.

c. Under **Start time**, enter the time of day when you want to generate the report.

d. To save the schedule, click **OK**.

8. To save the report task, click **OK**.

The report task is added to the results pane for **Scheduled Report Tasks**. Tasks are identified by the reports to be generated, the namespace to be reported on, and report schedule.

In addition, you can view the current status of the report (whether or not the report is running), the last run time and the result of that run, and the next scheduled run time.

# Generate reports on demand

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

During daily operations, you may want to generate reports on demand to analyze different aspects of current disk usage on the server. Use the **Generate reports now** action to generate one or more reports. Before the reports are generated, current data is gathered.

When you generate reports on demand, the reports are saved in the reports repository, but no report task is created for later use. You can optionally view the reports immediately when they are complete.

| **Note** |
| --- |
| If you choose to open the reports immediately, you must wait while the reports are generated. Processing time varies, depending on the types of reports and the scope of the data. |

**To generate reports immediately**

1. Right-click the **Scheduled Report Tasks** node, and click **Generate reports now**. This opens the **Storage Reports Task Properties** dialog box.

2. In **Scope**, add each volume or folder that you want to report on.

3. In **Report data**, select and format each report that you want to include:

   a. To add a report to the task, select the check box for the report.

   b. To edit the parameters of a report, highlight the report label and click **Edit Parameters**. When you finish editing the parameters, click **OK**.

4. In **Report format**, select each file format that you want to save the report in.

5. To deliver the reports by e-mail, on the **Delivery** tab, select the **E-mail report to the following administrators** check box. Then, enter each e-mail address that you want the report delivered to. Use the format *account@domain*; use semicolons to separate multiple accounts.

6. To gather the data and generate the reports, click **OK**.

7. In the dialog box that opens, choose whether to open the reports when they are complete or generate the reports in the background, in which case the reports are not displayed.

   Both options save the reports in the formats that you selected. If you choose to open the reports after they are generated, each report opens in its own Internet Explorer window.

# Troubleshooting File Server Resource Manager

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

This section lists a few common issues you may encounter when using File Server Resource Manager.

**What problem are you having?**

- I am not receiving any e-mail notifications
- I am only receiving one e-mail notification, even though the event that caused it happened several times in a row
- My storage reports keep failing and no or little information is available in the Event Log regarding the source of the failure
- My File Audit reports do not contain any information
- The "Used" and "Available" values for some of the quotas I have created do not correspond to the actual "Limit" setting

| **Note** |
| --- |
| A good troubleshooting option is to look for event logs generated by File Server Resource Manager. All event log entries for File Server Resource Manager can be found in the Application event log under the source: **SRMSVC**. |

**I am not receiving any e-mail notifications.**
**Cause:**

The e-mail options have not been configured or have been configured incorrectly.

**Solution:**

Verify that the SMTP server and e-mail settings in the File Server Resource Manager options have been specified and are valid. Send a test e-mail to confirm that the information is correct and that the SMTP server used to send the notifications is working properly. For more information see Configure E-mail Notifications.

**I am only receiving one e-mail notification, even though the event that triggered that notification happened several times in a row.**
**Cause:**

When a user attempts several times to save a blocked file, or a file that exceeds a quota limit, and there is an e-mail notification configured for that file screening or quota event, then only one e-mail will be sent to the administrator for a period of 60 minutes. This prevents over-flooding of messages in the administrator's e-mail account.

**Solution:**

This is a feature of File Server Resource Manager.

**My storage reports keep failing and no or little information is available in the Event Log regarding the source of the failure.**
**Cause:**

The volume where the reports are being saved may be corrupted.

**Solution:**

Run **chkdsk** on the volume and try generating reports again.

**My File Audit reports do not contain any information.**
**Cause:**

The auditing database is empty (that is, no file screening activity has been reported) or the File Screen Audit properties have not been configured.

**Solution:**

In the **File Server Resource Manager Options** dialog box, on the **File Screen Audit** tab, verify that the **Record file screening activity in the auditing database**check box is selected. For more information, see Configure File Screen Audit.

**The "Used" and "Available" values for some of the quotas I have created do not correspond to the actual "Limit" setting.**
**Cause:**

You may have a nested quota, where the quota that applies to a folder will be a more restrictive quota that derives from one of its parent folders.

**Solution:**

Under **Quota Management**, go to **Quota**, and then select the quota entry that you are troubleshooting. Click **View quotas affecting folder** on the actions pane, and look for quotas applied to parent folders. This will allow you to identify which quotas have restrictive settings on the quota you have selected (that is, which parent folder quotas have a lower storage limit setting).

# Identity Management for UNIX: Welcome

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Identity Management for UNIX**
Identity Management for UNIX makes it easy to integrate users of Windows operating systems into existing UNIX environments. It provides manageability components that simplify network administration and account management across both platforms.

With Identity Management for UNIX, you can:

- Manage user accounts and passwords on Windows and UNIX systems using Network Information Service (NIS).
- Automatically synchronize passwords between Windows and UNIX operating systems.

For details about Identity Management for UNIX, see Identity Management for UNIX overview. For information about installable components, see Identity Management for UNIX components.

**In this section**

- Identity Management for UNIX overview
- Identity Management for UNIX components
- Connect to a computer you want to manage
- Identity Management for UNIX: Server for NIS
- Identity Management for UNIX: Password Synchronization
- Accessibility Features of Identity Management for UNIX

# Identity Management for UNIX overview

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Identity Management for UNIX overview**

Identity Management for UNIX makes it easy to integrate computers running Windows into your existing UNIX enterprise. Active Directory network administrators can use Server for NIS to manage Network Information Service (NIS) domains, and Password Synchronization automatically synchronizes passwords between Windows and UNIX operating systems.

With minor differences, Identity Management for UNIX is compliant with Internet Engineering Task Force (IETF) standard Request for Comments (RFC) 2307, meaning that your network's password and NIS attributes can be resolved by the Lightweight Directory Access Protocol (LDAP). For more information about RFC 2307, including a complete list of attributes specified in the RFC 2307 schema, see the RFC database Web site.

Identity Management for UNIX: Server for NIS completely integrates UNIX NIS networks with Windows Active Directory. Identity Management for UNIX includes an easy-to-use wizard that a Windows domain administrator can use to export NIS domain maps to Active Directory entries. Once this is done, an Active Directory domain controller running Server for NIS becomes the master server for the NIS domain.

Identity Management for UNIX: Password Synchronization automatically changes a user password on the UNIX network when the user changes his or her Windows password, and vice versa. This allows users to maintain just one password for both networks.

Password Synchronization supports Sun Solaris version 8 running on x86-based computers and Scalable Processor Architecture (SPARC)–based computers; Solaris version 9 running on SPARC–based computers; Hewlett Packard HP-UX version 11i; IBM AIX version 5L 5.2; and Red Hat Linux versions 8 and 9 running on x86-based computers and 64-bit AMD-based computers. Server for NIS should work with any operating system or product that uses LDAP.

# Identity Management for UNIX components

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Identity Management for UNIX components**

You can use the Identity Management for UNIX installation program to install the following:

- **Administration components**. Provides utilities for administering Identity Management for UNIX.
- **Password Synchronization**. Password Synchronization makes it easy for users to maintain one password for Windows domains and UNIX systems, synchronizing them when one of them changes.
- **Server for NIS**. Enables a Windows-based server to function as a Network Information Service (NIS) server, integrating NIS domains with Active Directory and giving Windows Active Directory administrators the ability to manage Windows and NIS domains together. Server for NIS can be installed only on an Active Directory domain controller.

# Connect to a computer you want to manage

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To connect to the computer you want to manage**

1. Open Identity Management for UNIX.
2. Do one of the following:
   - Right-click the **Microsoft Identity Management for UNIX** node at the top of the hierarchy pane, and then click **Connect to another computer**. On the **Select Computer** dialog box, select **Another Computer**.
   - In the **Actions** pane, click **Connect to another computer**, and then select **Another Computer**.
   - With the **Microsoft Identity Management for UNIX** node at the top of the hierarchy pane highlighted, click **Connect to another computer** on the **Action** menu. On the **Select Computer** dialog box, select **Another Computer**.
3. In the box, type the name of the computer to use, or click **Browse**.
4. When you have identified or found the computer you want, click **OK**.

| **Note** |
| --- |
| You must be logged on with an account that has administrator privileges on the remote computer.<br><br>There is no command-line method for this procedure.<br><br>To open Identity Management for UNIX, click **Start**, point to **All Programs**, point to **Identity Management for UNIX**, and then click **Identity Management for UNIX**. |

# Identity Management for UNIX: Server for NIS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Server for NIS**
Server for NIS enables a Microsoft Windows–based Active Directory domain controller to administer UNIX Network Information Service (NIS) networks.

- Before you start using Server for NIS, see Server for NIS Checklists.
- For tips about using Server for NIS, see Best practices for Server for NIS.
- For help with specific tasks, see How To.....
- For general background information, see Concepts of Server for NIS.
- For detailed reference information about command utilities for managing Server for NIS, see Server for NIS command-line utilities.
- For problem-solving instructions, see Server for NIS Troubleshooting.

# Server for NIS Checklists

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Checklists**

- Checklist: Setting up Server for NIS
- Checklist: NIS migration to Active Directory using the NIS Data Migration wizard

# Checklist: NIS migration to Active Directory using the NIS Data Migration wizard

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Checklist: NIS migration to Active Directory using the NIS Data Migration wizard**

| Step | Reference |
|---|---|
| Read more about Network Information Service (NIS) migration. | Understanding NIS Data Migration |
| Back up your Windows domain controllers, or use a test domain controller. | Windows documentation |
| Log on as a member of the Domain Admins group. | Windows documentation |
| Identify the NIS domain to migrate and how it will be migrated, keeping in mind the following:<br>• You can migrate only one NIS domain at a time, but you can merge the NIS domain with a previously migrated NIS domain.<br>• If you do not merge the domain, you can preserve the existing domain name or create a new name for the migrated domain.<br>• You should migrate an NIS domain to only one Active Directory domain. | NIS administrator |
| Make sure that the source files for the NIS maps that you want to migrate can be accessed by the computer running the NIS Data Migration wizard. (NIS map source files are the plain text files from which the NIS map databases are compiled.) You can make the files available to the Windows-based computer by using network file system (NFS), or by copying them to the Windows-based computer through File Transfer Protocol (FTP). All standard and nonstandard map source files should be in the same directory. | |
| Determine which standard NIS maps to migrate, and the directory paths to the map source files, keeping in mind the following:<br>• You can migrate maps in steps, that is, migrate one map first, then another, and so on.<br>• You should migrate the passwd map before migrating other maps (such as group or shadow maps) that rely on it.<br>• You must migrate the networks map before migrating netmasks. | NIS administrator<br>Managing standard and nonstandard NIS maps |
| Determine any nonstandard NIS maps to migrate, their formats, and the directory paths to their map source files. All standard and nonstandard map source files should be in the same directory. | NIS administrator |
| Examine NIS map source files for multiple entries having the same primary key (for example, more than one user with the same user identifier (UID) in the passwd file) and eliminate the duplicate primary keys. | NIS administrator |
| Determine Active Directory containers to which you will migrate the NIS domain. | |

| | |
|---|---|
| Decide on the strategy to migrate using one of the following two alternatives. If there are conflicts between the existing map entry and the entry being migrated during the migration process, you can choose one of the following methods:<br>• Overwrite the existing entry with data from the entry being migrated.<br>• Preserve data from the existing entry and ignore the entry being migrated.<br>• Resolve conflicts by changing the Windows account name in Active Directory. If objects of different types have the same name, the names of both objects are changed before the data is migrated. | Best practices for Server for NIS |
| Determine whether you want to run the wizard first without migrating to examine all events that will take place during migration (recommended), or migrate all data the first time the wizard is run. The migration wizard can be configured to log all the migration steps without actually migrating the data to Active Directory. | |
| Migrate NIS maps to Active Directory on a computer running Windows Server and Active Directory. | Migrate NIS domains |
| Review the log files after migration for errors or conflicts. Resolve log conflicts and migrate the resolved entries again. | Resolving migration conflicts |
| Configure any UNIX NIS subordinate (also known as slave) servers to use Server for NIS as the master NIS server. | Configuring a UNIX NIS server to use Server for NIS as the master server |
| Configure any UNIX NIS client computers to use Server for NIS as the master NIS server. | Configuring UNIX clients to use Server for NIS as the master server |
| Set the passwords of new Windows user accounts (created as a result of the NIS migration) to a known, temporary value, inform the users of the temporary password and instruct them to change their Windows password as soon as possible. | |

# Checklist: Setting up Server for NIS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Checklist: Setting up Server for NIS**

| Step | Reference |
|---|---|
| Read about Server for NIS. | Concepts of Server for NIS |
| Migrate Network Information Service (NIS) maps to Active Directory. | Checklist: NIS migration to Active Directory using the NIS Data Migration wizard |
| Set how often maps are propagated to subordinate (also known as slave) NIS servers. | Change the frequency of map updates to UNIX subordinate (slave) NIS servers |
| Review and, if needed, add or remove UNIX subordinate servers in the domain. | Add or remove UNIX subordinate (slave) servers |
| As needed, install Server for NIS on other domain controllers, which will automatically be configured as subordinate servers. Install Password Synchronization on all other domain controllers. This will ensure that when a user's password is changed, the password will be updated across the domain. Server for NIS will receive the updated passwords when the data is replicated to the domain controller. | Install Server for NIS<br><br>Synchronizing passwords with an NIS domain |

# Best practices for Server for NIS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The following information provides best practices for using Server for NIS.

**Best practices when migrating a Network Information Service (NIS) domain**

- Before performing the actual migration, carefully review Checklist: NIS migration to Active Directory using the NIS Data Migration wizard.
- Before starting the wizard, decide whether the domain you are migrating will remain a separate domain or will be merged with another domain on Server for NIS.
- If you migrate maps separately, you should migrate **passwd** maps before you migrate **group** or **shadow** maps. This ensures that the UNIX passwords will be stored properly.
- Be sure you know the structure of your nonstandard maps before starting the wizard. In particular, you should know the field separators, key field, file name, and map name. Nonstandard maps are accessed using only one key.
- Use the **Do not migrate (log only)** option first, so that the wizard performs all the steps but does not actually migrate the data. After analyzing the log files, run the wizard again, choosing the **Migrate and log** option.
- After examining the log, correct any problems before you migrate the data. If the same user name exists in both the Windows and NIS domains, determine whether the duplicate user names represent the person. If not, change the user name of one of the users. If the user names refer to the same person, determine whether the UNIX properties are the same. If not, determine which are correct. You can then preserve the existing entry in Active Directory, or overwrite it with the information in the UNIX map.
- If a conflict is reported during the actual migration, even though none was reported in the test migration, there might be conflicts within the NIS maps themselves. When the wizard is run with the **Log only** option, it reports only conflicts between NIS maps and Active Directory, not conflicts within the NIS maps themselves. If a conflict happens during the actual migration, resolve the conflict in the NIS maps and then migrate the NIS data that was not migrated using the command line **nis2ad –r yes** option.

**Make sure that subordinate (slave) servers are kept up-to-date**
If your NIS domain is active (that is, changes to the domain occur frequently), you should increase the frequency at which Server for NIS checks for changes. This will ensure that UNIX-based subordinate servers are updated soon after a change is registered on the master server. You can also click **Check for updates now** to immediately update subordinate servers.

**Do not migrate an NIS domain to more than one Windows Active Directory domain**
Although you can migrate an NIS domain to computers running Server for NIS in more than one Windows domain, this is strongly discouraged, because changes made in one Windows domain will not be replicated to the other domains.

**Discourage users from using yppasswd to change their NIS passwords**
Instead, users should change their NIS password by changing their Windows password. Server for NIS will then change the NIS password to match.

Server for NIS does not fully support the **yppasswd** utility available on UNIX systems. When a user runs **yppasswd**, Server for NIS changes the user's password in the NIS **passwd** map. Because **yppasswd** encrypts the new password before sending it to the NIS master server, however, Server for NIS cannot obtain a plain-text password to set the user's Windows password. Consequently, the Windows and UNIX passwords will no longer be the same. In addition, **yppasswd** can create security issues because it also sends the old password in plain text. Because the old password could also be the user's Windows password, this might expose the user's Windows password on the network.

Using Password Synchronization, you can provide users with a method for changing their NIS password using the **yppasswd** command. For more information, see Synchronizing passwords with an NIS domain.

# How To....

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

- Install Server for NIS
- Start Server for NIS
- Stop Server for NIS
- Add or remove UNIX subordinate (slave) servers
- Change a subordinate (slave) server to a master server
- Manage NIS Maps

# Install Server for NIS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To install Server for NIS**

1. Click **Start**, click **Control Panel**, and then click **Add or Remove Programs**.
2. Click **Add/Remove Windows Components**.
3. When the Windows Components Wizard opens, fill the **Active Directory Services** check box.
4. With **Active Directory Services** highlighted, click **Details**.
5. When the **Active Directory Services** dialog box opens, fill the **Identity Management for UNIX** check box.
6. With **Identity Management for UNIX** highlighted, click **Details**.
7. When the **Identity Management for UNIX** dialog box opens, fill the **Server for NIS** check box.

   Because Administration Components are required for Server for NIS operation, **Administration Components** are automatically selected for installation when you select Server for NIS.
8. Click **OK**.

   The Windows Components Wizard begins installing the Identity Management for UNIX components you selected.
9. If you are prompted to locate files required for Server for NIS installation, insert the Windows Server 2003 R2 product CD, or browse to the network location of your Windows Server 2003 R2 installation files.
10. If NIS map data compatible with Windows Services for UNIX 3.5 is stored in Active Directory, the Server for NIS installation process automatically migrates the data, and uses it to populate Server for NIS maps.
11. When installation completes, restart your computer to begin working with Server for NIS.

| **Note** |
| --- |
| To open **Add or Remove Programs**, click **Start**, point to **Control Panel**, and then click **Add or Remove Programs**.<br><br>Server for NIS can be installed only on an Active Directory domain controller. |

# Start Server for NIS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To start Server for NIS**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Identity Management for UNIX.
2. If necessary, connect to the computer you want to manage.
3. Right-click **Server for NIS**, and then click **Start**.

| **Note** |
| --- |
| To open Identity Management for UNIX, click **Start**, point to **All Programs**, point to **Identity Management for UNIX**, and then click **Identity Management for UNIX**. |

**Using a command line**

- At a command prompt, type:

  **nisadmin** [*server*] **start** [**–u** *user* [**–p** *password*]]

| Argument | Description |
| --- | --- |
| *server* | The name of the server you want to start. |
| *user* | The name of the user who has administrative permissions on the server to be started, if different from the current user. |
| *password* | The password of the user who has administrator permissions on the server to be started, if different from the current user. If you type a user name but omit the password, you will be prompted for the password. |

# Add or remove UNIX subordinate (slave) servers

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To add or remove UNIX subordinate (slave) servers**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Identity Management for UNIX.
2. If necessary, connect to the computer you want to manage.
3. In the console tree, expand **Server for NIS** and view the list of Network Information Service (NIS) domains.
4. Click the domain you want to modify.
5. In the details pane, click the **NIS Servers** tab, and then do one of the following:
   - To add a subordinate (also known as slave) server, in **Server Name**, type the name of the server you want to add, and then click **Add**.
   - To remove a subordinate server, in **Servers and modes**, click the server you want to remove, and then click **Remove**.
6. To save the settings, click **Apply**.

| **Note** |
| --- |
| To open Identity Management for UNIX, click **Start**, point to **All Programs**, point to **Identity Management for UNIX**, and then click **Identity Management for UNIX**. |

**Using a command line**

- To add a UNIX subordinate (slave) server, at a command prompt, type:

  **nismap add -e "***NewSubordinate***" -a** *NISDomain* **ypservers**

  To remove a server, at a command prompt, type:

  **nismap del -k "***NewSubordinate***" -a** *NISDomain* **ypservers**

| Argument | Description |
| --- | --- |
| *NewSubordinate* | The new UNIX Network Information Service (NIS) server to be added to the NIS domain. |
| *NISDomain* | The name of the NIS domain. |

| **Note** |
| --- |

To view the complete syntax for this command, at a command prompt, type:

# Change a subordinate (slave) server to a master server

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To change a subordinate (slave) server to a master server**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Identity Management for UNIX.
2. If necessary, connect to the computer you want to manage.
3. In the console tree, click **Server for NIS** and view the list of Network Information Service (NIS) domains.
4. Select the domain you want to modify.
5. In the details pane, click **NIS Servers**, select the Windows server you want to make the new master server, and then click **Promote**.

| **Note** |
| --- |
| To open Identity Management for UNIX, click **Start**, point to **All Programs**, point to **Identity Management for UNIX**, and then click **Identity Management for UNIX**.<br><br>Only an Active Directory domain controller can be promoted to be the master server.<br><br>When you change a subordinate server to a master server, the previous master server automatically changes to a subordinate server. |

**Using a command line**

Do one of the following:

- To change a master server to a subordinate server, at a command prompt, type:

  **nisadmin** [*server*] **mkslave –m** *newMaster***–d** *domainName* **–u** *username***–p** *password*

- Or, to change a subordinate server to a master server, at a command prompt, type:

  **nisadmin** [*server*] **mkmaster –d** *domainName***–u** *username* **–p** *password*

| Argument | Description |
| --- | --- |
| *server* | The domain controller server that is hosting Active Directory. If not specified, the current server is used. |
| *newMaster* | The name of the new master server, required for the **mkslave** command. |
| *domainName* | The name of the domain for which the change is being made. |
| *username* | The name of the user who has administrator permissions on the server to be changed, if different from the current user. |

| | |
|---|---|
| *password* | The password for the user who has administrator permissions on the server to be changed. If the password is not supplied, you will be prompted for it. |

**Note**

To view the complete syntax for this command, at a command prompt, type **nisadmin /?**.

Only an Active Directory domain controller can be promoted to be the master server.

# Manage NIS Maps

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Manage maps**

- Migrate NIS domains
- Add a group to an NIS domain
- Set the encryption method for a domain
- Change the frequency of map updates to UNIX subordinate (slave) NIS servers
- Propagate selected maps now
- Propagate changed maps now
- Use ypmatch to view an entry in an NIS map
- Use ypcat to print values in an NIS map
- Edit Maps
- Manage NIS Users
- Manage NIS Groups
- Manage NIS Computers

# Migrate NIS domains

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To migrate NIS domains**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open the NIS Data Migration wizard.
2. Follow the step-by-step directions in the wizard.

| **Note** |
|---|
| To start the NIS migration wizard, click **Start**, point to **All Programs**, point to **Identity Management for UNIX**, and then click **Identity Management for UNIX**. Click **Server for NIS** in the navigation pane. With **Server for NIS** highlighted in the navigation pane, click the **NIS Data Migration Wizard** command in the **Actions** pane. You can also click **NIS Data Migration Wizard** on the **Action** menu, or right-click **Server for NIS**, then click **NIS Data Migration Wizard** on the shortcut menu.<br><br>Password file entries with names longer than eight characters will not be migrated.<br><br>Windows user accounts created as a result of the migration are disabled. After performing the migration, you must enable the accounts. For security reasons, it is recommended that you assign a temporary password to these accounts and instruct the affected users to change their Windows password as soon as possible. |

**Using a command line**

The following arguments are required.

| Argument | Description |
|---|---|
| **-y** *UNIXNISDomain* | Specifies the name of the Network Information Service (NIS) domain that contains the map to migrate. |
| **-a** *ActiveDirectoryNISDomain* | Specifies the NIS domain name in Active Directory. |
| *MapfileToMigrate* | Specifies the name of the NIS map source file to migrate. NIS map source files are the plain text files from which the NIS map databases are compiled. |

The **nis2ad** utility accepts the following options.

| Option | Description |
|---|---|
| **-m** | Perform the migration. If this option is omitted, the program finds and reports conflicts but does not actually perform the migration. |
| **-c** *FileName* | Specifies the file where conflict details are written. Uses a default file (%sfudir%\nis\conflicts.log) if not specified. |
| **-t** *TargetContainer* | Specifies the target container name. Applicable only when creating a new NIS domain. If not specified, uses the default or uses the container of the target domain. |
| **-f** *FileName* | Specifies the name of the log file. If not specified, **nis2ad** uses a default file (%sfudir%\nis\nis2ad.log). |

| | |
|---|---|
| **-r yes\|no** | Replace object in Active Directory with object being migrated. Default is no. |
| **-n** | Resolves conflicts by changing the Windows account name in Active Directory. If objects of different types have the same name, the name of both objects is changed before the data is migrated. |
| **-p** *Password* | If needed and if not specified, the user will be prompted. |
| **-d** *Directory* | Specifies the path of the directory that contains NIS map source files. |
| **-s** *Server* | Specifies the domain controller server hosting Active Directory. Otherwise use the current server. |
| **-u** *User* | Specifies the name of the user having administrator privileges on this computer. If not specified, **nis2ad** uses the current user. |

**Note**

To view the complete syntax for this command, at a command prompt type:

**nis2ad /?**

You can migrate only one map at a time using **nis2ad**. To migrate more than one map at a time, use the NIS Data Migration wizard.

Password file entries with names longer than eight characters will not be migrated.

Windows user accounts created as a result of the migration will be disabled. After performing the migration, you must enable the accounts. For security reasons, it is recommended that you assign a temporary password to these accounts and instruct the affected users to change their Windows password as soon as possible.

Even if you specify another user by using the **-u** option, the currently logged on user must have write permissions for the folder that will contain the log and conflict files. If necessary, modify the permissions on the folder to grant write access to the user who will be running the **nis2ad** utility before running the utility.

# Set the encryption method for a domain

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To set the encryption method for a domain**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Identity Management for UNIX.
2. If necessary, connect to the computer you want to manage.
3. In the console tree, expand **Server for NIS** and view the list of NIS domains.
4. Select the domain for which you want to set an encryption method.
5. In the details pane, click the **Maps** tab.
6. In the **UNIX passwords are encrypted using** list, click the encryption method used by all UNIX computers in the domain.

| **Note** |
|---|
| To open Identity Management for UNIX, click **Start**, point to **All Programs**, point to **Identity Management for UNIX**, and then click **Identity Management for UNIX**.<br><br>You can select the MD5 encryption method for a UNIX domain that consists exclusively of computers running Linux and using MD5 encryption. Domains that contain one or more computers using the crypt algorithm or that run any other operating system must use crypt. Although Linux versions 6.2 and later support MD5 encryption, Identity Management for UNIX is not supported for versions of Linux prior to version 8. |

**Using a command line**

- At a command prompt, type:

  **nisadmin** [*computer*] **encryptiontype -d** *domain* {**crypt** | **md5**} [**-u** *usr* [**-p** *pword*]]

| Argument | Description |
|---|---|
| *computer* | Specifies the remote computer you want to administer. You can specify the computer using a WINS or DNS name, or by Internet Protocol (IP) address. |
| *domain* | Specifies the name of the domain for which the change is being made. |
| *usr* | Specifies the user name of the user whose credentials are to be used. It might be necessary to add the domain name to the user name in the form *domain******username*. |
| *pword* | Specifies the password of the user specified using the **-u** option. If you specify the **-u** option but omit the **-p** option, you are prompted for the user's password. |

| **Note** |
|---|

To view the complete syntax for this command, at a command prompt, type: **nisadmin /?**

You can select the MD5 encryption method for a UNIX domain that consists exclusively of computers running Linux and using MD5 encryption. Domains that contain one or more computers using **crypt** or that run any other operating system must use **crypt**. Although Linux versions 6.2 and later support MD5 encryption, Identity Management for UNIX is not supported for versions of Linux prior to version 8.

Password encryption can only be set to one encryption method at a time. Changing the encryption method invalidates user passwords. All passwords must be reset if the encryption method is changed.

# Change the frequency of map updates to UNIX subordinate (slave) NIS servers

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To change frequency of map updates to UNIX subordinate (slave) NIS servers**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Identity Management for UNIX.
2. If necessary, connect to the computer you want to manage.
3. Click **Server for NIS**.
4. In the details pane, type the update interval you want, and then click **Apply**.

| **Note** |
|---|
| To open Identity Management for UNIX, click **Start**, point to **All Programs**, point to **Identity Management for UNIX**, and then click **Identity Management for UNIX**. |

**Using a command line**

- At a command prompt, type:

  **nisadmin config pushint=**[[*days***:**]*hh***:**]*mm* [**-s** *Server*] [**-u** *User*] [**-p** *Password*]

| Argument | Description |
|---|---|
| [[*days***:**]*hh***:**]*mm* | Specifies the interval at which the service checks changes to Network Information Service (NIS) maps in Active Directory and propagates them to secondary NIS servers for all domains, in days, hours, and minutes. If *hh* is specified, *hh* must be in the range 0–23 and *mm* must be in the range 0–59. |
| *Server* | The master server for the domain. |
| *User* | The name of the user who has administrative privileges on the server to be started, if different from the current user. |
| *Password* | The password of the user who has administrative privileges on the server to be started, if different from the current user. If you type a user name but omit the password, you will be prompted for the password. |

| **Note** |
|---|

Connect to a computer you want to manage

# Propagate selected maps now

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To propagate selected maps now**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Identity Management for UNIX.
2. If necessary, connect to the computer you want to manage.
3. In the console tree, expand **Server for NIS** and view the list of NIS domains.
4. Select the domain of interest.
5. In the details pane, click the **Maps** tab.
6. In the **NIS maps in this domain** list, click the maps to propagate, and then click **Propagate**. To select more than one map, press and hold the CTRL key while clicking the maps.

| **Note** |
| --- |
| To open Identity Management for UNIX, click **Start**, point to **All Programs**, point to **Identity Management for UNIX**, and then click **Identity Management for UNIX**. |

**Using a command line**

- At a command prompt, type:

  **yppush** [**-d** *ActiveDirectoryNISDomain*] [**-q**] [**-t** *Timeout*] [**-h** *Hosts*] *MapName*

| Argument | Description |
| --- | --- |
| **-d** *ActiveDirectoryNISDomain* | Network Information Service (NIS) domain name in Active Directory. |
| **-q** | Quiet mode. Do not wait for response from subordinate (slave) servers and do not report errors. |
| **-t** *Timeout* | The number of seconds to wait for a response from the subordinate server before sending the next request. Must be greater than zero. The default value is **30**. |
| **-h** *Hosts* | The hosts to notify of changes. Default is all subordinate servers in the domain. Can be used multiple times for more than one computer. |
| *MapName* | The name of the NIS map to be transferred. |

**Note**

This command propagates a single map. Run the command again to propagate additional maps.

The **yppush** command pushes map data only from the Windows-based NIS master server to UNIX-based NIS subordinate servers. It does not push map data to NIS subordinate servers running Windows operating systems. Active Directory updates Windows-based NIS subordinate servers.

To view the complete syntax for this command, at a command prompt type:

**yppush /?**

# Propagate changed maps now

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To propagate changed maps now**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Identity Management for UNIX.
2. If necessary, connect to the computer you want to manage.
3. Click **Server for NIS**.
4. Click **Check Now**.

| **Note** |
| --- |
| ReplaceThisText<br><br>To open Identity Management for UNIX, click **Start**, point to **All Programs**, point to **Identity Management for UNIX**, and then click **Identity Management for UNIX**. |

**Using a command line**

- At a command prompt, type:

  **nisadmin** [*server*] **syncall** [**–u** *user* [**–p** *password*]]

| Argument | Description |
| --- | --- |
| **syncall** | Propagate all maps. |
| *server* | The name of the server where the maps are stored. |
| *user* | The name of the user who has administrator permissions on the server, if different from the current user. |
| *password* | The password of the user who has administrator permissions on the server, if different from the current user. If you type a user name but omit the password, you will be prompted for the password. |

| **Note** |
| --- |
| The **nisadmin syncall** command propagates maps only on UNIX-based NIS subordinate servers. It does not propagate maps on NIS subordinate servers running Windows operating systems. Active Directory updates Windows-based NIS subordinate servers.<br><br>To view the complete syntax for this command, at a command prompt, type:<br><br>**nisadmin /?** |

# Use ypmatch to view an entry in an NIS map

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To use ypmatch to view an entry in an NIS map**

- At a command prompt, type:

  **ypmatch** [**-d** *Domain*] [**-h** *HostName*] [**-t**] [**-k**] *Key* [*Key* ...] *MapName*

  or

  **ypmatch -x**

| Argument | Description |
|---|---|
| *Domain* | A domain other than the default domain. |
| *HostName* | The name of the Network Information Service (NIS) server to which you want to send the request. |
| **-t** | Inhibits translation of nickname to map name. |
| **-k** | Prints a key followed by a colon before printing the value of the key. This is useful only if your keys do not have duplicate values, and you do not have an unreasonable number of keys to clutter the output. |
| *Key* | The key for which you want to print the value. |
| *MapName* | The name or the nickname of a map. |
| **-x** | Lists the nicknames as specified by the *MapName* parameter. |

| **Note** |
|---|
| There is no Windows interface method for this procedure.<br><br>To view the complete syntax for this command, at a command prompt, type:<br><br>**ypmatch /?** |

# Use ypcat to print values in an NIS map

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To use ypcat to print values in an NIS map**

- At a command prompt, type:

  **ypcat** [**-k**] [**-d** *DomainName*] [**-t**] [**-h** *NISServer*] *MapName*

  or

  **ypcat -x**

| Argument | Description |
|---|---|
| **-k** | Displays keys and their values. |
| *DomainName* | Searches the specified domain for the specified map. |
| **-t** | Forces the **ypcat** command to bypass the nickname translation table and search only for the map specified by the *MapName* parameter. |
| *NISServer* | Name of the Network Information Service (NIS) server where the map is stored. |
| *MapName* | The name of the map to be listed. |
| **-x** | Lists the nicknames as specified by the *MapName* parameter. |

| **Note** |

# Edit Maps

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Edit maps**

- Edit passwd, group, and host map entries using Active Directory Users and Computers
- Edit standard and nonstandard map entries using the command line interface
- Create the structure of a nonstandard map

# Edit passwd, group, and host map entries using Active Directory Users and Computers

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To edit passwd, group, and host map entries using Active Directory Users and Computers**

1. Open Active Directory Users and Computers.
2. In the console tree, click the Active Directory domain that contains the map you want to edit, and then do one of the following:
   - To edit passwd or group maps, click **Users**.
   - To edit the host map, click **Computers**.
3. Double-click the user or computer whose properties you want to edit.
4. Click the **UNIX Attributes** tab.
5. In the boxes provided, edit the properties you want to change.
6. To save the changes and keep the dialog box open, click **Apply**. To save the changes and close the dialog box, click **OK**.

| **Important** |
| --- |
| Do not use Active Directory Users and Computers to modify attributes of special users and groups, that is, users and groups with user identifiers (UIDs) or group identifiers (GIDs) of less than 100. If you do, the data returned by Server for NIS will be incorrect for those users and groups. Use the procedure described in "Using a command line" instead. |

| **Note** |
| --- |
| To open Active Directory Users and Computers, click **Start**, point to **All Programs**, point to **Administrative Tools**, and then click **Active Directory Users and Computers**. |

# Edit standard and nonstandard map entries using the command line interface

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To edit standard and nonstandard map entries using the command line**
At a command prompt, do one of the following:

- To add a user to a passwd map, type:

  **nismap add –e "***passwdEntry***" –a** *nisDomain***passwd**

- To modify a user in a passwd map, type:

  **nismap mod –e "***passwdEntry***" –k** *username***–a** *nisDomain* **passwd**

- To delete a user from a passwd map, type:

  **nismap del –k** *username* **–a** *nisDomain***passwd**

- To add a group to a group map, type:

  **nismap add –e "***groupEntry***" –a** *nisDomain***group**

- To modify a user from group map, type:

  **nismap mod –e "***groupEntry***" –k** *groupName***–a** *nisDomain* **group**

- To delete a user from group map, type:

  **nismap del –k** *groupName* **–a** *nisDomain***group**

| Argument | Description |
|---|---|
| *passwdEntry* | An entry from the passwd map. |
| *nisDomain* | The Network Information Service (NIS) domain. |
| *username* | The name of the user. |
| *groupEntry* | An entry from the group map. |
| *groupName* | The name of the group to which the user belongs. |

**Note**

To view the complete syntax for this command, at a command prompt, type:

**nismap /?**

When you use **nismap** to delete a user, group, or host object, only the UNIX attributes of the object are deleted. To delete the object from Active Directory, use the Active Directory administration tools.

Managing standard and nonstandard NIS maps

# Create the structure of a nonstandard map

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To create the structure of a nonstandard map**

- At a command prompt, type:

  **nismap create –i** *fieldNumber* **–g** "*separator*" *mapName*

| Argument | Description |
|---|---|
| *fieldNumber* | The number of the field that contains the key to the map. |
| " *separator* " | The character used to separate fields, in quotation marks. To specify a space as a separator, enclose the space in double quotation marks (" "). For example:<br><br>**nismap create –i 1 –g " " Phones**<br><br>creates a map called Phones in which the key field is the first field and the separator character is a space. Other white-space characters, such as tab, are also accepted. |
| *mapName* | The name of the map. |

**Notes**

| Note |
|---|
| There is no Windows interface method for this procedure.<br><br>After this structure is created, there is no way to remove it.<br><br>This structure applies to all NIS domains, so it is important to ensure that the format is consistent across all NIS domains.<br><br>Do not use the hash character (#) as a field separator because this character is used in standard maps to mark the beginning of a comment.<br><br>To view the complete syntax for this command, at a command prompt, type:<br><br>**nismap /?** |

# Understanding Server for NIS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Understanding Server for NIS**
Server for NIS integrates Windows and Network Information Service (NIS) networks by giving a Windows–based Active Directory domain controller the ability to act as a master NIS server for one or more NIS domains. Server for NIS stores both standard and nonstandard NIS map data in Active Directory. (Standard maps consist of aliases, bootparams, ethers, hosts, group, netgroup, netid, netmasks, networks, passwd, protocols, rpc, services, pservers, and shadow; all other maps are non-standard.) Server for NIS thus creates a single name space for the Windows and NIS domains that can be managed by the Windows administrator using a single set of tools. The administrator can easily create, modify, and delete user accounts for Windows and UNIX domains at the same time. A user who has accounts on both Windows and UNIX can be managed from Active Directory with all attributes necessary for the respective domain and name space.

Server for NIS can also be installed on other domain controllers in the same domain as the master NIS server, giving them the ability to function as NIS subordinate (also known as slave) servers. In this case, the NIS data in Active Directory is automatically replicated among the Windows domain controllers running Server for NIS. In addition, UNIX-based computers can continue to function as subordinate servers in the NIS domain; Server for NIS uses **yppush** to propagate changes to the NIS data to UNIX-based NIS servers just as a UNIX-based master NIS server would.

After you install Server for NIS, your first major task is to migrate NIS maps from UNIX-based NIS servers to the computer running Server for NIS. You can use either a Windows-based migration wizard, or you can use a command-line utility to carry out this process. After the maps for an NIS domain have been migrated, Server for NIS is ready to act as a master server for the NIS domain. You can migrate multiple NIS domains to the same Windows–based Active Directory domain controller. These domains can be merged with each other or kept separate. You can migrate NIS map data in a staged manner by migrating NIS maps one at a time.

Server for NIS can support multiple NIS domains concurrently. Maps that belong to multiple domains can also reside concurrently in Active Directory. Requests from a client or another server in a domain receive data from a map in the same domain.

You can manage Server for NIS using the Windows-based Identity Management for UNIX. You can manage the passwd, group and hosts maps that you have migrated to Active Directory using Windows–based tools such as Active Directory Users and Computers. You can also use the command-line tools nismap and nisadmin to manage all standard and non-standard maps and to manage Server for NIS. You can monitor Server for NIS performance using Windows administrative tools, including using Event Viewer to audit significant events and errors logged by Server for NIS.

In addition to using administrative tools provided by Windows, you can also create additional administrative tools using Active Directory Service Interfaces (ADSI) or Lightweight Directory Access Protocol (LDAP).

Server for NIS implements the NIS remote procedure calls necessary to serve requests from UNIX-based and Windows-based NIS clients, as well as other subordinate NIS servers. Server for NIS supports both broadcast mode and the normal binding mode.

This section contains information about:

# Understanding NIS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Understanding NIS**

Formerly known as Yellow Pages (yp), Network Information Service (NIS) provides a simple network look-up service that consists of databases and processes. An NIS domain consists of a client and one or more servers. Clients use the NIS protocol to look up information stored in NIS databases, which are replicated among servers. A single master server is used to update databases; subordinate (also known as slave) servers provide read-only services. Databases are synchronized by copying them from master servers to subordinate servers periodically or upon change.

A database served by NIS is called an NIS map. The NIS lookup calls require a map (database) name and an NIS domain name. An NIS domain consists of a collection of such maps. In addition to map databases, the master NIS server maintains the time stamp that indicates when each database was last modified.

Each database is created from a source file. For example, passwd.byname and passwd.byuid databases are created from the source file named passwd. When source files change, administrators either execute a shell script called **ypmake** or a makefile to update the databases. In addition, the makefiles used to create the databases push the databases to subordinate NIS servers using **yppush**. The transfer uses ypxfr, a program that runs on the subordinate servers.

Clients can use many functions and remote procedure calls to connect to the network lookup service, including **yp_match**, **yp_first**, **yp_next**, **yp_all**, **yp_order**, **yp_master**, **yperr_string**, and **ypprot_err**. In addition there are usually many tools for administering NIS, such as **ypwhich**, **yppoll**, **ypset**, **ypcat**, and **domainname**.

| **Note** |
| --- |
| Server for NIS does not support **ypxfrd**, which might cause some UNIX subordinate (also known as slave) Network Information Service (NIS) servers to display warning messages. The warning messages originate in **ypinit** and do not indicate actual errors. Some UNIX subordinate NIS servers run **ypxfrd** on the master NIS server to replicate NIS maps. If they fail to connect to **ypxfrd**, they obtain copies of NIS maps by using **yp_all**. |

# Master and subordinate (slave) modes

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Master and subordinate (slave) modes**

Server for NIS can operate in a master mode or subordinate mode. (If Server for NIS is used in a domain, the master server in the domain must be Server for NIS.) In UNIX, the primary difference between the two is that both subordinate and master servers can read map data, while only the master server can update maps. Additionally, the master Network Information Service (NIS) server provides periodic updates of the maps to subordinate servers.

In Windows with Server for NIS, because the data is stored in Active Directory, both master and subordinate servers share the same replicated Active Directory database. This makes them peers as far as map updates or write access are concerned. Server for NIS in either master mode or subordinate mode will allow updates to Network Information Service (NIS) map data stored in Active Directory. Changes to Active Directory on any of these servers are propagated to other Servers for NIS in the domain by the Active Directory synchronization mechanism.

Although these servers run as peers for data updates, there must still be only one master server as far as the UNIX subordinate servers and UNIX clients are concerned. UNIX subordinate servers will continue to receive map updates from the Server for NIS that is designated as the master server. Similarly, they will continue to send passwd changes only to the master server.

For information about changing a subordinate server to a master server, see Change a subordinate (slave) server to a master server.

# Understanding NIS Data Migration

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Understanding NIS data migration**
Server for NIS allows Network Information Service (NIS) map data to be migrated to Active Directory.

After the migration, and upon receiving NIS requests from clients or other servers, Server for NIS searches Active Directory to reply to NIS queries.

Migration consists of the following three steps:

1. Migrate the NIS maps to a Windows-based server.

   - Using the command line

     Identity Management for UNIX includes a command-line tool called **nis2ad** to migrate maps from UNIX-based NIS servers to Active Directory–based Server for NIS.

   - Using the migration wizard

     The NIS Data Migration wizard in Identity Management for UNIX extracts the information necessary to perform the migration. Even when using the migration wizard, however, you must complete steps 2 and 3, which follow.

   The migration wizard and the **nis2ad** command read map data from NIS map source files, which are the plain text files from which the NIS map databases are compiled. These source files must be located in a location that can be accessed by the domain controller during migration, such as on a disk on the domain controller or in a shared directory accessible by the domain controller.

2. Inform the existing subordinate (also known as slave) NIS servers of the new master NIS server.

   After the migration, the original UNIX-based NIS server must send an update of maps to all subordinate NIS servers with the name of the new master server in the maps.

3. Disable the original NIS server.

UNIX-based subordinate NIS servers can continue to work as before; however, they will receive map updates from the Windows-based computer instead of the UNIX-based computer. Client computers will continue to get NIS maps or data from the new master.

This section provides information about the following:

- Migrating NIS to Active Directory
- Migrating standard and nonstandard maps
- Resolving migration conflicts
- Handling special users during migration to Active Directory

# Migrating NIS to Active Directory

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Migrating NIS to Active Directory**
During migration, Server for NIS can migrate each Network Information Service (NIS) domain and preserve it as a separate domain in Active Directory. It can also merge the data in an existing domain, however. This domain can be one of the previously migrated domains or a special NIS domain that is created when Server for NIS is installed.

One of the advantages of migrating NIS maps to Windows is to merge UNIX and Windows users and objects to create a common name space. Another advantage is that objects common in two networks can have a unique identity.

During migration, you must specify the Active Directory container in which migrated objects will be created. It is strongly recommended that you create these objects in the same container as the other Windows objects. If the container is not specified, new objects will be created in the default container that is the same as Windows.

If you migrate passwd, groups, or host maps to a container other than the default container, migrated entities will not appear by default in Windows Active Directory Users and Computers. To view all objects, select **Advanced features** in the **View** menu of the **Active Directory Users and Computers** console.

Windows user accounts created as a result of the migration will be disabled. After performing the migration, you must enable the accounts when you are ready for them to be used. For security reasons, it is recommended that you also assign a temporary password to these accounts and instruct the users to change their Windows password as soon as possible.

See Server for NIS Troubleshooting for information about dealing with migration problems.

**Staged migration**
After the maps are migrated to the Windows Active Directory domain controller, other UNIX-based subordinate (also known as slave) servers can also be migrated to other domain controllers in the same Windows domain. Migration of subordinate servers does not require migration of the data. Because of the architecture of Active Directory, other domain controllers in the Windows domain share the same Active Directory schema and database. Consequently, these domain controllers already have the NIS data. After the Server for NIS is installed on a domain controller in the same Windows domain, it is ready to act as a subordinate NIS server for the NIS domain.

The steps in the migration of a subordinate NIS server are as follows:

1. Make sure the master server of the NIS domain is migrated to Server for NIS.

2. Install Server for NIS on another Active Directory domain controller. The subordinate NIS server that you are migrating to Windows can continue to work as before. This will mean that each subnet can have more than one subordinate NIS server.

3. Disable the subordinate NIS server on the UNIX-based computer.

The NIS map source files of an NIS domain need not be migrated all at once. (NIS map source files are the plaintext files from which the NIS map databases are compiled.) In fact, each NIS map that belongs to a domain is migrated separately. The administrator can specify the domain name to which this map will be migrated. If a domain with that name does not exist, Server for NIS creates a new NIS domain.

After you migrate NIS maps to Server for NIS, there might be some delay before this data is available to Server for NIS.

**Migrating multiple NIS domains**
The migration utility or migration wizard allows migration of multiple NIS domains to Active Directory. During migration of a map, the administrator must specify the domain from which the data is being migrated. Server for NIS keeps the name of the domain with the map entries created in Active Directory. Subsequently, these map entries are returned to clients or subordinate servers from that domain only.

In addition, however, the migration wizard can also merge a map from one domain into another NIS domain. This can be one of the previously migrated NIS domains or a special domain that is created when Server for NIS is installed. The administrator must specify the name of the NIS domain to which the data will be migrated.

If you migrate multiple domains, you can manage individual domains through Identity Management for UNIX Administration.

Server for NIS supports a maximum of 960 unique combinations of NIS domains and maps. For example, Server for NIS cannot support more than 64 domains with 15 maps each (64×15=960).

# Migrating standard and nonstandard maps

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Migrating standard and nonstandard maps**

The command-line migration program and the NIS Data Migration wizard are both designed to migrate standard Network Information Service (NIS) maps, such as passwd, group, and services. The NIS Data Migration wizard provides a list of NIS map source files (that is, the plaintext files from which the NIS map databases are compiled) from which the administrator chooses the maps to migrate. The migration wizard then uses the standard format of these NIS map source files to migrate the data to Active Directory.

The following are considered standard maps. All other maps are nonstandard maps.

- aliases
- bootparams
- ethers
- hosts
- group
- netgroup
- netid
- netmasks
- networks
- passwd
- protocols
- rpc
- services
- ypservers
- shadow

Note that domain names are not case sensitive. Domains cannot be migrated if they have the same name, even if the case of the names is different.

Migration is handled in one of two ways, depending on whether the map being migrated has an equivalent in Active Directory. For standard maps such as passwd, group, and hosts, that have an equivalent Active Directory class, auxiliary classes are added. For example, an auxiliary class called posixAccount is added to the class user, which, in turn, adds attributes such as uidNumber and unixHomeDirectory. For standard NIS maps that have no equivalent in Active Directory, such as services and rpc, additional classes are created.

Because Identity Management for UNIX is compliant with Internet Engineering Task Force (IETF) standard Request for Comments (RFC) 2307, map attributes match those identified in the RFC 2307 schema, with the following exceptions:

- The Identity Management for UNIX equivalent of the RFC 2307 attribute **userPassword** is **unixUserPassword**.

- The Identity Management for UNIX equivalent of the RFC 2307 attribute **homeDirectory** is **unixHomeDirectory**.
- In Identity Management for UNIX, **posixgroup** is not a unique class as defined by RFC 2307. It is an auxiliary class.

For each map entry being migrated during the migration of standard maps, the migration wizard either creates a new object of the corresponding class or adds appropriate attributes to the auxiliary class.

Because the classes and attributes found in non-standard maps may not have matching correspondents in Active Directory, the migration wizard relies upon a key field to make a one-to-one match between entries in the existing map and entries created in Active Directory. Using the key field as a reference, the migration wizard copies to Active Directory other classes in the nonstandard map as they appear in the map source file.

| **Important** |
| --- |
| When you migrate passwd and group maps, users will not appear as members of their primary group. If you want users to be members of their primary group in Active Directory, you must use Active Directory Users and Computers to add users to their primary group. |

Before you migrate a nonstandard map, you must provide the syntax of the map. You must provide the name of the nonstandard map, the delimiter between the fields, and the field number of the key field.

For information about managing maps after migration, see Managing standard and nonstandard NIS maps.

**Migrating passwd maps**

If a new Windows user is created as a result of the migration, the user's Windows account is disabled. Before the user can log on to the Windows domain or a UNIX computer in the NIS domain, you must enable the Windows account. For security reasons, it is recommended that you change the user's Windows password to a known, temporary value, inform the user what the temporary password is, and then instruct the user to change the Windows password as soon as possible. When the user changes the Windows password, the new password will be propagated to UNIX-based NIS clients the next time the NIS maps are refreshed. After this refresh occurs, the user can log on to UNIX computers in the NIS domain.

If migration results in adding UNIX attributes to an existing Windows user, the UNIX password in Active Directory will be set to the existing UNIX password, and the Windows password will remain unchanged.

Server for NIS is designed so that whenever a user's Windows password is changed, the password in the NIS passwd map stored in Active Directory is changed. The reverse is not true, however. That is, when the user runs **yppasswd** on a UNIX client computer to change the user's NIS password, only the password in the NIS passwd map will be changed; the Windows password will not change. As a result, the UNIX and Windows passwords will differ. Users should change passwords only in Windows to ensure that Windows and UNIX passwords in the NIS map are identical. Note, however, that you can install and configure Password Synchronization to provide two-way password synchronization between Server for NIS and UNIX hosts in an NIS domain. For more information, see Synchronizing passwords with an NIS domain.

**Migrating ypservers maps**

Keys within the ypservers map are the ASCII names of the computers on which the NIS servers run. That is, the ypservers map can contain only a list of NIS servers, each one listed on a separate line. If your ypservers map contains aliases, before migrating the map, edit the ypservers map to contain only the host names of the servers, one per line. The following list is an example of a valid ypservers map:

```
ypserver_1
ypserver_2
ypserver_3
```

**Migrating Automount File System (AutoFS) maps**

You can migrate Automount File System (AutoFS) maps by importing the **auto_master** and **auto_home** files from a UNIX computer. You can use either command-line tools or the NIS Data Migration wizard.

Before performing the migration, you must copy the auto_master and auto_home files from the UNIX computer to any directory (such as %TEMP%) on the Windows-based computer.

When you use the wizard to migrate AutoFS maps, specify **auto_master** or **auto_home**, depending on which map you are migrating. Specify a blank space as the field separator and **1** (one) as the key field. Verify that the **Key is part of value** check box is not selected.

You can use the wizard to import other AutoFS maps as well. For example, you can migrate the auto.redirect map by copying and then importing the auto_redirect map file, making sure that the **Key is part of value** check box is not selected.

Using command-line tools to migrate AutoFS maps involves using the nismap utility to create the corresponding structure in the Active Directory schema and then running the nis2ad utility to import the map data.

For example, the following commands would migrate AutoFS maps from the NIS domain named NIS01 to the Windows domain named WIN01 by using files located in C:\Temp:

```
nismap create -i 1 -g " " -y auto.master
nismap create -i 1 -g " " -y auto.home
nis2ad -y NIS01 -a WIN01 -d C:\Temp -s localhost -r yes -m auto_master
nis2ad -y NIS01 -a WIN01 -d C:\Temp -s localhost -r yes -m auto_home
```

You can use the same method to migrate other AutoFS maps. For example, to migrate the auto.redirect map, use the **nismap** utility to create the structure for the auto.redirect map in Active Directory, copy the auto_redirect file to the Windows-based computer, and then run the **nis2ad** utility to import the data in the auto_redirect file.

**Migrating nonstandard maps**

Active Directory includes a class that applies to any NIS map. This class requires the name of the map, the key, and the rest of the entry.

To migrate nonstandard maps, the administrator must provide the name of the map source file and the format of the map entries to the migration wizard or command-line utility. The migration wizard uses the key field and the separator to migrate the data and create appropriate objects in Active Directory.

| **Important** |
| --- |
| If you migrate passwd, group, or hosts maps to a container other than the default container (**CN=users,**...), some migrated objects do not typically display in Windows Active Directory Users and Computers. To view all objects in Active Directory Users and Computers, select the domain and then click **Advanced Features** on the **View** menu. |

# Resolving migration conflicts

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Resolving migration conflicts**

During migration, conflicts may occur when Server for NIS attempts to merge incoming user accounts, groups, and computer names into classes that already exist in Active Directory. Conflicts can also occur because Server for NIS allows one Network Information Service (NIS) domain to merge with another NIS domain that has already been migrated to Server for NIS.

For example, consider a passwd map source file being migrated to Server for NIS. Suppose there is a UNIX user with a user name of johnwood. If there is no existing user with a user name of johnwood, migration of this user to Server for NIS is simple. If there is already a user with that user name previously migrated from another NIS domain, however, a conflict would occur.

When the NIS Data Migration wizard encounters a potential name conflict during migration, it resolves the conflict by prefixing the name being migrated. If the name being migrated is a user name, the prefix consists of the NIS domain name plus the characters _**u**_. If the name being migrated is a group name, the prefix consists of the NIS domain plus the characters _**g**_. This allows the migration to complete even if there is a conflict.

For example, if you are migrating a user named johnwood in an NIS domain named mktg, and a user with the same name was previously migrated from another NIS domain, then the user name of johnwood in the mktg domain will be changed to mktg_u_johnwood during the migration.

When such conflicts occur, you need to examine the migration logs and then determine how to handle each case. You need to consider whether the conflicting name represents the same user or group in both domains, or different users or groups. If not, you will probably want to rename one or both users or groups. If they do represent the same user or group, then you will need to decide whether the user or group really needs to be in both domains (in which case, at least one of them needs to be renamed) or whether the user or group in one of the domains can be deleted.

Rather than deal with the conflict after the domain migration has occurred, you can determine in advance whether a conflict will occur and then take steps to prevent the conflict (such as by changing the name of a user or group in the NIS domain).

By default, the NIS Data Migration wizard performs what is known as a dummy migration. During this process, the wizard goes through all the steps required to migrate an NIS domain to Active Directory, but does not actually change Active Directory. This lets you record the anticipated migration results in a log file and then, if potential conflicts are found, deal with those conflicts appropriately before actually performing the migration.

When identical names are detected during a dummy or actual migration, the conflict can be logged to a conflicts file. This file lists conflicts that have arisen during the migration of a particular map. If there was a conflict, the conflicts file lists the NIS entry being migrated and the existing entry in Active Directory. Consider the following two examples. In the first one, the conflicts file states that there were no conflicts in the migration of the passwd file.

```
--------------
## Tue Jun 1 16:22:47 1999 : Conflicts between entries from map file 'passwd' and
existing entries in Active Directory. ##
-------------
```

In the next example, the conflicts file states that there was a conflict in the migration of the map. It lists the existing entry in Active Directory and the new entry being migrated.

```
-------------
## Tue Jun 1 16:22:52 1999 : Conflicts between entries from map file 'aliases' and
existing entries in Active Directory. ##
EXISTS : having DN = 'CN=al1,CN=nisadmin,CN=DefaultMigrationContainer,DC=nis,
DC=sfu,DC=nttest,DC=microsoft,DC=com'
OLD : staff:wnj,mosher,sam
NEW : staff:pradeep,peter,wjs
-------------
```

According to the file, the "staff" map already exists in Active Directory. The entry in Active Directory is different from the entry being added. In such a case, you can change the name of the alias "staff" either in Active Directory or in the map source file, that is, the plain text file from which the NIS map database is compiled. You can also preserve or replace the existing entries by force.

In addition to a conflicts file, you can specify a log file where the entire migration steps will be logged. The following is a

sample output of such a log file:

```
## Start of NIS to Active Directory migration of 'passwd' @ Tue Jun 1 16:26:21 1999 ##
MESSAGE : Migrating 'passwd' entries from UNIX NIS domain 'nis01' to Active Directory
domain 'CorpDomain.'
SUCCESS : Migration of object 'nis0101' of class 'User' into
'LDAP://localhost/CN=Users,DC=nis,DC=sfu,DC=nttest,DC=microsoft,DC=com'.
SUCCESS : Migration of object 'nis0102' of class 'User' into
'LDAP://localhost/CN=Users,DC=nis,DC=sfu,DC=nttest,DC=microsoft,DC=com'.
## Start of NIS to Active Directory migration of 'passwd' @ Tue Jun 1 16:41:46 1999 ##
MESSAGE : Migrating 'passwd' entries from UNIX NIS domain 'conflicts' to Active
Directory domain 'conflicts'.
CONFLICT : Can't migrate 'nis0101' to
'LDAP://localhost/CN=Users,DC=nis,DC=sfu,DC=nttest,DC=microsoft,DC=com'. An object
having same attributes(name/uidNumber/gidNumber) exists at
'CN=nis0101,CN=Users,DC=nis,DC=sfu,DC=nttest,DC=microsoft,DC=com'.
```

For more information about dealing with migration problems, see Server for NIS Troubleshooting.

# Handling special users during migration to Active Directory

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Handling special users during migration**

During migration, for special users with user identifiers (UIDs) that are less than 20, Windows accounts are created such that the first nine characters of their Network Information Service (NIS) domain are appended to their UNIX user name to create a Windows logon name. Their UNIX user name is unaffected. For example, if you migrate root from physlab to Server for NIS, a new Windows user will be created called *physlab_u_root*. The UNIX user name is still root, and NIS queries from physlab domain will be unaffected.

A group called root from such a domain, if migrated, will create a group called *physlab_g_root*.

# Administering Server for NIS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Administering Server for NIS**
This section provides information about:

- Installing and uninstalling Server for NIS
- Starting and stopping Server for NIS
- Configuring a UNIX NIS server to use Server for NIS as the master server
- Configuring UNIX clients to use Server for NIS as the master server
- Using the migration wizard
- Using the command-line utility for migration
- Managing standard and nonstandard NIS maps
- Managing NIS users
- Managing NIS groups
- Managing NIS computers
- Synchronizing user passwords
- Setting UNIX passwords to special values
- Synchronizing and propagating NIS changes
- Sending periodic map updates to subordinate (slave) NIS servers
- Pushing map updates immediately

# Installing and uninstalling Server for NIS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Installing and uninstalling Server for NIS**

**The NIS domain**

Upon installation, Server for NIS creates a Network Information Service (NIS) domain with the same name as the Active Directory domain. Administrators can add users, groups, or computers to this domain. Moreover, administrators can migrate UNIX NIS domain data to Server for NIS and designate the Server for NIS computer as the master NIS server for the migrated domain.

**Uninstalling in master mode**

If you uninstall Server for NIS while it is running on a master server, you must verify that another server takes over the tasks of the master server. If other Windows-based subordinate (also known as slave) NIS servers are in the domains supported by the master server you uninstall, you must assign one of these servers the role of master server. Server for NIS cannot be a subordinate server to a master NIS server running on a UNIX operating system.

**Uninstalling in subordinate mode**

If you uninstall Server for NIS running as a subordinate server, the domain controller on which it was running will continue to receive NIS map updates through Active Directory Synchronization.

# Starting and stopping Server for NIS

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Starting and stopping Server for NIS**

You can use Identity Management for UNIX to start or stop Server for NIS. When Server for NIS is stopped, it will not respond to Network Information Service (NIS) requests from clients, including requests for password changes.

Even when Server for NIS is stopped, you can continue to make changes to NIS map data through Active Directory. UNIX-based computers respond differently in this situation, however. If the NIS server is down on UNIX, changes to maps undertaken through **make** will not be updated in the NIS database.

In addition, when Server for NIS is stopped, NIS map changes will not be propagated to subordinate (also known as slave) NIS servers running on UNIX. However, subordinate NIS servers running on Windows domain controllers will continue to receive updates.

# Configuring a UNIX NIS server to use Server for NIS as the master server

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Configuring a UNIX NIS server to use Server for NIS as the master server**
To change a UNIX-based Network Information Service (NIS) server from a master server to a subordinate (also known as slave) server, follow these steps:

1. Migrate maps from the UNIX master NIS server.

2. Transfer the maps from the old master server to other subordinate NIS servers by providing the name of the new Server for NIS for each map. At a command prompt, type:

   **ypxfr –h** *newserver mapname*

   where *newserver* is the name of the new NIS master server, and *mapname* is the name of the map to be transferred.

3. Run this command for each map on each of the subordinate servers. After this step, the UNIX subordinate servers will recognize the new Server for NIS master server.

# Configuring UNIX clients to use Server for NIS as the master server

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Configuring UNIX clients to use Server for NIS as the master server**

For each UNIX client computer on which you want to use Server for NIS as the master server, do the following:

1. If the domain name has changed, run the following command:

   **domainName** *newdomain*

2. Stop **ypbind** by running the following command:

   **kill –9 ypbindpid**

3. Restart **ypbind** by running the following command:

   **ypbind**

- Network Information Service (NIS) subordinate (also known as slave) servers require that the NIS master server name in the local /etc/hosts file match the master server name in the NIS maps exactly, including the case of the letters of these names. Make sure the case of the host name in /etc/hosts matches exactly the master server name as returned by the Server for NIS. Server for NIS typically returns the host computer name in all uppercase.

# Using the migration wizard

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Using the migration wizard**

Identity Management for UNIX provides a wizard that you can use to migrate your Network Information Service (NIS) system easily to Windows. The wizard takes you through a step-by-step process to complete the migration. Before using the wizard, review the following:

- Checklist: NIS migration to Active Directory using the NIS Data Migration wizard.
- Best practices for Server for NIS
- Migrating NIS to Active Directory

| **Caution** |
| --- |
| The migration of NIS to Active Directory is not reversible. Always back up your UNIX NIS systems and Windows-based server before performing an NIS migration. |

# Using the command-line utility for migration

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Using the command-line utility for migration**

Instead of using the migration wizard, you can use a command-line utility to migrate maps. For information about the command-line tool, see nis2ad.

| **Caution** |
| --- |
| The migration of Network Information Service (NIS) to Active Directory is not reversible. Make sure you back up your UNIX NIS systems and Windows server before doing the migration. |

# Managing standard and nonstandard NIS maps

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Managing standard and nonstandard maps**
You can use a Windows-based Network Information Service (NIS) server to manage both standard and nonstandard maps. You can manage maps that are part of a domain served by a Windows-based NIS server through two different mechanisms:

- The Identity Management for UNIX graphical user interface (GUI).
- Command-line utilities.

In many cases, you can use either method to perform a task. In some cases, however, only one method or the other can be used.

For information about migrating maps, see Migrating standard and nonstandard maps

**Managing passwd maps**
You can use Active Directory Users and Computers to manage passwd maps for Server for NIS. You can also use Active Directory Users and Computers to manage password file–related attributes for a user in the Windows domain, or for the users migrated from a given NIS domain.

**Managing group maps**
Data for group maps for Server for NIS are managed through Active Directory Users and Computers. Each group in the Windows domain or from the groups migrated from a given NIS domain can be managed by using Active Directory Users and Computers.

Note that, for a given group, the UNIX members are different from the Windows users for the same group.

**Managing hosts maps**
You can manage data for hosts maps for Server for NIS by using Active Directory Users and Computers. Each computer in the Windows domain, as well as the hosts migrated from a given NIS domain, can be managed through this snap-in.

**Managing other maps and nonstandard maps**
Server for NIS does not include GUI tools for managing standard NIS maps other than passwd, group, and hosts. Maps other than these can be managed using tools provided as part of Active Directory. In particular, administrators can use the adsiedit snap-in to view and edit NIS maps.

Standard maps include:

- passwd
- group
- hosts
- aliases
- bootparams
- ethers
- netgroup
- netid
- netmasks
- networks

- protocols
- rpc
- services
- ypservers
- shadow password maps

# Managing NIS users

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Managing NIS users**
UNIX systems store basic information about authorized users in the passwd file. This file consists of a series of lines, one for each authorized user. Each line can contain the following information about a user:

- User name
- Password (in encrypted form)
- User identifier (UID)
- Group identifier (GID) of the user's primary group
- User's full name and other information (known as the gecos field)
- Default login shell
- Home directory

Conventional Network Information Service (NIS) servers generate two maps from the passwd file, passwd.byname and passwd.byuid, which contain the same information as the passwd file, but are indexed to provide quick access to the records.

Instead of storing this information in files, Server for NIS maintains user information in Active Directory entries for each user. This allows you to manage the Windows and UNIX (NIS) information together by using the user properties dialog box in Active Directory Users and Computers. When adding a new user, for example, you have to enter the information shared by Windows and NIS (the user name, password, and full name and other gecos-type information) only once. In the case of UNIX-specific information (UID, primary GID, login shell, and UNIX home directory), you can enter this information using the **UNIX Attributes** tab of the same dialog box.

For more information about how to manage UNIX user accounts using Active Directory Users and Computers, see Manage NIS Users.

# Managing NIS groups

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Managing NIS groups**
UNIX systems store basic information about groups of users in the group file. This file consists of a series of lines, one for each group. Each line can contain the following information about a group:

- Group name
- Group identifier (GID)
- List of users belonging to the group

Conventional Network Information Service (NIS) servers generate two maps from the group file, group.byname and group.bygid, which contain the same information as the group file, but are indexed to provide quick access to the records.

Instead of storing this information in files, Server for NIS maintains group information in Active Directory entries for each group. This allows you to manage the Windows and UNIX (NIS) information together by using the group properties dialog box in Active Directory Users and Computers. When creating a new group, for example, you must enter the group name, which is shared by Windows and NIS, only once. In the case of UNIX-specific information (GID and members), you can enter this information using the **UNIX Attributes** tab of the same dialog box.

For more information about how to manage UNIX group accounts using Active Directory Users and Computers, see Manage NIS Groups.

# Managing NIS computers

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Managing NIS computers**
UNIX systems store basic information about host computers on the network in the hosts file. This file consists of a series of lines, one for each computer. Each line can contain the following information about a computer:

- Internet Protocol (IP) address
- Computer name
- List of aliases

A UNIX computer consults this list to determine the IP address of another computer when that computer is referred to by name or alias, rather than by address.

Instead of storing this information in a file, Server for NIS maintains information about network computers in Active Directory entries for each computer. This allows you to manage the Windows and UNIX (NIS) information together by using the computer properties dialog box in Active Directory Users and Computers. When adding a computer to the Windows and Network Information Service (NIS) domains, for example, you must enter the computer name, which is shared by Windows and NIS, only once. In the case of UNIX-specific information (IP address and aliases), you can enter this information using the **UNIX Attributes** tab of the same dialog box.

Note that you have to enter the IP address only if it is statically assigned. If the address is assigned by a DHCP server, the hosts map will be automatically updated whenever the computer's IP address changes.

For more information about how to manage UNIX computer name and address information using Active Directory Users and Computers, see Manage NIS Computers.

# Synchronizing user passwords

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Synchronizing user passwords**

Server for NIS provides limited support for keeping passwords synchronized between a user's Windows and UNIX accounts. Whenever a user's Windows password is changed, Password Synchronization (which you can install with Server for NIS for this purpose) captures the new password, encrypts it, and then stores the password in the passwd map in Active Directory. The new password is then propagated to UNIX-based Network Information Service (NIS) secondary servers and clients when Server for NIS performs its periodic map update.

If Server for NIS is installed in a Windows domain with multiple domain controllers, it is recommended that you install Password Synchronization on all domain controllers in the domain. This is because any domain controller can potentially respond to a request to change a user's password, and so it is recommended that Password Synchronization be running on that domain controller to ensure that the NIS passwd map is updated. If you install Password Synchronization on a domain controller solely to support Server for NIS in this fashion, it is not necessary to configure UNIX hosts to work with Password Synchronization running on the domain controller. On the other hand, you can configure Password Synchronization on a domain controller and selected UNIX hosts to provide two-way password synchronization. This will allow users of the UNIX hosts to use the **passwd** command (instead of **yppasswd**) on those hosts to change their NIS domain password as well.

When synchronizing passwords, Server for NIS can use either **crypt** or Message Digest 5 (MD5). Server for NIS can support different encryption methods for multiple domains, but all UNIX computers in a particular domain must use the same encryption method. See Set the encryption method for a domain for how to specify the encryption method.

# Setting UNIX passwords to special values

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Setting UNIX passwords to special values**

You can set the password for a UNIX user to a special value, such as NP (no password) or * (no login) without affecting the user's Windows password. To do this, use **nismap** to change the Network Information Service (NIS) password entry for specific user, as follows:

- To set password to no password (usually a blank):

  **nismap mod -e "username::***uid***:***gid***:***gecos***:/***home***/***username***:/***login_shell***" -k** *username* **passwd**

- To set password to * (no logon):

  **nismap mod -e "***username***:*:***uid***:***gid***:***gecos***:/***home***/***username***:/***login_shell***" -k** *username* **passwd**

- To set password to *LK* (locked):

  **nismap mod -e "username:*LK*:***uid***:***gid***:***gecos***:/***home***/***username***:/***login_shell***" -k** *username* **passwd**

# Synchronizing and propagating NIS changes

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Synchronizing and propagating NIS changes**
A Windows-based master Network Information Service (NIS) server can propagate changes in maps to subordinate (also known as slave) NIS servers in the same domain. These changes are propagated to subordinate NIS servers using the features of the NIS protocol.

The master NIS server supports the following transfer modes:

- Periodic transfer of NIS maps.
- On-demand transfer of NIS maps to subordinate servers. Typically, NIS maps get transferred to subordinate servers upon change through **make**. The Windows-based NIS server does not use **make**; instead, the server pushes immediately.
- Subordinate NIS servers can request transfer of maps at any time.

# Sending periodic map updates to subordinate (slave) NIS servers

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Sending periodic map updates to subordinate (slave) NIS servers**
In Network Information Service (NIS), a master NIS server sends periodic map updates to subordinate NIS servers to ensure that both the master and subordinate servers have the same view of the maps. This process uses **yppush**. Server for NIS also sends periodic map updates to subordinate NIS servers. You can set the frequency of map updates through Server for NFS Administration.

Server for NIS uses **yppush** to send map updates only to subordinate NIS servers running on UNIX.

Because Server for NIS uses Active Directory to store data, both master and subordinate servers share the same replicated Active Directory database. Changes to maps for a given domain are propagated to other Servers for NIS running in subordinate mode by Active Directory's synchronization mechanism. Thus, Windows-based subordinate NIS servers receive updates from the master NIS server with every change. The update frequency is the property of the Server for NIS and is fixed for all domains that server supports.

For information about how to change the frequency of map updates, see Change the frequency of map updates to UNIX subordinate (slave) NIS servers.

For information about using **yppush**, see yppush.

# Pushing map updates immediately

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Pushing map updates immediately**

In Network Information Service (NIS), whenever a change is made to map data, administrators run **make** to make corresponding changes to the NIS database. Typically, as a part of this process, **make** also propagates the changes to subordinate (also known as slave) servers through **yppush**. This provides a way for administrators to push changes immediately to subordinate servers.

Because Server for NIS does not use **make** to make changes to the database, it provides an explicit **yppush** command to immediately propagate changes to UNIX-based subordinate servers. Server for NIS also provides a control in Identity Management for UNIX to immediately push maps to subordinate NIS servers.

Note that you use **yppush** to push changes only to subordinate NIS servers running on UNIX. Because Server for NIS uses Active Directory to store data, both master and subordinate servers running Windows operating systems share the same replicated Active Directory database. Changes to Active Directory are immediately propagated to other Servers for NIS. Thus, it is not necessary to use **yppush** to push changes to subordinate NIS servers running Windows operating systems.

For information about propagating maps immediately, see Propagate selected maps now and Propagate changed maps now.

For information about using yppush, see yppush.

# Server for NIS command-line utilities

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Command-line Utilities**

The following command-line utilities are available to administer Server for NIS:

nis2ad

nisadmin

nismap

ypcat

ypclear

ypmatch

yppush

# yppush

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**yppush**
**NAME**
yppush - Force propagation of a changed Network Information Service (NIS) map

**SYNOPSIS**

```
yppush [-d adNisDomain] [-q] [-t timeout] [-h host[...]]mapname
```

**DESCRIPTION**
The **yppush**(1w) Windows command-line utility sends a request to UNIX-based subordinate (also known as slave) NIS servers to transfer a new version of the NIS map specified by *mapname* from the master NIS server. It is run only on the master NIS server after the NIS map has been changed. If the **-h** option is specified, the transfer request is sent only to the specified server. Otherwise, **yppush** first constructs a list of NIS server hosts by reading the ypservers NIS map within the domain. For more information about the correct format of the ypservers map, see "Note" later in this topic.

The **yppush** command sends a transfer map request from the NIS server to the transfer agent on each subordinate host computer. A host's transfer agent is the utility that copies map data from the master server. When the transfer has completed, whether the transfer operation succeeded or failed, the transfer agent returns a status message, the contents of which can be printed to standard output. Transfer agents also return messages when a transfer is not possible; for example, when the **yppush** request is undeliverable to one or more host computers, or when the time-out period on responses from host computers has expired.

The **yppush** command accepts the following options and arguments:

| Term | Definition |
|---|---|
| **-d** *adNisDomain* | Specifies the NIS domain. If this option is not used, the NIS domain is assumed to be the domain named in the **DEFAULT_NIS_DOMAIN** environment variable. |
| **-q** | Quiet mode. Does not wait for a response from subordinate servers, and does not report errors. |
| **-t** *timeout* | Specifies a time-out value, in seconds, that **yppush** will wait for a response from the subordinate server. This value must be greater than zero. The default value is **30 seconds**. |
| **-h** *host*[...] | The name of the host to notify of the map change. You can specify multiple host names, separated by spaces. If you do not specify this option, the notification is sent to all subordinate servers in the domain. |

**Note**

Keys within the ypservers map are the ASCII names of the computers on which the NIS servers run. That is, the ypservers map should contain a list of NIS servers, each one listed on a separate line. If your ypservers map contains aliases, edit the ypservers map to contain only the host names of the servers, one per line. The following list is an example of a valid ypservers map:

```
ypserver_1
ypserver_2
ypserver_3
```

Identity Management for UNIX: Server for NIS

# ypclear

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**ypclear**
**NAME**
ypclear - Windows command-line utility to clear the Network Information Service (NIS) server cache for an NIS map and its dependent maps

**SYNOPSIS**

```
ypclear [-d domainName] [-t] [-h nisServer] mapname
ypclear -x
```

**DESCRIPTION**
The **ypclear**(1w) Windows command-line utility tells the specified Network Information Service (NIS) server in a specified domain that a map has changed and that the server should clear its cache. Without this notification, the NIS server can sometimes serve out-of-date information.

The **ypclear** command can be used to rebuild the map cache of an NIS server that still displays obsolete map data, even when Active Directory shows a current and accurate map of the network. Typically, using **ypclear** corrects the problem.

The **ypclear** command accepts the following options and arguments:

| Term | Definition |
|---|---|
| **-d** *domain* | Specifies the NIS domain. If this option is not used, the NIS domain is assumed to be the domain named in the **DEFAULT_NIS_DOMAIN** environment variable. |
| **-t** | Inhibits map nickname translation. |
| **-h** *nisServer* | Specifies the name of the NIS server. If this option is not used, the NIS server is assumed to be the server named in the **NIS_SERVER** environment variable. |
| **-x** | Displays the map nickname translation table. |

**See Also**
**Concepts**
Identity Management for UNIX: Server for NIS

# ypmatch

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**ypmatch**
**NAME**
ypmatch - Windows command-line utility to display the values of one or more keys from a Network Information Service (NIS) map

**SYNOPSIS**

```
ypmatch [-k] [-t] [-d domain] [-h nisServer]key[...]mapname
ypmatch -x
```

**DESCRIPTION**
The **ypmatch**(1w) Windows command-line utility displays the values one or more keys from the Network Information Service (NIS) map specified by *mapname*, which may be a map name or a map nickname.

The **ypmatch** command accepts the following options and arguments:

**-k**
Displays map keys. This option is useful with maps in which the values are null or the key is not part of the value.

**-t**
Inhibits map nickname translation.

**-d *domain***
Specifies the NIS domain. If this option is not used, the NIS domain is assumed to be the domain named in the *DEFAULT_NIS_DOMAIN* environment variable.

**-h *nisServer***
Specifies the name of the NIS server. If this option is not used, the NIS server is assumed to be the server named in the *NIS_SERVER* environment variable. If *NIS_SERVER* is not set, **ypmatch** broadcasts the request.

***key***
The key for which you want to display the value. To display the value of more than one key, specify the keys separated by spaces. If any key begins with a slash mark (/), backslash (\) or hyphen (-), these special characters must be preceded by a backslash (\). For example, if the key name is **\mykey**, then use **\\mykey**.

**-x**
Displays the map nickname translation table.

ypcat
Identity Management for UNIX: Server for NIS

# ypcat

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**ypcat**
**NAME**
ypcat - Windows command-line utility to print values of all keys in an NIS map

**SYNOPSIS**

```
ypcat [-k] [-t] [-h nisServer] [-d domain]mapname
ypcat -x
```

**DESCRIPTION**
The **ypcat**(1w) Windows command-line utility prints the values of all keys from the Network Information Service (NIS) database specified by *mapname*, which can be a map name or a map nickname.

The **ypcat** command accepts the following options and arguments:

| Term | Definition |
|---|---|
| **-k** | Displays map keys. This option is useful with maps in which the values are null or the key is not part of the value. |
| **-t** | Inhibits map nickname translation. |
| **-d** *domain* | Specifies the NIS domain. If this option is not used, the NIS domain is assumed to be the domain named in the *DEFAULT_NIS_DOMAIN* environment variable. |
| **-h** *nisServer* | Sends a request to the server name represented by the *nisServer* variable. The **-h** option broadcasts the request to all other NIS servers in the domain specified with the **-d** option, if no server name is provided. |
| **-x** | Displays the map nickname translation table. |

Identity Management for UNIX: Server for NIS

# nisadmin

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**nisadmin**
**NAME**
nisadmin - Windows command-line utility to administer Server for NIS

**SYNOPSIS**

```
nisadmin [computer] [-u usr[-p pword]]
nisadmin [computer] [-u usr[-p pword]] mkmaster -d domain
nisadmin [computer] [-u usr[-p pword]] mkslave -d domain -m server
nisadmin [computer] [-u usr[-p pword]] config option[...]
nisadmin [computer] [-u usr[-p pword]] syncall
nisadmin [computer] [-u usr[-p pword]] start
nisadmin [computer] [-u usr[-p pword]] stop
nisadmin [computer] [-u usr[-p pword]] pause
nisadmin [computer] [-u usr[-p pword]] continue
nisadmin [computer] [-u usr[-p pword]] encryptiontype
         -d domain{crypt | md5}
```

**DESCRIPTION**
The **nisadmin** Windows command-line utility administers Server for NIS on the local computer or on a remote computer. If you are logged on with an account that does not have the required privileges, you can specify a user name and password of an account that does. The action performed by **nisadmin** depends on the command argument you supply.

In addition to specific command arguments, **nisadmin** accepts the following options and arguments:

| Term | Definition |
|---|---|
| *computer* | Specifies the remote computer you want to administer. You can specify the computer using a Windows Internet Name Service (WINS) or Domain Name System (DNS) name, or by Internet Protocol (IP) address. |
| **-u** *usr* | Specifies the user name of the user whose credentials are to be used. It might be necessary to add the domain name to the user name in the form *domain\username*. |
| **-p** *pword* | Specifies the password of the user specified using the **-u** option. If you specify the **-u** option but omit the **-p** option, you are prompted for the user's password. |

The specific action that **nisadmin** performs depends on the command argument you specify:

| Term | Definition |
|---|---|
| **mkmaster** | Changes a subordinate (also known as slave) server to a master server. The following option and argument are required when you use **mkmaster**:<br>• **-d** *domain* Specifies the name of the domain for which the change is being made. |
| **mkslave** | Changes a master server to a subordinate (slave) server. The following options and arguments are required when you use **mkslave**:<br>• **-d** *domain* Specifies the name of the domain for which the change is being made.<br>• **-m** *server* Specifies the name of the domain controller to be promoted to master server. |

| | |
|---|---|
| **config** | Configures service parameters. You must supply one or more of the following options when you use **config**:<br>• **pushint =**[[*days***:**]*hh***:**]*mm* Specifies the interval at which the service checks changes to Network Information Service (NIS) maps in Active Directory and propagates them to secondary NIS servers for all domains, in days, hours, and minutes. If *hh* is specified, *hh* must be in the range 0-23 and *mm* must be in the range 0-59.<br>• **logging =**{**n**[**ormal**] \| **v**[**erbose**]} Specifies the amount of information to be available in event logs. Specify **normal** (or **n**) to log only failure events; specify **verbose** (or **v**) to log failure, warning, and success events. |
| **syncall** | Synchronizes changed maps with those on UNIX-based subordinate servers immediately. |
| **start** | Starts the Server for NIS service. |
| **stop** | Stops the Server for NIS service. |
| **pause** | Pauses the Server for NIS service. |
| **continue** | Continues running the Server for NIS service. |
| **encryptiontype** | Specifies the method used to encrypt UNIX passwords for the specified *domain*. For domains whose UNIX-based computers are all running Linux with MD5 encryption, this value can be **md5**. For domains containing one or more UNIX-based computers running any other operating system or encryption method, this value must be **crypt** (the default). All computers in the domain must use the same method.<br>Password encryption can only be set to one encryption method at a time. Changing the encryption method invalidates user passwords. All passwords must be reset if the encryption method is changed. |

If you do not supply a command argument, **nisadmin** displays the current Server for NIS settings.

Identity Management for UNIX: Server for NIS

# nis2ad

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**nis2ad**
**NAME**
nis2ad - Windows command-line utility to migrate maps from Network Information Service (NIS) to Active Directory directory service

**SYNOPSIS**

```
nis2ad.exe -y NIS_Domain -a AD_domain [options]mapfile
```

**DESCRIPTION**
The **nis2ad** Windows command-line utility transfers the entries in the Network Information Service (NIS) map source file specified by *mapfile* located in the UNIX NIS domain specified by *NIS_domain* to the Active Directory domain specified by *AD_domain*. NIS map source files are the plain text files from which the NIS map databases are compiled.

The **-m** option must be specified to perform the actual migration; otherwise, **nis2ad** performs the actions it would perform in an actual migration without actually changing Active Directory, including logging any conflicting entries.

The **nis2ad** utility accepts the following options and arguments:

| Term | Definition |
|---|---|
| **-d** *directoryname* | Specifies the name of the directory that contains NIS map source files. |
| **-s** *server* | Specifies the domain controller server hosting Active Directory; otherwise, uses the current server. |
| **-u** *user* | Specifies the name of a user having administrator permissions on this computer; otherwise, uses the current user. |
| **-p** *password* | If a password is needed but is not specified, **nis2ad** prompts the user for the password. |
| **-f** *logfile* | Specifies the name of the log file. The log file must be on your local computer. The default is %sfudir%\nis\nis2ad.log. |
| **-c** *conflictfile* | Specifies the file where conflict details are written. The default is %sfudir%\nis\conflicts.log. |
| **-r** {**yes**\|**no**} | Replaces the object in Active Directory with the object being migrated. The default is **no**. |
| **-n** | Resolves conflicts by changing the Windows account name in Active Directory. If objects of different types have the same name, the name of both objects is changed before the data is migrated. |
| **-t** *targetContainer* | Specifies the target container name. Applicable only when creating a new NIS domain. If not specified, uses default or uses the container of the target domain. |
| **-m** | Performs the migration. If this option is omitted, the program finds and reports conflicts, but does not actually perform the migration. |
| **-h/-?** | Displays usage information for the command. |

**Note**

The currently logged on user must have write permissions for the folder that will contain the log and conflict files, even if another user is specified with the **-u** option. If necessary, modify the permissions on the folder to grant write access to the user who will be running the **nis2ad** utility before running the utility.

**Concepts**

# nismap

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**nismap**
**NAME**
nismap - Windows command-line utility to manage Network Information Service (NIS) maps

**SYNOPSIS**

```
nismap add [common_option[...]] -e "mapentry"
           [-r {yes | no}] [-c conflictfile]mapname
nismap mod [common_option[...]] -e "mapentry" -k key mapname
nismap del [common_option[...]] -k key mapname
nismap create [common_option[...]] -i fieldnum -g separator [-y]mapname
```

**DESCRIPTION**
The **nismap** Windows command-line utility manages the Network Information Service (NIS) map specified by *mapname* maintained by Server for NIS on a local computer or a remote computer. If you are logged on with an account that does not have the required privileges, you can specify the user name and password of an account that does. The specific action that **nismap** performs depends on the command argument you specify.

In addition to specific command arguments, **nismap** accepts the following common options and arguments, represented by *common_option* in the command synopsis:

| Term | Definition |
|---|---|
| **-a** *AD_domain* | The name of the NIS domain in Active Directory. This option is not available for the **create** command argument. |
| **-f** *logfile* | Specifies the fully qualified path and name of the log file. Logged events are appended to this file. The default path and file name is %temp%\conflicts.log. |
| **-s** *server* | Specifies the name of the domain controller. The default is the domain controller of the domain of the computer on which the command is executed. |
| **-u** *usr* | Specifies the user name of the user whose credentials are to be used. It might be necessary to add the domain name to the user name in the form *domain******username*. |
| **-p** *pword* | Specifies the password of the user specified using the **-u** option. If you specify the **-u** option but omit the **-p** option, you are prompted for the user's password. |
| **-h/-?** | Displays usage information for the command. |

The following command arguments are accepted by **nismap**:

| Term | Definition |
|---|---|
| **add** | Adds a map entry. The following options and arguments are used with **add**:<br>• **-e "** *mapentry* **"** Specifies the new map entry as a string in the appropriate NIS map format. The string must be enclosed in quotation marks (**" "**).<br>• **-r {yes \| no}** Specifies whether the existing object in Active Directory is to be replaced with this entry. The default is **no**.<br>• **-c** *conflictfile* Specifies the name of the file in which conflict information is to be recorded. If this option is not provided, a default file name is used. |

| | |
|---|---|
| **mod** | Modifies an existing map entry. The following options and arguments are required with **mod**<br>• **-e "** *mapentry* **"** Specifies the replacement map entry as a string in the appropriate NIS map format. The string must be enclosed in quotation marks (**" "**).<br>• **-k** *key* Specifies the search key that identifies the map entry to be modified. |
| **del** | Deletes an existing map entry. The following option and argument are required with **del**:<br>• **-k** *key* Specifies the search key that identifies the map entry to be deleted. |
| **create** | Creates a structure for a nonstandard map. The following options and arguments are required with **create**:<br>• **-i** *fieldnum* Specifies the field number of the key field.<br>• **-g** *separator* Specifies the character that separates fields in the map.<br>• **-y** Specifies that the key is not part of the value for this map. |

**Note**

When you use **nismap** to delete a user, group, or host object, only the UNIX attributes of the object are deleted from Active Directory. To delete the object from Active Directory, use the Active Directory administration tools.

Do not use **nismap** to change a user's password. Use net.exe or the Windows interface (CTRL+ALT+DELETE) instead. The **nismap** utility will fail if you change the passwd entry using the **nismap mod** command. This value is the encrypted string of the user's password. If you need to change the passwd entry, use ypcat(1w) or ypmatch(1w) to retrieve the user's current passwd entry and to ensure that the password field is identical.

If you try to modify a mail alias using the **nismap mod** command, Server for NIS adds the new alias to the original one instead of replacing it. To change the alias, first use **nismap del** to delete the original alias, and then use **nismap add** to add the modified alias.

# Server for NIS Troubleshooting

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Troubleshooting**
What trouble are you having?

- NIS Data Migration wizard or command-line utility completes successfully, but no maps are added to Server for NIS
- Migration conflicts occur even though test migration with "Do Not Migrate" option succeeded
- A conflict occurs while trying to migrate more than one user with the same user identifier (UID)
- NIS Data Migration wizard or command-line utility reports Network Information Service (NIS) name conflicts with system account
- The ypmatch utility on an HP-UX computer fails
- The first request to Server for NIS fails
- Objects migrated to nonstandard containers do not appear in Windows Active Directory Users and Computers
- The ypcat utility sometimes displays incorrect passwd information, but ypmatch provides accurate information
- Users with new Windows accounts created by NIS migration cannot log on to Windows and cannot log on to NIS client computers
- A user account disabled in Active Directory is not also disabled on UNIX hosts
- A newly migrated user is not authenticated from a UNIX client

**NIS Data Migration wizard or command-line utility completes successfully, but no maps are added to Server for NIS.**
**Cause:** The "Do Not Migrate (log only)" option was in effect.

**Solution:** Because migration is irreversible, the "Do Not Migrate (log only)" option is the default. You can override the default when running the wizard by selecting either **Overwrite** or **Preserve**. To override the default when you are running the command-line utility (Nis2ad.exe), specify the **-m** option on the command line.

**Migration conflicts occur even though test migration with "Do Not Migrate" option succeeded.**
**Cause:** If data in the Network Information Service (NIS) maps being migrated conflicts, the conflict might not be reported until the maps are actually migrated because only conflicts between NIS maps and Active Directory are reported.

**Solution:** Resolve the conflicts in the original NIS maps and then migrate the NIS data that was not migrated using the **nis2ad –r yes** option.

**A conflict occurs while trying to migrate more than one user with the same user identifier (UID).**
**Cause:** The NIS Data Migration wizard cannot migrate users that have the same UID. Only the first user will be successfully migrated.

**Solution:** Make sure all users have unique UIDs before migrating NIS maps.

**NIS Data Migration wizard or command-line utility reports Network Information Service (NIS) name conflicts with system account.**
**Cause:** A user name in NIS is identical to a reserved Windows account name. Reserved account names include such names as Network, System, Users, and Computers.

**Solution:** Resolve the conflict by renaming the UNIX account, and then remigrate the entry.

**The ypmatch utility on an HP-UX computer fails.**
**Cause:** A map contains keys in mixed case. HP-UX converts all keys to lowercase before sending the NIS request. This is an

issue with HP-UX that is beyond the control of Server for NIS.

**Solution:** Convert keys to lowercase before migrating them.

**The first request to Server for NIS fails.**
**Cause:** If the number of objects migrated to Server for NIS was very large, Server for NIS can take a long time to build the map cache.

**Solution:** Make the request again after waiting 30 minutes or more. Subsequent requests might succeed.

**Objects migrated to nonstandard containers do not appear in Windows Active Directory Users and Computers.**
**Cause:** Active Directory Users and Computers does not display nonstandard containers by default.

**Solution:** On the **View** menu, click **Advanced Features**.

**The ypcat utility sometimes displays incorrect passwd information, but ypmatch provides accurate information.**
**Cause:** Server for NIS data has not yet updated the map cache after data in Active Directory has changed. The **ypcat** utility takes its information from this cache; the **ypmatch** utility takes its information directly from Active Directory.

**Solution:** Decrease the refresh interval between updates to the map cache, or check that the updates have been cached immediately upon making changes in Active Directory. For more information, see Change the frequency of map updates to UNIX subordinate (slave) NIS servers and Propagate changed maps now.

**Users with new Windows accounts created by NIS migration cannot log on to Windows and cannot log on to NIS client computers.**
**Cause:** To avoid exposing new accounts to misuse, the migration wizard disables the new accounts.

**Solution:** After completing migration, enable new accounts only when users are ready to use them. For security reasons, it is recommended that you change the password on all newly created Windows user accounts to temporary values. Notify users of the temporary passwords and instruct them to change their Windows passwords as soon as possible. Inform them of how often map changes are propagated (see Sending periodic map updates to subordinate (slave) NIS servers) so they will know when they can expect their UNIX passwords to be updated.

**A user account disabled in Active Directory is not also disabled on UNIX hosts.**
**Cause:** Windows and UNIX accounts must be disabled separately because the mechanism for doing so is fundamentally different, and the method for disabling UNIX accounts differs based on system version and administrator preference.

**Solution:** After disabling an account using Active Directory Users and Groups, you must also disable or lock the corresponding UNIX account by the usual means (such as by changing the password to a value unknown to the user, by adding a special character to the user's password in the **passwd** file, by changing the account's login shell, or all three).

**A newly migrated user is not authenticated from a UNIX client.**
**Cause:** Possible configuration errors on the client computer.

**Solution:** Perform the following troubleshooting steps for the indicated client operating system.

**On a Solaris client:**

- Ensure that the Windows server that is running Server for NIS is added to the **/etc/hosts** file on the Solaris client. Then run the **ypwhich** command on the client and check that it shows the correct Windows server.

- Ensure that the **/etc/nsswitch.conf** file contains an entry similar to the following:

  **passwd: files [NOTFOUND=continue] nis**

- Ensure that the user is not listed in the local **passwd** file.

- Add the following to the end of the **/etc/passwd** file on the client computer:

  **+::::::**

- Ensure that shadow files, if any, are also migrated to Server for NIS.

- Ensure that the **ypcat password** command does not show **X** in the user's password field.

- Ensure that the file **/var/yp/securenets** is configured to allow authentication from the client computer.

**On a Linux client**

- Ensure that the Windows server running Server for NIS has been added to the **/etc/hosts** file on the client computer and that the **ypwhich** command on the client computer correctly shows the name of the Windows-based computer.

- Ensure that the **USENIS** entry in the **/etc/sysconfig/authconfig** is set to **USENIS=yes**.

- Ensure that the **nsswitch.conf** file is properly configured.

# Identity Management for UNIX: Password Synchronization

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Password Synchronization makes it easy for users to maintain one user name and password for Windows domains and UNIX systems, synchronizing the passwords when one of them changes.

Depending on how Password Synchronization and the UNIX servers are configured, synchronization can be one way or two way.

- Before you begin using Password Synchronization, see Checklists for Password Synchronization.
- For information about how to implement Password Synchronization most effectively, see Best practices for Password Synchronization.
- For help with specific tasks, see How To .....
- For general background information, see Password Synchronization Concepts.
- For problem-solving instructions, see Troubleshooting Password Synchronization.
- For information about the Password Synchronization command-line utility, see Command-line utility.

# Checklists for Password Synchronization

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Checklists**

- Checklist: Setting up Password Synchronization for use with standalone UNIX hosts
- Checklist: Setting up Password Synchronization for use with an NIS domain (UNIX master server)
- Checklist: Setting up Password Synchronization for use with an NIS domain (Server for NIS master server)

# Checklist: Setting up Password Synchronization for use with standalone UNIX hosts

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Checklist: Setting up Password Synchronization for use with standalone UNIX hosts**

**Configuring Windows systems**

| Step | Reference |
|---|---|
| Read about Password Synchronization. | Password Synchronization Concepts |
| Log on as a member of the Administrators group. | |
| Install Password Synchronization on the appropriate Windows-based computers. If the passwords of local accounts on a server are to be synchronized, install Password Synchronization on the server. If Windows domain passwords are to be synchronized, install Password Synchronization on all domain controllers. | Install Password Synchronization |
| Change the encryption key. | Set the default encryption key |
| Change other settings, as needed. | Configure Password Synchronization |
| Add UNIX computers with which passwords will be synchronized. If you want to use nondefault values, specify values for the port number, encryption key, or both. | Add and remove computers for synchronization |
| Ensure that the Password Synchronization configurations on all domain controllers in the domain are identical. | |

**Configuring UNIX systems**

| Step | Reference |
|---|---|
| Install and configure the Password Synchronization single sign-on daemon (SSOD) on all UNIX computers with which passwords will be synchronized. Be sure to change the default encryption key in the sso.conf file to match the Password Synchronization encryption key set in previous steps before copying it to the UNIX computers. | Install the Password Synchronization daemon |
| Specify which users will and will not be allowed to synchronize passwords. | Controlling password synchronization for user accounts |
| Start the Password Synchronization daemon. | Start the Password Synchronization daemon |
| Install and configure the Password Synchronization pluggable authentication module (PAM) on all UNIX computers from which password changes are to be synchronized with Windows passwords. | Configure UNIX Computers for UNIX-to-Windows Synchronization |

# Checklist: Setting up Password Synchronization for use with an NIS domain (UNIX master server)

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Checklist: Setting up Password Synchronization for use with an NIS domain (UNIX master server)**

**Configuring Windows systems**

| Step | Reference |
|---|---|
| Read about Password Synchronization. | Password Synchronization Concepts |
| Log on as a member of both the Schema Administrators and Enterprise Administrators groups. | |
| Install Password Synchronization on the appropriate Windows-based computers. If the passwords of local accounts on a server are to be synchronized, install Password Synchronization on the server. If Windows domain passwords are to be synchronized, install Password Synchronization on all domain controllers. | Install Password Synchronization |
| Change the encryption key. | Set the default encryption key |
| Change other settings, as needed. Be sure to select the **Synchronize password changes from computers that run UNIX to computers that run Windows** check box. | Configure Password Synchronization |
| Add the Network Information Service (NIS) master server to the list of computers with which the Windows-based computer will synchronize passwords. Select the NIS master server in the list, click **Configure**, select both the **Synchronize password changes to** and **Synchronize password changes from** check boxes, and then click **OK**. | Add and remove computers for synchronization |
| Add UNIX computers with which passwords will be synchronized. For each computer, select the computer in the list, click **Configure**, clear the **Synchronize password changes to** check box, select the **Synchronize password changes from** check box, and then click **OK**. If you want to use nondefault values, specify values for the port number, encryption key, or both. | Add and remove computers for synchronization |
| Specify which users will and will not be allowed to synchronize passwords. | Controlling password synchronization for user accounts |
| Ensure that the Password Synchronization configurations on all domain controllers in the domain are identical. | |

**Configuring UNIX systems**

| Step | Reference |
|---|---|
| Install and configure the Password Synchronization single sign-on daemon (SSOD) on the NIS master server. Be sure to change the default encryption key in the sso.conf file to match the Password Synchronization encryption key set in previous steps before copying it to the server, and edit it to specify the following:<br>• **USE_NIS=1**<br>• **NIS_UPDATE_PATH=** *Makefile_path*, where *Makefile_path* is the path and name of the NIS makefile, such as /var/yp/Makefile | |

| | |
|---|---|
| Install and configure the Password Synchronization pluggable authentication module (PAM) on all UNIX computers from which password changes are to be synchronized with Windows passwords. Typically, this would be any computer on which users would run **yppasswd** and any standalone computers (computers that do not belong to the domain). | Configure UNIX Computers for UNIX-to-Windows Synchronization |
| Copy the sso.conf file from the NIS master server to the /etc directory of each computer on which the Password Synchronization PAM module is installed. | |
| On each NIS client on which you installed the Password Synchronization PAM module, replace the yppasswd binary file with a link to the passwd binary file, and then edit the /etc/nsswitch.conf file to change the passwd and shadow lines, as shown:<br>`passwd:  files [NOTFOUND=continue] nis`<br>`shadow:  files [NOTFOUND=continue] nis` | |
| Start the Password Synchronization daemon on the NIS master server. | Start the Password Synchronization daemon |

# Checklist: Setting up Password Synchronization for use with an NIS domain (Server for NIS master server)

# Best practices for Password Synchronization

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Best practices**

- **Install Password Synchronization on appropriate domain controllers** To ensure consistent synchronization of domain passwords with UNIX passwords, Password Synchronization must be installed on the primary domain controller and, in the case of a Windows 2000 domain, all domain controllers in a domain.

    - If you add a domain controller to a domain, you should install Password Synchronization on the new domain controller as soon as possible and configure it to match the other domain controllers.

    - If you need to remove Password Synchronization from any domain controller, you should demote the server to a member server before uninstalling Password Synchronization.

- **Ensure consistent password policies** If you are providing only for one-way password synchronization, make sure that the password policy on the computer from which passwords will be synchronized is at least as restrictive in all areas as the policy on the computer to which passwords will by synchronized. For example, if you configure Windows-to-UNIX synchronization, the Windows password policy must be at least as restrictive as the policy of the UNIX computers with which it will synchronize passwords. If you are supporting two-way synchronization, the password policies must be equally restrictive on both systems. Failure to ensure that password policies are consistent can result in synchronization failure when a user changes a password on the less restrictive system, or the password might be changed on the more restrictive system even though it does not conform to the system's policies.

  Also make sure that Windows users are aware of any special password restrictions on the UNIX systems with which their passwords will be synchronized. For example, some versions of UNIX support a maximum password length of eight characters. For maximum compatibility with the default Windows password policy and these UNIX limitations, passwords should be seven or eight characters long unless you are sure that all UNIX systems can support longer passwords.

- **Configure Password Synchronization to provide the maximum protection for your users' passwords**

  Follow these recommendations to maintain optimal security:

    - **Explicitly list the users whose passwords are to be synchronized** To provide maximum control over which users can synchronize passwords, do not use the ALL keyword with the SYNC_USERS list in sso.conf on the UNIX host. Instead, you should explicitly list each user for whom password synchronization is allowed or blocked. On the Windows-based computer running Password Synchronization, create the PasswordPropAllow group and add the accounts of users whose passwords you want to synchronize. For more information, see Controlling password synchronization for user accounts.

    - **Do not synchronize passwords for disabled UNIX accounts** On some versions of UNIX, changing the password of a disabled user account activates that account. Consequently, if a user has a disabled account on a UNIX computer that is configured to synchronize passwords with a Windows-based computer, the user or an administrator can activate the UNIX account by changing the user's Windows password. To prevent this, use the PasswordPropDeny group to block synchronization for disabled UNIX accounts.

      Also, when an administrator disables a UNIX account, the administrator should use the SYNC_USERS entry in sso.conf to block password synchronization for the account.

    - **Avoid synchronizing administrator passwords** Do not synchronize passwords for members of the Windows Administrators groups or the passwords of UNIX superuser or root accounts.

    - **Perform the Windows Server 2003 Service Pack 1 (SP1) compatibility check** when selecting **Enable Windows to NIS (AD) Password Sync** in the **Password Synchronization Properties** dialog box, **Configuration** tab. To protect the security of user account passwords in your enterprise, it is strongly

recommended that you allow Password Synchronization to identify all domain controllers in the forest that are not running Windows Server 2003 SP1 or later releases.

Password Synchronization prompts you to allow the compatibility check when you select the **Enable Windows to NIS (AD) Password Sync** option. With Windows Server 2003 SP1, or a later release installed on all the domain controllers in a forest, the risk of exposing user password hashes to unauthorized viewers is greatly reduced. When Windows Server 2003 SP1 is not the minimum functional level of all the domain controllers in a forest, it is possible for any authenticated user on the domain to view the password hash for any UNIX user whose account has been migrated to Active Directory.

In the event an unauthorized user breaks the password hash for a UNIX-based user account in Active Directory, the Windows-based password for the account is no longer secure.

When Password Synchronization is installed, members of the local Administrators group and the Domain Admins group are added to the PasswordPropDeny group, which prevents their passwords from being synchronized. If you add a user to either the Administrators or Domain Admins group, be sure to add the user to the PasswordPropDeny group as well.

Use the SYNC_USERS statement in the sso.conf file on all UNIX systems to prevent the passwords of superusers from being synchronized.

- **Do not use the default port number and encryption key** If you use the default port number and encryption key, you make it possible for an attacker to set up an impostor UNIX host to capture passwords. You should protect the port number and encryption keys used to synchronize passwords as carefully as the passwords themselves.

- **Secure the sso.conf file** The sso.conf file on each UNIX host contains important configuration information that could be used to compromise security. It is recommended that you set the mode bit mask of the file to 600.

- **Ensure that the directory identified by TEMP_FILE_PATH is properly protected** The temporary files created on UNIX hosts by Password Synchronization contain information that could be used by an attacker to compromise system security. For this reason, you should ensure that any directory referenced by TEMP_FILE_PATH in sso.conf has read access only for the root account and cannot be accessed by any other users.

- **Ensure log files are appropriately protected** On the UNIX host, Password Synchronization uses the syslogd daemon to log messages that result from synchronization operations. The resulting logs contain such information as the names of users whose passwords are being synchronized and with which computers, propagation errors, and so on. These log files should be protected to ensure that only administrators can read them.

- **Restart the Password Synchronization daemon after changing its configuration** When you make changes to the Password Synchronization daemon configuration file (sso.conf), you must stop and restart the daemon to make sure that the configuration changes take effect.

- **Configure systems to handle user name case sensitivity correctly** Unless you rigorously enforce a policy to ensure that Windows and UNIX user names match in both spelling and case, make sure that the CASE_IGNORE_NAME option in the sso.conf file is set to 1 (the default). UNIX user names are case sensitive; therefore, passwords might not synchronize properly if the user names do not match exactly because the Password Synchronization daemon is unable to associate the Windows user name with the corresponding UNIX user name.

- **Make sure that password file type and name are consistent** When you configure the Password Synchronization daemon, make sure that the password file type (specified by USE_SHADOW) and path name (set by FILE_PATH) are appropriate for each other. For example, on most systems, if USE_SHADOW is set to 0 (to indicate that the passwd file is used for synchronization), then the FILE_PATH option should be set to /etc/passwd. However, if USE_SHADOW is set to 1 (to indicate that the shadow file is used instead), then the FILE_PATH option should be set to /etc/shadow. (On AIX systems, the path and name of the shadow file is /etc/security/passwd.)

# How To ....

# Use UNIX Components

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Use UNIX Components**

- Install the Password Synchronization daemon
- Start the Password Synchronization daemon
- Stop the Password Synchronization daemon
- Configure UNIX Computers for UNIX-to-Windows Synchronization

# Install the Password Synchronization daemon

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To install the Password Synchronization daemon**

1. Copy the appropriate source binary file from IDMU\Unix\Bins on the Windows Server 2003 R2 CD to /usr/bin or /usr/local/bin on the UNIX computer, and change its name to ssod. The name of the source binary file depends on the version of UNIX you are using.

   - If the computer is running Hewlett-Packard HP-UX, the source binary file name is ssod.hpx.
   - If the computer is running Red Hat Linux, the source binary file name is ssod.rhl.
   - If the computer is running Sun Microsystems Solaris, the source binary file name is ssod.sol.
   - If the computer is running IBM AIX, the source binary file name is ssod.aix.

2. Using a binary file-copy method such as File Transfer Protocol (FTP) to avoid corrupting CR/LF (carriage-return/line-feed) pairs, copy Sso.cfg from \Unix\Bins on the Windows Server 2003 R2 CD to /etc on the UNIX computer, and change its name to sso.conf.

3. Open sso.conf with a text editor.

4. If you have changed the default encryption key, edit the following line to specify the new default key. This value must match the default key specified on all domain controllers with which this computer will synchronize passwords:

   **ENCRYPT_KEY=***encryptionKey*

5. If you have changed the default port, edit the following line to specify the new port. This value must match the port number specified on all domain controllers with which this computer will synchronize passwords.

   **PORT_NUMBER=***portNumber*

6. Edit the following line to specify one domain controller in each Windows domain with which the computer is to synchronize passwords. If you have specified a nondefault port number or encryption key for the UNIX computer when configuring Password Synchronization on the Windows domain controllers, specify that value where indicated; otherwise, leave the value blank:

   **SYNC_HOSTS=(***domainController*[**,** *portNumber* [**,** *encryptionKey*]]**)** ...

   Each entry in the list must be enclosed by parentheses (the "(" and ")" characters) and separated from the next entry by a blank space.

7. If the computer is a Network Information Service (NIS) master server, and if you want passwords to be synchronized throughout the NIS domain, edit the following line as shown to enable NIS synchronization:

   **USE_NIS=1**

   Also, if required, edit the following line to specify the location of the NIS makefile:

   **NIS_UPDATE_PATH=***makefilePath*

8. Set the file permissions of sso.conf to read/write for the root user only, and deny access to all other users.

9. If the computer is running Linux, copy /etc/pam.d/system-auth to /etc/pam.d/ssod.

**Important**

The sso.conf file contains encryption keys and other sensitive information. For this reason, it must be accessible only by system administrators.

**Note**

This daemon program must be installed on the computer running UNIX to enable Password Synchronization to change users' passwords on that computer.

Password Synchronization supports synchronization with UNIX computers running any of the following operating systems:

- Hewlett-Packard HP-UX version 11i
- IBM AIX version 5L 5.2
- Red Hat Linux versions 8 and 9
- Sun Solaris version 8 running on x86-based computers and Scalable Processor Architecture (SPARC)–based computers, and Solaris version 9 running on SPARC–based computers

Applies To: Windows Server 2003 R2

**Configure UNIX computers for UNIX-to-Windows synchronization**

- Install the pluggable authentication module (PAM) on AIX
- Install the pluggable authentication module (PAM) on HP-UX
- Install the pluggable authentication module (PAM) on Linux
- Install the pluggable authentication module (PAM) on Solaris

# Install the pluggable authentication module (PAM) on AIX

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To install the pluggable authentication module (PAM) on AIX**

1. Copy pam_sso.aix from IDMU\Unix\Bins on the Windows Server 2003 R2 CD to /usr/lib/ on the UNIX computer, and change its name to pam_sso.aix.1.

2. On the UNIX computer, log on as root, and then enter the following commands:

   **chown root /usr/lib/pam_sso.aix.1 chmod 555 /usr/lib/pam_sso.aix.1**

3. If necessary, create the /etc/pam.conf file according to your network requirements, setting the owner to root and the base permissions to 644. For more information about creating the pam.conf file, see "Pluggable Authentication Modules" in *System Management Guides: Security Guide* in your AIX documentation.

   Sample pam.conf file

```
#
# Authentication management
#
OTHER   auth     required       /usr/lib/security/pam_aix

#
# Account management
#
OTHER   account  required       /usr/lib/security/pam_aix

#
# Session management
#
OTHER   session  required       /usr/lib/security/pam_aix
```

4. Open /etc/pam.conf with a text editor.

5. In the **Password management** section, add the following line:

   **passwd password required /usr/lib/security/pam_sso.aix.1**

   Sample pam.conf file with this line added

```
#
# Authentication management
#
OTHER   auth     required       /usr/lib/security/pam_aix

#
# Account management
#
```

```
OTHER   account  required       /usr/lib/security/pam_aix

#
# Session management
#
OTHER   session  required       /usr/lib/security/pam_aix

#
# Password management
#
passwd   password required       /usr/lib/security/pam_sso.aix.1
```

6. Open /usr/lib/security/methods.cfg with a text editor and add the following lines at the end of the file:

   **PAM:  program = /usr/lib/security/PAM**

   **PAMfiles:  options = auth=PAM,db=BUILTIN**

7. Open /etc/security/user with a text editor and add authentication information for the specific users whose passwords you want to synchronize. For example:

   user1:  admin = false  SYSTEM = PAMfiles[*] AND "compat"  registry = PAMfiles

| **Note** |
| --- |
| You can choose to change the default section of /etc/security/user to allow all users to synchronize their passwords. In this case, to restrict access to Password Synchronization, you can use the SYNC_USERS attribute in the /etc/sso.conf file to restrict access. For more information, see Using sso.conf to configure Password Synchronization on the UNIX computer.<br><br>To disable UNIX-to-Windows password synchronization, remove the entry in /etc/pam.conf that you added in step 5. |

# Install the pluggable authentication module (PAM) on HP-UX

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To install the pluggable authentication module (PAM) on HP-UX**

1. Copy pam_sso.hpx from IDMU\Unix\Bins on the Windows Server 2003 R2 CD to /usr/lib/security on the UNIX computer, change its name to pam_sso.hp.1, and then set its file-mode bits to 544.

2. On the UNIX computer, open /etc/pam.conf with a text editor.

3. In the **Password management** section, locate the following line:

   **other password required /usr/lib/security/libpam_unix.1**

4. Immediately following the line located in the previous step, add the following line:

   **other password required /usr/lib/security/pam_sso.hp.1**

| **Note** |
| --- |
| To disable UNIX-to-Windows password synchronization, remove the entry in /etc/pam.conf that you added in step 4.<br><br>Before installing the pam_sso module, make sure that PAM support is properly installed and configured on the UNIX computer. The following file samples show a typical configuration. Actual contents of these files may differ, depending on your system configuration.<br><br>Sample HP-UX PAM configuration file |

```
#
# PAM configuration
#
# Authentication management
#
login    auth required  /usr/lib/security/libpam_unix.1
su       auth required  /usr/lib/security/libpam_unix.1
dtlogin  auth required  /usr/lib/security/libpam_unix.1
dtaction auth required  /usr/lib/security/libpam_unix.1
ftp      auth required  /usr/lib/security/libpam_unix.1
OTHER    auth required  /usr/lib/security/libpam_unix.1
#
# Account management
#
login    account required       /usr/lib/security/libpam_unix.1
su       account required       /usr/lib/security/libpam_unix.1
dtlogin  account required       /usr/lib/security/libpam_unix.1
dtaction account required       /usr/lib/security/libpam_unix.1
ftp      account required       /usr/lib/security/libpam_unix.1
#
OTHER    account required       /usr/lib/security/libpam_unix.1
#
# Session management
#
login    session required       /usr/lib/security/libpam_unix.1
dtlogin  session required       /usr/lib/security/libpam_unix.1
dtaction session required       /usr/lib/security/libpam_unix.1
OTHER    session required       /usr/lib/security/libpam_unix.1
#
# Password management
#
login    password required      /usr/lib/security/libpam_unix.1
dtlogin  password required      /usr/lib/security/libpam_unix.1
```

```
dtaction password required      /usr/lib/security/libpam_unix.1
other    password required      /usr/lib/security/libpam_unix.1
other    password required      /usr/lib/security/pam_sso.hp.1
```

The file-mode bits for pam_sso.hp.1 must be set to 544 (o:r-x,g:r--,w:r--) or it will not function properly.

# Install the pluggable authentication module (PAM) on Linux

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To install the pluggable authentication module (PAM) on Linux**

1. Copy pam_sso.rhl from IDMU\Unix\Bins on the Windows Server 2003 R2 CD to /lib/security on the UNIX computer, and change its name to pam_sso.so.1.

2. On the UNIX computer, copy /etc/pam.d/system-auth to /etc/pam.d/ssod.

3. Open /etc/pam.d/system-auth with a text editor, and locate the following line:

   **passwordrequired/lib/security/pam_cracklib.soretry=3**

4. After the line in the previous step, add the following line:

   **password required /lib/security/pam_sso.so.1**

5. Locate and delete the following line:

   **passwordrequired/lib/security/pam_deny.so**

6. Save the modified file.

| **Note** |
| --- |
| These instructions apply to the typical Linux configuration. If you have configured PAM support differently, you might have to adjust these instructions to your specific configuration.<br><br>To disable UNIX-to-Windows password synchronization, remove the entry in /etc/pam.d/system-auth that you added in step 4.<br><br>Before installing the pam_sso module, make sure that PAM support is properly installed and configured on the UNIX computer. # Set default synchronization

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To set default synchronization**

1. Open Identity Management for UNIX.
2. If necessary, connect to the computer you want to manage.
3. Click **Password Synchronization**, and then click the **Default** tab.
4. To allow password synchronization from UNIX-based computers to Windows-based computers, click **Synchronize password changes from computers that run UNIX to computers that run Windows.**
5. To allow password synchronization from Windows-based computers to UNIX-based computers, click **Synchronize password changes from computers that run Windows to computers that run UNIX.**
6. To save the new settings, click **Apply**.

**Note**

To open Identity Management for UNIX, click **Start**, point to **All Programs**, point to **Identity Management for UNIX**, and then click **Identity Management for UNIX**.

To perform this task in the command line environment, see psadmin.

These settings affect the default synchronization for UNIX hosts when they are added for synchronization. It does not affect computers that have already been added for synchronization.

# Set the default encryption key

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To set the default encryption key**

1. Open Identity Management for UNIX.
2. If necessary, connect to the computer you want to manage.
3. Click **Password Synchronization**, and then click the **Default** tab.
4. In the **Encryption key** text box, type the key you want to use, or, to have the program produce a key for you, click **New Key**.
5. To save the new settings, click **Apply**.

**Note**

To open Identity Management for UNIX, click **Start**, point to **All Programs**, point to **Identity Management for UNIX**, and then click **Identity Management for UNIX**.

To perform this task in the command line environment, see psadmin.

This setting affects the default encryption key for UNIX hosts when they are added for synchronization as well as the port used for UNIX-to-Windows synchronization. If you change this setting, you must edit the /etc/sso.conf file to specify the same encryption key on UNIX hosts that are configured for UNIX-to-Windows password synchronization with this computer.

For maximum security, you should use a key that is the maximum 21 characters in length.

# Set the default port

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To set the default port**

1. Open Identity Management for UNIX.
2. If necessary, connect to the computer you want to manage.
3. Click **Password Synchronization**, and then click the **Default** tab.
4. To use a port other than 6677, in the **Port number** box, type the port number you want.
5. To save the new settings, click **Apply**.

**Note**

To open Identity Management for UNIX, click **Start**, point to **All Programs**, point to **Identity Management for UNIX**, and then click **Identity Management for UNIX**.

This setting affects the default port number for UNIX hosts when they are added for synchronization as well as the port used for UNIX-to-Windows synchronization. If you change this setting, you must edit the /etc/sso.conf file to specify the same port on UNIX hosts that are configured for UNIX-to-Windows password synchronization with this computer.

For maximum security, use a port number other than the default (6677).

To perform this task in the command line environment, see psadmin.

# Add and remove computers for synchronization

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**To add and remove computers for synchronization**

1. Open Identity Management for UNIX.
2. If necessary, connect to the computer you want to manage.
3. Click **Password Synchronization**.
4. Click the **Advanced** tab, and then do one of the following:
   - To add a computer to the list of participating computers, in **Computer name**, type the name of the UNIX-based computer you want to add, and then click **Add**.
   - To remove a computer, in the **Current computers** list, click the UNIX-based computer you want to remove, and then click **Remove**.
5. To save the new settings, click **Apply**.

**Note**

To open Identity Management for UNIX, click **Start**, point to **All Programs**, point to **Identity Management for UNIX**, and then click **Identity Management for UNIX**.

To perform this task in the command line environment, see psadmin.

In addition to adding a UNIX-based computer to the list, if you want to change the user's password on the UNIX computer when the corresponding Windows user's password is changed, you must install the Password Synchronization single sign-on daemon (SSOD) on the UNIX-based computer . If you want to change the Windows user's password when the corresponding UNIX-based computer user's password is changed, you must install the pluggable authentication module (PAM) on the UNIX-based computer.

# Understanding Password Synchronization

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Understanding Password Synchronization**
Password Synchronization helps integrate Windows and UNIX networks by simplifying the process of maintaining secure passwords in both environments. Users are freed of the difficulty of maintaining separate passwords for their Windows and UNIX accounts or having to remember to change the password wherever it is used. With Password Synchronization, whenever a user's password is changed on a Windows-based computer or domain, the password can also be automatically changed on every UNIX host for which the user has an account. Password Synchronization can also be configured to change the user's Windows password when the user's UNIX password is changed.

This makes it possible to administer passwords from a single computer, which simplifies things for administrators as well as individual users. Password Synchronization is also flexible: administrators can exclude specific users and systems from being synchronized. Password Synchronization can synchronize passwords on stand-alone Windows-based computers (such as computers running Windows 2000 Server that do not belong to a domain) or for an entire Windows domain. Similarly, Password Synchronization can be used to manage passwords on individual UNIX hosts or on all computers in a Network Information Service (NIS) domain.

Password Synchronization propagates passwords securely by transmitting only encrypted passwords over TCP/IP sockets. This eliminates the need to use nonsecure methods (such as scripts) to administer passwords remotely. Passwords are also synchronized immediately. This means that, unlike methods such as **rdist**, which batches the password propagation, there is no appreciable delay between the time that a password is changed on one system and when it is changed on all other affected systems. This eliminates confusion and frustration for active users. Even more important, perhaps, it eliminates a potential security risk if a password needs to be changed to block a user's access to the network. To enhance network security even further, different encryption keys can be used for each Windows-based computer/UNIX host pair.

Password Synchronization is a combination of three software components:

- The Password Synchronization service running on one or more Windows-based computers
- The Password Synchronization daemon running on one or more UNIX computers
- The Password Synchronization pluggable authentication module (PAM) installed on one or more UNIX computers.

When Password Synchronization is configured for Windows-to-UNIX synchronization and a password is changed on a Windows-based computer running Password Synchronization, the Password Synchronization service determines whether the user's password is to be synchronized on UNIX computers. If it is, the service encrypts the password and sends it to the Password Synchronization daemon on each computer with which the Windows-based computer is configured to be synchronized. The daemon then decrypts the password and changes the password on the UNIX host. If the UNIX host is an NIS master server and it is configured to do so, the daemon also runs **make** to propagate the password change throughout the NIS domain.

When Password Synchronization is configured for UNIX-to-WINDOWS synchronization, passwords that are changed on UNIX hosts are synchronized on Windows-based computers and domains. The Password Synchronization PAM module makes this possible by intercepting the password change request on the UNIX host, encrypting the password, and then sending the password change request to the Password Synchronization service running on the Windows-based computers with which it is configured to be synchronized.

For information about implementing Password Synchronization, see Implementing Password Synchronization.

# Administering Password Synchronization

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

# Implementing Password Synchronization

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Implementing Password Synchronization**

Password Synchronization changes a user's UNIX password whenever the user's password is changed on a Windows-based computer or domain. In addition, Password Synchronization and the affected UNIX hosts can be configured to change the user's Windows password whenever the UNIX password is changed.

Two-way password synchronization is supported on UNIX computers running any of the following operating systems:

- Hewlett-Packard HP-UX version 11i, 32-bit environment
- IBM AIX version 5L 5.2, 32-bit environment
- Red Hat Linux versions 8 and 9, 32-bit environment
- Sun Solaris version 8 running on x86-based computers and Scalable Processor Architecture (SPARC)–based computers, and Solaris version 9 running on SPARC–based computers. The 32-bit environment has been tested on SPARC-based computers.

For more information about how Password Synchronization works on Windows and UNIX computers, see Understanding Password Synchronization.

The remainder of this topic provides information about how to implement password synchronization on Windows and UNIX computers.

**Installing Password Synchronization in Windows**

You can use Password Synchronization to synchronize passwords between a Windows domain and one or more UNIX hosts, or you can use it to synchronize passwords between a stand-alone computer running Windows and one or more UNIX hosts.

To synchronize local account passwords on a Windows-based computer, install Password Synchronization on that computer only. To synchronize Windows domain passwords, you must install Password Synchronization on all domain controllers for that domain. This will ensure that when a domain controller processes a password change request, the Password Synchronization service on that domain controller will be able to synchronize the new password with the appropriate UNIX hosts. For this reason, before you remove Password Synchronization from a domain controller, you should demote the domain controller to a member server to prevent password discrepancies between the Windows domain and the UNIX hosts.

For information about installing Password Synchronization on Windows-based computers, see Install Password Synchronization.

**Installing the Password Synchronization daemon on UNIX hosts**

To allow synchronization of Windows passwords with UNIX hosts, you must install the Password Synchronization daemon on each UNIX host on which passwords are to be synchronized. For information about installing the daemon, see Install the Password Synchronization daemon.

When Password Synchronization receives a request for a password change, it encrypts the password and sends it to all UNIX hosts that are to be synchronized with the Windows-based computer or domain. To process the password change request, the UNIX host must be running the Password Synchronization daemon. This daemon receives the request and changes the password on the UNIX host. In addition, if the UNIX host is a master Network Information Service (NIS) server, the Password Synchronization daemon runs **make** to rebuild the NIS passwd map so it can be replicated to subordinate (slave) servers in the NIS domain.

The Password Synchronization daemon performs event logging through the syslogd daemon running on the UNIX host.

**Installing the pluggable authentication module on UNIX hosts**

Pluggable authentication modules (PAMs) allow a UNIX computer to support multiple authentication technologies. Password Synchronization uses this facility to provide UNIX-to-Windows password synchronization.

To allow passwords on Windows-based computers or domains to be changed when users change their UNIX password, the

Password Synchronization PAM module (pam_sso) must be installed on each UNIX host where users can change their passwords. Much like Password Synchronization running on a Windows-based computer, the Password Synchronization PAM module on a UNIX computer intercepts the password change request, encrypts the password, and then transmits the request to the appropriate Windows-based computers running Password Synchronization.

Like the Password Synchronization daemon, the Password Synchronization PAM module performs event logging through the syslogd daemon running on the UNIX host.

For information about configuring UNIX computers for UNIX-to-Windows synchronization, see Configure UNIX Computers for UNIX-to-Windows Synchronization.

**Synchronizing passwords between Windows and NIS domains**

In addition to synchronizing passwords between Windows-based computers and standalone UNIX hosts, you can also use Password Synchronization to provide one-way (Windows-to-UNIX) synchronization as well as two-way synchronization. For more information, see Synchronizing passwords with an NIS domain.

For security reasons, it is recommended that you perform the Windows Server 2003 Service Pack 1 (SP1) compatibility check when selecting **Enable Windows to NIS (AD) Password Sync** in the Password Synchronization Properties dialog box, Configuration tab. For more information about the compatibility check, see Best practices for Password Synchronization.

**Coordinating account names and password policies**

The password policies on both systems must be similar. If the policy on one system is stronger (more restrictive) than the policy on the other system, Password Synchronization might fail to synchronize passwords, and the failure might not be reported.

In addition, Password Synchronization can only synchronize the passwords of accounts with identical user names. Windows and UNIX administrators must ensure that the user names for the Windows and UNIX accounts of a given user match exactly (including case).

If you are configuring Password Synchronization for one-way (Windows-to-UNIX) synchronization, you should consider disabling the ability of users to change passwords on the UNIX hosts that are to be synchronized with the Windows-based computers. Otherwise, if users change their UNIX passwords, their passwords will no longer be synchronized.

# Synchronizing passwords with an NIS domain

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Synchronizing passwords with an NIS domain**

Using Password Synchronization, you can provide one-way (Windows-to-UNIX) and two-way password synchronization between Windows domains and Network Information Service (NIS) domains. You can do this regardless of whether the master server of the NIS domain is running on UNIX or on Windows (Server for NIS).

If the NIS master server is running UNIX, all that is required to provide one-way synchronization is to install Password Synchronization on all Windows-based computers (for example, on the domain controllers) from which you want to synchronize passwords, and then install the single sign-on daemon (SSOD) on the NIS master server. You then edit the sso.conf file on the NIS master server to do the following:

- Set USE_NIS to 1
- Set NIS_UPDATE_PATH to specify the location of the NIS makefile

This instructs the SSOD to run the makefile and push the changed maps whenever a password change request is received from the Windows domain. For more information and additional instructions, see Install the Password Synchronization daemon.

If Server for NIS is acting as the master server for the NIS domain, no action is required to provide one-way password synchronization because whenever a Windows user's password is changed, Server for NIS automatically updates the UNIX password for NIS clients. If you also need to synchronize passwords with UNIX computers that are not part of the NIS domain, you can install Password Synchronization on the Windows domain controllers and configure the UNIX computers as described earlier in this topic.

Providing UNIX-to-Windows synchronization is similar for both types of NIS domains, and is accomplished by performing the following operations:

- If the NIS master server is running UNIX, set it up for one-way synchronization as described earlier in this topic.
- Install Password Synchronization on all domain controllers. If the NIS master server is a UNIX computer, configure Password Synchronization on Windows for two-way synchronization with the master server. Finally, add each NIS client to the list of computers that Password Synchronization will synchronize with, being sure to enable UNIX-to-Windows synchronization and disabling Windows-to-UNIX synchronization. Windows-to-UNIX synchronization should be enabled *only* for the NIS master server. For more information about adding and configuring computers, see Add and remove computers for synchronization and Set computer-specific synchronization properties.
- Install the Password Synchronization pluggable authentication module (PAM) on each NIS client, and then copy the sso.conf file from the master server to the /etc directory of those clients.
- If the NIS master server is a Windows-based computer running Server for NIS, copy Sso.cfg to one of the NIS clients, set SYNC_HOSTS to specify the computer running Server for NIS as the Windows-based computer to synchronize passwords with, and then copy that file to the other UNIX clients. See Using sso.conf to configure Password Synchronization on the UNIX computer to learn more about settings in this file.
- Configure each UNIX computer to allow users to use the **yppasswd** command to change their passwords. To do this, replace the yppasswd binary file on the UNIX computer with a link to the passwd binary file, and then edit the /etc/nsswitch.conf file to replace the passwd and shadow lines with the following:

  ```
  passwd:  files [NOTFOUND=continue] nis
  shadow:  files [NOTFOUND=continue] nis
  ```

  After you do this, when a user runs the yppasswd command to change the user's password, it is actually the passwd binary file that is run to change the password. If the user's passwd entry is not found in the local passwd and shadow files, the NIS password is changed instead.

# Password Synchronization administration

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Password Synchronization administration**
When you have installed Password Synchronization on the appropriate Windows–based computer, you can administer it with Password Synchronization administration (part of Identity Management for UNIX). You must have administrator privileges on the computer you want to administer.

You can use Password Synchronization administration to:

- Select the server to be administered.
- Set the default settings that apply to the entire configuration of UNIX-based computers defined for the Windows–based computer or domain. The settings determine what the Event Log displays, the maximum number of times to resend the failed password update, and the time the service waits before resending a password update that has failed.
- Add or remove a UNIX-based computer from the list of computers designated to receive password updates.
- Create or modify the configuration for the UNIX-based computer, including the custom settings (the default settings applied to that single computer) and the encryption settings for secure communication. The order in which the names of the UNIX hosts appear in the list determines their order in the registry and the order in which they are processed for password synchronization.

# Password encryption

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Password encryption**

A Windows-based computer can send and receive updated passwords to and from a UNIX-based computer as encrypted text only. The Password Synchronization single sign-on daemon (SSOD) receives the encrypted password and decrypts it before requesting the password change on the UNIX host. Similarly, if Password Synchronization is configured to support UNIX-to-Windows synchronization, the pluggable authentication module (PAM) encrypts the password before sending it to Password Synchronization on the Windows-based computer, which then decrypts the password before requesting the password change on the Windows-based computer.

The password can be successfully decrypted only if Password Synchronization and the SSOD or PAM module use the same encryption key to encrypt and decrypt the password. Before installing the SSOD on any UNIX computer, you must first set the default encryption key. You must then specify the same key in the sso.conf file when you install the SSOD on each UNIX host. This will ensure that Password Synchronization and the SSOD on the UNIX hosts will use the same encryption key. For more information about setting the default encryption key, see Set the default encryption key. For information about installing and configuring the SSOD, see Install the Password Synchronization daemon.

For added security, you can specify an encryption key that is used only between a particular Windows-based computer and a UNIX host. For information about configuring Password Synchronization to use a computer-specific encryption key, see Set computer-specific synchronization properties. For information about setting the computer-specific encryption key on the UNIX computer, see Install the Password Synchronization daemon.

# Encryption key requirements

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Encryption key requirements**

The encryption key must meet the following requirements:

- It must be 16 to 21 characters long (21 is recommended).
- It must contain characters from at least three of the following four groups:
  - Uppercase English letters (A–Z)
  - Lowercase English letters (a–z)
  - Westernized Arabic numerals (0–9)
  - Punctuation symbols ` ~ ! @ # $ % ^ & * _ – + = | \ { } [ ] : ; \ " ' < > . ?
- It must not contain a left or right parentheses (that is a "(" or ")" character), a comma (,), or a blank space ( ).

# Controlling password synchronization for user accounts

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Controlling password synchronization for user accounts**

You can control which users' passwords are synchronized by creating two local user groups: PasswordPropAllow and PasswordPropDeny. (Use the Windows User Manager to create these groups.)

In the PasswordPropAllow group, add the user names for which passwords should be synchronized. In the PasswordPropDeny group, add the user names for which passwords should not be synchronized.

Passwords are synchronized for users who are in PasswordPropAllow and are not in PasswordPropDeny.

If PasswordPropAllow does not exist, the effect is the same as if it did exist with all user names in it. If PasswordPropDeny does not exist, the effect is the same as if it did exist with no user names in it.

These rules apply to synchronization from Windows to UNIX and from UNIX to Windows. If a user's password cannot be synchronized from Windows to UNIX, it cannot be synchronized from UNIX to Windows.

The UNIX administrator can ensure that the passwords for certain users are never synchronized, even if synchronization is allowed by the Password Synchronization server. To ensure that a UNIX user account will never have its password synchronized with the Windows password, edit the sso.conf file to place the user name of the account, preceded by a minus sign (–), after **SYNC_USERS=**. For example, to ensure that the password of the root account is never synchronized with a Windows account by that name, make sure that the following line appears in sso.conf:

**SYNC_USERS=–root**

# Using sso.conf to configure Password Synchronization on the UNIX computer

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Using sso.conf to configure Password Synchronization on the UNIX computer**

To change settings and customize how Password Synchronization works on a UNIX-based computer, you change settings in the sso.conf file. For information about installing the sso.conf file, see Install the Password Synchronization daemon.

The following table describes the values you can set in the sso.conf file.

| Value | Description |
|---|---|
| CASE_IGNORE_NAME | Specifies whether Password Synchronization will ignore differences in uppercase and lowercase letters in user names when it compares Windows and UNIX user names. To allow case-insensitive comparisons, set this entry to 1 (the default). To force Password Synchronization to use case-sensitive comparisons, set this entry to 0. |
| ENCRYPT_KEY | Specifies the default key used to encrypt passwords exchanged with Windows servers. You can use settings in the SYNC_HOSTS value to specify a different encryption key for a specific Windows server. For information about valid encryption keys, see Encryption key requirements. |
| FILE_PATH | Specifies the full path and name of the passwd or shadow file (such as /etc/passwd). This file must contain the encrypted passwords for users, and the type of file (passwd or shadow) must be the same as specified by USE_SHADOW. On AIX systems, the path and name of the shadow file is /etc/security/passwd. |
| IGNORE_PROPAGATION_ERRORS | When set to **1**, specifies that the Password Synchronization PAM module is to ignore any error that occurs when a Windows password is being changed and to continue synchronization with other hosts specified in SYNC_HOSTS. |
| NIS_UPDATE_PATH | Specifies the full path to the NIS makefile. This value is ignored unless USE_NIS is set to **1**. |
| PORT_NUMBER | Specifies the default number of the port on which the Password Synchronization daemon will listen for password changes from Windows servers. You can use settings in the SYNC_HOSTS value to specify a different port number for a specific Windows server. |
| SYNC_DELAY | Specifies the number of seconds the Password Synchronization PAM module will wait between synchronization attempts. |

| | |
|---|---|
| SYNC_HOSTS | Specifies the Windows servers or domain controllers with which passwords are to be synchronized. In addition, you can specify a port number or encryption key (or both) for a specific server. Enclose each entry in parentheses and separate items with a blank space. You can have multiple entries on separate lines, each of which cannot exceed 269 characters. The total list of servers or domain controllers is generated by concatenating all entries. For example:<br><br>`SYNC_HOSTS=(Marketing)`<br>`SYNC_HOSTS=(Sales,ASDFhjkl4321ZyXw) (Accounting,6678)`<br>`SYNC_HOSTS=(Shipping,6678,ASDFhjkl4321ZyXw)`<br><br>synchronizes passwords with the Marketing server using the default port and encryption key, with the Sales server using ASDFhjkl4321ZyXw as the encryption key, with the Accounting server using 6678 as the port number, and with the Shipping server using 6678 as the port number and ASDFhjkl4321ZyXw as the encryption key.<br><br>If you use server-specific port number or encryption key settings, you must use the same values to configure Password Synchronization on the Windows server, or the passwords will not be synchronized. For information about configuring Password Synchronization on the Windows server, see Configure Password Synchronization. |
| SYNC_RETRIES | Specifies the number of times that the Password Synchronization PAM module will attempt to synchronize a password change with a Windows server or domain controller. |
| SYNC_USERS | Specifies UNIX users whose passwords are to be synchronized. You can specify ALL to synchronize passwords for all users or NONE to disable password synchronization for users. You can also specify particular users. If you specify one or more users preceded by plus signs (**+**), only those users will have their passwords synchronized. If you specify one or more users preceded by minus signs (**–**), all users except the specified users will have their passwords synchronized. For example, to allow only users bobg and kimr to synchronize their passwords, specify:<br><br>`SYNC_USERS=+bobg +kimr`<br><br>To prevent only root and bobg from having their passwords synchronized, specify:<br><br>`SYNC_USERS=-root -bobg`<br><br>The minus sign always takes precedence, regardless of the order in which entries appear. For example, the following specifies that the password for user chrisa will not be synchronized:<br><br>`SYNC_USERS=+chrisa -chrisa +chrisa` |
| TEMP_FILE_PATH | Specifies the full path of the directory to be used to hold a temporary file while the passwd or shadow file is updated. This should be the same directory in which the passwd or shadow file is located. For security reasons, only the administrator should have access to this directory. |
| USE_NIS | Set to **0** if Password Synchronization is not synchronizing with an Network Information Service (NIS) domain; set to **1** if Password Synchronization is synchronizing with an NIS domain. If USE_NIS is set to **1**, specify a valid path for NIS_UPDATE_PATH. |
| USE_SHADOW | Set to **0** if the passwd file is to be used for synchronization; set to **1** if the shadow file is to be used. |

# Troubleshooting Password Synchronization

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Troubleshooting**
What trouble are you having?

- User cannot log on to UNIX system after changing Windows password
- Passwords fail to synchronize in a Windows domain, seemingly at random
- User's password is changed on some, but not all, computers
- Error ID 4104 is recorded in the event log for a system account, which usually has a name ending with a dollar sign ($)
- An error message about the encryption key is recorded in Event Viewer after Password Synchronization installation completes
- I cannot stop the single sign-on daemon (SSOD) using kill -TERM on Linux

**User cannot log on to UNIX system after changing Windows password**
**Cause:** Windows does not report a problem if an attempt to synchronize a UNIX password with a new Windows password fails.

**Solution:** Check the Windows event log to determine why the attempt to change the password on the UNIX system failed.

**Passwords fail to synchronize in a Windows domain, seemingly at random**
**Cause:** Password Synchronization is not configured identically on all domain controllers in the domain. As a result, if a nonconforming domain controller accepts a user's password change, it might not be able to change the password on UNIX computers.

**Solution:** Ensure that Password Synchronization is configured identically on all domain controllers, particularly host settings and default settings for encryption keys and ports.

**User's password is changed on some, but not all, computers**
**Cause:** Password policies are more restrictive on some computers, user names do not match between Windows and UNIX computers, or the user changed the password on a UNIX computer when two-way synchronization is not set up.

**Solution:** Ensure that password policies on Windows and UNIX computers that synchronize passwords are similar. Otherwise, if the user changes the password on the less restrictive computer, the more restrictive system might not accept the new password. Password policies that govern minimum and maximum length, character case and alphanumeric mix, expiration, and reuse must be as close as possible between Windows and UNIX computers that synchronize passwords. Also, Windows and UNIX system administrators must ensure that that user names, including case, are identical on the Windows and UNIX computers.

**Error ID 4104 is recorded in the event log for a system account, which usually has a name ending with a dollar sign ($)**
**Cause:** This error does not indicate a problem. It is logged when a backup domain controller or domain member server resets its secure channel with the domain. When this happens, the server password is also reset. Password Synchronization intercepts these password change requests; because they are for computer accounts rather than for user or group accounts, Password Synchronization logs error number 4104.

**Solution:** No corrective measures are necessary.

**An error message about the encryption key is recorded in Event Viewer after Password Synchronization installation completes**
**Cause:** This error does not indicate a problem; it is a reminder for the Password Synchronization administrator to change the default encryption key. Changing the default encryption key is a security best practice for Password Synchronization, and helps prevent unauthorized users from obtaining passwords. Typically, the description text of this error message is "Default encryption key is insecure. Please generate new encryption key."

**Solution:** Set a new encryption key by using the procedure in the topic Set the default encryption key.

**I cannot stop the single sign-on daemon (SSOD) using kill -TERM on Linux**

**Cause:** This is a known limitation.

**Solution:** Use **kill 9** *SSOD_PID* instead.

# Command-line utility

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**Command-line Utility**
The following command-line utility is available to administer Password Synchronization:

psadmin

# psadmin

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

**psadmin**
**NAME**
psadmin - Windows command-line utility to manage Password Synchronization

**SYNOPSIS**

```
psadmin [computername] [common_option] [add | delete | list]
psadmin [computername] [common_option] config [config_option]
```

**DESCRIPTION**
The **psadmin** Windows command-line utility manages the Password Synchronization component of Identity Management for UNIX, either on a specified computer, or globally. The specific action that **psadmin** performs depends on the command argument you specify.

In addition to specific command arguments, **psadmin** accepts the following common options and arguments, represented by *common_option* in the command synopsis:

| Term | Definition |
|---|---|
| **-u** *username* | The account name of the user whose password synchronization behavior you want to modify or view. |
| **-p** *password* | The password for the user account whose password synchronization behavior you want to modify or view. |
| **-?** | Displays usage information for the command. |

The following configuration options are accepted by **psadmin**:

| Term | Definition |
|---|---|
| **-comp** *name* | Computer to which configuration options are applied. If **-comp** is unspecified, Password Synchronization modifies the default configuration settings. If **-comp** is the only option specified, then Password Synchronization configuration of the specified computer is displayed. |
| **-enable** *direction* | Specifies the direction of password synchronization. The variable *direction* can contain one of the following values:<br><br>**WintoUnix**: Synchronize password changes from computers that run Windows operating systems to computers that run UNIX operating systems.<br><br>**UnixToWin**: Synchronize password changes from computers that run UNIX operating systems to computers that run Windows operating systems.<br><br>**BothDir**: Enable two-way password synchronization. |
| **-key** *keyvalue* | Sets the encryption and decryption key for the computer specified by **-comp**. If *keyvalue* is random, Password Synchronization uses a random encryption key. |
| **-port** *number* | Sets the port number for the specified computer. |
| **-retry** *number* | Specifies the number of retries allowed. Because this option is a global setting, it can be used only when **-comp** is not used. |
| **-interval** *secs* | Specifies the elapsed time period, in seconds, between retries. Because this option is a global setting, it can be used only when **-comp** is not used. |
| **-log** [**yes** \| **no**] | Enables or disables logging. Because this option is a global setting, it can be used only when **-comp** is not used. |

| | |
|---|---|
| **-?** | Displays **psadmin** usage and arguments. |

The following command arguments are accepted by **psadmin**:

| Term | Definition |
|---|---|
| **add** *computername* | Adds the specified computer to the list of computers participating in password synchronization. |
| **delete** *computername* | Deletes the specified computer from the list of computers participating in password synchronization. |
| **list** | Displays the list of computers participating in Password Synchronization. |

Configure Password Synchronization

# Accessibility Features of Identity Management for UNIX

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Products in the Windows Server 2003 family include a number of accessibility features that can improve display, sound, mouse, and keyboard settings for users who are blind, have motion disabilities, or are deaf or hard of hearing. Many accessibility features are also useful to people without disabilities.

**Accessibility Features and Options**
Because Identity Management for UNIX tasks can be completed using either a Windows-based interface or shell commands, accessibility options are available for both computing environments.

**Accessibility Features and Options for Windows-based Tools in Identity Management for UNIX**
For more information about accessibility features and options, see Accessibility for People with Disabilities on the Microsoft Windows Server 2003 TechCenter.

Because the Windows-based management tool for Identity Management for UNIX is a Microsoft Management Console (MMC) 3.0 snap-in, Identity Management for UNIX shares applicable MMC 3.0 accessibility features. For more information about accessibility in MMC, see Accessibility for MMC.

**Accessibility Features and Options for the Command-line Environment**
For information about keyboard shortcuts that can provide greater accessibility to users of command-line and UNIX-based shell computing environments, refer to the Help and release notes provided with the Utilities and Software Development Kit (SDK) for UNIX-based Applications installation package, available for download from the Microsoft Web site.

# Welcome to Subsystem for UNIX-based Applications

Updated: March 13, 2006

Applies To: Windows Server 2003 R2

Subsystem for UNIX-based Applications (SUA) is a source-compatibility subsystem for compiling and running custom UNIX-based applications on a computer running a Windows server-class operating system. You can make your UNIX applications fully interoperable with Windows in SUA with little or no change to your original source code.

Subsystem for UNIX-based Applications provides an operating system for Portable Operating System Interface (POSIX) processes. SUA, along with its package of support utilities (such as shells and a Telnet client) available for download on the Microsoft Web site, provides a complete UNIX environment. The download package includes a comprehensive set of scripting utilities, and a software development kit (SDK) designed to fully support the development capabilities of SUA and to provide a complete UNIX-based application development experience.

SUA also supports case-sensitive file names, job control, compilation tools, and the use of over 300 UNIX commands, utilities, and shell scripts. Because the subsystem installs separately from the Windows kernel, it offers true UNIX functionality without any emulation.

**New features for Windows Server 2003 Release 2**
New features for Windows Server 2003 Release 2 (R2) include the following:

- **Database (OCI/ODBC) library connectivity.** SUA supports connectivity to Oracle and SQL Server from database applications by using the Oracle Call Interface (OCI) and the Open Database Connectivity (ODBC) standard.
- **Microsoft Visual Studio Debugger Extension for debugging POSIX applications.** SUA includes support for debugging your POSIX processes using Visual Studio IDE.
- **Utilities based on SVR-5 and BSD UNIX environments.** The SUA download package supports two different UNIX environments: SVR-5 and BSD.
- **Support for 64-bit applications.** Using a process called thunking, SUA provides support not only for 64-bit applications running on a 64-bit operating system, but also default support for 32-bit binaries running on a 64-bit operating system.

For more information, and to download the scripting utilities and SDK, see the Microsoft Web site.

**In this topic**

- Subsystem for UNIX-based Applications Overview
- Installing and Using Utilities and SDK for Subsystem for UNIX-based Applications
- Case Sensitivity in Subsystem for UNIX-based Applications
- Setting setuid in Subsystem for UNIX-based Applications
- POSIX Compliance in Subsystem for UNIX-based Applications

# Subsystem for UNIX-based Applications Overview

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Subsystem for UNIX-based Applications (SUA) is the next-generation of Microsoft's POSIX subsystem, similar to the Interix subsystem that formerly shipped with Windows Services for UNIX 3.5 or previous POSIX subsystems that shipped with Windows 2000 and NT 4.0. Subsystem for UNIX-based Applications and its accompanying utilities provide you with an environment that resembles any other UNIX system. It also includes case-sensitive file names, job control, compilation tools, and the use of over 300 UNIX commands and utilities and shell scripts. Because the Subsystem for UNIX-based Applications is layered on top of the Windows kernel, it offers true UNIX functionality without any emulation.

**Installing Subsystem for UNIX-based Applications**
Subsystem for UNIX-based Applications is available with Windows Server 2003 Release 2 (R2). You can install SUA using the procedures provided in the topic Install an optional component by using Add/Remove Windows Components.

**Computing Environments with Subsystem for UNIX-based Applications**
A computer running SUA provides two different command-line environments: the UNIX environment and the Windows environment. Applications run on specific subsystems and in specific environments. When you load Subsystem for UNIX-based Applications, you are using a UNIX environment; when you run applications on the Windows subsystem, you are using a Windows environment.

For example, when you use the Korn shell or C shell available with the download package Utilities and Software Development Kit (SDK) for UNIX-based Applications, or any other application that was compiled to run on SUA, you are using a UNIX environment. Among other things, this environment features case-sensitive file names and path names that use the format /usr/examples. For more information about the commands and utilities that are available in the Subsystem for UNIX-based Applications, see the Help files that ship with the download package Utilities and Software Development Kit (SDK) for UNIX-based Applications. This download package is available from the Microsoft Web site.

When you use the command processor **cmd.exe**, you are using the Windows environment. This environment includes case-insensitive file names, and path names that include drive letters, as shown in the following example: C:\SUA\usr\examples. For more information about path names in the Subsystem for UNIX-based Applications and Windows, see the Help files that ship with the download package Utilities and Software Development Kit (SDK) for UNIX-based Applications.

**Porting Applications by Using Subsystem for UNIX-based Applications**
Subsystem for UNIX-based Applications provides both the tools and the application programming interface (API) libraries for porting applications to run on Windows-based computers. With the Software Development Kit (SDK), which provides a front end for Microsoft Visual C++, you can have a UNIX environment for development, but still have the benefits of the native compiler for Windows. For more information about path names in Subsystem for UNIX-based Applications and Windows, see the Help files that ship with the download package Utilities and Software Development Kit (SDK) for UNIX-based Applications.

# Installing and Using Utilities and SDK for Subsystem for UNIX-based Applications

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The download package available from the Microsoft Web site, **Utilities and Software Development Kit (SDK) for UNIX-based Applications**, is designed to work with the Subsystem for UNIX-Based Applications (SUA) component that ships with Microsoft Windows Server 2003 Release 2 (R2).

**Components Included with Download Package**
The download package contains the following components:

- Base Utilities
- SVR-5 Utilities
- Base SDK
- GNU SDK
- GNU Utilities
- UNIX Perl
- Visual Studio Debugger Extension

In addition to the features provided in Windows Services for UNIX 3.5, the download package supports 64-bit application development with SUA. The download also enables development and porting of custom UNIX applications using the Windows Oracle Call Interface (OCI) and Windows ODBC libraries (collectively referred to as "mixed mode" throughout this document).

**Base Utilities, GNU Utilities, SDK and UNIX Perl**
These components include all utilities that formerly installed with Windows Services for UNIX 3.5. This consists of the nearly 300 BSD-based and optional SUA GNU utilities. Many of these utilities (approximately 80) are also available in 64-bit versions.

GNU components include utilities and SDK tools distributed under the terms of the GNU General Public License (GPL).

See the Help and release notes provided with the installation package for a complete listing of base utilities.

**SVR-5 Utilities**
This set consists of a Korn shell and approximately 150 utilities, most of which support SVR-5. These utilities currently are available in 32-bit versions, and may fail in specific 64-bit scenarios; however, the utilities run on WOW 64-bit platforms.

See the Help and release notes provided with the installation package for a complete listing of SVR-5 utilities.

**Base SDK**
The current release supports most of the libraries and headers installed with Windows Services for UNIX 3.5. These support both 32-bit and 64-bit SUA-related software migration and development.

This SDK consists of the following libraries and corresponding header files: Standard C Library, Standard C++ Library and Math Library. The C++ library and the math library are functional equivalents of those supplied by Microsoft as part of their Visual Studio environment. Standard C Library and Math Library are available for both 32-bit and 64-bit platforms. Standard C++ Library is available for both 32-bit and 64-bit binaries, and supports multithreaded applications.

**Compiler Compatibility**
The Base SDK package can be used with either the gcc (GNU C compiler) and g++ (GNU C++ compiler) compilers, or the Visual Studio 2005 compiler. Linking to shared objects is not supported with the Visual Studio 2005 compiler. The C++ library supplied with this package is compatible with the Visual Studio 2005 compiler, and can be used with c89.

The g++ compiler uses its own library for C++ compilation.

**System Requirements**
The Utilities and SDK for Subsystem for UNIX-based Applications package installs only on Windows Server 2003 R2.

The minimum system requirements for installing Utilities and SDK for Subsystem for UNIX-based Applications depends on which components you are installing and the file system of the disk where the components will be installed.

The maximum disk space required to install all Utilities and SDK for Subsystem for UNIX-based Applications components is approximately 350 MB.

**Additional Requirements**

- To receive product support, you must install the latest Windows service pack before installing Utilities and SDK for Subsystem for UNIX-based Applications, and then continue to install additional Windows service packs as they become available.
- You must install Utilities and SDK for Subsystem for UNIX-based Applications on a partition that is formatted with the NTFS file system. File system operations on FAT partitions are not supported.
- It is recommended that the computer have at least 16 MB of RAM in addition to the recommended minimum configuration for the operating system.

**Installation Options**
You can choose one of the following installation options when installing Utilities and SDK for Subsystem for UNIX-based Applications:

- Standard Installation
- Custom Installation

The following table shows which components are installed on a computer as part of the standard installation (Standard) and which additional components are available as part of a customized installation (Custom). If you select the customized installation, you can choose not to install components that are automatically installed as part of the standard installation. These components can only be installed on Windows Server 2003 R2.

| Component | Type of Installation |
|---|---|
| Base utilities | Standard |
| Base SDK | Standard |
| SVR-5 utilities | Custom |
| GNU utilities | Custom |
| GNU SDK | Custom |
| UNIX Perl | Custom |
| Visual Studio Debugger Extension | Custom |

**Note**
If you are upgrading from Windows Services for UNIX 3.5, existing settings are saved during R2 installation, and are restored during the setup process for Utilities and SDK for Subsystem for UNIX-based Applications.

**Installing Utilities and SDK for Subsystem for UNIX-based Applications by Using the Windows Interface**
The following installation options are available:

- Standard Installation
- Custom Installation

#### Standard Installation

### To perform a standard installation

1. Download the Utilities and SDK for Subsystem for UNIX-based Applications from the Microsoft Web site
2. In the Utilities and SDK for Subsystem for UNIX-based Applications Wizard dialog box, click **Next**.
3. In the **User name** text box, type your name. If the name of your organization does not show in the **Organization** field, enter the name of your organization.
4. Read the End User License Agreement (EULA) carefully. If you accept the terms of the agreement, click **I accept the terms in the License Agreement**, and then click **Next** to continue installation. If you click **I do not accept the License Agreement (Exit Setup)**, the installation procedure terminates.
5. To install default Utilities and SDK for Subsystem for UNIX-based Applications components in the default directory, click **Standard Installation**, and then click **Next**. To customize your installation, see Custom Installation.

#### Custom Installation

### To perform a custom installation

1. Download the Utilities and SDK for Subsystem for UNIX-based Applications from the Microsoft Web site .
2. In the Utilities and SDK for Subsystem for UNIX-based Applications Wizard dialog box, click **Next**.
3. In the **User name** text box, type your name. If the name of your organization does not show in the **Organization** field, enter the name of your organization.
4. Read the End User License Agreement (EULA) carefully. If you accept the terms of the agreement, click **I accept the terms in the License Agreement**, and then click **Next** to continue installation. If you click **I do not accept the License Agreement (Exit Setup)**, the installation procedure terminates.
5. To install default Utilities and SDK for Subsystem for UNIX-based Applications components in the default directory, click **Standard Installation**, and then click **Next** (see Standard Installation in the preceding section). If you want to specify a different set of components or a different installation location, click **Custom Installation**, and then click **Next**.
6. Click to fill the check boxes for each component that you want to install, and then click the appropriate option. If you do not want to install a component, click the icon next to the component, and then click **Entire feature will not be available**. When you are finished specifying the components to install, click **Next**.
7. If you are installing the GNU Software Development Kit (SDK), read the information about the GNU Library General Public License carefully. If you want to install the GNU SDK, click **Next** to continue installation. To make changes to the components you have selected click **Back**.

**Note**

After you have installed Utilities and SDK for Subsystem for UNIX-based Applications, you can install additional components or remove installed components.

Utilities and SDK for Subsystem for UNIX-based Applications components cannot be run from a network server. All files must be installed on the local computer.

Standard installation does not provide a complete UNIX development environment. To obtain all of the GNU compilers, build tools, and other SDK components, you must select **Custom Installation** and then select **GNU SDK**.

Once Utilities and SDK for Subsystem for UNIX-based Application is installed, **setuid** behavior is disabled by default. This affects the behavior of certain SUA programs.

In this installation, case sensitivity will not be enabled for object names (such as file names) in non-Win32 subsystems.

#### Installing Utilities and SDK for Subsystem for UNIX-based Applications by Using the Command Line

Perform the following step to start a command-line installation of the Utilities and SDK for Subsystem for UNIX-based Applications.

**To perform a command-line installation**

- At a command prompt, enter the following:

  **msiexec /i** [path\]**setup.msi** [**ADDLOCAL="**component[,component...]**"**] {/**qb**|/**q**}

The following table describes the arguments and options for this command.

| Argument/Option | Description |
|---|---|
| path | The fully qualified path of the Utilities and SDK for Subsystem for UNIX-based Applications setup.msi file. If you omit the path, the setup.msi file must be in the current directory. |
| /qb | Installs Utilities and SDK for Subsystem for UNIX-based Applications with a basic user interface. You must specify either the /q or /qb option; otherwise, the results will be unpredictable. |
| /q | Installs Utilities and SDK for Subsystem for UNIX-based Applications with no user interface or display. This option allows you to perform an unattended installation. You must specify either the /q or /qb option; otherwise, the results will be unpredictable. |

**Note**

This command completes only a standard installation.

For security purposes, all SUA services (also called daemons) are disabled by default. To manage SUA services, edit the **/etc/inetd.conf** file.

# Case Sensitivity in Subsystem for UNIX-based Applications

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

In Windows-based operating systems, the names of most objects (such as files and directories) are case preserving, but case insensitive. That means you can use uppercase and lowercase characters when naming such objects, but Windows does not distinguish between names based on case alone. For example, you cannot have two files in the same directory named sample.txt and Sample.txt because Windows regards the names to be identical for the purposes of identifying files.

**Case Sensitivity and Subsystem for UNIX-based Applications**

The UNIX operating system, by contrast, is fully case sensitive, and so UNIX computers distinguish between object names when the only difference between those names is the case of characters used in the object names. On most UNIX computers, therefore, sample.txt and Sample.txt could be stored in the same directory, and the UNIX computer would distinguish between them when performing operations on the files. For example, the command **rm S*.txt** would delete Sample.txt, but not sample.txt.

In order to implement typical UNIX behavior, the Subsystem for UNIX-based Applications is normally case sensitive when working with file names. This can present security issues, particularly for Windows users who are accustomed to the case-insensitive conventions of Windows. For example, a Trojan horse version of edit.exe named EDIT.EXE could be stored in the same directory as edit.exe. If a user were to type **edit** at a Windows command prompt, the Trojan horse version (EDIT.EXE) could be executed instead of the standard version. If case sensitivity is enabled, Windows users should be made aware of this possibility.

**Restoring Case Sensitivity Defaults**

In Windows XP and in Windows Server 2003 operating systems, the default behavior of subsystems other than the Win32 subsystem is to be case preserving but case insensitive; in previous versions of Windows, such subsystems were fully case sensitive by default. To support standard UNIX behavior, you can change the default Windows XP and Windows Server 2003 behavior for non-Win32 subsystems when installing the base utilities that are part of the download package Utilities and SDK for Subsystem for UNIX-based Applications. If you enable case sensitivity and then subsequently uninstall the base utilities, setup restores the default, case-insensitive behavior of non-Win32 subsystems.

For more information about changing case sensitivity settings, see Configuring case sensitivity for file and folder names.

# Setting setuid in Subsystem for UNIX-based Applications

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

On many systems, a root user or superuser has complete control of the system. Subsystem for UNIX-based Applications (SUA) does not recognize a root user. When the Portable Operating System Interface (POSIX) standard was developed, the concept of a root user was considered an administrative issue. Instead of a root user, the POSIX standard defines appropriate privileges for some operations.

**In This Topic**

setuid and setgid

Subsystem for UNIX-based Applications and Identities

Setup Considerations for setuid in Subsystem for UNIX-based Applications

**setuid and setgid**

The **setuid** and **setgid** mechanisms allow a program, when run, to adopt certain aspects of a security principal other than that of the user running the program. They allow the program to alternate these aspects between those of the invoking user and those of another security principal.

Appropriate privileges are distinct from this. The setuid and setgid mechanisms allow an application to control the answer to the question: "Who are you?" Appropriate privileges answer the question: "What can you do?"

**Subsystem for UNIX-based Applications and Identities**

In typical UNIX environments, there is exactly one user to whom all privileges are granted. That user, typically called **root**, has **uid == 0**. In SUA, all supported privileges on a given system are granted to users who are members of either the Administrators group or the Domain Administrators group on that system. You do not need to log on as Administrator. Any user with membership in either the Administrators group or the Domain Administrators group possesses **root** privileges. Not all privileges defined in POSIX or UNIX are available in SUA; that is, there are certain privileges that are not granted to any user.

Appropriate privileges are typically required for a variety of actions. These include accessing the file system, sending signals to other processes (process control), or changing the effective user identifier (UID) or group identifier (GID) for a process in order to change the ability of that process to perform certain actions.

According to the POSIX standard, a file has permissions that include bits to set a UID (**setuid**) and set a GID (**setgid**). If either or both bits are set on a file, and a process executes that file, the process gains the UID or GID of the file. When used carefully, this mechanism allows a nonprivileged user to execute programs that run with the higher privileges of the file's owner or group. When used incorrectly, however, this can present security risks by allowing nonprivileged users to perform actions that should only be performed by an administrator. For this reason, SUA does not support this mechanism by default. Instead, if you attempt to execute a file with either the **setuid** or **setgid** bit set, SUA does not execute the file and returns the error code **ENOSETUID**.

**Setup Considerations for setuid in Subsystem for UNIX-based Applications**

If you rely on an application that requires standard POSIX behavior, you can configure SUA to execute files with the **setuid** or **setgid** bits set. If SUA is configured in this way, when a process executes a file that has the **setuid** or **setgid** bit set, SUA constructs local security tokens for the process with the privileges assigned to the owner or group of the file. Because the tokens are local, they are not recognized by other computers on the network. This means that, even if the file is owned by a member of the Domain Administrators group, for example, the process does not have trusted access through Windows networking to other computers in the domain. Instead, the privileges will be effective only on the computer on which the process is running.

For example, a process executes a program file with its **setuid** bit set and owned by a member of the Domain Administrators group. If that program attempts to change a domain user's password, that attempt will fail because the security tokens of the process are local and so are not recognized by other systems in the domain. If, on the other hand, the program attempts to change a local user's password, the attempt will succeed because the file's owner is a member of the Domain Administrators group, which typically belongs to the local computer's Administrators group. For information about how to configure SUA to execute files with the **setuid** or **setgid** bits set, see the Help files that ship with the download package Utilities and Software Development Kit (SDK) for UNIX-based Applications.

For the **setuid(2)**, **setgid(2)**, and **chroot(2)** functions, a process must have the effective UID that maps back to the system account, the Administrator account for the local domain, or the Administrator account for the principal domain. The local

Administrator account can only change the UID or GID to another ID in the same domain.

For **chown(1)**, **chmod(1)**, and **chgrp(1)**, an account must have the Windows privileges SE_BACKUP and SE_RESTORE to perform **make** operations on files owned by another user or group, or to modify permissions on a file owned by another user. These permissions typically belong to the Administrator and Backup Operator accounts.

# POSIX Compliance in Subsystem for UNIX-based Applications

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

Subsystem for UNIX-based Applications (SUA) provides a Portable Operating System Interface-compliant (POSIX-compliant) subsystem that runs UNIX shells, utilities, and applications natively alongside Windows applications. This topic describes some of the working considerations for users requiring a POSIX-compliant operating system.

**POSIX Shell Compatibility**

The SUA Korn shell follows traditional Korn shell behavior, which is almost identical to POSIX behavior. If you need strict POSIX conformance, which some work environments require, see the differences between the Korn shell and POSIX in the **ksh(1)** documentation in the Help files found in the download package Utilities and Software Development Kit (SDK) for UNIX-based Applications.

To get full POSIX.2 conformance from the Korn shell, you must run it in POSIX mode. To run the Korn shell in POSIX mode, either open the Korn shell with the **-o posix** option, run the command set **-o posix** from within the shell, or set the **POSIXLY_CORRECT** shell parameter.

POSIX conformance is not supported in the C shell. Unlike the Korn shell, the C shell has no POSIX-mode command options.

**Traverse Checking of Directory Permissions**

By default, Windows users have permissions to move through a directory tree, though they might not have permissions to access each directory in the path. On POSIX systems, you cannot access a directory unless you have permission to access every directory in the path to the directory. This POSIX behavior is known as traverse checking.

For example, if you do not have permission to access a directory, you cannot change the current directory to any of its subdirectories, even if you have permission to access the subdirectories. By default in Windows, you can change the current directory to any subdirectories for which you have permission.

In Windows, there is a special permission called the Traverse Folder/Execute File permission, which you can set for a user or group. You can configure this permission to allow or deny movement through a directory tree. The Traverse Folder permission takes effect only when the group or user is not granted the Bypass Traverse Checking user right in the Group Policy snap-in. In Windows 2000, by default, the **Everyone** group is given the Bypass Traverse Checking user right. In Windows XP and the Windows Server 2003 operating systems, the **Administrators**, **Backup Operators**, **Everyone**, **Power Users**, and **Users** groups are all given this right. For strict conformance with POSIX standards, remove the Bypass Traverse Checking right from all users and groups except **Backup Operators**. To conform to privileges granted to the root user on many other UNIX implementations, remove the Bypass Traverse Checking right from all users except **Administrators** and **Backup Operators**.

# System Calls Supported by Subsystem for UNIX-based Applications

Updated: August 22, 2005

Applies To: Windows Server 2003 R2

The **syscall**(2) function performs the system call whose assembly language interface has the specified number with the specified arguments. Symbolic constants for system calls can be found in the header file **<sys/syscall.h>**.

For more information about the **syscall** function, see the Help and release notes provided with the Utilities and Software Development Kit (SDK) for UNIX-based Applications installation package, available for download from the Microsoft Web site.

**Supported System Calls**

The following system calls are supported by Subsystem for UNIX-based Applications:

| | | | | | | |
|---|---|---|---|---|---|---|
| _control87 | _controlfp | _exit | _getInstallPath | _getInstallPath_Win | _prefixInstallPath | _prefixInstallPath_Win |
| _tolower | _toupper | Aa64l | abort | abs | accept | access |
| acos | acosh | alarm | alloca | alphasort | arc4random_addrandom | arc4random |
| arc4random_stir | asctime | asctime_r | asin | asinh | assert | atan |
| atan2 | atan2f | atanf | atanh | atexit | atof | atoi |
| atol | auth_destroy | authenticateuser | authnone_create | authunix_create | authunix_create_default | Bbasename |

# Anonymous Users and Traverse Checking Settings

Applies To: Windows Server 2003 R2

On computers running Windows XP and Windows Server 2003 operating systems, the Everyone group no longer includes anonymous users by default. This change reduces the number of network resources available by default to anonymous users and simplifies how network administrators can control access by anonymous users.

**Implications of Limiting Anonymous Access**
With the default denial of anonymous user access, it is easier for administrators to configure a secure system.

The default access control lists (ACLs) on earlier versions of Windows that granted the Everyone group access to resources, and potentially exposed them to attack, no longer grant this access to anonymous users after the computer has been upgraded to Windows XP or Windows Server 2003 operating systems.

Anonymous users cannot accidentally be granted access to resources as in the past, when administrators may not have been aware that anonymous users were included in the Everyone group.

This change affects anonymous users attempting to access resources hosted on computers running Windows XP and Windows Server 2003 operating systems. When a Windows 2000-based system is upgraded to Windows XP or Windows Server 2003, resources with ACLs that grant access to everyone (and not explicitly to Anonymous Logon), are no longer available to anonymous users after the upgrade. In most cases, this is an appropriate restriction of anonymous access.

You can still allow anonymous access to selected shared directories and files by adding the Anonymous Logon group to the discretionary access control lists (DACLs) protecting those resources. In addition, you should grant the **Bypass Traverse Checking** user right to the Anonymous Logon group. For more information, see. To bypass traverse checking for anonymous users in Windows XP and Windows Server 2003 operating systems.

In some situations, it may be difficult to determine which resources must grant anonymous access, or to modify the permissions on all the necessary resources. If so, you can configure Windows XP and Windows Server 2003 to permit anonymous access by the Everyone group. For more information, see To allow anonymous access by the Everyone group in Windows XP and Windows Server 2003 operating systems.

**To bypass traverse checking for anonymous users in Windows XP and Windows Server 2003 operating systems**

1. Click **Start**, point to **Control Panel**, point to **Administrative Tools**, and then click **Local Security Policy** (or **Domain Security Policy** on a domain controller).

2. In the console tree, open **Security Settings**, open either **Local Policies** or **Domain Policies**, and then click **User Rights Assignment**.

3. In the details pane, right-click **Bypass traverse checking**, and then click **Properties**.

4. Click **Add User or Group**.

5. In the **Select Users, Computers, or Groups** dialog box, type **Anonymous Logon** in the **Enter the object names to select** list box.

6. Click **Check names** to verify that your entry is valid, and then click **OK**.

| **Note** |
| --- |
| There is no command-line method for this procedure. |

**To allow anonymous access by the Everyone group in Windows XP and Windows Server 2003 operating systems**

1. Click **Start**, point to **Control Panel**, point to **Administrative Tools**, and then click **Local Security Policy** (or **Domain Security Policy** on a domain controller).

2. In the console tree, open **Security Settings**, open either **Local Policies** or **Domain Policies**, and then click **Security**

**Options**.

3. In the details pane, right-click **Network access: Let Everyone permissions apply to anonymous users**, and then click **Properties**.

4. To allow permissions applied to the **Everyone** group to apply to anonymous users, click **Enabled**.

5. Or, to prevent permissions applied to the **Everyone** group from applying to anonymous users, click **Disabled**.

6. Click **OK**.

| **Note** |
| --- |
| There is no command-line method for this procedure. |

# Print Management feature overview

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2

Print Management in the Microsoft® Windows Server™ 2003 R2 operating system provides a single interface that administrators can use to perform printer and print server management tasks efficiently with detailed control. You can use Print Management from any computer running Windows Server 2003 R2, and you can manage all network printers on print servers running Windows 2000 Server, Windows Server 2003, or Windows Server 2003 R2.

Use Print Management to perform the following tasks:

- Add printers to the local print server automatically
- Add and remove print servers
- Create a new printer filter
- Perform printer management tasks
- View extended features for your printer
- Deploy printers by using Group Policy
- Resources for Print Management

© 2005 Microsoft Corporation. All rights reserved.

# Add printers to the local print server automatically

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Vista

Print Management (Printmanagement.msc) can automatically detect all printers located on the same subnet as the print server, install the appropriate printer drivers, set up the queues, and share the printers. Unless a printer driver cannot be found, no intervention is needed.

If you want to automatically detect printers for a branch office or another location beyond the subnet of your server, use Remote Desktop to log on to the remote print server and start the process from that computer. You need to have administrator permissions on the computer where the printers will be added. Once you connect to the remote server by using Remote Desktop, you can search for network printers by starting Print Management or by running `\windows\pmcsnap\fnprinters.exe` from the command line.

| **Note** |
| --- |
| The print server role must be installed and you must be a member of the **Administrators** group to perform these procedures. |

**To add network printers to the local printer server automatically**

1. Open the Administrative Tools folder, and then double-click **Print Management**.
2. In the Printer Management tree, right-click *ServerName* **(local)**, click **Automatically Add Network Printers**, and then click **Start** to automatically locate and install printers found on this server's local subnet.

| **Note** |
| --- |
| You may be prompted to specify which driver you want to install for a printer, but otherwise, the process is automatic. |

# Add and remove print servers

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Vista

Print Management (Printmanagement.msc) allows you to manage printers that are running on print servers running Windows 2000 or later.

| **Note** |
| --- |
| The print server role must be installed and you must be a member of the Administrators group to perform these procedures. |

**To add print servers to Print Management**

1. Open the Administrative Tools folder, and then double-click **Print Management**.
2. In the Print Management tree, right-click **Print Management**, and then click **Add/Remove Servers**.
3. In the **Add/Remove Servers** dialog box, under **Specify print server**, in **Add server**, do one of the following:
   - Type the name.
   - Click **Browse** to locate and select the print server.
4. Click **Add to List**.
5. Add as many print servers as you want, and then click **OK**.

| **Note** |
| --- |
| You can add the local server on which you are working by clicking **Add the Local Server**. |

**To remove print servers from Print Management**

1. Open the Administrative Tools folder, and then double-click **Print Management**.
2. In the Print Management tree, right-click **Print Management**, and then click **Add/Remove Servers**.
3. In the **Add/Remove Servers** dialog box, under **Print servers**, select one or more servers, and click **Remove**.

# Create a new printer filter

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2008, Windows Vista

Filters display only those printers that meet a certain set of criteria. For example, it might be helpful to filter for printers with certain error conditions or those printers in a group of buildings regardless of the print server they use. Filters are stored in the Custom Printer Filters folder in the Print Management tree and are dynamic, so the data is always current.

Two default filters are provided with Print Management (Printmanagement.msc). For each filter that you create, you have the option to set up an e-mail notification or to run a script when the conditions of the filter are met. This is useful when you want to be alerted about printer problems, particularly in an organization with multiple buildings and administrators.

For example, you can set up a filter of all printers managed by a particular print server where the status does not equal Ready. Then, if a printer changes from the Ready status to any other status, the administrator could receive a notification e-mail from Print Management.

| **Note** |
| --- |
| The print server role must be installed and you must be a member of the **Administrators** group to perform these procedures. |

**To set up and save a filtered view**

1. Open the Administrative Tools folder, and then double-click **Print Management**.
2. In the Print Management tree, right-click the **Custom Printer Filters** folder, and then click **Add New Printer Filter**. This will launch the **New Printer Filter Wizard**.
3. On the **Printer Filter Name and Description** wizard page, type a name for the printer filter. The name will appear in the **Custom Printer Filters** folder in the Print Management tree.
4. In **Description**, type an optional description.
5. To display the number of printers that satisfy the conditions of a filter, select the **Display the total number of printers next to the name of the printer filter** check box
6. Click **Next**.
7. On the **Define a printer filter** wizard page, do the following:
   a. In the **Field** list, click the print queue or printer status characteristic.
   b. In the **Condition** list, click the condition.
   c. In the **Value** box, type a value.
   d. Continue adding criteria until your filter is complete, and then click **Next**.
8. On the **Set Notifications (Optional)** wizard page, do one or both of the following:
   - To set an e-mail notification, select the **Send e-mail notification** check box, and type one or more recipient and sender e-mail addresses. An SMTP server must be specified to route the message. Use the format *account@domain* and semicolons to separate multiple accounts.
   - To set a script to run, select the **Run script** check box, and then type the path where the script file is located. To add more arguments, type them in **Additional arguments**.
9. Click **Finish**.

| **Note** |
| --- |

To set notifications on existing printer filters, right-click a filtered view, and then click **Set Notifications**.

**Setting Optional Notifications**

When you create or modify a filter, you have the option of sending an automatic e-mail notification to someone or running a script when the conditions of the filter are met. This is useful for resolving printer problems, particularly in an organization with multiple buildings and administrators.

For example, you can set up a view of all printers managed by a particular print server where the status does not equal Ready. Then, if a printer changes from the Ready status to another status, the administrator could receive a notification e-mail from Print Management.

In addition to setting notifications on a custom set of printers, you can set notifications on printer server objects. For example, if the server is offline, or the spooler goes down, an e-mail notification can be sent.

Setting script notifications are useful for resolving printer problems and troubleshooting. For example, you could automatically run a script to restart a spooler when printers go offline. You could also automatically run a script that prints a test page.

Scripts can be written in Visual Basic Script (.vbs) or any scripting language available on the computer. The script has to be on the computer with Print Management. The script should be running with your credentials and you need to have the permissions to do whatever it is that you want the script to do.

# Perform printer management tasks

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Vista

You can use Print Management (Printmanagement.msc) to manage all of the printers in your enterprise, including printers in branch offices. You can use the same interface to perform bulk operations, update drivers, and list or remove printers from Active Directory.

| **Note** |
| --- |
| The print server role must be installed and you must be a member of the **Administrators** group to perform these procedures. |

**Perform Bulk Operations**

Bulk operations can be performed on all the printers on a particular server or all the printers under a particular filter.

The following is a list of the tasks that are possible to perform on multiple printers simultaneously:

- Pause Printing
- Resume Printing
- Cancel All Jobs
- List in Directory
- Remove from Directory
- Delete

**Update Device Drivers**

Printer driver details are shown separately for each server that you have added to Print Management. By default, the driver name, driver version, environment, and provider columns are visible. You can add columns to show more details such as the config file path, data file path, default datatype, driver file path, manufacturer, and so on.

You can export the list of details to a text file for use outside of Print Management.

### To manage device drivers

1. Open the Administrative Tools folder, and then double-click **Print Management**.
2. In the Print Management tree, under the appropriate print server, right-click **Drivers**, and then click **Manage Drivers**.
3. Do one or more of the following:
    - To add a printer driver, click **Add**, and then complete the **Add Printer Driver Wizard**.
    - To remove a printer driver, select a driver from the list, and then click **Remove**.
    - To reinstall a printer driver, select a driver, and then click **Reinstall**.
    - To view the details for a printer driver, select the driver, and then click **Properties**.

**List and Remove Printers in Active Directory**

Listing printers in Active Directory makes it easier for users to locate and install printers. After you install printers on a printer server, you can use Print Management to list them in Active Directory.

In fact, you can list more than one printer simultaneously. You may want to set up a filter to show all of the printers to list or remove, so that you can easily select all of the printers at the same time.

**To list or remove printers in Active Directory**

1. Open the Administrative Tools folder, and then double-click **Print Management**.
2. In the Print Management tree, under the appropriate print server, click **Printers**.
3. In the results pane, right-click the printer you want to list or remove, and then click **List in Directory** or **Remove from Directory**.

# View extended features for your printer

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Vista

In Print Management (Printmanagement.msc), extended view displays beneath the columns in the right pane, separated by a splitter bar. Extended view is useful when you want more information about the status of a print job, its owner, the number of pages, the size of the job, when it was submitted, its port, its priority, and so on.

In addition, when the printer has a Web page, extended view displays a **Printer Web Page** tab. The Web page provides details about the physical properties of the printer and specifications, and sometimes allows remote administration.

| **Note** |
| --- |
| The print server role must be installed and you must be a member of the **Administrators** group to perform these procedures.. |

**To show extended view**

1. Open the Administrative Tools folder, and then double-click **Print Management**.
2. In the Print Management tree, under any print server, right-click **Printers**, and then click **Show Extended View**.

| **Note** |
| --- |
| To display or hide columns in extended view, select a printer. On the **Jobs** tab, right-click the column heading row, and then click the name of the column that you want to display or hide. |

# Deploy printers by using Group Policy

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Vista

Print Management (Printmanagement.msc) can be used with Group Policy to automatically add printer connections to a computer's Printers and Faxes folder.

To do this, you use the **Deploy with Group Policy** dialog box to automatically add a printer connection setting to an existing Group Policy object (GPO) in Active Directory. When Group Policy processing runs on client computers, the printer connection settings are applied to the users or computers associated with the GPO. This is called deploying printer connections. Printers you deploy by using this method appear in the **Deployed Printers** object of Print Management tree when the print server they are connected to is being monitored.

This method of installing a printer is useful in a laboratory, classroom, or branch office setting where every computer in the room or office needs access to the same printer. It is also useful in large organizations, where computers and printers are often separated by function, workgroup, or department, such as marketing or human resources.

A printer connection that has been installed by using a per-user connection is available to the user no matter what computer the user logs on to in the network. A printer connection that has been installed by using a per-machine connection appears in the Printers and Faxes folder, ready for use by any user of that computer.

| **Note** |
| --- |
| Only per-user printer connections are supported on computers running Windows 2000. Per-machine printer connections are supported on computers running Windows XP or later. |

To deploy printer connections using Group Policy, add the PushPrinterConnections.exe utility to a machine startup script (for per-machine connections) or to a user logon script (for per-user connections). The utility reads the printer connection settings made in the GPO and adds the printer connection.

| **Important** |
| --- |
| In order for the PushPrinterConnections.exe utility to work, you must update your Active Directory schema with the Windows Server 2003 R2 changes. For more information about these schema updates, see the Microsoft Web site (http://go.microsoft.com/fwlink?linkid=51166). |

Once you deploy printer connection settings to a GPO, the PushPrinterConnections.exe utility will run on the client computers upon logon or restart. The utility reads the settings from the GPO and adds the deployed printer connections to the users or computers to which the GPO applies. You can reuse the GPO used to deploy per-user or per-machine printer connections. For more information about Group Policy and Printers, see Set Group Policy for Printers on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=50998).

It is a good idea to use the same GPO for deploying the printer connection settings and the PushPrinterConnections.exe computer startup or user logon script. This ensures that only users (or computers) that receive the printer connection settings will run the PushPrinterConnections.exe utility.

| **Important** |
| --- |
| The print server role must be installed and you must be a member of the **Administrators** group to perform these procedures. You must also have write access to the Group Policy object to use it to manage printers. Before you install printers by using Group Policy, you must have a GPO for your printer connections settings that is assigned to the appropriate users and computers. You can use the Group Policy Object Editor or Active Directory Users and Computers to create a GPO. |

For more information about using Group Policy, see Enterprise Management with the Group Policy Management Console on the Microsoft Web site (http://go.microsoft.com/fwlink?linkid=22814).

**To install printers to groups of users or computers by using Group Policy**

1. Open the Administrative Tools folder, and then double-click **Print Management**.

2. In the Print Management tree, under the appropriate print server, click **Printers**.
3. In the results pane, right-click the printer you want to deploy, and then click **Deploy with Group Policy**.
4. In the **Deploy with Group Policy** dialog box, click **Browse**, and then choose a Group Policy object.
5. Click **OK**.
6. To assign the printer connection setting to the GPO, do one or both of the following:
   - As a per-user setting, select the **The users that this GPO applies to (per user)** check box.
   - As a per-machine setting, select the **The computers that this GPO applies to (per machine)** check box.
7. Click **Add**.
8. Repeat steps 3 to 6 to add the printer connection setting to another GPO.
9. Click **OK**.

**To use the PushPrinterConnections.exe file**

1. Using Group Policy Management console (gpmc.msc), right-click the GPO with your printer connections settings, and then click **Edit**.
2. In the Group Policy Object Editor tree, navigate to one following locations:
   - If the printer connections are deployed per-machine, go to **Computer Configuration**, **Windows Settings**, **Scripts (Startup/Shutdown)**.
   - If the printer connections are deployed per-user, go to **User Configuration**, **Windows Settings**, **Scripts (Logon/Logoff)**.
3. Right-click **Startup** or **Logon**, and then click **Properties**.
4. In the **Logon Properties** or **Startup Properties** dialog box, click **Show Files**.
5. Copy the PushPrinterConnections.exe file to this location and then close the window.
6. In the **Logon Properties** or **Startup Properties** dialog box, click **Add**.
7. Type **PushPrinterConnections.exe** in the **Script Name** box.
8. If you want to enable logging, type **–log** in the **Script Parameters** box. Log files are written to %windir%\temp\ppcMachine.log (for per-computer connections) and %temp%\ppcUser.log (for per-user connections) on the computer on which the policy is applied.
9. Click **OK**.

| **Note** |
| --- |
| For per-computer connections, the printer connections will be added when the client computer restarts. For per-user connections, the printer connections will be added when the user logs on. If you remove the printer connection settings from the GPO, PushPrinterConnections.exe will remove the corresponding printers from the client computer on the next restart or user logon. |

# Resources for Print Management

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Vista

The following resources provide additional information about Print Management.

- For information about using scripts, see Script Repository: Printing on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=50001).

- For more information about Print Services, see Print Services on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=50121).

# Windows Server 2003: Security and Protection

This collection contains information about security technologies in Windows Server 2003.

- Auditing

  Security auditing is one of the most powerful tools to help maintain the security of your system. Auditing should identify attacks, either successful or not, that pose a threat to your network, or attacks against resources that you have determined to be valuable in your risk assessment.

- Authorization and Access Control

  Access control is the process of authorizing users, groups, and computers to access objects on the network by using permissions, user rights, and object auditing.

- Authorization Manager

  Authorization Manager is a Microsoft Management Console (MMC) snap-in that can help provide effective control of access to resources.

- Kerberos Authentication

  Kerberos is an authentication mechanism used to verify the identity of a user or host.

- Logon and Authentication

  Logon and authentication includes passwords, Kerberos, NTLM, Transport Layer Security/Secure Sockets Layer (TLS/SSL), and Digest. In addition, some protocols are combined into authentication packages, such as Negotiate and Schannel, as part of an extensible authentication architecture.

- Public Key Infrastructure

  A public key infrastructure (PKI) is a system of digital certificates, certification authorities (CAs), and other registration authorities that verify and authenticate the validity of each party involved in an electronic transaction.

- Security Configuration Wizard

  Security Configuration Wizard (SCW) is an attack-surface reduction tool that guides administrators in creating security policies based on the minimum functionality required for a server's role or roles.

- Security Policy

  Security policy is the configurable set of rules that the operating system follows when determining the permissions to grant in response to a request for access to resources.

- Smart Cards

  Smart cards are used to securely store certificates, public and private keys, passwords, and other types of personal information.

# Auditing

Updated: March 16, 2008

Applies To: Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This page lists resources for security auditing in Windows Server 2003. Security auditing is one of the most powerful tools to help maintain the security of your system. Auditing should identify attacks, either successful or not, that pose a threat to your network, or attacks against resources that you have determined to be valuable in your risk assessment.

**Getting Started**

- Checklist: Setting up object access auditing

  This checklist provides an overview of the steps needed to set up object access auditing.

**Planning and Architecture**

- Auditing Security Events Best practices

  This topic lists best practices for auditing security events.

**Operations**

- Auditing Security Events How To...

  Procedures are available for the following auditing tasks:

  - Define or modify auditing policy settings for an event category
  - Apply or modify auditing policy settings for a local file or folder
  - Apply or modify auditing policy settings for an object using Group Policy
  - View the security log

**Technical Reference**

- Auditing Policy

  This reference describes the event categories that you can choose to audit.

**Additional Resources**

- For information about auditing in Windows Server 2008, see Security Auditing.

# Authorization and Access Control

Updated: March 16, 2008

Applies To: Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This page lists resources for authorization and access control in Windows Server 2003. Access control is the process of authorizing users, groups, and computers to access objects on the network by using permissions, user rights, and object auditing.

**Getting Started**

- Security identifiers

  This topic provides information about well-known security identifiers.

**Planning and Architecture**

- Best practices for assigning permissions on Active Directory objects

  This topic lists best practices for assigning permissions on Active Directory objects.

- Best practices for permissions and user rights

  This topic lists best practices for permissions and user rights.

**Deployment**

- Designing a Resource Authorization Strategy

  This deployment guide provides information about establishing a resource authorization method, defining policies for security group management, and delegating security group maintenance.

**Operations**

- Access Control How To...

  Procedures are available for the following access control tasks:

  - Set, View, Change, or Remove Permissions on an Object
  - Secure a file or folder
  - Apply or modify permission entries for objects using Group Policy
  - Take ownership of a file or folder
  - View effective permissions on files and folders

**Technical Reference**

- Authorization and Access Control Technologies

  The following technical references are available for authorization and access control technologies:

  - Security Descriptors and Access Control Lists Technical Reference

    - Access Tokens Technical Reference
    - Permissions Technical Reference
    - Security Principals Technical Reference
    - Security Identifiers Technical Reference
- Data Security Technologies

  The following technical reference is available for data security technologies:

    - Encrypting File System Technical Reference

**Troubleshooting**

- Troubleshooting Access Control

  This guide provides troubleshooting information for access control in Windows XP and Windows Server 2003. It is designed to help you identify and resolve problems that are related to access control.

**Additional Resources**

- For changes in authorization and access control from Windows Server 2003 to Windows Server 2008, see What's New for Access Control in Windows Server 2008 in Changes in Functionality in Windows Server 2008.
- For more information about authorization and access control in Windows Server 2008, see Access Control.

# Authorization Manager

Updated: March 16, 2008

Applies To: Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This page lists resources for Authorization Manager in Windows Server 2003. Authorization Manager provides a flexible framework for integrating role-based access control into applications. It enables administrators who use those applications to provide access through assigned user roles that relate to job functions. Authorization Manager applications store authorization policy in the form of authorization stores that are stored in Active Directory or XML files and apply authorization policy at run time.

**Getting Started**

- Checklist: Before you start using Authorization Manager

  This checklist provides an overview of the steps you should take before you start using Authorization Manager.

**Planning and Architecture**

- Role-Based Access Control for Multi-tier Applications Using Authorization Manager

  This white paper provides information about how Authorization Manager can be used to provide role-based access control for multi-tier applications.

**Operations**

- Authorization Manager How To...

  Procedures are available for the following Authorization Manager tasks:

  - Start Authorization Manager
  - Set Authorization Manager options
  - Assign an application group to a role
  - Assign a Windows user or group to a role
  - Add an authorization rule
  - Refresh Authorization Manager
  - Reload an authorization store
  - Work with Authorization Stores
  - Work with Applications
  - Work with Role, Task, and Operation Definitions
  - Work with Scopes

**Additional Resources**

- For changes in Authorization Manager from Windows Server 2003 to Windows Server 2008, see Authorization Manager in Changes in Functionality in Windows Server 2008.

- For more information about Authorization Manager in Windows Server 2008, see Authorization Manager.

# Kerberos Authentication

Updated: March 24, 2009

Applies To: Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Kerberos is an authentication mechanism used to verify user or host identity. This page contains the information you need to evaluate, plan, and deploy Kerberos, the preferred authentication method for services in Windows Server 2003.

**Product Evaluation**

- What's New in Windows Server 2003 Kerberos Authentication

  This page outlines the new features in Kerberos authentication and provides the basic information administrators need to begin using these features.

**Planning and Architecture**

- Kerberos Protocol Transition and Constrained Delegation

  This document examines ways to authenticate the users of Web applications and discusses how the new extensions to the Kerberos authentication protocol can satisfy these requirements.

- Planning and Implementing Federated Forests in Windows Server 2003

  This paper examines common scenarios where you can deploy Active Directory forest trusts and describes the related technologies in Windows Server 2003.

**Deployment**

- Server Clusters: Security Best Practices, Windows 2000 and Windows Server 2003, General Assumptions

  To ensure security in server cluster environments, organizations can implement these general assumptions and operational best practices for the infrastructure.

- Kerberos authentication for load balanced web sites

  This document explains how to configure Kerberos in a way that enables applications to use its authentication capabilities in a cluster that also uses network load balancing.

- Planning and Implementing Federated Forests in Windows Server 2003

  This paper examines common scenarios where you can deploy Active Directory forest trusts and describes the related technologies in Windows Server 2003.

- Planning and Implementing Multitier Applications Using Windows Server 2003 Security Services

  This white paper introduces Windows Server 2003 security technologies and describes how they operate and interact with each other to allow you to build multitier applications that use these technologies to provide enhanced security.

**Interoperability**

- Solution Guide: Building Security and Directory Solutions for UNIX Using the Windows Server 2003 Active Directory Kerberos and LDAP Services

  This guide covers evaluating, planning, building, and deploying a security and directory infrastructure based on Windows Server 2003 by using Active Directory, Kerberos, and LDAP services.

**Operations**

- Troubleshooting Kerberos Errors

  This white paper helps you troubleshoot Kerberos authentication problems by outlining simple troubleshooting basics, explaining the causes of common Kerberos errors, and summarizing common troubleshooting tools.

- Troubleshooting Kerberos Delegation

  This white paper explains how to troubleshoot delegation issues that can arise in Kerberos authentication scenarios, summarizes required infrastructure, and describes Windows authentication scenarios.

- SPN Query

  This script queries the Active Directory Global Catalog for a security principal with a specified service principal name (SPN).

**Technical Reference**

- Kerberos Authentication Technical Reference

  This reference explains Kerberos authentication and how the Kerberos version 5 protocol and extensions supported by Windows Server 2003 work.

- Utilizing the Windows Authorization Data in Kerberos Tickets for Access Control to Resources

  This document describes the structure of the Windows authorization data that is used by servers in performing access control. The information applies to Microsoft Windows 2000 Server and Windows Server 2003.

# Logon and Authentication

Updated: March 16, 2008

Applies To: Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This page lists resources for logon and authentication in Windows Server 2003, which includes passwords, Kerberos, NTLM, Transport Layer Security/Secure Sockets Layer (TLS/SSL), and Digest. In addition, some protocols are combined into authentication packages, such as Negotiate and Schannel, as part of an extensible authentication architecture.

**Planning and Architecture**

- Password Best practices

  This topic lists best practices for passwords.

- Stored User Name and Password Best practices

  This topic lists best practices for stored user names and passwords.

**Deployment**

- Designing an Authentication Strategy

  This deployment guide provides information about creating a foundation for authentication, securing the authentication process, extending your authentication framework, enabling supplemental authentication strategies, and educating users about the authentication process.

- Account Passwords and Policies in Windows Server 2003

  This white paper describes the reasons why you should take a structured approach to setting the account and password policy features and provides information about the tools and log files that you can use to troubleshoot account lockouts. In addition, it shows you how to determine from which computer the account lockouts are being generated, as well as the program or service that is generating the lockout.

**Operations**

- Authentication Protocol How To...

  Procedures are available for the following authentication tasks:

  - Configure Kerberos policy
  - Allow a computer to be trusted for delegation for specific services
  - Allow a user to be trusted for delegation for specific services
  - Allow a computer to be trusted for delegation
  - Allow a user to be trusted for delegation
  - Map an account from a trusted non-Windows kerberos realm to a user account

- Password How To...

  Procedures are available for the following password tasks:

- Change an existing password
- Reset a password
- Reset a local user account password with a password reset disk
- Create a password reset disk
- Apply or modify password policy
- Apply or modify account lockout policy
- Create or update a system key

**Technical Reference**

- Logon and Authentication Technologies

  The following technical references are available for logon and authentication technologies:

  - Digest Authentication Technical Reference
  - Interactive Logon Technical Reference
  - Kerberos Authentication Technical Reference
  - TLS/SSL Technical Reference

**Troubleshooting**

- Password Troubleshooting
- Stored User Name and Password Troubleshooting

**Additional Resources**

- For changes in logon and authentication from Windows Server 2003 to Windows Server 2008, see What's New for Identity Management in Windows Server 2008.
- For more information about logon and authentication in Windows Server 2008, see Windows Authentication.
- For information about Kerberos authentication, see Kerberos Authentication.

# Public Key Infrastructure

Updated: March 16, 2008

Applies To: Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This page lists resources for public key infrastructure (PKI) in Windows Server 2003. A PKI is a system of digital certificates, certification authorities (CAs), and other registration authorities that verify and authenticate the validity of each party involved in an electronic transaction.

**Getting Started**

- Checklist: Configuring certificate autoenrollment

  This checklist provides an overview of the steps needed to configure certificate autoenrollment.

- Checklist: Creating a certification hierarchy with an offline root certification authority

  This checklist provides an overview of the steps needed to create a certification hierarchy with an offline root CA.

- Checklist: Credential roaming

  This checklist provides an overview of the steps needed to use credential roaming.

- Checklist: Decommissioning a certification authority

  This checklist provides an overview of the steps needed to decommission a CA.

**Planning and Architecture**

- Certificate Services Best practices

  This topic provides a list of best practices for Certificate Services.

- Certificate Templates Best practices

  This topic provides a list of best practices for certificate templates.

- Implementing and Administering Certificate Templates in Windows Server 2003

  This white paper discusses the best practices in designing, administering, and implementing version 2 certificate templates by using Windows Server 2003 Enterprise Edition and enterprise CAs.

- Planning and Implementing Cross-Certification and Qualified Subordination Using Windows Server 2003

  This white paper provides a technical reference and planning guide for PKI administrators who want to perform PKI cross-certification, deploy bridge CAs, and understand how to implement qualified subordination in Windows Server 2003.

**Deployment**

- Best Practices for Implementing a Microsoft Windows Server 2003 Public Key Infrastructure

  This document is a quick start guide that you can use to set up a Windows Server 2003 PKI.

- Certificate Autoenrollment in Windows Server 2003

  This white paper includes information about autoenrollment, including configuration, certificate renewal, autoenrollment

functions, advanced features, supported hardware, and troubleshooting.

- Designing a Public Key Infrastructure

  This deployment guide provides information about defining certificate requirements, designing and extending your PKI, defining certificate configuration options, creating a certificate management plan, and deploying the PKI.

**Operations**

- Advanced Certificate Enrollment and Management

  This white paper explains several remote deployment scenarios along with the step-by-step procedures to perform X.509 certificate enrollment to implement a secure infrastructure.

- Key Archival and Management in Windows Server 2003

  This white paper covers best practices and procedures in a key recovery strategy as well as migration procedures for moving from a Microsoft Exchange Key Management Server (KMS) environment to a Windows Server 2003–based CA.

- Windows Server 2003 PKI Operations Guide

  This guide provides information about configuring and operating a Windows-based CA, including various operational scenarios, custom configuration information, sample commands, and best practices.

**Technical Reference**

- PKI Technologies

  The following technical references are available for PKI technologies:

  - CA Certificates Technical Reference
  - Certificates Technical Reference
  - Certificate Services Technical Reference

**Troubleshooting**

- Certificate Services Troubleshooting
- Certificate Templates Troubleshooting
- Certificates Troubleshooting

**Additional Resources**

- For changes in PKI from Windows Server 2003 to Windows Server 2008, see Active Directory Certificate Services Role in Changes in Functionality in Windows Server 2008.
- For more information about Active Directory Certificate Services in Windows Server 2008, see Active Directory Certificate Services.

# Security Configuration Wizard

Updated: March 16, 2008

Applies To: Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This page lists resources for the Security Configuration Wizard (SCW) in Windows Server 2003. SCW is an attack-surface reduction tool that guides administrators in creating security policies based on the minimum functionality required for a server's role or roles.

**Getting Started**

- Security Configuration Wizard Quick Start Guide

  This guide provides system requirements, installation instructions, steps for getting started with SCW, and instructions for troubleshooting simple problems.

**Deployment**

- Deployment Guide for the Security Configuration Wizard

  This deployment guide shows you how to deploy SCW and SCW policies to your computers running Windows Server 2003 with Service Pack 1 (SP1).

**Additional Resources**

- For changes in SCW from Windows Server 2003 to Windows Server 2008, see Security Configuration Wizard in Changes in Functionality in Windows Server 2008.

- For more information about SCW in Windows Server 2008, see Security Configuration Wizard.

# Security Policy

Updated: March 16, 2008

Applies To: Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This page lists resources for security policy in Windows Server 2003. Security policy is the configurable set of rules that the operating system follows when determining the permissions to grant in response to a request for access to resources.

**Getting Started**

- Checklist: Using software restriction policies to help protect your computer against an e-mail virus

  This checklist provides an overview of the steps needed to use software restriction policies to help protect your computer against an e-mail virus.

**Planning and Architecture**

- Software Restriction Policies Best Practices

  This topic lists best practices for software restriction policies.

**Operations**

- Software Restriction Policies How To...

  Procedures are available for the following software restriction policies tasks:

  - Create new software restriction policies
  - Open Software Restriction Policies
  - Apply software restriction policies to DLLs
  - Prevent software restriction policies from applying to local administrators
  - Enable certificate rules
  - Create a certificate rule
  - Create a hash rule
  - Create an Internet zone rule
  - Create a path rule
  - Create a registry path rule
  - Add or delete a designated file type
  - Change the default security level of software restriction policies
  - Set trusted publisher options

**Technical Reference**

- Security Policy Settings

  This provides a reference of security policy settings in Windows Server 2003.

**Troubleshooting**

- Software Restriction Policies Troubleshooting

**Additional Resources**

- For information about security policy management in Windows Server 2008, see Server Security Policy Management.

# Smart Cards

Updated: March 16, 2008

Applies To: Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This page lists resources for smart cards in Windows Server 2003. Smart cards are used to securely store certificates, public and private keys, passwords, and other types of personal information.

**Getting Started**

- Checklist: Deploying smart cards for logging on to Windows

  This checklist provides an overview of the steps needed to deploy smart cards for use in Windows logon.

**Deployment**

- Planning a Smart Card Deployment

  This deployment guide provides information about deploying smart cards, including creating a plan for smart card use, selecting smart card hardware, creating a smart card deployment plan, and planning for ongoing smart card support.

**Additional Resources**

- For changes in smart cards from Windows Server 2003 to Windows Server 2008, see What's New for Identity Management in Windows Server 2008.

# Windows Server 2003 Glossary

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - #**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**$$Rename.txt**
A file that lists all files contained in a particular folder that need to be renamed from an 8.3 format name to a long file name during Setup. All file names must be in 8.3 format if you run Setup using Winnt.exe, or if you copy a set of files from one computer to another using MS-DOS.

**.cab file**
Cabinet file. A single cabinet file that stores multiple compressed files. These files are commonly used in software installation and to reduce the file size and the associated download time for Web content.

**.cer file format**
A file format that is used for the storage of public key certificates.

See also: public key

**.inf**
The file name extension for files that contain device information or scripts to control hardware operations.

See also: device

**.NET Passport**
A service that is part of Microsoft .NET Framework. .NET Passport includes a passport authentication protocol, and it provides the ability to map passport IDs to Active Directory accounts.

See also: Active Directory  authentication  passport authentication  service

**.pfx file format**
A file format that is used for the storage of public key certificates and their associated private keys.

See also: private key  public key

**1.2.840.113556.1.4.1851**
The object identifier that is assigned to Active Directory Application Mode (ADAM). You can use this object identifier programmatically to differentiate ADAM from other directory services.

**100baseT**
The Ethernet standard for local area networks using twisted-pair cable carrying data at 100 megabits per second (Mbps).

**3DES**
See other term: Triple DES (3DES)

**802.1X authentication**
An Institute of Electrical and Electronic Engineers (IEEE) standard for port-based network access control that provides authenticated network access to Ethernet networks and wireless 802.11 local area networks (LANs).

See also: access control  authentication  local area network (LAN)  port  port based network access control

# Windows Server 2003 Glossary - A

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - A**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**AAAA (quad-A) resource record**
A resource record used to map a DNS domain name to a host Internet Protocol version 6 (IPv6) address on the network.

See also: domain name  Domain Name System (DNS)  IP address  resource record (RR)

**AAL**
See other term: ATM adaptation layer (AAL)

**ABR**
See other term: area border router (ABR)

**access control**
A security mechanism that determines which operations a user, group, service, or computer is authorized to perform on a computer or on a particular object, such as a file, printer, registry subkey, or directory service object.

See also: group  object  permission  registry  service

**access control entry (ACE)**
An entry in either a securable object's discretionary access control list (DACL) or an object's system access control list (SACL). In a DACL, the entry grants or denies permissions to a user or group. In a SACL, the entry specifies which security events to audit for a particular user or group or controls the Windows Integrity Level for the object.

See also: access control  access control list (ACL)  discretionary access control list (DACL)  object  permission  security descriptor  system access control list (SACL)

**access control list (ACL)**
A list of security protections that apply to an entire object, a set of the object's properties, or an individual property of an object. There are two types of access control lists: discretionary and system.

See also: access control entry (ACE)  discretionary access control list (DACL)  object  security descriptor  system access control list (SACL)

**access number**
A phone number that subscribers can dial to reach online services.

**access token**
A data structure that contains authentication and authorization information for a user. Windows creates the access token when the user logs on and the user's identity is confirmed. The access token contains the user's security ID (SID), the list of groups that the user is a member of, and the list of privileges held by that user. Each process or thread started for the user inherits a copy of the access token. In some cases a user may have more than one access token, with different levels of authority.

See also: privilege  security ID (SID)  security principal

**account lockout**
A Windows security feature that locks a user account if a number of failed logon attempts occur within a specified amount of time, based on security policy lockout settings. Locked accounts cannot log on.

See also: policy  user account

**account logon event category**
In auditing, a group of events that are logged when a user logs on to a computer that uses another computer to validate the user account. Events in this event category are logged on the computer that validates the user account.

See also: auditing  event  user account

**account management event category**
In auditing, a group of events that are logged when user or group account information is modified.

See also: auditing  event  group account  user account

**account partner**
A federation partner that is trusted by the Federation Service to provide security tokens. The account partner issues these tokens to its users - that is, users in the account partner realm - so that they can access Web-based applications in the resource partner.

**ACE**
See other term: access control entry (ACE)

**ACID**
See definition for: atomicity, consistency, isolation, durability (ACID)

**ACK (acknowledgment)**
A message transmitted to indicate that data has been received correctly. The Transmission Control Protocol (TCP) requires that the recipient acknowledge successful receipt of data. Such acknowledgments (ACKs) generate additional network traffic, decreasing the rate at which data passes but increasing reliability. To reduce the impact on performance, most hosts send an acknowledgment for every other segment or when a specified time interval has passed.

See also: host

**acknowledgment message**
For Message Queuing, a message class that indicates that a message arrived or was retrieved by the target application (a positive acknowledgment), or that an error occurred before the original message could be retrieved (a negative acknowledgment). These messages are sent to administration queues on the source computer.

See also: administration queue  Message Queuing

**ACL**
See other term: access control list (ACL)

**ACPI**
See other term: Advanced Configuration and Power Interface (ACPI)

**active**
Describes the window or icon that you are currently using or that is currently selected. The operating system always applies the next keystroke or command you choose to the active window. Windows or icons on the desktop that are not selected are inactive.

**Active Accessibility**
An application programming interface (API) built into a variety of Windows operating systems, including Windows 2000, Windows XP, and products in the Windows Server 2003 family. Active Accessibility allows an accessibility aid (or other Active Accessibility client) to collect meaningful information from an application`s user interface and convey that information to the user. For example, Microsoft Active Accessibility allows a screen reader to convey to the user that an application is displaying a pop-up message asking whether to save or discard file changes. Because Active Accessibility reduces the need for application-specific code, it reduces overall maintenance costs and allows software developers to innovate in their user interface without sacrificing compatibility with accessibility aids.

See also: application programming interface (API)

**active caching**
A feature in Microsoft Internet Security and Acceleration (ISA) Server that retrieves files for Web pages that are accessed frequently.

See also: caching

**active content**
Interactive or animated content used on the Internet. Active content includes ActiveX controls and web browser add-ons.

See also: channel

**Active Directory**
The Windows-based directory service. Active Directory stores information about objects on a network and makes this

information available to users and network administrators. Active Directory gives network users access to permitted resources anywhere on the network using a single logon process. It provides network administrators with an intuitive, hierarchical view of the network and a single point of administration for all network objects.

See also: directory partition  directory service  domain  forest  object  replication

**Active Directory Application Mode (ADAM)**
A stand-alone directory service that is designed specifically for use with directory-enabled applications. Active Directory Application Mode (ADAM) does not require or depend on Active Directory forests or domains. ADAM stores and replicates only application-related information. ADAM does not store or replicate network operating system (NOS)-related information.

**Active Directory Application Mode (ADAM) instance**
For Active Directory Application Mode (ADAM), a single copy of the ADAM directory service, along with its associated directory store, assigned Lightweight Directory Access Protocol (LDAP) and Secure Sockets Layer (SSL) ports, and application event log. You can run multiple ADAM instances simultaneously on a single ADAM server.

See also: Active Directory Application Mode (ADAM)  directory service  Lightweight Directory Access Protocol (LDAP)  Secure Sockets Layer (SSL)

**Active Directory Federation Services (ADFS)**
A Windows Server 2003 R2 component that provides Web single-sign-on (SSO) technologies to authenticate a user to multiple Web applications over the life of a single online session. ADFS accomplishes this by securely sharing digital identity and entitlement rights across security and enterprise boundaries. ADFS in Windows Server 2003 R2 supports the WS-Federation Passive Requestor Profile (WS-F PRP).

**Active Directory Installation Wizard**
The tool that is used to install and remove Active Directory.

See also: Active Directory

**Active Directory replication**
The synchronization of Active Directory partition replicas between domain controllers. Replication automatically copies the changes that originate on a writable directory partition replica to all other domain controllers that hold the same directory partition replica. More specifically, a destination domain controller pulls these changes from the source domain controller.

See also: Active Directory  domain controller  global catalog  replica  replication

**Active Directory Service Interfaces (ADSI)**
A directory service model and a set of Component Object Model (COM) interfaces. ADSI enables Windows applications and Active Directory clients to access several network directory services, including Active Directory. ADSI is supplied as a software development kit (SDK).

See also: Active Directory  Component Object Model (COM)  directory service

**Active Directory Users and Computers**
An administrative tool used by an administrator to perform day-to-day Active Directory administration tasks. The tasks that can be performed with this tool include creating, deleting, modifying, moving, and setting permissions on objects stored in the directory. Examples of objects in Active Directory are organizational units, users, contacts, groups, computers, printers, and shared file objects.

See also: Active Directory  object  permission

**Active Directory-integrated zone**
A primary Domain Name System (DNS) zone that is stored in Active Directory so that it can use multimaster replication and Active Directory security features.

See also: Active Directory  Domain Name System (DNS)  multimaster replication  primary zone

**active partition**
A partition from which a computer starts up. The active partition must be a primary partition on a basic disk. If you use Windows exclusively, the active partition can be the same as the system volume.

See also: basic disk  primary partition  system partition  system volume  x86

**active volume**
The volume from which the computer starts up. The active volume must be a simple volume on a dynamic disk. You cannot

mark an existing dynamic volume as the active volume, but you can upgrade a basic disk containing the active partition to a dynamic disk. After the disk is upgraded to dynamic, the partition becomes a simple volume that is active.

See also: active partition  basic disk  dynamic disk  dynamic volume  simple volume

**ActiveX**
A set of technologies that allows software components to interact with one another in a networked environment, regardless of the language in which the components were created.

See also: ActiveX component

**ActiveX component**
A reusable software component that can be used to incorporate ActiveX technology.

See also: ActiveX

**ADAM**
See other term: Active Directory Application Mode (ADAM)

**ADAM instance**
See other term: Active Directory Application Mode (ADAM) instance

**address**
A unique identifier that identifies a network node to other nodes on the network. Also known as the net address or MAC address.

See also: media access control (MAC) address  node

**address (A) resource record**
A resource record (RR) used to map a DNS domain name to a host Internet Protocol version 4 (IPv4) address on the network.

See also: domain name  Domain Name System (DNS)  IP address  resource record (RR)

**address class**
A predefined grouping of Internet addresses that defines a network of a certain size. The range of numbers that can be assigned for the first octet in the IP address is based on the address class. Class-based IP addressing has been superceded by Classless Interdomain Routing (CIDR).

See also: Class A IP address  Class B IP address  Class C IP address  Classless Interdomain Routing (CIDR)

**address pool**
The addresses within a DHCP scope range of addresses that are available for leased distribution to clients.

See also: address  Dynamic Host Configuration Protocol (DHCP)  lease  scope

**Address Resolution Protocol (ARP)**
In TCP/IP, a protocol that uses broadcast traffic on the local network to resolve a logically assigned Internet Protocol version 4 (IPv4) address to its physical hardware or media access control (MAC) layer address. In asynchronous transfer mode (ATM), ARP is used two different ways. For classical IPv4 over ATM (CLIP), ARP is used to resolve addresses to ATM hardware addresses. For ATM LAN emulation (LANE), ARP is used to resolve Ethernet/802.3 or Token Ring addresses to ATM hardware addresses.

See also: asynchronous transfer mode (ATM)  classical IP over ATM (CLIP)  Internet Protocol (IP)  IP address  LAN emulation (LANE)  media access control (MAC) address  Message Authentication Code (MAC)  packet  Transmission Control Protocol/Internet Protocol (TCP/IP)

**Address Windowing Extensions (AWE) API**
A set of application programming interfaces (APIs) developed by Microsoft that allows software developers to create applications that use up to 64 GB of physical nonpaged memory in a 32-bit virtual address space on 32-bit platforms. This technology allows for windowed views to this physical memory from within the application`s virtual address space.

See also: application programming interface (API)  virtual address

**adjacency**
A relationship formed between selected neighboring Open Shortest Path First (OSPF) routers for the purpose of exchanging routing information. When the link state databases of two neighboring routers are synchronized, the routers are said to be

adjacent. Not every pair of neighboring routers becomes adjacent.

See also: link state database  Open Shortest Path First (OSPF)  router

**administration queue**
For Message Queuing, a queue that stores acknowledgment messages.

See also: acknowledgment message  Message Queuing  queue

**administrative alerts**
Alerts that relate to server and resource use. They notify users about problems in areas such as security and access, user sessions, server shutdown due to power loss (when an uninterruptible power supply (UPS) is available), directory replication, and printing. When a computer generates an administrative alert, a message is sent to a predefined list of users and computers.

See also: Alerter service  uninterruptible power supply (UPS)

**administrative credentials**
Logon information that is used to identify a member of an administrative group. Groups that use administrative credentials include Administrators, Domain Admins, and DNS Admins. Most system-wide or domain-wide tasks require administrative credentials.

See also: Administrators group  group

**administrator**
In the Windows Server 2003 family, a person who is responsible for setting up and managing local computers, stand-alone servers, member servers, or domain controllers. An administrator sets up user and group accounts, assigns passwords and permissions, and helps users with networking problems. Administrators can be members of the Administrators group on local computers or servers. A person who is a member of the Administrators group on a local computer or server has full access to that computer or server and can assign access control rights to users as necessary. Administrators can also be members of the Domain Admins group on domain controllers and have full control over user and computer accounts residing in that domain.

See also: access control  computer account  domain  domain controller  group account  member server  network administrator  stand-alone server  user account

**administrator account**
On a local computer, the first account that is created when you install an operating system on a new workstation, stand-alone server, or member server. By default, this account has the highest level of administrative access to the local computer, and it is a member of the Administrators group. In an Active Directory domain, the first account that is created when you set up a new domain by using the Active Directory Installation Wizard. By default, this account has the highest level of administrative access in a domain, and it is a member of the Administrators, Domain Admins, Domain Users, Enterprise Admins, Group Policy Creator Owners, and Schema Admins groups.

See also: Active Directory  Administrators group  local computer  member server  stand-alone server  user account

**Administrators group**
On a local computer, a group whose members have the highest level of administrative access to the local computer. Examples of administrative tasks that can be performed by members of this group include installing programs; accessing all files on the computer; auditing access control; and creating, modifying, and deleting local user accounts. In an Active Directory domain, a group whose members have the highest level of administrative access in the domain. Examples of administrative tasks that can be performed by members of this group include setting domain policy; assigning and resetting domain user account passwords; setting up and managing domain controllers; and creating, modifying, and deleting domain user accounts.

See also: access control  Active Directory  auditing  domain  domain controller  group  local computer  object  user account

**ADSI**
See other term: Active Directory Service Interfaces (ADSI)

**Advanced Configuration and Power Interface (ACPI)**
An open industry specification that defines power management on a wide range of mobile, desktop, and server computers and peripherals. ACPI is the foundation for the OnNow industry initiative that allows system manufacturers to deliver computers that start at the touch of a keyboard. ACPI design is essential to take full advantage of power management and Plug and Play.

**affinity**

For Network Load Balancing, the method used to associate client requests to cluster hosts. When no affinity is specified, all network requests are load balanced across the cluster without respect to their source. Affinity is implemented by directing all client requests from the same IP address to the same cluster host.

**agent**
An application that runs on a Simple Network Management Protocol (SNMP) managed device. The agent application is the object of management activities. A computer running SNMP agent software is also sometimes referred to as an agent.

See also: Simple Network Management Protocol (SNMP)

**Alerter service**
A service used by the server and other services to notify selected users and computers of administrative alerts that occur on a computer. The Alerter service requires the Messenger service.

See also: administrative alerts  Messenger service  service

**algorithm**
In cryptography, a mathematical process that is used in cryptographic operations such as the encryption and digital signing of data. An algorithm is commonly used with a cryptographic key to enhance security.

See also: encryption  public key encryption  symmetric encryption

**allocation unit**
The smallest amount of disk space that can be allocated to hold a file. All file systems used by Windows organize hard disks based on allocation units. The smaller the allocation unit size, the more efficiently a disk stores information. If you do not specify an allocation unit size when formatting the disk, Windows picks default sizes based on the size of the volume. These default sizes are selected to reduce the amount of space that is lost and the amount of fragmentation on the volume. Also called a cluster.

See also: file system  volume

**American Standard Code for Information Interchange (ASCII)**
A standard single-byte character encoding scheme used for text-based data. ASCII uses designated 7-bit or 8-bit number combinations to represent either 128 or 256 possible characters. Standard ASCII uses 7 bits to represent all uppercase and lowercase letters, the numbers 0 through 9, punctuation marks, and special control characters used in U.S. English. Most current x86-based systems support the use of extended (or "high") ASCII. Extended ASCII allows the eighth bit of each character to identify an additional 128 special symbol characters, foreign-language letters, and graphic symbols.

See also: Unicode

**Anonymous access**
An authentication mechanism by which users who are able to connect to an Internet site without credentials are assigned to the IUSR_ComputerName account and granted the access rights that are assigned to that account.

See also: access control  Anonymous authentication  authentication

**Anonymous authentication**
An authentication mechanism that does not require user accounts and passwords. Anonymous authentication grants remote users the identity IUSR_ComputerName. Anonymous authentication is used on the Internet to grant visitors restricted access to predefined public resources.

See also: Anonymous access  authentication  password  user account

**answer file**
A text file used to automate Setup or other installation processes. Using this text file, you can provide custom answers to Setup-related questions. Typically, you must point the Setup program to use the answer file at the same time Setup is started. Answer files can only be used on applications and operating systems that support them.

See also: Setup

**API**
See other term: application programming interface (API)

**APIPA**
See other term: Automatic Private IP Addressing (APIPA)

**AppleShare**

Client software that is shipped with all Macintosh computers and with Apple Computer server software. Macintosh computers can use their AppleShare client software to connect to computers running Services for Macintosh.

See also: client  server

**AppleTalk Control Protocol (ATCP)**
A network control protocol defined within Point-to-Point Protocol (PPP). ATCP allows clients to connect to a Windows server by running PPP over AppleTalk. ATCP negotiates the AppleTalk parameters to use during the PPP session.

See also: Network Control Protocol  Point-to-Point Protocol (PPP)

**AppleTalk Filing Protocol**
The presentation-layer protocol that manages access to remote files in an AppleTalk network.

See also: protocol

**AppleTalk Phase 2**
The extended AppleTalk Internet model designed by Apple Computer that supports multiple zones within a network and extended addressing capacity.

See also: zone

**AppleTalk Protocol**
The set of network protocols on which AppleTalk network architecture is based. The AppleTalk Protocol is installed with Services for Macintosh to help users access resources on a network.

See also: protocol  resource

**AppleTalk Transport**
The layer of AppleTalk Phase 2 protocols that delivers data to its destination on the network.

See also: AppleTalk Phase 2

**application assignment**
A process that uses Software Installation (an extension of Group Policy) to assign programs to groups of users. The programs appear on the users` desktop when they log on.

See also: Group Policy

**application directory partition**
An Active Directory directory partition that stores application-specific data that can be dynamic (subject to Time to Live restrictions). Application directory partitions can store any type of object except security principals and are not replicated to the global catalog. The replication scope of an application directory partition can be configured to include any set of domain controllers in the forest.

See also: Active Directory  directory partition  Time to Live (TTL)

**application memory tuning**
A feature of Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition. Application memory tuning can be enabled on computers with between 2 gigabytes (GB) and 4 GB of physical RAM, and it allows applications running on these computers to address 3 GB of virtual memory instead of the 2 GB normally allocated to each application process. Also known as 4-gigabyte tuning (4GT).

See also: virtual memory

**application programming interface (API)**
A set of routines that an application uses to request and carry out lower-level services performed by a computer`s operating system. These routines usually carry out maintenance tasks such as managing files and displaying information.

**area border router (ABR)**
An Open Shortest Path First (OSPF) router that is attached to multiple areas. ABRs maintain separate topological databases for each area.

See also: Open Shortest Path First (OSPF)  topological database

**ARP**
See other term: Address Resolution Protocol (ARP)

**AS**
See other term: autonomous system (AS)

**ASBR**
See other term: autonomous system boundary router (ASBR)

**ASCII**
See other term: American Standard Code for Information Interchange (ASCII)

**ASR**
See other term: Automated System Recovery (ASR)

**asynchronous communication**
A form of data transmission in which information is sent and received at irregular intervals, one character at a time. Because data is received at irregular intervals, the receiving modem must be signaled to let it know when the data bits of a character begin and end. This is done by means of start and stop bits.

See also: modem (modulator/demodulator)

**asynchronous transfer mode (ATM)**
A high-speed, connection-oriented, virtual circuit-based packet switching protocol used to transport many different types of network traffic. ATM packages data in 53-byte, fixed-length cells that can be switched quickly between logical connections on a network.

**ATCP**
See other term: AppleTalk Control Protocol (ATCP)

**ATM**
See other term: asynchronous transfer mode (ATM)

**ATM adaptation layer (AAL)**
The layer of the asynchronous transfer mode (ATM) protocol stack that parses data into the payload portion of the ATM cell for transport across an ATM network.

See also: asynchronous transfer mode (ATM)

**atomicity, consistency, isolation, durability (ACID)**
The four essential properties of an electronic transaction. Atomicity is the ability to do or undo a transaction completely; consistency is the ability of a transaction to change a system from one consistent state to another consistent state; isolation is the ability for a transaction to occur independently of other transactions made at the same time; and durability is the ability of a transaction to persist, even during system failure.

**attribute**
For files, information that indicates whether a file is read-only, hidden, ready for archiving (backing up), compressed, or encrypted, and whether the file contents should be indexed for fast file searching.

See also: Active Directory  class  object  object class  schema

**audit entry**
Data that is recorded in the event log when specified system, application, and security-related events take place. Audit entries provide valuable data about system operations that can be used to identify system use and to diagnose system behavior.

See also: auditing  event

**audit logging**
Enhanced logging capabilities that monitor and manage the growth and size of log files used by DHCP on an ongoing daily basis.

See also: Dynamic Host Configuration Protocol (DHCP)

**audit policy**
Policy that determines the security events to be reported to the network administrator.

See also: policy  security

**auditing**
The process that tracks the activities of users by recording selected types of events in the security log of a server or a

workstation.

See also: security log

**authentication**
The process of verifying the identity of a user, computer, process, or other entity by validating the credentials provided by the entity. Common forms of credentials are digital signatures, smart cards, biometric data, and a combination of user names and passwords.

See also: cryptography  Kerberos V5 authentication protocol  nonrepudiation  NTLM authentication protocol  smart card  trust relationship

**Authentication Header (AH)**
A header that provides authentication, integrity, and anti-replay for the entire packet (the Internet Protocol (IP) header and the data payload carried in the packet).

See also: authentication  Internet Protocol (IP)  packet

**authentication protocol**
The protocol by which an entity on a network proves its identity to a remote entity. Typically, identity is proved with the use of a secret key, such as a password, or with a stronger key, such as the key on a smart card. Some authentication protocols also implement mechanisms to share keys between client and server to provide message integrity or privacy.

See also: authentication  identity  Kerberos V5 authentication protocol  key  NTLM authentication protocol  protocol  smart card

**authoritative**
Describes a DNS server that hosts a primary or secondary copy of a DNS zone.

See also: authoritative restore  DNS server  Domain Name System (DNS)  resource record (RR)  zone

**authoritative restore**
In Backup, a type of restore operation performed on an Active Directory domain controller in which the objects in the restored directory are treated as authoritative, replacing (through replication) all existing copies of those objects.

See also: Active Directory  domain controller  nonauthoritative restore  object  replication

**authorization**
The process that determines what a user is permitted to do on a computer system or network.

See also: authentication

**authorization store**
A database that stores Authorization Manager policy.

**automated library**
A tape or disk library with an automatic mechanism, such as a robotic arm, that loads and unloads media into a drive or drives without manual intervention from the user. Automated libraries are sometimes known as autoloaders, changers, jukeboxes, media changers, and robotic libraries.

**Automated System Recovery (ASR)**
A feature that helps you recover a system that will not start. To use Automated System Recovery, you must first use the Automated System Recovery Preparation Wizard (part of Backup). This wizard backs up the partition used by the operating system, but it does not back up other partitions, such as program or data partitions. Those partitions must be backed up using Backup or other standard routines.

See also: partition

**automatic file replication**
The replication of files and directories between computers as performed automatically by the File Replication service (FRS). In a domain distributed file system, FRS provides automatic file and directory replication between targets. The user configures automatic replication through the DFS administration tool. Files in a stand-alone distributed file system must be replicated between targets manually or by using other utilities.

See also: Distributed File System (DFS)  domain DFS  File Replication service (FRS)  replication

**Automatic Private IP Addressing (APIPA)**

A TCP/IP feature in Windows XP and Windows Server 2003 that automatically configures a unique IP address from the range 169.254.0.1 through 169.254.255.254 with a subnet mask of 255.255.0.0 when the TCP/IP protocol is configured for dynamic addressing and a DHCP server is not available. The APIPA range of IP addresses is reserved by the Internet Assigned Numbers Authority (IANA) for use on a single subnet, and IP addresses within this range are not used on the Internet.

See also: DHCP server  Dynamic Host Configuration Protocol (DHCP)  IP address  Transmission Control Protocol/Internet Protocol (TCP/IP)

**autonomous system (AS)**
A group of routers exchanging routing information by using a common routing protocol.

See also: autonomous system boundary router (ASBR)  router

**autonomous system boundary router (ASBR)**
A router that exchanges routing information with routers that belong to other autonomous systems. The ASBR then advertises external routes throughout the autonomous system. ASBRs can be internal or area border routers, and they might or might not be connected to the backbone.

See also: area border router (ABR)  autonomous system (AS)  backbone  router

**auto-static updates**
The process of adding static routes to the routing table automatically. When you configure an interface to use auto-static update mode, the router sends a request to other routers and inherits routes. The routes are saved in the routing table as auto-static routes and are kept even if the router is restarted or the interface goes down. Auto-static updates are supported in Routing Information Protocol (RIP) for Internet Protocol (IP) and in RIP for Internetwork Packet Exchange (IPX), but they are not available for use with Open Shortest Path First (OSPF).

See also: Open Shortest Path First (OSPF)  routing  Routing Information Protocol over IPX (RIPX)  static routes

**availability**
A level of service provided by applications, services, or systems. Highly available systems have minimal downtime, whether planned or unplanned. Availability is often expressed as the percentage of time that a service or system is available, for example, 99.9 percent for a service that is down for 8.75 hours a year.

**available bit rate (ABR)**
An asynchronous transfer mode (ATM) service type that supports available-bit-rate traffic, minimum guaranteed transmission rate, and peak data rates. ABR also allows bandwidth allocation depending on availability, and it uses flow control to communicate bandwidth availability to the end node.

See also: asynchronous transfer mode (ATM)  bandwidth  node

**AXFR**
See other term: full zone transfer (AXFR)

# Windows Server 2003 Glossary - B

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - B**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**backbone**
In Open Shortest Path First (OSPF), an area common to all other OSPF areas that is used as the transit area for inter-area traffic and for distributing routing information between areas. The backbone must be contiguous.

See also: Open Shortest Path First (OSPF)

**backbone router**
In Open Shortest Path First (OSPF), a router that is connected to the backbone area. This includes routers that are connected to more than one area (area border routers (ABRs)). However, backbone routers do not have to be ABRs. Routers that have all networks connected to the backbone are internal routers.

See also: area border router (ABR) backbone Open Shortest Path First (OSPF) router

**background program**
A program that runs while the user is working on another task. The computer`s microprocessor assigns fewer resources to background programs than foreground programs.

See also: foreground program

**backup**
A duplicate copy of a program, a disk, or data, made either for archiving purposes or for safeguarding valuable files from loss in case the active copy is damaged or destroyed. Some application programs automatically make backup copies of data files, maintaining both the current version and the preceding version.

**backup domain controller (BDC)**
A domain controller running Windows NT Server 4.0 or earlier that receives a read-only copy of the directory database for the domain. The directory database contains all account and security policy information for the domain.

See also: Active Directory mixed mode primary domain controller (PDC)

**backup media pool**
A logical collection of data-storage media that has been reserved for use by Microsoft Windows Backup. Backup uses Removable Storage to control access to specific media within a library.

See also: library media pool Removable Storage

**Backup Operators group**
A type of local or global group that contains the user rights you need to back up and restore files and folders. Members of the Backup Operators group can back up and restore files and folders regardless of ownership, permissions, encryption, or auditing settings.

See also: auditing global group local group user rights

**backup set**
A collection of files, folders, and other data that has been backed up and stored in a file or on one or more tapes.

See also: backup set catalog on-disk catalog on-media catalog

**backup set catalog**
A summary of the files and folders that have been saved in a backup set.

See also: backup set

**backup types**

A type that determines which data is backed up and how it is backed up. There are five backup types: copy, daily, differential, incremental, and normal.

See also: copy backup  daily backup  differential backup  incremental backup  normal backup

**bandwidth**
The data transfer capacity of a transmission medium. In digital communications, the transfer capacity expressed in bits per second (bps) or megabits per second (Mbps). For example, Ethernet accommodates a bandwidth of 10,000,000 bps or 10 Mbps. In analog communications, the difference between the highest and lowest frequencies in a specific range. For example, an analog telephone line accommodates a bandwidth of 3,000 hertz (Hz), the difference between the lowest (300 Hz) and highest (3,300 Hz) frequencies that it can carry.

See also: bits per second (bps)

**Bandwidth Allocation Protocol (BAP)**
A Point-to-Point Protocol (PPP) control protocol that is used on a multiprocessing connection to dynamically add and remove links.

See also: Point-to-Point Protocol (PPP)

**BAP**
See other term: Bandwidth Allocation Protocol (BAP)

**base priority**
A precedence ranking that determines the order in which the threads of a process are scheduled for the processor. Use Task Manager to view and change base priorities. For Message Queuing, a property that specifies the queue`s priority in a public queue. You can set the base priority from -32,768 to 32,767; the default priority is 0. Private queues do not support base priority. Message Queuing routes and delivers messages first by base priority, then by message priority.

See also: Message Queuing  private queue  public queue

**Basic authentication**
An authentication mechanism that is supported by most browsers, including Internet Explorer. Basic authentication encodes user name and password data before transmitting it over the network. Note that encoding is not the same as encryption. Also known as plaintext authentication.

See also: Anonymous authentication  authentication  Digest authentication  encryption  password  user name

**basic disk**
A physical disk that can be accessed by MS-DOS and all Windows-based operating systems. Basic disks can contain up to four primary partitions, or three primary partitions and an extended partition with multiple logical drives.

See also: dynamic disk  extended partition  logical drive  MS-DOS (Microsoft Disk Operating System)  primary partition

**basic input/output system (BIOS)**
The set of essential software routines that test computer hardware at startup, start the operating system, and support the transfer of information between hardware devices. The BIOS is stored in read-only memory (ROM) so that it can be run when the computer is turned on. Although critical to performance, the BIOS is usually invisible to computer users.

See also: Extensible Firmware Interface (EFI)  read-only memory (ROM)  x86

**basic storage**
A storage method in MS-DOS and Windows for primary partitions, extended partitions, and logical drives.

See also: dynamic storage  extended partition  logical drive

**basic volume**
A primary partition or logical drive that resides on a basic disk.

See also: basic disk  logical drive  primary partition

**batch program**
An ASCII (unformatted text) file that contains one or more operating system commands. A batch program`s file name has a .cmd or .bat extension. When you type the file name at the command prompt, or when the batch program is run from another program, its commands are processed sequentially. Also called batch files.

See also: American Standard Code for Information Interchange (ASCII)  logon script

**baud rate**
The speed at which a modem communicates. Baud rate refers to the number of times the condition of the line changes. This is equal to bits per second only if each signal corresponds to one bit of transmitted data. Modems must operate at the same baud rate in order to communicate with each other. If the baud rate of one modem is set higher than that of the other, the faster modem usually alters its baud rate to match that of the slower modem.

See also: bits per second (bps)  modem (modulator/demodulator)

**B-channel**
A single channel of an Integrated Services Digital Network (ISDN) line that is used to carry either voice or data information. ISDN Basic Rate Interface (BRI) has 2 B-channels. ISDN Primary Rate Interface (PRI) in North America has 23 B-channels. ISDN Primary Rate Interface (PRI) in Europe has 23 B-channels. Also called bearer channel.

See also: Integrated Services Digital Network (ISDN)

**BDC**
See other term: backup domain controller (BDC)

**Berkeley Internet Name Domain (BIND)**
An implementation of Domain Name System (DNS) written and ported to most available versions of the UNIX operating system. The Internet Software Consortium maintains the BIND software.

See also: BIND boot file  Domain Name System (DNS)

**BGP**
See other term: Border Gateway Protocol (BGP)

**binary**
A base-2 number system in which values are expressed as combinations of two digits, 0 and 1.

**BIND**
See other term: Berkeley Internet Name Domain (BIND)

**BIND boot file**
A configuration file used by DNS servers running under versions of the Berkeley Internet Name Domain (BIND) software implementation. The BIND boot file is a text file, Named.boot, where individual lines in the file list boot directives used to start a service when the DNS server is started. By default, Microsoft DNS servers use DNS service parameters stored in the registry, but they allow the use of a BIND boot file as an alternative for reading boot configuration settings.

See also: Berkeley Internet Name Domain (BIND)  DNS server  registry boot

**bindery**
A database in Novell NetWare 3.x that contains organizational and security information about users and groups.

**BIOS**
See other term: basic input/output system (BIOS)

**B-ISDN**
See other term: broadband integrated services digital network (B-ISDN)

**bit (binary digit)**
The smallest unit of information handled by a computer. One bit expresses a 1 or a 0 in a binary numeral, or a true or false logical condition. A group of 8 bits makes up a byte, which can represent many types of information, such as a letter of the alphabet, a decimal digit, or other character. Also known as a binary digit.

See also: binary

**bits per second (bps)**
The number of bits transmitted every second, used as a measure of the speed at which a device, such as a modem, can transfer data.

See also: modem (modulator/demodulator)

**blank password**
A password that does not contain any characters. Also called a null password.

See also: password policy  strong password  weak password

**block inheritance**
In Group Policy, the method of preventing a child container from inheriting the policy settings from all parent containers. Block inheritance does not apply to Group Policy object (GPO) links that are enforced.

See also: enforce  Group Policy Management console (GPMC)  Group Policy object link  inheritance  precedence

**boot**
The process of starting or resetting a computer. When first turned on (cold boot) or reset (warm boot), the computer runs the software that loads and starts the computer's operating system, which prepares it for use.

**boot files**
The system files needed to start Windows. The boot files include Ntldr and Ntdetect.com.

See also: partition boot sector

**Boot Information Negotiation Layer service (BINLSVC)**
A service that runs on a Remote Installation Services (RIS) server that acts on client boot requests. The display name of BINLSVC is Remote Installation.

See also: Remote Installation Services (RIS)

**Boot Logging**
A process in which a computer that is starting (booting) creates a log file that records the loading of each device and service. The log file is called Ntbtlog.txt, and it is saved in the systemroot directory.

See also: systemroot

**boot partition**
The partition that contains the Windows operating system and its support files. The boot partition can be, but does not have to be, the same as the system partition.

See also: partition  Primary disk  system partition

**boot volume**
The volume that contains the Windows operating system and its support files. The boot volume can be, but does not have to be, the same as the system volume.

See also: system volume  volume

**bootable CD**
A CD-ROM that can be used to start a computer. An automated installation uses a bootable CD to start a computer.

**BOOTP**
See other term: bootstrap protocol (BOOTP)

**BOOTP extensions**
A set of optional information types defined originally in RFC 1497 for use with BOOTP service and later supported by DHCP. In DHCP, these extensions form the legacy core set of client parameters available and supported by most standard DHCP and BOOTP servers.

See also: bootstrap protocol (BOOTP)  Dynamic Host Configuration Protocol (DHCP)  Request for Comments (RFC)

**bootstrap protocol (BOOTP)**
A protocol used primarily on TCP/IP networks to configure diskless workstations. RFCs 951 and 1542 define this protocol. DHCP is a later boot configuration protocol that uses this protocol. The Microsoft DHCP service provides limited support for BOOTP service.

See also: Dynamic Host Configuration Protocol (DHCP)  Request for Comments (RFC)  Transmission Control Protocol/Internet Protocol (TCP/IP)

**Border Gateway Protocol (BGP)**
A routing protocol designed for use between autonomous systems. BGP is especially useful for detecting routing loops.

See also: autonomous system (AS)  routing  routing protocol

**bps**
See other term: bits per second (bps)

**bridgehead server**
In Active Directory replication, a single server in a site that is designated to perform site-to-site replication for a specific domain and transport. In a messaging system, a server that receives and forwards e-mail traffic at each end of a connection agreement, similar to the task a gateway performs.

See also: Active Directory  Active Directory replication  gateway  replication  site

**broadband integrated services digital network (B-ISDN)**
An International Telecommunication Union - Telecommunication [Standardization Sector] (ITU-T) communication standard for high-speed networking that provides new services, including voice, video, and data on the same network.

See also: International Telecommunication Union - Telecommunication [Standardization Sector] (ITU-T)

**broadcast**
The transmission of packets by an Internet Protocol version 4 (IPv4) host to all computers on the subnet.

See also: broadcast address  Internet Protocol (IP)  packet  subnet

**broadcast address**
An Internet Protocol version 4 (IPv4) address that is destined for all hosts on a particular network segment.

See also: broadcast  host  Internet Protocol (IP)  IP address

**broadcast and unknown server (BUS)**
A multicast service on an emulated local area network (ELAN) that forwards broadcast, multicast, and initial unicast data traffic sent by a LAN emulation client (LEC).

See also: emulated local area network (ELAN)  LAN emulation client (LEC)  service

**broadcast message**
A network message sent from a single computer that is distributed to all other devices on the same segment of the network as the sending computer.

**broadcast network**
A network that supports more than two attached routers and has the ability to address a single physical message to all of the attached routers (broadcast). Ethernet is an example of a broadcast network.

See also: router

**browsing**
The process of creating and maintaining an up-to-date list of computers and resources on a network or part of a network by one or more designated computers running the Computer Browser service.

See also: Computer Browser service

**bucket brigade attack**
See other term: man-in-the-middle attack

**buffer**
An area of memory reserved for temporarily holding data before that data is used by a receiving device or application. Buffering protects against the interruption of data flow.

**built-in groups**
The default security groups installed with the operating system. Built-in groups have been granted useful collections of rights and built-in abilities. In most cases, built-in groups provide all the capabilities needed by a particular user. For example, members of the built-in Backup Operators group can back up and restore files and folders. To provide a needed set of capabilities to a user account, assign it to the appropriate built-in group.

See also: group

**bus**
A communication line used for data transfer among the components of a computer system. A bus essentially allows different parts of the system to share data. For example, a bus connects the disk-drive controller, memory, and input/output ports to the microprocessor.

See also: expansion slot  universal serial bus (USB)

# Windows Server 2003 Glossary - C

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - C**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**CA**
See other term: certification authority (CA)

**cache**
A special memory subsystem in which frequently used data values are duplicated for quick access.

See also: cache file  file system cache

**cache file**
A file used by DNS servers and clients to store responses to DNS queries. For Windows DNS servers, the cache file is named Cache.dns by default.

See also: authoritative  cache  DNS client  DNS server  Domain Name System (DNS)

**caching**
The process of temporarily storing recently accessed information in a special memory subsystem for quicker access.

See also: cache  caching resolver

**caching resolver**
A program that extracts information from DNS servers in response to client requests.

See also: cache  cache file  caching  DNS server

**caching-only server**
A DNS sever that does not host any DNS zones but that performs name resolution and stores the results in its cache.

See also: caching  DNS server  DNS zone  name resolution

**Callback Control Protocol (CBCP)**
The Network Control Protocol that negotiates the use of callback over PPP links.

See also: Point-to-Point Protocol (PPP)

**callback number**
The number that a remote access server uses to call back a user. This number can be preset by the administrator or specified by the user at the time of each call, depending on how the administrator configures the user`s callback options. The callback number should be the number of the phone line to which the user`s modem is connected.

See also: preset-to callback  remote access server  set-by-caller callback

**callback security**
A form of network security in which a remote access server calls a user back at a preset number after the user has made an initial connection and has been authenticated.

See also: preset-to callback  remote access server

**called subscriber ID (CSID) string**
A string that specifies the called subscriber ID transmitted by the receiving fax machine when receiving an inbound fax. This string is usually a combination of the fax or telephone number and the name of the business. It is often the same as the transmitter subscriber ID.

See also: string  transmitting station ID (TSID) string

**canonical (CNAME) resource record**

A resource record used to map an alternate alias name to a primary canonical DNS domain name used in the zone.

See also: resource record (RR)

**canonical name**
An object`s distinguished name presented with the root first and without the Lightweight Directory Access Protocol (LDAP) attribute tags (such as: CN=, DC=). The segments of the name are delimited with forward slashes (/). For example, CN=MyDocuments,OU=MyOU,DC=Microsoft,DC=Com is presented as microsoft.com/MyOU/MyDocuments in canonical form.

See also: distinguished name  Lightweight Directory Access Protocol (LDAP)

**capture**
To assign a port to a printer. Documents that you print are sent to the printer through the captured port. For Network Monitor, the process by which frames are copied.

See also: frame

**capture password**
A password that allows the user to capture statistics from the network and to display captured data.

See also: display password  password

**capture trigger**
A set of conditions that, when met, stop the capture or execute a program or command file to perform another type of action related to the capture.

**CardBus**
A 32-bit PC Card.

**cartridge font**
A font contained in a plug-in cartridge and used to add fonts to laser, ink-jet, or high-end dot-matrix printers. Cartridge fonts are distinguished both from internal fonts, which are contained in read-only memory (ROM) in the printer and are always available, and from downloadable (soft) fonts, which reside on disk and which can be sent to the printer as needed.

See also: downloadable fonts  font  font cartridge  read-only memory (ROM)

**cascading hubs**
A network configuration in which hubs are connected to other hubs.

See also: hub

**catalog**
For Indexing Service, a collection of all index information and stored properties for a particular group of file system directories. By default, Indexing Service indexes the System and Web catalogs on your hard drive.

See also: Indexing Service  property

**CBCP**
See other term: Callback Control Protocol (CBCP)

**CBR**
See other term: constant bit rate (CBR)

**CCP**
See other term: Compression Control Protocol (CCP)

**CDFS**
See other term: Compact Disc File System (CDFS)

**certificate**
A digital document that is commonly used for authentication and to help secure information on a network. A certificate binds a public key to an entity that holds the corresponding private key. Certificates are digitally signed by the certification authority that issues them, and they can be issued for a user, a computer, or a service.

**certificate revocation list (CRL)**
A document maintained and published by a certification authority that lists certificates that have been revoked.

See also: certification authority (CA)

**Certificate Services**
A software service that issues certificates for a particular certification authority (CA). It provides customizable services for issuing and managing certificates for the enterprise. Certificates can be used to provide authentication support, including secure e-mail, Web-based authentication, and smart-card authentication.

See also: authentication certification authority (CA) Internet Authentication Service (IAS) service

**certificate store**
A permanent storage where certificates, certificate revocation lists, and certificate trust lists are stored.

See also: certificate revocation list (CRL) certificate trust list (CTL)

**certificate template**
A Windows construct that specifies the format and content of certificates based on their intended usage. When requesting a certificate from a Windows enterprise certification authority (CA), certificate requestors can select from a variety of certificate types that are based on certificate templates.

See also: certification authority (CA)

**certificate trust list (CTL)**
A signed list of root certification authority certificates that an administrator considers reputable for designated purposes, such as client authentication or secure e-mail.

See also: certification authority (CA) root certificate

**certification authority (CA)**
An entity responsible for establishing and vouching for the authenticity of public keys belonging to subjects (usually users or computers) or other certification authorities. Activities of a certification authority can include binding public keys to distinguished names through signed certificates, managing certificate serial numbers, and certificate revocation.

See also: public key root certification authority

**certification hierarchy**
A model of trust for certificates in which certification paths are created by means of the establishment of parent-child relationships between certification authorities.

See also: certification authority (CA) certification path

**certification path**
An unbroken chain of trust, consisting of certificates from trusted certification authorities, from a specific certificate to the root certification authority in a certification hierarchy.

See also: certification authority (CA) certification hierarchy public key

**Challenge Handshake Authentication Protocol (CHAP)**
A challenge-response authentication protocol for Point-to-Point Protocol (PPP) connections described in RFC 1994. It uses the industry-standard MD5 hashing algorithm to hash the combination of a challenge string issued by the authenticating server and the user`s password in the response.

See also: MD5 message digest Point-to-Point Protocol (PPP)

**change journal**
A feature that tracks changes to NTFS volumes, including additions, deletions, and modifications. The change journal exists on the volume as a sparse file.

See also: NTFS file system sparse file volume

**channel**
A path or link through which noncontrol information passes between two devices. A single Basic Rate Interface (BRI) connection, for example, has one physical connection but two channels for exchanging information between devices. This is often called a bearer channel, implying a channel that carries information. On the Internet, a Web site designed to deliver content from the Internet to your computer, similar to subscribing to a favorite Web site.

See also: active content B-channel D-channel

**character mode**
A display mode in which the monitor can display letters, numbers, and other text characters, but no graphical images or character formatting (italics, superscript, and so on).

See also: graphics mode

**child domain**
For DNS and Active Directory, a domain located in the namespace tree directly beneath another domain (the parent domain). For example, example.microsoft.com would be a child domain of the parent domain microsoft.com. Also known as a subdomain.

See also: Active Directory domain Domain Name System (DNS) parent domain

**child object**
An object that resides in another object. A child object implies relation. For example, a file is a child object that resides in a folder, which is the parent object.

See also: object parent object

**Chooser**
The Macintosh desk accessory with which users select the network server and printers they want to use.

**Chooser Pack**
A collection of files, some of which contain PostScript information. When a Macintosh computer sends a print job to a PostScript printer, the printer uses a Chooser Pack to interpret PostScript commands in the print job.

See also: PostScript PostScript printer

**cipher**
The particular algorithm used to transform a readable message (called plaintext or cleartext) into an unreadable, scrambled, or hidden message (called ciphertext).

**circuit switching**
A technology in which a connection is established by closing a switch, for example, by dialing a telephone. This creates a circuit in which all the information transmitted over the connection follows the same route to the destination. The circuit is dedicated to the connection until it is closed.

**claim**
A statement that a server makes (for example, name, identity, key, group, privilege, or capability) about a client.

**claim mapping**
The act of mapping, removing or filtering, or passing claims between various claim sets.

**claims-aware application**
A Microsoft ASP .NET application that performs authorization based on the claims that are present in an Active Directory Federation Services (ADFS) security token.

**class**
A category of objects that share a common set of characteristics. Each object in the directory is an instance of one or more classes in the schema.

See also: object schema

**Class A IP address**
A unicast IP address that ranges from 1.0.0.1 through 127.255.255.254. The first octet indicates the network, and the last three octets indicate the host on the network. Class-based IP addressing has been superceded by Classless Interdomain Routing (CIDR).

See also: Class B IP address Class C IP address Classless Interdomain Routing (CIDR) IP address

**Class B IP address**
A unicast IP address that ranges from 128.0.0.1 through 191.255.255.254. The first two octets indicate the network, and the last two octets indicate the host on the network. Class-based IP addressing has been superceded by Classless Interdomain Routing (CIDR).

See also: Class A IP address Class C IP address Classless Interdomain Routing (CIDR) IP address

**Class C affinity**
Specifies that Network Load Balancing direct multiple requests from the same TCP/IP Class C address range to the same cluster host.

See also: affinity  Network Load Balancing  single affinity

**Class C IP address**
A unicast IP address that ranges from 192.0.0.1 to 223.255.255.254. The first three octets indicate the network, and the last octet indicates the host on the network. Network Load Balancing provides optional session support for Class C IP addresses (in addition to support for single IP addresses) to accommodate clients that make use of multiple proxy servers at the client site. Class-based IP addressing has been superceded by Classless Interdomain Routing (CIDR).

See also: Class A IP address  Class B IP address  Classless Interdomain Routing (CIDR)  IP address  Network Load Balancing  proxy server

**classical IP over ATM (CLIP)**
A proposed Internet standard, described in RFC 2225, that allows Internet Protocol (IP) communication directly on the asynchronous transfer mode (ATM) layer, bypassing an additional protocol (such as Ethernet or Token Ring) in the protocol stack.

See also: asynchronous transfer mode (ATM)  Internet Protocol (IP)

**Classless Interdomain Routing (CIDR)**
An IP address and routing management method that allocates IP addresses in a way that reduces the number of routes stored on any individual router, while also increasing the number of available IP addresses. CIDR replaces class-based IP address allocation.

See also: IP address  router

**clear**
To turn off an option by removing the X or check mark from a check box. You clear a check box by clicking it, or by selecting it and then pressing the SPACEBAR.

**cleartext**
See other term: plaintext

**cleartext passwords**
Passwords that are not scrambled, thus making them more susceptible to network sniffers.

See also: password  plaintext

**client**
Any computer or program connecting to, or requesting the services of, another computer or program.

See also: server

**client access**
The ability of client computers to connect to a server or resource, for example, a file on a server or a cluster resource.

See also: client  cluster  resource  server

**client account partner discovery Web page**
The Web page that is used to interact with a user to determine which account partner the user belongs to when Active Directory Federation Services (ADFS) cannot automatically determine which of the account partners should authenticate the user.

**client application**
A Windows-based application that can display and store linked or embedded objects. For distributed applications, the application that imitates a request to a server application.

See also: server application

**client authentication**
A method of authentication by which the client in a client-server communication proves its identity to the server.

See also: authentication  client  identity  server

**client failback**
The process in which a namespace client, after failing over to another target, fails back to the previous target.

**client failover**
The process in which a namespace client attempts to access subsequent targets in a referral if the first target is (or becomes) unavailable.

**client logoff Web page**
When Active Directory Federation Services (ADFS) performs a logoff operation, a Web page that is executed to provide visual feedback to the user that the logoff has occurred.

**client logon Web page**
When Active Directory Federation Services (ADFS) collects client credentials, a Web page that is executed to perform the user interaction. The client logon Web page may use any necessary business logic to determine the type of credentials to collect.

**client request**
A service request from a client computer to a server computer or a cluster of server computers.

See also: client  server

**Client Service for NetWare**
A service included that allows clients to make direct connections to resources on computers running NetWare 2.x, 3.x, 4.x, or 5.x server software by using the Internetwork Packet Exchange (IPX) protocol only. This service is included with Windows XP Professional and the Windows Server 2003 family.

See also: Internetwork Packet Exchange (IPX)  service

**CLIP**
See other term: classical IP over ATM (CLIP)

**ClipBook Server**
A system service that supports ClipBook Viewer, which allows pages to be seen by remote ClipBooks.

**cluster**
In data storage, the smallest amount of disk space that can be allocated to hold a file. All file systems used by Windows organize hard disks based on clusters, which consist of one or more contiguous sectors. The smaller the cluster size, the more efficiently a disk stores information. If no cluster size is specified during formatting, Windows picks defaults based on the size of the volume. These defaults are selected to reduce the amount of space that is lost and the amount of fragmentation on the volume. Also called an allocation unit. In computer networking, a group of independent computers that work together to provide a common set of services and present a single-system image to clients. The use of a cluster enhances the availability of the services and the scalability and manageability of the operating system that provides the services.

See also: availability  client  file system  scalability  volume

**cluster adapter**
The adapter that, when using multiple network adapters in each host of a Network Load Balancing cluster, handles the network traffic for cluster operations (the traffic for all hosts in the cluster). This adapter is programmed with the host`s cluster IP address.

See also: cluster  dedicated adapter  host  IP address  Network Load Balancing

**Cluster Administrator**
An application that configures a cluster and its nodes, groups, and resources. Cluster Administrator can run on any member of the trusted domain regardless of whether the computer is a cluster node.

See also: cluster  Cluster.exe  node  server cluster

**Cluster Administrator extension**
A software component that implements the Cluster Administrator extension application programming interface (API) for allowing Cluster Administrator to configure a new resource type.

See also: application programming interface (API)  cluster  Cluster Administrator

**Cluster API**
A collection of functions that are implemented by the cluster software and used by a cluster-aware client or server application, a cluster management application, or a Resource DLL. The Cluster API is used to manage the cluster, cluster objects, and the

cluster database.

See also: cluster  Resource DLL  server cluster

**cluster full Internet name**
A full Internet name for the Network Load Balancing cluster (for example, cluster.microsoft.com). This name is used for the cluster as a whole and should be the same for all hosts in the cluster.

See also: affinity  Network Load Balancing  single affinity

**cluster IP address**
The Network Load Balancing cluster`s IP address in standard Internet dotted notation (for example, w.x.y.z). The address is a virtual IP address used to address the cluster as a whole, and it should be the IP address that maps to the full Internet name that you specify for the cluster. In a Network Load Balancing cluster, this address must be set identically for all hosts in the cluster.

See also: Network Load Balancing  Network Load Balancing cluster

**cluster log**
An optionally enabled trace record of Cluster service events on a node. Not synonymous with quorum log.

See also: cluster  node  quorum log

**cluster network address**
The network (media access control) address for the network adapter that is to be used for handling client-to-cluster traffic in a Network Load Balancing cluster.

See also: Network Load Balancing  Network Load Balancing cluster

**Cluster service**
The essential software component that controls all aspects of server cluster operation and manages the cluster database. Each node in a server cluster runs one instance of the Cluster service.

See also: cluster  node  server cluster

**cluster storage**
Storage where one or more attached disks hold data used either by server applications running on the cluster or by applications for managing the cluster. Each disk on the cluster storage is owned by only one node of the cluster. The ownership of disks moves from one node to another when the disk group fails over or moves to the other node.

See also: cluster  failover  node

**Cluster.exe**
An alternative to using Cluster Administrator to administer clusters from the command prompt. You can also call Cluster.exe from command scripts to automate many cluster administration tasks.

See also: cluster  Cluster Administrator

**cluster-aware application**
An application that can run on a cluster node and that can be managed as a cluster resource. Cluster-aware applications use the Cluster API to receive status and notification information from the server cluster.

See also: cluster  Cluster API  cluster-unaware application  server cluster

**cluster-unaware application**
An application that can run on a cluster node and be managed as a cluster resource but that does not support the Cluster API.

See also: cluster  Cluster API  cluster-aware application  node

**CMYK color space**
Multidimensional color space consisting of the cyan, magenta, yellow, and black intensities that make up a given color. Commercial color printing devices generally use this system of four-color process inks.

See also: color management  color space

**cn (Common-Name)**
The descriptive relative distinguished name for the schema object.

See also: distinguished name  schema

**code page**
A means of providing support for character sets and keyboard layouts for different countries or regions. A code page is a table that relates the binary character codes used by a program to keys on the keyboard or to characters on the display.

**codec**
Hardware that can convert audio or video signals between analog and digital forms (coder/decoder), hardware or software that can compress and uncompress audio or video data (compression/decompression), or the combination of coder/decoder and compression/decompression. Generally, a codec compresses uncompressed digital data so that the data uses less memory.

**color gamut**
The particular range of colors that a device is able to produce. A device such as a scanner, monitor, or printer can produce a unique range of colors, which is determined by the characteristics of the device itself.

See also: color profile  rendering intent

**color management**
Process of producing accurate, consistent color among a variety of input and output devices. A color management system (CMS) maps colors between devices such as scanners, monitors, and printers; transforms colors from one color space to another (for example, RGB to CMYK); and provides accurate on-screen or print previews.

See also: CMYK color space  RGB color space

**color profile**
A profile that contains the data needed for translating the values of a color gamut. This data includes information about color, hue, saturation, and brightness.

See also: color gamut  hue  saturation

**color space**
A set of three values that defines how a color can be represented on computer devices such as monitors, scanners, and printers. For example, in the LAB color space, the terms luminance or whiteness (L), redness-greenness (A), and yellowness-blueness (B) are used; in the HVC system, the terms are hue (H), value (V), and chroma (C). Color space refers to the three-dimensional space that is defined by the respective values, such as L, A, and B.

See also: CMYK color space  color space  RGB color space

**COM**
See other term: Component Object Model (COM)

**COM Internet Services Proxy**
Software that supports distributed applications that use Hypertext Transfer Protocol (HTTP) to communicate through Internet Information Services (IIS).

See also: Hypertext Transfer Protocol (HTTP)  Internet Information Services (IIS)

**Command Prompt window**
A window displayed on the desktop used to interface with the MS-DOS operating system. MS-DOS commands are typed at an entry point identified by a blinking cursor.

See also: MS-DOS (Microsoft Disk Operating System)

**common groups**
Groups that appear in the program list on the Start menu for all users who log on to the computer. Only administrators can create or change common groups.

See also: group

**communication port**
A port on a computer that allows asynchronous communication of one byte at a time. Also called a serial port.

See also: asynchronous communication  serial port

**communication settings**
Operating parameters, such as bits per second (bps) and modem type, that apply to serial ports on a computer.

See also: bits per second (bps)  modem (modulator/demodulator)  serial port

**community name**
A name that identifies groups of Simple Network Management Protocol (SNMP) hosts. This name is placed in SNMP messages that are sent between SNMP-managed devices such as servers running Windows Server 2003 and SNMP management stations. Typically, all hosts belong to Public, which is the standard name for a common community of all SNMP hosts.

See also: host  Simple Network Management Protocol (SNMP)  trap

**Compact Disc File System (CDFS)**
A 32-bit protected-mode file system that controls access to the contents of CD-ROM drives.

**Component Object Model (COM)**
An object-based programming model designed to promote software interoperability; it allows two or more applications or components to easily cooperate with one another, even if they were written by different vendors, at different times, in different programming languages, or if they are running on different computers running different operating systems. OLE technology and ActiveX are both built on top of COM.

See also: ActiveX  OLE

**Compression Control Protocol (CCP)**
A protocol used in the negotiation process in a Point-to-Point Protocol (PPP) connection. CCP is one type of Network Control Protocol. Network Control Protocols are used to establish and configure different network protocol parameters for Internet Protocol (IP), Internetwork Packet Exchange (IPX), and NetBIOS Extended User Interface (NetBEUI).

See also: Internet Protocol (IP)  Internetwork Packet Exchange (IPX)  NetBIOS Extended User Interface (NetBEUI)  Network Control Protocol  Point-to-Point Protocol (PPP)

**computer account**
An account that is stored in Active Directory and that uniquely identifies a computer in a domain. A computer account uses the same name as the computer joining the domain.

See also: Active Directory  domain

**Computer Browser service**
A service that maintains an up-to-date list of computers that share resources on your network and that supplies the list to programs that request it. The Computer Browser service is used to view a list of available network resources.

See also: resource  service

**Computer Management**
A component you can use to view and control many aspects of the computer configuration. Computer Management combines several administration utilities into a single console tree, providing easy access to a local or remote computer`s administrative properties and tools.

See also: console tree

**computer name**
A unique name of up to 15 uppercase characters that identifies a computer to the network. The name cannot be the same as any other computer or domain name in the network.

See also: domain name

**computer quota**
For Message Queuing, the storage size limit for messages on a computer, based on the total size of the messages. When a computer quota is reached, Message Queuing can no longer send messages to that computer until one or more messages are removed from queues. Message Queuing enforces the computer quota before it enforces the queue quota on a computer.

See also: Message Queuing  queue quota

**computer-telephony integration (CTI)**
The practice of using a computer to control one or more telephone and communications functions.

**configuration set**
For Active Directory Application Mode (ADAM), a set of ADAM instances that share and replicate to a common schema partition and a common configuration partition.

**conflict detection**
For DHCP, an optional server-side mechanism for detecting if a scope IP address is in use on the network. When enabled, the DHCP server will ping an address first before offering that address to clients, and then it will briefly await a response. If the pinged address responds, a conflict is registered and that address is not offered to clients obtaining a lease from the server.

See also: DHCP server  Dynamic Host Configuration Protocol (DHCP)  lease  ping  scope

**connect**
To assign a drive letter, port, or computer name to a shared resource so that you can use it.

See also: shared resource

**connected user**
A user who has access to a computer or a resource across the network.

See also: resource

**connected, authenticating user**
A user's status when a telephone connection has been established but authentication has not yet taken place. The user may be trying to prove security clearance, or the system may be idle. If this condition occurs, followed by the Waiting for Call phase, then the user was unable to provide a correct user name or password. If this phase is repeated, followed by the Waiting for Call phase, an unauthorized attempt to access the network may be under way.

See also: authentication  Waiting for Call

**connection**
For DFS Replication, a one-way replication path between two members of a replication group.

**connection object**
An Active Directory object that represents a replication connection from one domain controller to another. The connection object is a child of the replication destinations NTDS Settings object and identifies the replication source server, contains a replication schedule, and specifies a replication transport. Connection objects are created automatically by the Knowledge Consistency Checker (KCC), but they can also be created manually. Automatically generated connections must not be modified by the user unless they are first converted into manual connections.

See also: Active Directory  Knowledge Consistency Checker (KCC)  replication

**connection request policy**
A set of conditions and profile settings that network administrators use to specify how Internet Authentication Service (IAS) servers handle incoming authentication and accounting request messages.

See also: authentication  Internet Authentication Service (IAS)  remote access policy

**connectionless**
A network protocol in which a sender broadcasts traffic on the network to an intended receiver without first establishing a connection to the receiver.

See also: protocol

**connection-oriented**
A type of network protocol that requires an end-to-end virtual connection between the sender and receiver before communicating across the network.

See also: protocol

**connector application**
For Message Queuing, an application that enables Message Queuing computers to communicate with computers that use other messaging systems.

See also: connector queue  foreign computer  Message Queuing

**connector queue**
For Message Queuing, a queue created on servers running a connector application. You can use the connector application to exchange messages with computers that are running other message-queuing products.

See also: connector application  foreign computer  Message Queuing

**console**
A framework for hosting administrative tools, such as Microsoft Management Console (MMC). A console is defined by the items in its console tree, which might include folders or other containers, World Wide Web pages, and other administrative items. A console has windows that can provide views of the console tree and the administrative properties, services, and events that are acted on by the items in the console tree.

See also: console tree  details pane  Microsoft Management Console (MMC)

**console tree**
The left pane in Microsoft Management Console (MMC) that displays the items contained in the console. The items in the console tree and their hierarchical organization determine the capabilities of a console.

See also: details pane  Microsoft Management Console (MMC)

**constant bit rate (CBR)**
An asynchronous transfer mode (ATM) service type that supports constant bandwidth allocation. This service type is used for voice and video transmissions that require little or no cell loss and rigorous timing controls during transmission.

See also: asynchronous transfer mode (ATM)  bandwidth

**constrained delegation**
The ability to specify that a service or computer account can perform Kerberos delegation to a limited set of services.

See also: delegation  Kerberos V5 authentication protocol  service

**container object**
An object that can logically contain other objects. For example, a folder is a container object.

See also: Active Directory  noncontainer object  object

**convergence**
The process of stabilizing a system after changes occur in the network. For dynamic routing, if a route becomes unavailable, routers send update messages throughout the network, reestablishing information about preferred routes. For Network Load Balancing, a process by which hosts exchange messages to determine a new, consistent state of the cluster and to elect the default host. During convergence, a new load distribution is determined for hosts that share the handling of network traffic for specific Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) ports.

See also: cluster  default host  host  Network Load Balancing  routing  User Datagram Protocol (UDP)

**copy backup**
A backup that copies all selected files but does not mark each file as having been backed up (in other words, the archive attribute is not cleared). Copying is useful if you want to back up files between normal and incremental backups because copying does not affect these other backup operations.

See also: daily backup  differential backup  incremental backup  normal backup

**copy set**
A duplicate of the media master that Remote Storage copies to a different tape or disk. Copy sets are typically used for backup purposes.

See also: media master  Remote Storage

**count to infinity**
A loop that happens when a link in a network goes down and routers on the network update their routing tables with incorrect hop counts. For example, a loop can develop if the link to Router C goes down. Router B then advertises that the link is down and that it has no route to C. Because Router A has a route to C with a metric of 2, it responds to Router B and sends its link to C. Router B then updates its table to include a link with metric 3, and the routers continue to announce and update their links to C until they reach the number 16. This is a count to infinity.

See also: router

**CPU Time**
In Task Manager, the total processor time, in seconds, used by a process since it started.

See also: Task Manager

**CPU Usage**

In Task Manager, the percentage of time that a process used the CPU since the last update. This percentage is displayed in Task Manager on the Processes tab, under the CPU column heading.

See also: Task Manager

**crash consistency**
A feature of shadow copy backups that ensures all files are backed up, regardless of their state.

See also: volume shadow copy

**Crash Dump Type**
Specifies the file format Dr. Watson will use to store the information. The Full format contains the entire memory space of the program, as well as the program image itself, the handle table, and other information that will be useful to the debugger. The Mini format may include the full memory and handle table, or it may simply contain information about a single thread. The Windows NT 4.0-compatible Full format provides you with the opportunity to use older tools to analyze the dump file. Crash Dump Type is only available when you have selected the Create Crash Dump File check box.

**CRC errors**
Errors caused by the failure of a cyclic redundancy check. A CRC error indicates that one or more characters in the data packet received were found garbled on arrival.

**credentials**
Information that includes identification and proof of identification that is used to gain access to local and network resources. Examples of credentials are user names and passwords, smart cards, and certificates.

See also: password  smart card

**CRL**
See other term: certificate revocation list (CRL)

**CRL distribution point**
An optional extension in an X.509 v3 certificate that identifies how information is obtained. Also, a directory entry or other distribution source for certificate revocation lists.

See also: certificate revocation list (CRL)  X.509 v3 certificate

**cross-reference object**
An object in which Active Directory stores information about directory partitions and external directory services. An example of an external directory service is another LDAP-compliant directory.

See also: Active Directory  directory partition  Lightweight Directory Access Protocol (LDAP)

**CryptoAPI**
An application programming interface (API) that is provided as part of Microsoft Windows. CryptoAPI provides a set of functions that allows applications to encrypt or digitally sign data in a flexible manner while providing protection for the user`s sensitive private key data. Actual cryptographic operations are performed by independent modules known as cryptographic service providers (CSPs).

See also: application programming interface (API)  cryptographic service provider (CSP)  private key

**cryptographic checksum**
A mathematical value that is a result of a calculation involving a cryptographic algorithm and a cryptographic key. Also known as an integrity check value (ICV) or a message integrity code (MIC).

See also: cryptography

**cryptographic service provider (CSP)**
The code that performs authentication, encoding, and encryption services that Windows-based applications access through CryptoAPI. A CSP is responsible for creating keys, destroying them, and using them to perform a variety of cryptographic operations. Each CSP provides a different implementation of the CryptoAPI. Some provide stronger cryptographic algorithms, while others use hardware components, such as smart cards.

See also: authentication  CryptoAPI  encryption  service  smart card

**cryptography**
The study or analysis of codes and encoding methods used to secure information. Cryptography is used to provide confidentiality, data integrity, authentication (entity and data origin), and nonrepudiation.

See also: authentication  nonrepudiation

**CSP**
See other term: cryptographic service provider (CSP)

**CTI**
See other term: computer-telephony integration (CTI)

**CTL**
See other term: certificate trust list (CTL)

**custom file type**
Typically, files with extensions that have been created for special kinds of files. Custom file types are not tracked by the system registry.

See also: registry

# Windows Server 2003 Glossary - D

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - D**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**DACL**

See other term: discretionary access control list (DACL)

**daily backup**

A backup that copies all selected files that have been modified the day the daily backup is performed. The backed-up files are not marked as having been backed up (in other words, the archive attribute is not cleared).

See also: copy backup  differential backup  incremental backup  normal backup

**Data Communications Equipment (DCE)**

One of two types of hardware that are connected by an RS-232-C serial connection, the other being a Data Terminal Equipment (DTE) device. A DCE is an intermediary device that often transforms input from a DTE before sending it to a recipient. A modem, for example, is a DCE that modulates data from a microcomputer (DTE) and sends it along a telephone connection.

See also: Data Terminal Equipment (DTE)  RS-232-C standard

**Data Encryption Standard (DES)**

An encryption algorithm that uses a 56-bit key and maps a 64-bit input block to a 64-bit output block. The key appears to be a 64-bit key, but one bit in each of the eight bytes is used for odd parity, resulting in 56 bits of usable key.

See also: key

**data fork**

One of two forks (resource fork and data fork) that make up each Macintosh file. The data fork holds most of the file's information and is shared between Macintosh and personal computer clients.

See also: resource fork

**data integrity**

A property of secure communications that allows a computer to verify that data has not been modified in transit from its source. For example, Internet Protocol security (IPSec)-protected data contains a cryptographic checksum that incorporates a secret key that is known only to the IPSec peers that are communicating. An intermediate node can modify the data, but without knowledge of the secret key, the node cannot recompute a correct cryptographic checksum.

See also: cryptographic checksum  Internet Protocol security (IPsec)

**Data Link Control (DLC)**

An address that uniquely identifies a node on a network. Every network adapter has a DLC address or DLC identifier (DLCI). Some network protocols, such as Ethernet and Token Ring, use DLC addresses exclusively. Other protocols, such as TCP/IP, use a logical address at the OSI Network layer to identify nodes. However, all network addresses must eventually be translated to DLC addresses. In TCP/IP networks, this translation is performed by the Address Resolution Protocol (ARP).

See also: Address Resolution Protocol (ARP)  node  Open Systems Interconnection (OSI) reference model

**data origin authentication**

A property of secure communications that allows a computer to verify that data originated from a valid source. For example, IPSec-protected data contains a cryptographic checksum that incorporates a secret key that is known only to the IPSec peers that are communicating. An invalid source can send data, but without knowledge of the secret key, the source cannot compute a correct cryptographic checksum.

See also: cryptographic checksum  cryptography  encryption  Internet Protocol security (IPsec)  key

**Data Terminal Equipment (DTE)**
In the RS-232-C hardware standard, any device, such as a remote access server or client, that has the ability to transmit information in digital form over a cable or a communications line.

See also: Data Communications Equipment (DCE)  remote access server  RS-232-C standard

**datagram**
One packet, or unit, of information that includes relevant delivery information, such as the destination address, that is sent through a packet-switching network.

See also: packet

**data-overrun error**
A state in which the sending computer is transmitting characters faster than the receiving computer can accommodate them. If this problem persists, reduce the bits-per-second (bps) rate.

See also: bits per second (bps)

**Dcdiag**
A Windows Support Tool that analyzes the state of domain controllers in a forest or enterprise and provides detailed information about how to identify abnormal behavior in a system. Domain controllers are identified and tested according to directives entered by the user at the command line. Also known as Domain Controller Diagnostic Tool.

See also: Command Prompt window  domain controller

**DCE**
See other term: Data Communications Equipment (DCE)

**D-channel**
A separate channel of an Integrated Services Digital Network (ISDN) line that is used for ISDN signaling. For ISDN Basic Rate Interface (BRI), the D-channel is 16 kilobits per second (Kbps). For ISDN Primary Rate Interface (PRI), the D-channel is 64 Kbps. Also called data channel.

See also: Integrated Services Digital Network (ISDN)  switch type

**DCOM**
See other term: Distributed Component Object Model (DCOM)

**DDE**
See other term: dynamic data exchange (DDE)

**dead-letter queue**
For Message Queuing, a queue that stores nontransactional messages that are undeliverable or expired. These queues store failed messages on the computer on which the message expired. Messages in these queues are written to disk and are therefore recoverable.

See also: Message Queuing  queue  transactional dead-letter queue  transactional message

**debugger**
A program designed to aid in detecting, locating, and correcting errors in another program by allowing the programmer to step through the program, examine the data, and monitor conditions such as the values of variables.

See also: variable

**dedicated adapter**
The network adapter that, when using multiple network adapters in each host of a Network Load Balancing cluster, handles network traffic not related to cluster operations (the traffic for individual hosts on the network). This adapter is programmed with the host`s dedicated IP address.

See also: cluster adapter  IP address  Network Load Balancing

**dedicated connection**
A communications channel that connects two or more geographic locations. Dedicated connections are private or leased lines, rather than public lines.

See also: channel

**dedicated IP address**
The IP address of a Network Load Balancing host used for network traffic that is not associated with the Network Load Balancing cluster (for example, Telnet access to a specific host within the cluster). This IP address is used to individually address each host in the cluster and therefore should be unique for each host.

See also: host  IP address  Network Load Balancing  Network Load Balancing cluster

**default button**
In some dialog boxes, the command button that is selected or highlighted when the dialog box is initially displayed. The default button has a bold border, indicating that it will be chosen automatically if you press ENTER. You can override a default button by clicking Cancel or another command button.

**default host**
The host with the highest host priority for which a drainstop command is not in progress. After convergence, the default host handles all of the network traffic for Transmission Control Protocol (TCP) and User Datagram Protocol (UDP) ports that are not otherwise covered by port rules.

See also: convergence  drainstop  host  host priority  port rule  User Datagram Protocol (UDP)

**default network**
In the Macintosh environment, the physical network on which the processes of a server reside as nodes and on which the server appears to users. The default network of the server must be one to which that server is attached. Only servers on AppleTalk Phase 2 internets have default networks.

See also: AppleTalk Phase 2  Internet  node

**default printer**
The printer to which a computer sends documents if you select the Print command without first specifying which printer you want to use with a program. You can have only one default printer; it should be the printer you use most often.

See also: printer

**default security level**
For software restriction policies, the default setting that defines whether software in a Group Policy object (GPO) is allowed to run. Exceptions can be made to the default security level by means of software restriction policies rules.

See also: Group Policy object (GPO)  software restriction policies  software restriction policies rule

**default tree and context**
The position of a User object in the file system of a Novell Directory Services (NDS) tree on a Novell NetWare network. The default tree and context is the default logon location in an NDS tree for a Microsoft Windows computer that is running Client Service for NetWare.

See also: Client Service for NetWare  Novell Directory Services (NDS)  object

**default user**
The profile that serves as a basis for all user profiles. Every user profile begins as a copy of the default user profile.

See also: user profile

**default zone**
The zone to which all Macintosh clients on the network are assigned by default.

See also: zone

**defragmentation**
The process of rewriting parts of a file to contiguous sectors on a hard disk to increase the speed of access and retrieval. In Active Directory, defragmentation rearranges how the data is written in the directory database file to compact it.

See also: Active Directory  fragmentation

**delegated authentication**
A method of authentication by which a trusted server (or service) is enabled to act as the client when it connects to third-tier application resources.

See also: authentication  client  server  service

**delegation**
An assignment of administrative responsibility to a user, computer, group, or organization. For Active Directory, an assignment of responsibility that allows users without administrative credentials to complete specific administrative tasks or to manage specific directory objects. Responsibility is assigned through membership in a security group, the Delegation of Control Wizard, or Group Policy settings. For DNS, an assignment of responsibility for a DNS zone. Delegation occurs when a name server (NS) resource record in a parent zone lists the DNS server that is authoritative for a child zone.

See also: Active Directory  administrative credentials  DNS server  Domain Name System (DNS)  Group Policy  security group  zone

**delta CRL**
A document that lists certificates that have been revoked after the last full certificate revocation list (CRL) has been published. Delta CRLs are maintained and published by a certification authority (CA), and they are normally much smaller than a full CRL.

See also: certificate revocation list (CRL)  certification authority (CA)

**demand-dial connection**
A connection, typically using a circuit-switched wide area network link, that is initiated when data needs to be forwarded. The demand-dial connection is typically terminated when there is no traffic.

See also: wide area network (WAN)

**demand-dial routing**
Routing that makes dial-up connections to connect networks based on need. For example, a branch office with a modem that dials and establishes a connection only when there is network traffic from one office to another.

See also: dial-up connection  modem (modulator/demodulator)

**demilitarized zone (DMZ)**
See other term: perimeter network

**denial-of-service attack**
A situation in which a person exploits a weakness or a design limitation of a network service to overload or halt the service, so that the service is not available for use. This type of attack is typically started to prevent other users from using a network service such as a web server or a file server.

See also: service  Web server

**dependency**
A relationship of reliance between two resources that makes it necessary for them to run in the same group on the same node. For example, an application is dependent on the disks that contain its data resources.

See also: node  resource

**dependency tree**
A diagram for visualizing the dependency relationships between resources.

See also: dependency  resource

**dependent client**
For Message Queuing, a computer that requires synchronous access to a Message Queuing server to perform all standard message queuing operations, such as sending and receiving messages and creating queues.

See also: independent client  Message Queuing server

**DES**
See other term: Data Encryption Standard (DES)

**descendent key**
All the subkeys that appear when a key in the registry is expanded. A descendent key is the same as a subkey.

See also: key  subkey

**desktop**
The on-screen work area on which windows, icons, menus, and dialog boxes appear.

**desktop pattern**

A design that appears across your desktop. You can create your own pattern or select a pattern provided by Windows.

See also: desktop

**destination document**
The document into which a package or a linked or embedded object is being inserted. For an embedded object, this is sometimes also called the container document.

See also: embedded object

**details pane**
The right pane in Microsoft Management Console (MMC) that displays details for the selected item in the console tree. The details can be a list of items or they can be administrative properties, services, and events that are acted on by a snap-in.

See also: console tree  Microsoft Management Console (MMC)  service  snap-in

**device**
Any piece of equipment that can be attached to a network or computer, for example, a computer, printer, joystick, adapter, or modem card, or any other peripheral equipment. Devices normally require a device driver to function with Windows. For Windows licensing, devices can be electronic equipment such as computers, workstations, terminals, and handheld computers that can access or use the services of Windows operating systems, including file sharing, print sharing, remote access, and authentication.

See also: device driver

**device conflict**
A conflict that occurs when the same system resources have been allocated to two or more devices. System resources include interrupt request (IRQ) lines, direct memory access (DMA) channels, input/output (I/O) ports, and memory addresses.

See also: direct memory access (DMA)  input/output (I/O) port  interrupt request (IRQ) lines  memory address  resource

**device driver**
Software that allows Windows to communicate with a specific hardware device. Before Windows can use any new hardware, a device driver must be installed.

See also: device  signed driver  unsigned driver  Windows Catalog

**device fonts**
See other term: printer fonts

**Device Manager**
An administrative tool that you can use to manage the devices on your computer. Using Device Manager, you can view and change device properties, update device drivers, configure device settings, and uninstall devices.

See also: device  uninstall

**DFS**
See other term: Distributed File System (DFS)

**DFS link**
An element in the Distributed File System (DFS) namespace that lies below the root and maps to one or more targets, each of which corresponds to a shared folder or another DFS root.

See also: DFS root  Distributed File System (DFS)  domain DFS

**DFS namespace**
A namespace consisting of a root and many links and targets. The namespace starts with a root that maps to one or more root targets. Below the root are links that map to their own targets. The Distributed File System (DFS) namespace provides the user with a logical view of distributed network shares.

See also: Distributed File System (DFS)  root

**DFS path**
The combination of a Distributed File System (DFS) root and a DFS link. An example of a DFS path is \\server\dfs\a\b\c\link, where \\server\dfs is the DFS root, and \a\b\c\ is the DFS link.

See also: DFS link  DFS root  Distributed File System (DFS)

**DFS root**
The starting point of the Distributed File System (DFS) namespace. The root is often used to refer to the namespace as a whole. A root maps to one or more root targets, each of which corresponds to a shared folder on a server.

See also: DFS link  DFS namespace  Distributed File System (DFS)

**DFS topology**
The overall logical hierarchy of the Distributed File System (DFS), including elements such as roots, links, shared folders, and replica sets, as depicted in the DFS administrative console. This is not to be confused with the DFS namespace, which is the logical view of shared resources seen by users.

See also: DFS link  DFS namespace  DFS root  Distributed File System (DFS)  domain DFS

**DHCP**
See other term: Dynamic Host Configuration Protocol (DHCP)

**DHCP acknowledgment message (DHCPACK)**
A message sent by the DHCP server to a client to acknowledge and complete a client`s request for leased configuration. This message will contain a committed IP address for the client to use for a stated period of time along with other optional client parameters. The DHCP acknowledgment message name is DHCPACK.

See also: DHCP server  Dynamic Host Configuration Protocol (DHCP)

**DHCP class identifier**
A special reserved option type used by DHCP clients to optionally identify membership in a specific DHCP option class, either a vendor or user class. For vendor class identification, hardware vendors can choose to predefine specific identifier values; for example, to identify a client`s hardware configuration. For user class identification, values can be defined administratively to identify a logical group of DHCP clients, such as all clients in a particular building and floor location.

See also: DHCP client  DHCP option  Dynamic Host Configuration Protocol (DHCP)

**DHCP client**
Any network-enabled device that supports the ability to communicate with a DHCP server for the purpose of obtaining dynamic leased IP configuration and related optional parameters information.

See also: DHCP server  Dynamic Host Configuration Protocol (DHCP)  lease

**DHCP client alternate configuration**
An alternate static configuration option for TCP/IP network connections that provides simplified computer migration between networks.

See also: Transmission Control Protocol/Internet Protocol (TCP/IP)

**DHCP decline message (DHCPDECLINE)**
A message sent by a DHCP client to the DHCP server to decline the offer of an IP address on the network. This message is used when the client detects a potential conflict because the IP address is found to be already in use on the network. The DHCP decline message name is DHCPDECLINE.

See also: DHCP client  DHCP server  Dynamic Host Configuration Protocol (DHCP)

**DHCP information message (DHCPINFORM)**
A reserved DHCP message type used by computers on the network to request and obtain information from a DHCP server for use in their local configuration. When this message type is used, the sender is already externally configured for its IP address on the network, which may or may not have been obtained using DHCP. The DHCP information message name is DHCPINFORM.

See also: DHCP server  Dynamic Host Configuration Protocol (DHCP)

**DHCP negative acknowledgment message (DHCPNAK)**
A message sent by a DHCP server to a client to indicate that the IP address that the client requested is not correct for the local IP network served by the DHCP server. This message is most often used when the client computer was moved to a new location, but it could also indicate that the client`s lease with the server has expired. The DHCP negative acknowledgment message name is DHCPNAK.

See also: DHCP server  Dynamic Host Configuration Protocol (DHCP)  lease

**DHCP offer message (DHCPOFFER)**

A message used by DHCP servers to offer the lease of an IP address to a DHCP client when it starts on the network. When this message is used, a client can receive more than one offer if multiple DHCP servers are contacted during the DHCP discovery phase, but the client will typically select the first address it is offered. The DHCP offer message name is DHCPOFFER.

See also: DHCP client  DHCP server  Dynamic Host Configuration Protocol (DHCP)

**DHCP option**
Address configuration parameters that a DHCP service assigns to clients. Most DHCP options are predefined, based on optional parameters defined in Request for Comments (RFC) 1542, although extended options can be added by vendors or users.

See also: DHCP service  Dynamic Host Configuration Protocol (DHCP)

**DHCP release message (DHCPRELEASE)**
A message sent by clients to the DHCP server to indicate release of its leased IP address. The client uses this message to cancel its currently active lease. You can perform address release manually using the ipconfig /release command at a command prompt. The DHCP release message name is DHCPRELEASE.

See also: DHCP server  Dynamic Host Configuration Protocol (DHCP)  lease

**DHCP request message (DHCPREQUEST)**
A message sent by clients to the DHCP server to request or renew lease of its IP address. The client uses this message to select and request a lease from a specific DHCP server, to confirm a previously leased IP address after the client system is restarted, or to extend the current IP address lease for the client. The DHCP request message name is DHCPREQUEST.

See also: DHCP server  Dynamic Host Configuration Protocol (DHCP)  lease

**DHCP server**
A computer running the Microsoft DHCP service that offers dynamic configuration of IP addresses and related information to DHCP-enabled clients.

See also: DHCP service  Dynamic Host Configuration Protocol (DHCP)  IP address

**DHCP service**
A service that enables a computer to function as a DHCP server and configure DHCP-enabled clients on a network. DHCP runs on a server, enabling the automatic, centralized management of IP addresses and other TCP/IP configuration settings for network clients.

See also: Dynamic Host Configuration Protocol (DHCP)  IP address  service

**DHCP service resource**
A resource type that provides DHCP services from a cluster.

See also: cluster  Dynamic Host Configuration Protocol (DHCP)

**DHCP/BOOTP Relay Agent**
The agent program or component responsible for relaying Dynamic Host Configuration Protocol (DHCP) and bootstrap protocol (BOOTP) broadcast messages between a DHCP server and a client across an Internet Protocol (IP) router. A DHCP relay agent supports DHCP/BOOTP message relay as defined in RFCs 1541 and 2131. The DHCP Relay Agent routing protocol component is managed using the Routing and Remote Access snap-in.

See also: bootstrap protocol (BOOTP)  DHCP server  Dynamic Host Configuration Protocol (DHCP)  Request for Comments (RFC)

**DHCPACK**
See other term: DHCP acknowledgment message (DHCPACK)

**DHCPDECLINE**
See other term: DHCP decline message (DHCPDECLINE)

**DHCPINFORM**
See other term: DHCP information message (DHCPINFORM)

**DHCPNAK**
See other term: DHCP negative acknowledgment message (DHCPNAK)

**DHCPOFFER**
See other term: DHCP offer message (DHCPOFFER)

**DHCPRELEASE**
See other term: DHCP release message (DHCPRELEASE)

**DHCPREQUEST**
See other term: DHCP request message (DHCPREQUEST)

**dial location**
The country code, area code, and specific dialing requirements for the place you are dialing from. Once you have created a dial location, you can select it to apply the dialing requirements to all your calls. To change dialing locations, select or create a different one.

**dial-in constraints**
Settings in a remote access policy that permit or deny access to remote access clients.

See also: remote access policy

**dial-up connection**
The connection to your network if you use a device that uses the telephone network. This includes modems with a standard telephone line, ISDN cards with high-speed ISDN lines, or X.25 networks. If you are a typical user, you might have one or two dial-up connections, for example, to the Internet and to your corporate network. In a more complex server situation, multiple network modem connections might be used to implement advanced routing.

See also: Integrated Services Digital Network (ISDN)  modem (modulator/demodulator)

**dial-up line**
A standard dial-up connection, such as telephone and Integrated Services Digital Network (ISDN) lines. Also called switched circuit.

See also: Integrated Services Digital Network (ISDN)

**differential backup**
A backup that copies files created or changed since the last normal or incremental backup. It does not mark files as having been backed up (in other words, the archive attribute is not cleared). If you are performing a combination of normal and differential backups, restoring files and folders requires that you have the last normal as well as the last differential backup.

See also: copy backup  daily backup  incremental backup  normal backup

**differential data**
Saved copies of changed data that can be applied to an original volume to generate a volume shadow copy.

See also: volume  volume shadow copy

**Diffie-Hellman key agreement protocol**
A cryptographic mechanism that allows two parties to establish a shared secret key without having any preestablished secrets between them. Diffie-Hellman is frequently used to establish the shared secret keys that are used by common applications of cryptography, such as Internet Protocol security (IPSec). It is not normally used for data protection.

See also: cryptography  Internet Protocol security (IPsec)  key

**digest**
See other term: Digest authentication

**Digest Access protocol**
A lightweight authentication protocol for parties involved in communications that are based on Hypertext Transfer Protocol (HTTP) or Simple Authentication and Security Layer (SASL).

**Digest authentication**
An authentication mechanism that hashes user name, password, and other data before transmitting it over the network.

See also: authentication  Basic authentication  encryption  hash  password  user name

**digital signature**
Data that binds a sender's identity to the information being sent. A digital signature may be bundled with any message, file, or other digitally encoded information, or transmitted separately. Digital signatures are used in public key environments and provide authentication and integrity services.

**Digital Signature Standard (DSS)**

A standard that uses the Digital Signature Algorithm (DSA) for its signature algorithm and Secure Hash Algorithm (SHA-1) as its message hash algorithm. DSA is a public-key cipher that is used only to generate digital signatures and cannot be used for data encryption.

See also: Secure Hash Algorithm (SHA-1)

**digital subscriber line (DSL)**
A special communication line that uses modulation technology to maximize the amount of data that can be sent over a local-loop, copper-wire connection to a central phone office. DSL is used for connections from telephone switching stations to a subscriber rather than between switching stations.

**digital video disc (DVD)**
A type of optical disc storage technology. A digital video disc (DVD) looks like a CD-ROM disc, but it can store greater amounts of data. DVDs are often used to store full-length movies and other multimedia content that requires large amounts of storage space.

See also: DVD decoder  DVD drive

**direct cable connection**
A link between the input/output (I/O) ports of two computers created with a single cable rather than a modem or other interfacing devices. In most cases, a direct cable connection is made with a null modem cable.

See also: input/output (I/O) port  null modem cable

**direct hosting**
For Microsoft networking, the sending of file and print sharing traffic using the Server Message Block (SMB) protocol (also known as the Common Internet File System (CIFS) protocol) without the use of network basic input/output system (NetBIOS). Direct hosting for the Microsoft redirector (the Workstation service) and file server (the Server service) is supported over both TCP/IP and Internetwork Packet Exchange (IPX). Although direct hosting may be more efficient, a direct hosting client can connect only to a direct hosting server.

See also: Internetwork Packet Exchange (IPX)  network basic input/output system (NetBIOS)  NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink)  Server Message Block (SMB)  Transmission Control Protocol/Internet Protocol (TCP/IP)

**direct memory access (DMA)**
Memory access that does not involve the microprocessor. DMA is frequently used for data transfer directly between memory and a peripheral device such as a disk drive.

See also: hardware configuration

**directory**
An information source that contains information about users, computer files, or other objects. In a file system, a directory stores information about files. In a distributed computing environment (such as a Windows domain), the directory stores information about objects such as printers, fax servers, applications, databases, and other users.

See also: domain  object

**directory database**
The physical storage for each replica of Active Directory. Also called the store.

See also: Active Directory  replica

**directory partition**
A contiguous subtree of Active Directory that is replicated as a unit to other domain controllers in the forest that contain a replica of the same subtree. In Active Directory, a single domain controller always holds at least three directory partitions: schema (class and attribute definitions for the directory), configuration (replication topology and related metadata), and domain (subtree that contains the per-domain objects for one domain). Domain controllers running Windows Server 2003 can also store one or more application directory partitions.

See also: Active Directory  application directory partition  attribute  domain  global catalog  replica  replication  schema

**directory service**
Both the directory information source and the service that makes the information available and usable. A directory service enables the user to find an object when given any one of its attributes.

See also: Active Directory  attribute  directory  object

**Directory Services Markup Language (DSML)**
An open, extensible, standards-based format for publishing directory service schemas and exchanging directory contents.

**directory store**
The physical storage for Active Directory directory partition replicas on a specific domain controller. The store is implemented using the Extensible Storage Engine.

See also: Active Directory  directory partition  domain controller  replica

**DirectX**
An extension of the Microsoft Windows operating system. DirectX technology helps games and other programs use the advanced multimedia capabilites of your hardware.

**dirty bit**
A bit that is used to mark modified data in a cache so that the modifications may be carried over to primary memory. For Windows file systems, a bit that is used to indicate that the file system is in an inconsistent and possibly corrupted state. When it is set, the file system`s dirty bit triggers the chkdsk command to run when the computer is restarted.

See also: bit (binary digit)  file system

**disable**
To make a device nonfunctional. For example, if you disable a device in a hardware configuration, you cannot use the device when your computer uses that hardware configuration. Disabling a device frees the resources that were allocated to the device.

See also: device  enable  hardware configuration

**discretionary access control list (DACL)**
The part of an object`s security descriptor that grants or denies specific users and groups permission to access the object. Only the owner of an object can change permissions granted or denied in a DACL; thus, access to the object is at the owner`s discretion.

See also: access control entry (ACE)  distribution group  object  security descriptor  security group  system access control list (SACL)

**disk**
A storage device that is attached to a computer.

See also: basic disk  dynamic disk

**disk configuration information**
Information in the Windows registry on assigned drive letters, simple volumes, striped volumes, mirrored volumes, spanned volumes, and RAID-5 volumes. You can change the disk configuration by using Disk Management.

See also: mirrored volume  RAID-5 volume  registry  simple volume  spanned volume  striped volume  volume

**disk mirroring**
A set of software processes that maintains a backup copy of a volume at all times. Each mirror of a volume resides on a different disk; ideally, each disk has its own controller. If one mirror becomes unavailable (due to a disk failure, for example), you can use the other mirror to gain access to the volume`s data.

See also: mirror  volume

**dismount**
To remove a removable tape or disc from a drive.

See also: library  mount

**display adapter**
See other term: video adapter

**display password**
A password that allows the user to open only previously saved capture (.cap) files.

See also: capture password  password

**distinguished name**
A name that uniquely identifies an object by using the relative distinguished name for the object, plus the names of container

objects and domains that contain the object. The distinguished name identifies the object as well as its location in a tree. Every object in Active Directory has a distinguished name. A typical distinguished name might be CN=MyName,CN=Users,DC=Microsoft,DC=Com. This identifies the MyName user object in the microsoft.com domain.

See also: Active Directory container object domain object relative distinguished name

**Distinguished Name Tag (DNT)**
An integer column that is maintained by the Extensible Storage Engine (ESE). Domain controllers use DNTs when they create objects, either locally or through replication. Each domain controller creates and maintains its own unique DNTs when it creates objects. DNTs are not shared or replicated between domain controllers. A domain controller can create a maximum of approximately 2 billion DNTs over its lifespan. Domain controllers that are installed with the Install from Media (IFM) option inherit the DNT values from the domain controller that was used to create the IFM backup. Therefore, using IFM installations can reduce the total number of DNTs that the newly installed domain controller can create over its lifespan, depending on the number of objects that are created by the domain controller from which the IFM backup was created.

**Distributed Component Object Model (DCOM)**
The Microsoft Component Object Model (COM) specification that defines how components communicate over Windows-based networks. Use the DCOM Configuration tool to integrate client/server applications across multiple computers. DCOM can also be used to integrate robust Web browser applications.

See also: Component Object Model (COM)

**Distributed File System (DFS)**
A service that allows system administrators to organize distributed network shares into a logical namespace, enabling users to access files without specifying their physical location and providing load sharing across network shares.

See also: service

**distribution group**
A group that is used solely for e-mail distribution and that is not security-enabled. Distribution groups cannot be listed in discretionary access control lists (DACLs) used to define permissions on resources and objects. Distribution groups can be used only with e-mail applications (such as Microsoft Exchange) to send e-mail to collections of users. If you do not need a group for security purposes, create a distribution group instead of a security group.

See also: discretionary access control list (DACL) security group

**DLC**
See other term: Data Link Control (DLC)

**DLL**
See other term: dynamic-link library (DLL)

**DMA**
See other term: direct memory access (DMA)

**DMZ**
See other term: perimeter network

**DNS**
See other term: Domain Name System (DNS)

**DNS client**
A client computer that queries DNS servers in an attempt to resolve DNS domain names. DNS clients maintain a temporary cache of resolved DNS domain names.

See also: client DNS server Domain Name System (DNS)

**DNS dynamic update protocol**
See other term: dynamic update

**DNS Security Extensions (DNSSEC)**
DNS extensions that use digital signatures to provide data authentication and integrity to compliant DNS resolvers and applications.

See also: authentication Domain Name System (DNS) resolver resource record (RR) secure zone

**DNS server**

A server that maintains information about a portion of the DNS database and that responds to and resolves DNS queries.

See also: DNS client  Domain Name System (DNS)  server

**DNS suffix**
For DNS, a character string that represents a domain name. The DNS suffix shows where a host is located relative to the DNS root, specifying a host's location in the DNS hierarchy. Usually, the DNS suffix describes the latter portion of a DNS name, following one or more of the first labels of a DNS name.

See also: domain name  Domain Name System (DNS)

**DNS zone**
In a DNS database, a contiguous portion of the DNS tree that is administered as a single, separate entity by a DNS server. The zone contains resource records for all the names within the zone.

See also: DNS server  Domain Name System (DNS)  resource record (RR)

**DNSSEC**
See other term: DNS Security Extensions (DNSSEC)

**docking station**
A unit for housing a portable computer that contains a power connection, expansion slots, and connections to peripherals, such as a monitor, printer, full-sized keyboard, and mouse. The docking station turns the portable computer into a desktop computer.

**document**
Any self-contained piece of work created with an application program and, if saved on disk, given a unique file name by which it can be retrieved.

See also: filter  property cache

**domain**
In Active Directory, a collection of computer, user, and group objects defined by the administrator. These objects share a common directory database, security policies, and security relationships with other domains. In DNS, any tree or subtree within the DNS namespace. Although the names for DNS domains often correspond to Active Directory domains, DNS domains should not be confused with Active Directory domains.

See also: Active Directory  directory database  Domain Name System (DNS)  object

**domain administrator**
A person who is a member of the Domain Admins group. Domain administrators can create, delete, and manage all objects that reside within the domain in which they are administrators. They can also assign and reset passwords and delegate administrative authority for network resources to other trusted users.

See also: domain  object  resource

**domain controller**
In an Active Directory forest, a server that contains a writable copy of the Active Directory database, participates in Active Directory replication, and controls access to network resources. Administrators can manage user accounts, network access, shared resources, site topology, and other directory objects from any domain controller in the forest.

See also: Active Directory  authentication  directory  forest  shared resource

**domain controller locator (Locator)**
An algorithm running in the context of the Net Logon service that enables a client to locate a domain controller. Locator can find domain controllers by using DNS or network basic input/output system (NetBIOS) names. The DNS service (SRV) resource records registered by Locator on behalf of domain controllers are also known as domain controller locator (Locator) resource records.

See also: domain controller  Domain Name System (DNS)  network basic input/output system (NetBIOS)  service (SRV) resource record

**domain DFS**
An implementation of Distributed File System (DFS) in which DFS topological information is stored in Active Directory. Because this information is made available on multiple domain controllers in the domain, domain DFS provides fault tolerance for any distributed file system in the domain.

See also: Active Directory DFS topology Distributed File System (DFS) fault tolerance

**domain functionality**
The functional level of an Active Directory domain that has one or more domain controllers running Windows Server 2003. The functional level of a domain can be raised to enable new Active Directory features that will apply to that domain only. There are four domain functional levels: Windows 2000 mixed, Windows 2000 native, Windows Server 2003 interim, and Windows Server 2003. The default domain functional level is Windows 2000 mixed. When the domain functional level is raised to Windows 2000 native, Windows Server 2003 interim, or Windows Server 2003, advanced domain-wide Active Directory features are available.

See also: Active Directory domain domain controller

**domain hierarchy**
The parent/child tree structure of domains.

See also: domain

**domain local group**
A security or distribution group that can contain universal groups, global groups, other domain local groups from its own domain, and accounts from any domain in the forest. Domain local security groups can be granted rights and permissions on resources that reside only in the same domain where the domain local group is located.

See also: distribution group domain tree forest global group security group universal group

**domain name**
The name given by an administrator to a collection of networked computers that share a common directory. Part of the DNS naming structure, domain names consist of a sequence of name labels separated by periods.

See also: domain Domain Name System (DNS) label

**Domain Name System (DNS)**
A hierarchical, distributed database that contains mappings of DNS domain names to various types of data, such as IP addresses. DNS enables the location of computers and services by user-friendly names, and it also enables the discovery of other information stored in the database.

See also: domain name IP address ping service Transmission Control Protocol/Internet Protocol (TCP/IP)

**domain namespace**
The database structure used by DNS.

See also: Domain Name System (DNS)

**domain naming master**
A domain controller that holds the domain naming operations master role in Active Directory. The domain naming master controls the addition or removal of domains in the forest. At any time, the domain naming master role can be assigned to only one domain controller in the forest.

See also: Active Directory domain controller operations master

**domain of origin**
The parent DNS domain name that is used to root either a zone or a resource record within a zone. This name is joined to the end of unqualified or relative domain names to form a fully qualified domain name (FQDN) within the zone. In DNS Manager, the domain of origin will correspond to the zone name as it appears in the Add Zone Wizard or the name that appears in the Parent domain name field for any resource records created within the zone.

See also: domain domain name Domain Name System (DNS) fully qualified domain name (FQDN) relative name resource record (RR) zone

**domain root**
A DFS namespace, for which the configuration information is stored in Active Directory. The path to access the root or a link starts with the host domain name. A domain root can have multiple root targets, which offer fault tolerance and load sharing at the root level.

See also: Active Directory DFS namespace root target

**domain suffix**
For DNS, an optional parent domain name that can be appended to the end of a relative domain name used in a name query

or host lookup. The domain suffix can be used to complete an alternate fully qualified DNS domain name to be searched when the first attempt to query a name fails.

See also: Domain Name System (DNS) fully qualified domain name (FQDN) parent domain

**domain tree**
In DNS, the inverted hierarchical tree structure that is used to index domain names. Domain trees are similar in purpose and concept to the directory trees used by computer filing systems for disk storage. For example, when numerous files are stored on disk, directories can be used to organize the files into logical collections. When a domain tree has one or more branches, each branch can organize domain names used in the namespace into logical collections. In Active Directory, a hierarchical structure of one or more domains, connected by transitive, bidirectional trusts, that forms a contiguous namespace. Multiple domain trees can belong to the same forest.

See also: Active Directory domain domain name Domain Name System (DNS) forest transitive trust two-way trust

**dots per inch (DPI)**
The standard used to measure screen and printer resolution, expressed as the number of dots that a device can display or print per linear inch. The greater the number of dots per inch, the better the resolution.

**downcasing**
The case-insensitive handling of DNS domain names. Windows DNS servers use downcasing to convert any uppercase letters used in domain names to equivalent lowercase letters. For example, the name HOST.example.Microsoft.com would be downcased to host.example.microsoft.com.

See also: DNS server domain name Domain Name System (DNS) upcasing

**downloadable fonts**
A set of characters stored on disk and sent (downloaded) to a printer`s memory when needed for printing a document. Downloadable fonts are most commonly used with laser printers and other page printers, although many dot-matrix printers can accept some of them. Also called soft fonts.

See also: font font cartridge PostScript fonts

**DPI**
See other term: dots per inch (DPI)

**drag**
To move an item on the screen by selecting the item and then pressing and holding down the mouse button while moving the mouse. For example, you can move a window to another location on the screen by dragging its title bar.

**drain**
For Network Load Balancing, a command that disables new traffic handling for the rule whose port range contains the specified port. All ports specified by the port rule are affected.

See also: cluster drainstop Network Load Balancing port port rule

**drainstop**
For Network Load Balancing, a command that disables all new traffic handling on the specified hosts. The hosts then enter draining mode to complete existing connections. While draining, hosts remain in the cluster and stop their cluster operations when there are no more active connections. To terminate draining mode, explicitly stop cluster mode with the stop command, or restart new traffic handling with the start command. To drain connections from a specific port, use the drain command.

See also: drain host Network Load Balancing

**drive**
An area of storage that is formatted with a file system and has a drive letter. The storage can be a floppy disk, a CD or DVD, a hard disk, or another type of disk.

See also: drive letter file system volume

**drive letter**
The naming convention Windows uses to identify disk drives or partitions on a computer. Drives are named by letter, beginning with A, followed by a colon.

See also: drive

**drop folder**

In the Macintosh environment, a folder for which you have the Make Changes permission but not the See Files or See Folders permission. You can copy files into a drop folder, but you cannot see what files and subfolders the drop folder contains.

See also: Make Changes

**DSL**
See other term: digital subscriber line (DSL)

**DSML**
See other term: Directory Services Markup Language (DSML)

**DSS**
See other term: Digital Signature Standard (DSS)

**DTE**
See other term: Data Terminal Equipment (DTE)

**dual boot**
A computer configuration that can start two different operating systems.

See also: boot  multiple boot  startup environment

**duplex**
A system capable of transmitting information in both directions over a communications channel.

See also: full-duplex  half-duplex

**DVD**
See other term: digital video disc (DVD)

**DVD decoder**
A hardware or software component that allows a digital video disc (DVD) drive to display movies on your computer screen.

See also: digital video disc (DVD)  DVD drive  hardware decoder  software decoder

**DVD drive**
A disk storage device that uses digital video disc (DVD) technology. A DVD drive reads both CD-ROM and DVDs; however, you must have a DVD decoder to display DVD movies on your computer screen.

See also: digital video disc (DVD)  DVD decoder

**DWORD**
A data type that is composed of hexadecimal data with a maximum allotted space of 4 bytes.

**dynamic data exchange (DDE)**
A form of interprocess communication (IPC) implemented in the Microsoft Windows family of operating systems. Two or more programs that support dynamic data exchange (DDE) can exchange information and commands.

See also: Network DDE service

**dynamic disk**
A physical disk that provides features that basic disks do not, such as support for volumes that span multiple disks. Dynamic disks use a hidden database to track information about dynamic volumes on the disk and other dynamic disks in the computer. You convert basic disks to dynamic by using the Disk Management snap-in or the DiskPart command-line tool. When you convert a basic disk to dynamic, all existing basic volumes become dynamic volumes.

See also: active volume  basic disk  basic volume  dynamic volume  partition  volume

**Dynamic Host Configuration Protocol (DHCP)**
A TCP/IP service protocol that offers dynamic leased configuration of host IP addresses and distributes other configuration parameters to eligible network clients. DHCP provides safe, reliable, and simple TCP/IP network configuration, prevents address conflicts, and helps conserve the use of client IP addresses on the network. DHCP uses a client/server model where the DHCP server maintains centralized management of IP addresses that are used on the network. DHCP-supporting clients can then request and obtain lease of an IP address from a DHCP server as part of their network boot process.

See also: DHCP client  DHCP server  IP address  lease  service  Transmission Control Protocol/Internet Protocol (TCP/IP)

**dynamic routing**
The use of routing protocols to update routing tables. Dynamic routing responds to changes in the internetwork topology.

See also: protocol  routing

**dynamic storage**
A storage method in Windows that allows disk and volume management without requiring operating system restart.

See also: basic storage

**dynamic update**
An update to the Domain Name System (DNS) standard that permits DNS clients to dynamically register and update their resource records in zones.

See also: DNS client  DNS server  Domain Name System (DNS)  resource record (RR)  zone

**dynamic volume**
A volume that resides on a dynamic disk. Windows supports five types of dynamic volumes: simple, spanned, striped, mirrored, and RAID-5. A dynamic volume is formatted by using a file system, such as file allocation table (FAT) or NTFS, and has a drive letter assigned to it.

See also: basic disk  basic volume  dynamic disk  mirrored volume  RAID-5 volume  simple volume  spanned volume  striped volume  volume

**dynamic-link library (DLL)**
An operating system feature that allows executable routines (generally serving a specific function or set of functions) to be stored separately as files with .dll extensions. These routines are loaded only when needed by the program that calls them.

See also: Resource DLL

# Windows Server 2003 Glossary - E

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - E**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**EAP**
See other term: Extensible Authentication Protocol (EAP)

**effective permissions**
Overall permissions that a user or group has on an object, taking into account group membership as well as inheritance from the parent object.

See also: group  inheritance  object  parent object  permission

**EFI**
See other term: Extensible Firmware Interface (EFI)

**EFI system partition**
A small portion on a GUID partition table (GPT) disk that is formatted with the file allocation table (FAT) file system and contains the files necessary to start the computer and pass execution to an operating system, which resides on another partition.

See also: Extensible Firmware Interface (EFI)  file allocation table (FAT)  GUID partition table (GPT)  Itanium  Microsoft Reserved (MSR) partition  system volume  x86

**EFS**
See other term: Encrypting File System (EFS)

**ELAN**
See other term: emulated local area network (ELAN)

**embedded object**
Information created in another program that has been pasted inside your document. When information is embedded, you can edit the information in the new document using toolbars and menus from the original program. To edit the embedded information, double-click it and the toolbars and menus from the program used to create the information appear. Embedded information is not linked to the original source. If you change information in one place, it is not updated in the other.

See also: linked object  OLE  package  source document

**emulated local area network (ELAN)**
A logical ATM network that emulates the services of an Ethernet or Token Ring LAN.

See also: asynchronous transfer mode (ATM)  local area network (LAN)  Token Ring

**enable**
To make a device functional. For example, if a device in your hardware configuration settings is enabled, the device is available for use when your computer uses that hardware configuration.

See also: disable  hardware configuration

**encapsulated PostScript (EPS) file**
A file that prints at the highest possible resolution for your printer. An EPS file may print faster than other graphical representations. Some Windows-based and non-Windows-based graphical programs can import EPS files.

See also: PostScript

**Encapsulating Security Payload (ESP)**
An Internet Protocol security (IPSec) protocol that provides confidentiality, in addition to authentication, integrity, and anti-replay. ESP can be used alone, in combination with Authentication Header (AH), or nested with the Layer Two Tunneling

Protocol (L2TP). ESP does not normally sign the entire packet unless it is being tunneled. Ordinarily, just the data payload is protected, not the IP header.

See also: authentication  Authentication Header (AH)  Internet Protocol security (IPsec)  Layer Two Tunneling Protocol (L2TP)

**encapsulation**
The method used to pass data from one protocol over a network within a different protocol. Data from one protocol is wrapped with the header of a different protocol. Encapsulation is described in RFC 1483.

See also: protocol  Request for Comments (RFC)

**encrypted channel**
A path or link through which encrypted information passes between two devices. This information typically includes the primary message content, not session configuration information.

See also: device  encryption

**encrypted password**
A password that is scrambled. Encrypted passwords are more secure than plaintext passwords, which are susceptible to network sniffers.

See also: encryption  password

**Encrypting File System (EFS)**
A Microsoft file-based encryption technology that enables users to encrypt files and folders on NTFS volumes. EFS helps protect the confidentiality of data by ensuring that only authorized users can decrypt the encrypted files or folders.

See also: NTFS file system  recovery agent

**encryption**
The process of disguising a message or data in such a way as to hide its substance.

See also: public key encryption  symmetric encryption

**enforce**
In Group Policy Management console (GPMC), to force the Group Policy object (GPO) links of the parent container to take precedence over the GPO links of the child containers. By default, the GPO links that are closest to the user or computer (links to the child container) have higher precedence than GPO links higher up (links to the parent container). Enforcement causes GPOs that are linked in parent containers to take precedence instead. In operating systems in the Windows Server 2003 family without GPMC, No Override is used instead of Enforce.

See also: block inheritance  Group Policy Management console (GPMC)  Group Policy object link  inheritance  No Override  precedence

**enhanced small device interface (ESDI)**
A standard that can be used with high-capacity hard disks, floppy disk drives, and tape drives to allow these devices to communicate with a computer at high speeds.

**enterprise certification authority**
A certification authority (CA) that is fully integrated with Active Directory.

See also: Active Directory  certification authority (CA)

**Enterprise Memory Architecture**
A feature of Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, that allows you to run applications that take advantage of large amounts of physical memory. Enterprise Memory Architecture supports two types of memory enhancement: application memory tuning, also known as 4-gigabyte tuning (4GT), and Physical Address Extension (PAE) X86.

**entry**
The lowest level element in the registry. Entries appear in the details pane of a Registry Editor window. Each entry consists of an entry name, its data type, and its value. Entries store the configuration data that affects the operating system and the programs that run on the system. As such, they are different from registry subtrees, keys, and subkeys, which are containers.

See also: key  registry  subkey  subtree

**environment variable**
A string consisting of environment information, such as a drive, path, or file name, associated with a symbolic name that can be used by Windows. You use System in Control Panel or the set command from the command prompt to define environment variables.

See also: string  variable

**error detection**
A technique for detecting when data is lost during transmission. This allows the software to recover lost data by notifying the transmitting computer that it needs to retransmit the data.

**ESDI**
See other term: enhanced small device interface (ESDI)

**ESP**
See other term: Encapsulating Security Payload (ESP)

**event**
Any significant occurrence in the system or an application that requires users to be notified or an entry to be added to a log.

**Event Log service**
A service that records events in the system, security, and application logs. The Event Log service is located in Event Viewer.

See also: event  event logging  Event Viewer  service

**event logging**
The process of recording an audit entry in the audit trail whenever certain events occur, such as services starting and stopping or users logging on and off and accessing resources.

See also: auditing  event  Event Viewer  service

**Event Viewer**
A component you can use to view and manage event logs, gather information about hardware and software problems, and monitor security events. Event Viewer maintains logs about program, security, and system events.

See also: event  event logging

**everyone category**
In the Macintosh environment, one of the user categories to which you assign permissions for a folder. Permissions granted to everyone apply to all users who use the server, including guests.

See also: permission

**exclusion range**
A small range of one or more IP addresses within a DHCP scope excluded from the DHCP service. Exclusion ranges ensure that these scope addresses will never be offered to clients by the DHCP server.

See also: DHCP server  DHCP service  scope

**expanded memory**
Type of memory that can be added to IBM personal computers. The use of expanded memory is defined by the Expanded Memory Specification (EMS), which supports memory boards containing RAM that can be enabled or disabled by software.

See also: extended memory

**expansion slot**
A socket in a computer, designed to hold expansion boards and connect them to the system bus.

See also: bus

**expire interval**
For DNS, the number of seconds that DNS servers operating as secondary masters for a zone will use to determine if zone data should be expired when the zone is not refreshed and renewed.

See also: DNS server  Domain Name System (DNS)  zone

**explicit permissions**
Object permissions that are defined when the object is created, specifically assigned, or changed by the owner of the object.

See also: object  permission

**express message**
For Message Queuing, a message that uses fewer resources and is faster than a recoverable message. However, because express messages are mapped to memory, they are lost if the computer storing them fails.

See also: Message Queuing  recoverable message

**extended memory**
Memory beyond one megabyte in 80286, 80386, 80486, and Pentium computers.

See also: expanded memory

**extended partition**
A type of partition that you can create only on basic master boot record (MBR) disks. Extended partitions are useful if you want to create more than four volumes on a basic MBR disk. Unlike primary partitions, you do not format an extended partition with a file system and then assign a drive letter to it. Instead, you create one or more logical drives within the extended partition. After you create a logical drive, you format it and assign it a drive letter. An MBR disk can have up to four primary partitions or three primary partitions, one extended partition, and multiple logical drives.

See also: basic disk  drive letter  logical drive  master boot record (MBR)  partition  primary partition  unallocated space  volume

**Extensible Authentication Protocol (EAP)**
An extension to the Point-to-Point Protocol (PPP) that allows for arbitrary authentication mechanisms to be employed for the validation of a PPP connection.

See also: Point-to-Point Protocol (PPP)

**Extensible Firmware Interface (EFI)**
A type of interface between a computer, firmware, hardware, and the operating system. EFI defines a new partition style called GUID partition table (GPT). EFI serves the same purpose as the basic input/output system (BIOS) found in most x86-based computers.

See also: basic input/output system (BIOS)  GUID partition table (GPT)  Itanium  x86

**Extensible Markup Language (XML)**
A meta-markup language that provides a format for describing structured data. This facilitates more precise declarations of content and more meaningful search results across multiple platforms. In addition, XML enables a new generation of Web-based data viewing and manipulation applications.

See also: Hypertext Markup Language (HTML)

**extension-type association**
The association of a file name extension with a Macintosh file type and file creator. By creating extension-type associations, you can choose which program starts automatically when you open a file with a particular extension. Services for Macintosh has many predefined extension-type associations.

**external network number**
A 4-byte hexadecimal number used for addressing and routing purposes on NetWare networks. The external network number is associated with physical network adapters and networks.

See also: internal network number  Internetwork Packet Exchange (IPX)

**external trust**
A trust that is manually created between two Active Directory domains that are located in different forests or between an Active Directory domain and a Windows NT 4.0 or earlier domain. External trusts are nontransitive and one-way.

See also: Active Directory  domain  forest  nontransitive trust  one-way trust  trust relationship

**extranet**
A limited subset of computers or users on a public network, typically the Internet, that can access an organization`s internal network. For example, the computers or users might belong to a partner organization.

# Windows Server 2003 Glossary - F

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - F**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**failback**
The process of moving resources, either individually or in a group, back to their preferred node after the node has failed and come back online.

See also: failback policy  node  resource

**failback policy**
Parameters that an administrator can set using Cluster Administrator that affect failback operations.

See also: Cluster Administrator  failback

**failed**
A state that applies to a resource or a node in a cluster. A resource or a node is placed in the failed state after an unsuccessful attempt has been made to bring it online.

See also: cluster  node  resource

**failover**
In server clusters, the process of taking resource groups offline on one node and bringing them online on another node. When failover occurs, all resources within a resource group fail over in a predefined order; resources that depend on other resources are taken offline before, and are brought back online after, the resources on which they depend.

See also: failover policy  node  offline  possible owner  server cluster

**failover policy**
Parameters that an administrator can set using Cluster Administrator that affect failover operations.

See also: Cluster Administrator  failover

**FAT**
See other term: file allocation table (FAT)

**FAT32**
A system used to store files on a computer drive. FAT32 is based on the file allocation table (FAT) file system, but it uses 32-bit values for storing files instead of the 16-bit values used by the original FAT file system. FAT32 offers more efficient drive space allocation by creating smaller clusters than FAT and supports volumes of up to 2 terabytes (TB) of size.

**fault tolerance**
The ability of computer hardware or software to ensure data integrity when hardware failures occur. Fault-tolerant features appear in many server operating systems and include mirrored volumes, RAID-5 volumes, and server clusters.

See also: cluster  mirrored volume  RAID-5 volume

**Fax Service**
A system service that provides fax services to local and remote network clients. Fax services include receiving faxes and faxing documents, fax wizard messages, and e-mail messages.

See also: service

**FCB**
See other term: file control block (FCB)

**Federal Information Processing Standard (FIPS)**
A standard entitled Security Requirements for Cryptographic Modules. FIPS 140-1 (1994) and FIPS 140-2 (2001) describe

government requirements for hardware and software cryptomodules used in the U.S. government.

See also: cryptography

**federation**
A pair of realms or domains that have established a federation trust.

**Federation Service**
A security token service that is built into Windows Server 2003 R2. The Federation Service provides tokens in response to requests for security tokens.

**Federation Service Proxy**
A proxy to the Federation Service in the perimeter network (also known as screened subnet). The Federation Service Proxy uses WS-Federation Passive Requestor Profile (WS-F PRP) protocols to collect user credential information from browser clients and Web applications and send the information to the Federation Service on their behalf.

**FEK**
See other term: file encryption key (FEK)

**FEP**
See other term: front-end processor (FEP)

**Fibre Channel**
A networking standard developed to connect devices that require the transmission of large volumes of data at a very high speed. A leading implementation of Fibre Channel technology has been in storage area networks (SANs. Although the term Fibre Channel implies the use of fiber-optic technology, copper coaxial cable is also supported.

**file allocation table (FAT)**
A file system used by MS-DOS and other Windows operating systems to organize and manage files. The file allocation table is a data structure that Windows creates when you format a volume by using FAT or FAT32 file systems. Windows stores information about each file in the file allocation table so that it can retrieve the file later.

See also: file system  NTFS file system

**file control block (FCB)**
A small block of memory temporarily assigned by a computer's operating system to hold information about a file that has been opened for use. An FCB typically contains such information as the file's identification, its location on disk, and a pointer that marks the user's current (or last) position in the file.

**file creator**
A four-character sequence that identifies which program was used to create a file. With Services for Macintosh, you can associate file name extensions with file creators and file types to specify which program starts automatically when you open a file with a particular extension.

See also: extension-type association

**file encryption key (FEK)**
A pseudo-random cryptographic key that Encrypting File System (EFS) uses to encrypt a file. The FEK is encrypted by the public key of the user performing the encryption, and it is typically different for each encrypted file.

See also: Encrypting File System (EFS)  encryption  key  public key

**file fork**
One of two subfiles of a Macintosh file. When Macintosh files are stored on a computer running Services for Macintosh, each fork is stored as a separate file. Each fork can be independently opened by Macintosh users.

**file group**
A File Server Resource Manager option that is used to define a namespace for a file screen, file screen exception, or storage report. It consists of a set of file name patterns, which in turn determine whether files are included or excluded from a group.

**File Replication service (FRS)**
A service that provides multimaster file replication for designated directory trees between designated servers running Windows Server 2003. The designated directory trees must be on disk partitions formatted with the version of NTFS used with the Windows Server 2003 family. FRS is used by Distributed File System (DFS) to automatically synchronize content between assigned replicas and by Active Directory to automatically synchronize content of the system volume information across domain controllers.

See also: Active Directory  NTFS file system  replica  replication  service

**file screen**
A File Server Resource Manager option that is used to block certain files from being saved on a volume or in a folder tree. A file screen is applied at the folder level and affects all folders and subfolders in the designated path.

**File Server for Macintosh**
A service that allows users of Macintosh computers to store, access, and share files on servers running Services for Macintosh. Also called MacFile.

See also: service

**File Server Resource Manager**
A suite of tools that allows administrators to understand, control, and manage the quantity and type of data stored on their servers.

**file share**
In a server cluster, any folder that has an associated File Share resource and is managed by the Cluster service. The file share can fail over from one node to another, but to the end user, the folder looks like a regular folder that remains in one location. Multiple users can access a file share.

See also: cluster  resource  service

**File Share resource**
A file share accessible by a network path that is supported as a cluster resource by a Resource DLL.

See also: Resource DLL

**file system**
In an operating system, the overall structure in which files are named, stored, and organized. NTFS, FAT, and FAT32 are types of file systems.

See also: FAT  FAT32  NTFS file system

**file system cache**
An area of physical memory that holds frequently used pages. It allows applications and services to locate pages rapidly and reduces disk activity.

See also: cache

**File Transfer Protocol (FTP)**
A member of the TCP/IP suite of protocols, used to copy files between two computers on the Internet. Both computers must support their respective FTP roles: one must be an FTP client and the other an FTP server.

See also: Transmission Control Protocol/Internet Protocol (TCP/IP)

**file type**
In the Windows environment, a designation of the operational or structural characteristics of a file. The file type identifies the program, such as Microsoft Word, that is used to open the file. File types are associated with a file name extension. For example, files that have the .txt or .log extension are of the Text Document type and can be opened using any text editor. In the Macintosh environment, a four-character sequence that identifies the type of a Macintosh file. The Macintosh Finder uses the file type and file creator to determine the appropriate desktop icon for that file.

**filter**
For Indexing Service, software that extracts content and property values from a document to index them. For Internet Protocol security (IPSec), a specification of Internet Protocol (IP) traffic that provides the ability to trigger security negotiations for a communication based on the source, destination, and type of IP traffic. For Internet Information Services (IIS), a feature of Internet Server Application Programming Interface (ISAPI) that allows preprocessing of requests and postprocessing of responses, permitting site-specific handling of Hypertext Transfer Protocol (HTTP) requests and responses. In IP and Internetwork Packet Exchange (IPX) packet filtering, a definition in a series of definitions that indicates to the router the type of traffic allowed or disallowed on each interface.

See also: Indexing Service  Internet Information Services (IIS)  Internet Protocol (IP)  Internet Protocol security (IPsec)  Internet Server Application Programming Interface (ISAPI)  Internetwork Packet Exchange (IPX)

**filtering mode**

For Network Load Balancing, the method by which network traffic inbound to a cluster is handled by the hosts within the cluster. Traffic can either be handled by a single server, load balanced among the hosts within the cluster, or disabled completely.

See also: cluster  host  load balancing  Network Load Balancing

**FIPS**
See other term: Federal Information Processing Standard (FIPS)

**firewall**
A security solution that segregates one portion of a network from another portion, allowing only authorized network traffic to pass through according to traffic filtering rules.

**Firewire**
See other term: IEEE 1394

**firmware**
Software routines and low-level input/output instructions stored in read-only memory (ROM). Unlike random-access memory (RAM), read-only memory stays intact even in the absence of electrical power.

See also: random access memory (RAM)  read-only memory (ROM)

**flexible single-master operations (FSMO)**
See other term: operations master

**folder**
A container for programs and files in graphical user interfaces, symbolized on the screen by a graphical image (icon) of a file folder. A folder is a means of organizing programs and documents on a disk and can hold both files and additional folders. For DFS Namespaces, any folder that appears after \\ServerOrDomainName\RootName. A folder can have optional folder targets.

**folder target**
A Universal Naming Convention (UNC) path of a shared folder or another namespace that is associated with a folder in a namespace.

**font**
A graphic design applied to a collection of numbers, symbols, and characters. A font describes a certain typeface, along with other qualities such as size, spacing, and pitch.

See also: OpenType font  PostScript fonts  screen font  Type 1 fonts

**font cartridge**
A plug-in unit available for some printers that contains fonts in several styles and sizes. As with downloadable fonts, printers using font cartridges can produce characters in sizes and styles other than those created by the fonts built into it.

See also: downloadable fonts  font

**foreground program**
The program that runs in the active window (the uppermost window with the highlighted title bar). The foreground program responds to commands issued by the user.

See also: background program  title bar

**foreign computer**
A computer that uses another message queuing system but, through a connector application, can exchange messages with computers that run Message Queuing.

See also: connector application  Message Queuing

**foreign security principal**
An object in a domain that represents a security principal that exists in a trusted domain located in a different forest. Foreign security principals are necessary for users in a domain to access resources that exist in a different forest.

See also: domain  forest  object  resource  security principal

**forest**
One or more Active Directory domains that share the same class and attribute definitions (schema), site and replication information (configuration), and forest-wide search capabilities (global catalog). Domains in the same forest are linked with

two-way, transitive trust relationships.

See also: Active Directory domain global catalog schema transitive trust two-way trust

**forest functionality**
The functional level of an Active Directory forest that has one or more domain controllers running Windows Server 2003. The functional level of a forest can be raised to enable new Active Directory features that will apply to every domain in the forest. There are three forest functional levels: Windows 2000, Windows Server 2003 interim, and Windows Server 2003. The default forest functional level is Windows 2000. When the forest functional level is raised to Windows Server 2003 interim or Windows Server 2003, advanced forest-wide Active Directory features are available.

See also: Active Directory domain domain controller forest

**forest root domain**
The first domain created in a new forest. The forest-wide administrative groups, Enterprise Admins and Schema Admins, are located in this domain. As a best practice, new domains are created as children of the forest root domain.

See also: child domain domain domain hierarchy forest

**forest trust**
A trust between two Windows Server 2003 forests that forms trust relationships between every domain in both forests. A forest trust can be created only between the forest root domains in each forest. Forest trusts are transitive, and they can be one-way or two-way. An administrator must manually establish a forest trust, unlike an automatically established trust, such as a parent-child trust.

See also: domain forest one-way trust parent-child trust root domain transitive trust trust relationship two-way trust

**form**
The specification of physical characteristics such as paper size (that is, letter or legal) and printer area margins of paper or other print media. For example, by default, the Letter form has a paper size of 8.5 inches by 11 inches and does not reserve space for margins.

**FORTEZZA**
A family of security products including PCMCIA-based cards, compatible serial port devices, combination cards (such as FORTEZZA/Modem and FORTEZZA/Ethernet), server boards, and others. FORTEZZA is a registered trademark held by the U.S. National Security Agency.

See also: serial port

**forward lookup**
A DNS query for a DNS name.

See also: Domain Name System (DNS)

**forwarder**
A DNS server designated by other internal DNS servers to be used to forward queries for resolving external or offsite DNS domain names.

See also: DNS server domain name Domain Name System (DNS)

**FQDN**
See other term: fully qualified domain name (FQDN)

**fragmentation**
The scattering of parts of the same disk file over different areas of the disk. Fragmentation occurs as files on a disk are deleted and new files are added. It slows disk access and degrades the overall performance of disk operations, although usually not severely.

See also: defragmentation

**frame**
In synchronous communication, a package of information transmitted as a single unit from one device to another.

See also: capture

**frame type**

The way in which a network type, such as Ethernet, formats data to be sent over a network. When multiple frame types are allowed for a particular network type, the packets are structured differently and are, therefore, incompatible. All computers on a network must use the same frame type to communicate. Also called frame format.

See also: frame  packet

**free media pool**
A logical collection of unused data-storage media that can be used by applications or other media pools. When media are no longer needed by an application, they are returned to a free media pool so that they can be used again.

See also: media pool  Removable Storage

**free space**
Available space that you use to create logical drives within an extended partition.

See also: extended partition  logical drive  unallocated space

**front-end processor (FEP)**
In communications, a computer that is located between communications lines and a main (host) computer and used to relieve the host of tasks related to communications; sometimes considered synonymous with communications controller. A front-end processor is dedicated entirely to handling transmitted information, including error detection and control; receipt, transmission, and possibly encoding of messages; and management of the lines running to and from other devices.

See also: host

**FRS**
See other term: File Replication service (FRS)

**FSMO**
See other term: operations master

**FTP**
See other term: File Transfer Protocol (FTP)

**full computer name**
A fully qualified domain name (FQDN). The full computer name is a concatenation of the computer name (for example, client1) and the primary DNS suffix of the computer (for example, reskit.com.). The same computer could be identified by more than one FQDN. However, it has only one full computer name.

See also: DNS suffix  fully qualified domain name (FQDN)

**Full Control**
An access control entry (ACE) that assigns all applicable rights to a file system or directory service object.

See also: access control entry (ACE)  object  permission

**full name**
A user`s complete name, usually consisting of the last name, first name, and middle initial. The full name is information that Local Users and Groups or Active Directory Users and Computers can maintain as part of the information identifying and defining a user account.

See also: Active Directory Users and Computers  user account

**full zone transfer (AXFR)**
The standard query type supported by all DNS servers to update and synchronize zone data when the zone has been changed. When a DNS query is made using AXFR as the specified query type, the entire zone is transferred as the response.

See also: DNS server  zone

**full-duplex**
A system capable of simultaneously transmitting information in both directions over a communications channel.

See also: duplex  half-duplex

**fully qualified domain name (FQDN)**
A DNS name that has been stated to indicate its absolute location in the domain namespace tree. In contrast to relative names, an FQDN has a trailing period (.) to qualify its position to the root of the namespace (host.example.microsoft.com.).

See also: domain name  Domain Name System (DNS)  domain namespace  relative name

# Windows Server 2003 Glossary - G

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - G**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**gateway**
A dedicated device (or a set of services running on a dedicated computer) that routes network traffic and enables communication between different networking protocols. A gateway is a multiprotocol Internet Protocol (IP) router that translates between different transport protocols or data formats.

See also: device  Internet Protocol (IP)

**GDI objects**
Objects from the Graphics Device Interface (GDI) library of application programming interfaces (APIs) for graphics output devices. In Task Manager, the number of GDI objects currently used by a process.

See also: application programming interface (API)  Task Manager

**Generic Application resource**
An application that is supported as a cluster resource by a Resource DLL.

See also: Resource DLL

**Generic Security Services Application Programming Interface (GSS-API)**
A generic API for performing client-server authentication that can be implemented over any authentication system. GSS-API makes it possible for applications to use the same API with different authentication mechanisms.

**Generic Service resource**
A Windows service that is supported as a cluster resource by a Resource DLL.

See also: Resource DLL  service

**GID**
See other term: group identifier (GID)

**global account**
In an Active Directory network, a normal user account in a user`s domain. Most user accounts are global accounts. If there are multiple domains in the network, it is best if each user in the network has only one user account in only one domain, and each user`s access to other domains is accomplished through the establishment of domain trust relationships. In Microsoft Provisioning System, the Exchange server maintains a list of global catalogs, and it maintains a load balance across global catalogs.

See also: Active Directory  domain  global catalog

**global catalog**
A directory database that applications and clients can query to locate any object in a forest. The global catalog is hosted on one or more domain controllers in the forest. It contains a partial replica of every domain directory partition in the forest. These partial replicas include replicas of every object in the forest, as follows: the attributes most frequently used in search operations and the attributes required to locate a full replica of the object. In Microsoft Provisioning System, the Exchange server maintains a list of global catalogs, and it maintains a load balance across global catalogs.

See also: Active Directory  attribute  domain controller  forest  replication

**global group**
A security or distribution group that can contain users, groups, and computers from its own domain as members. Global security groups can be granted rights and permissions for resources in any domain in the forest.

See also: group  local group  member server  permission  user account

**globally unique identifier (GUID)**
A 16-byte value generated from the unique identifier on a device, the current date and time, and a sequence number. A GUID is used to identify a particular device or component.

See also: device

**glue chasing**
In DNS, queries to resolve delegation name server (NS) resource records that do not have corresponding glue address (A) resource records in the same zone.

See also: address (A) resource record  delegation  Domain Name System (DNS)  glue record  name server (NS) resource record  zone

**glue record**
In DNS, a delegation resource record used for locating the authoritative DNS servers for a delegated zone. These records are used to glue zones together and provide an effective delegation and referral path for other DNS servers to follow when resolving a name.

See also: authoritative  delegation  DNS server  Domain Name System (DNS)  glue chasing  resource record (RR)  zone

**GPMC**
See other term: Group Policy Management console (GPMC)

**GPO**
See other term: Group Policy object (GPO)

**GPO link**
See other term: Group Policy object link

**GPT**
See other term: GUID partition table (GPT)

**graphics mode**
A display mode in which lines and characters on the screen are drawn pixel by pixel. Graphics mode displays images by grouping individual dots into shapes, such as the arrowhead of a mouse pointer. It can also preview character formatting, such as boldface and italics, as it will appear in print.

See also: character mode

**gratuitous ARP**
An Address Resolution Protocol (ARP) Request frame sent by a host for the host`s own Internet Protocol version 4 (IPv4) address when the TCP/IP protocol obtains addressing information. Gratuitous ARPs are used to check for duplicate IPv4 addresses on the subnet. If the host receives a reply to the gratuitous ARP request from another host or computer, it detects a conflict for its configured IPv4 address and will not use it.

See also: Address Resolution Protocol (ARP)  frame  host  IP address  subnet

**group**
A collection of users, computers, contacts, and other groups. Groups can be used as security or as e-mail distribution collections. Distribution groups are used only for e-mail. Security groups are used both to grant access to resources and as e-mail distribution lists.

See also: domain  global group  local group

**group account**
A collection of user accounts. By making a user account a member of a group, you give the related user all the rights and permissions granted to the group.

See also: group  user account

**group identifier (GID)**
An identifier in UNIX that associates a user with a group of other users that have something in common. A user can be a member of one or more groups.

**group memberships**
The groups to which a user account belongs. Permissions and rights granted to a group are also provided to its members. In most cases, the actions a user can perform in Windows are determined by the group memberships of the user account to

which the user is logged on.

See also: group  user account

**Group Policy**
The infrastructure within Active Directory directory service that enables directory-based change and configuration management of user and computer settings, including security and user data. You use Group Policy to define configurations for groups of users and computers. With Group Policy, you can specify policy settings for registry-based policies, security, software installation, scripts, folder redirection, remote installation services, and Internet Explorer maintenance. The Group Policy settings that you create are contained in a Group Policy object (GPO). By associating a GPO with selected Active Directory system containers—sites, domains, and organizational units—you can apply the GPO`s policy settings to the users and computers in those Active Directory containers. To create an individual GPO, use the Group Policy Object Editor. To manage Group Policy objects across an enterprise, you can use the Group Policy Management console.

See also: Active Directory  Group Policy Management console (GPMC)  Group Policy object (GPO)  Group Policy Object Editor  Group Policy object link

**Group Policy Management console (GPMC)**
An optional tool that unifies and centralizes administration of Group Policy.

See also: Group Policy

**Group Policy object (GPO)**
A collection of Group Policy settings. GPOs are essentially the documents created by the Group Policy Object Editor. GPOs are stored at the domain level, and they affect users and computers that are contained in sites, domains, and organizational units. In addition, each computer has exactly one group of policy settings stored locally, called the local Group Policy object.

See also: Group Policy  Group Policy Management console (GPMC)  Group Policy Object Editor  Group Policy object link

**Group Policy Object Editor**
The Microsoft Management Console (MMC) snap-in that is used to edit Group Policy objects (GPOs).

See also: Group Policy Management console (GPMC)  Group Policy object (GPO)  Group Policy object link  Microsoft Management Console (MMC)

**Group Policy object link**
A method of applying settings in a Group Policy object (GPO) to an Active Directory container (site, domain, or organizational unit). Linking a GPO applies the settings of that GPO to the users and computers in a site, domain, or organizational unit and, by default, to the users and computers in all child containers.

See also: Active Directory  Group Policy Management console (GPMC)  Group Policy object (GPO)  inheritance  precedence

**Group Policy Security Settings**
The subtrees of the Group Policy Object Editor that allow a security administrator to manually configure security levels assigned to a Group Policy object (GPO) or local computer policy.

See also: Group Policy object (GPO)  Group Policy Object Editor

**GSS-API**
See other term: Generic Security Services Application Programming Interface (GSS-API)

**guest**
A user who does not have a user account or who does not provide a password.

See also: password  user account

**Guest account**
A built-in account used to log on to a computer running Windows when a user does not have an account on the computer or domain or in any of the domains trusted by the computer`s domain.

See also: domain  user account

**GUI mode**
The portion of Setup that uses a graphical user interface (GUI).

See also: Setup  text mode

**GUID**
See other term: globally unique identifier (GUID)

**GUID partition table (GPT)**
A disk-partitioning scheme that is used by the Extensible Firmware Interface (EFI). GPT offers more advantages than master boot record (MBR) partitioning because it allows up to 128 partitions per disk, provides support for volumes up to 18 exabytes in size, allows primary and backup partition tables for redundancy, and supports unique disk and partition IDs (GUIDs).

See also: Extensible Firmware Interface (EFI)  Itanium  master boot record (MBR)

# Windows Server 2003 Glossary - H

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - H**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**H.323**
The International Telecommunication Union - Telecommunication (ITU-T) standard for packet-based multimedia communications.

See also: International Telecommunication Union - Telecommunication [Standardization Sector] (ITU-T)  packet

**half-duplex**
A system capable of transmitting information in only one direction at a time over a communications channel.

See also: duplex  full-duplex

**handle**
In the user interface, an interface added to an object that facilitates moving, sizing, reshaping, or other functions pertaining to an object. In programming, a pointer to a pointer, that is, a token that lets a program access an identified resource.

**handle count**
In Task Manager, the number of object handles in a process`s object table.

See also: Task Manager

**handshaking**
A series of signals acknowledging that communication can take place between computers or other devices. A hardware handshake is an exchange of signals over specific wires (other than the data wires), in which each device indicates its readiness to send or receive data. A software handshake consists of signals transmitted over the same wires used to transfer data, as in modem-to-modem communications over telephone lines.

See also: device  modem (modulator/demodulator)

**Hardware Compatibility List (HCL)**
A hardware list that Microsoft compiled for specific products, including Windows 2000 and earlier versions of Windows. The list for a specific product, such as Windows 2000, includes the hardware devices and computer systems that are compatible with that version of the product. For products in the Windows Server 2003 family, you can find the equivalent information on the Windows Catalog Web site.

See also: device  Windows Catalog

**hardware compression**
A feature available on some tape devices that automatically compresses the data that is being stored on the device. This is usually an option that is turned on or off in a backup program.

See also: backup  device

**hardware configuration**
Resource settings that have been allocated for a specific device. Each device on your computer has a hardware configuration, which can consist of interrupt request (IRQ) lines, direct memory access (DMA), an input/output (I/O) port, or memory address settings.

See also: device  direct memory access (DMA)  input/output (I/O) port  interrupt request (IRQ) lines  memory address

**hardware decoder**
A type of digital video disc (DVD) decoder that allows a DVD drive to display movies on your computer screen. A hardware decoder uses both software and hardware to display movies.

See also: DVD decoder  DVD drive  software decoder

**hardware profile**
Data that describes the configuration and characteristics of specific computer equipment. This information can be used to configure computers for using peripheral devices.

See also: device

**hardware type**
A classification for similar devices. For example, Imaging Device is a hardware type for digital cameras and scanners.

See also: device

**hash**
A fixed-size result that is obtained by applying a one-way mathematical function (sometimes called a hash algorithm) to an arbitrary amount of data. If there is a change in the input data, the hash changes. The hash can be used in many operations, including authentication and digital signing. Also called a message digest.

See also: authentication  hash algorithm

**hash algorithm**
An algorithm that produces a hash value of some piece of data, such as a message or session key. With a good hash algorithm, changes in the input data can change every bit in the resulting hash value; for this reason, hashes are useful in detecting any modification in a data object, such as a message. Furthermore, a good hash algorithm makes it computationally infeasible to construct two independent inputs that have the same hash. Typical hash algorithms include MD2, MD4, MD5, and SHA-1. Also called a hash function.

See also: Hash-based Message Authentication Mode (HMAC)  MD2  MD4  MD5  message digest  Secure Hash Algorithm (SHA-1)

**Hash-based Message Authentication Mode (HMAC)**
A mechanism for message authentication using cryptographic hash functions. HMAC can be used with any iterative cryptographic hash function (for example, MD5 and SHA-1) in combination with a secret shared key. The cryptographic strength of HMAC depends on the properties of the underlying hash function.

See also: hash algorithm  MD5  Secure Hash Algorithm (SHA-1)

**HCL**
See other term: Hardware Compatibility List (HCL)

**header error control (HEC)**
The fifth byte in the asynchronous transfer mode (ATM) cell header used to detect and correct errors in the ATM header.

See also: asynchronous transfer mode (ATM)

**headless server**
See other term: remotely administered server

**heartbeat**
A signal emitted at regular intervals by software to indicate that it is still running.

See also: Network Load Balancing  Network Load Balancing cluster  server cluster

**HEC**
See other term: header error control (HEC)

**heterogeneous environment**
An internetwork with servers and workstations running different operating systems, such as Microsoft Windows, Apple Macintosh, or Novell NetWare, using a mix of different transport protocols.

See also: protocol  server

**hexadecimal**
A base-16 number system represented by the digits 0 through 9 and the uppercase or lowercase letters A (equivalent to decimal 10) through F (equivalent to decimal 15).

**high availability**
For server clusters, the restarting of a failed application or the dispersion of the work to remaining computers when a computer or application in the server cluster fails.

See also: server cluster

**histogram**
A chart consisting of horizontal or vertical bars, the widths or heights of which represent the values of certain data.

**hive**
A file in which the system stores a portion of the registry (named for their resemblance to the cellular structure of a beehive). A hive is backed by a single file and a .log file, which are in either the %SYSTEMROOT%\System32\Config folder or the %SYSTEMROOT%\Profiles\%USERNAME% folder. By default, most hive files (Default, SAM, Security, and System) are stored in the %SYSTEMROOT%\System32\Config folder. The %SYSTEMROOT%\Profiles folder contains the user profile for each user of the computer. Because a hive is a file, it can be moved from one system to another. However, you must use the Registry Editor, Regedit.exe, to edit the file.

See also: key  registry  systemroot

**HMAC**
See other term: Hash-based Message Authentication Mode (HMAC)

**home folder**
A folder (usually on a file server) that administrators can assign to individual users or groups. Administrators use home folders to consolidate user files onto specific file servers for easy backup. Home folders are used by some programs as the default folder for the Open and Save As dialog boxes. Sometimes referred to as home directories.

See also: group

**hop count**
The value in the Transport Control field that indicates the number of Internetwork Packet Exchange (IPX) routers that have processed the IPX packet.

See also: Internetwork Packet Exchange (IPX)  packet  router

**host**
Any device on a TCP/IP network that has an Internet Protocol (IP) address. Examples of hosts include servers, workstations, network-interface print devices, and routers. Sometimes used to refer to a specific network computer that is running a service used by network or remote clients. For Network Load Balancing, a cluster consists of multiple hosts connected over a local area network (LAN).

See also: client  cluster  local area network (LAN)  Network Load Balancing  server  service  Transmission Control Protocol/Internet Protocol (TCP/IP)

**host domain**
The domain in which a DFS namespace has been configured.

See also: DFS namespace  domain

**host ID**
The portion of the IP address that identifies a computer within a particular network ID.

See also: IP address  network ID

**host name**
The DNS name of a device on a network. These names are used to locate computers on the network. To find another computer, its host name must either appear in the Hosts file or be known by a DNS server. For most Windows-based computers, the host name and the computer name are the same.

See also: DNS server  Domain Name System (DNS)

**host priority**
For Network Load Balancing, a host`s precedence for handling default network traffic for TCP and UDP ports. It is used if a host within the cluster goes offline, and it determines which host within the cluster will assume responsibility for the traffic previously handled by the offline host.

See also: cluster  host  Network Load Balancing  User Datagram Protocol (UDP)

**host server**
The server on which a root target is located.

See also: root  root target  server

**Hosts file**
A local text file in the same format as the 4.3 Berkeley Software Distribution (BSD) UNIX /etc/hosts file. This file maps host names to IP addresses, and it is stored in the \%Systemroot%\System32\Drivers\Etc folder.

See also: systemroot

**HTML**
See other term: Hypertext Markup Language (HTML)

**HTTP**
See other term: Hypertext Transfer Protocol (HTTP)

**HTTPS**
See other term: Secure Hypertext Transfer Protocol

**hub**
A common connection point for devices in a network. Typically used to connect segments of a local area network (LAN), a hub contains multiple ports. When data arrives at one port, it is copied to the other ports so that all segments of the LAN can see the data.

See also: local area network (LAN)  port  switching hub

**hubbed mode**
A mode in which the Address Resolution Protocol/multicast address resolution service (ARP/MARS) provides asynchronous transfer mode (ATM) addresses to requesting clients in the form of a multicast server (MCS) list value. In this mode, ARP/MARS acts as a multicast server, providing active forwarding of all multicast and broadcast traffic destined for IP addresses contained within the ranges specified in the list.

See also: Address Resolution Protocol (ARP)  asynchronous transfer mode (ATM)  IP address  multicast address resolution service (MARS)  multicast server (MCS)  nonhubbed mode

**hue**
The position of a color along the color spectrum. For example, green is between yellow and blue. This attribute can be set using Display in Control Panel.

See also: saturation

**Hypertext Markup Language (HTML)**
A simple markup language used to create hypertext documents that are portable from one platform to another. HTML files are simple ASCII text files with codes embedded (indicated by markup tags) to denote formatting and hypertext links.

See also: American Standard Code for Information Interchange (ASCII)

**Hypertext Transfer Protocol (HTTP)**
The protocol used to transfer information on the World Wide Web. An HTTP address (one kind of Uniform Resource Locator (URL)) takes the following form: http://www.microsoft.com.

See also: protocol

# Windows Server 2003 Glossary - I

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - I**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**IAS**
See other term: Internet Authentication Service (IAS)

**ICMP**
See other term: Internet Control Message Protocol (ICMP)

**IDE**
See other term: integrated device electronics (IDE)

**identity**
A person or entity that must be verified by means of authentication, based on criteria such as a password or a certificate.

See also: authentication  password

**Identity Management for UNIX**
A feature of Windows that integrates computers running Windows into an existing UNIX enterprise.

**IEEE**
Institute of Electrical and Electronics Engineers, founded in 1963. IEEE is an organization composed of engineers, scientists, and students, best known for developing standards for the computer and electronics industry.

**IEEE 1394**
A standard for high-speed serial devices such as digital video and digital audio editing equipment.

See also: device

**IETF**
See other term: Internet Engineering Task Force (IETF)

**IGMP**
See other term: Internet Group Management Protocol (IGMP)

**IIS**
See other term: Internet Information Services (IIS)

**IIS Server Instance resource**
A server-instance designation used with Internet Information Services (IIS) that supports the WWW and FTP services. IIS server instances are supported as cluster resources by a Resource DLL. IIS Server Instance resources can have dependencies on IP Address resources, Network Name resources, and Physical Disk resources. Access information for server instances does not fail over.

See also: dependency  failover  Internet Information Services (IIS)  Resource DLL

**IKE**
See other term: Internet Key Exchange (IKE)

**ILMI**
See other term: integrated local management interface (ILMI)

**Image Name**
The name of a process as displayed in Task Manager.

See also: Task Manager

**impersonation**
The ability of a thread to run in the security context of a security principal different from the security principal that started the process. This is usually so that a process can gain access to resources on behalf of a user.

**impersonation token**
An access token that captures the security information of a client process, allowing a service to "impersonate" the client process in security operations.

See also: access token

**import media pool**
A logical collection of data-storage media that has not been cataloged by Removable Storage. Media in an import media pool is cataloged as soon as possible so that they can be used by an application.

See also: media pool  Removable Storage

**in-addr.arpa domain**
A special top-level DNS domain reserved for reverse mapping of IP addresses to DNS host names.

See also: Domain Name System (DNS)  reverse lookup  top-level domains

**in-band connection**
A connection between two computers that relies on a standard network, such as a local area network (LAN) or the Internet, and standard remote administration tools, such as Remote Desktop or Telnet. An in-band connection can only be used to manage computers remotely if both the local and remote computers are in a functional state and accessible on the network.

See also: local area network (LAN)  out-of-band connection  Telnet

**Incoming Forest Trust Builders group**
A group whose members can create incoming, one-way forest trusts to the forest-root domain. For example, members of this group residing in forest A can create a one-way incoming forest trust from forest B. This one-way incoming forest trust allows users in forest A to access resources that are located in forest B. Members of this group are assigned the permission Create Inbound Forest Trust on the forest-root domain. This group has no default members.

See also: forest  forest root domain  forest trust  group  one-way trust  permission  resource

**incremental backup**
A backup that copies only those files created or changed since the last normal or incremental backup. It marks files as having been backed up (in other words, the archive attribute is cleared). If you use a combination of normal and incremental backups to restore your data, you will need to have the last normal backup and all incremental backup sets.

See also: copy backup  daily backup  differential backup  normal backup

**incremental zone transfer (IXFR)**
In DNS, a zone transfer request involving only incremental resource record changes between each version of the zone. An IXFR contrasts with a full zone transfer (AXFR) request for all resource records.

See also: DNS server  Domain Name System (DNS)  full zone transfer (AXFR)  zone  zone transfer

**independent client**
A computer with Message Queuing installed that can host queues and store messages locally. Independent clients do not require synchronous access to a Message Queuing server to send and receive messages, but they can use Message Queuing servers with routing enabled for efficient message routing.

See also: dependent client  Message Queuing server  routing services

**indexed sequential access method (ISAM)**
A technique for indexing database records that allows sequential or random access of records. When records are accessed sequentially they are accessed in the order in which they were entered in the database, and when records are accessed randomly, the records are accessed through an index.)

**Indexing Service**
Software that provides search functions for documents stored on disk, allowing users to search for specific document text or properties.

**infrared (IR)**
Light that is beyond red in the color spectrum. While the light is not visible to the human eye, infrared transmitters and

receivers can send and receive infrared signals.

See also: Infrared Data Association (IrDA)  infrared device  infrared port

**Infrared Data Association (IrDA)**
The industry organization of computer, component, and telecommunications vendors who establish the standards for infrared communication between computers and peripheral devices, such as printers.

See also: infrared (IR)

**infrared device**
A computer, or a computer peripheral such as a printer, that can communicate by using infrared light.

See also: infrared (IR)

**infrared file transfer**
Wireless file transfer between a computer and another computer or device using infrared light.

See also: infrared (IR)

**infrared network connection**
A direct or incoming network connection to a remote access server using an infrared port.

See also: infrared port  remote access server

**infrared port**
An optical port on a computer that enables communication with other computers or devices by using infrared light, without cables. Infrared ports can be found on some portable computers, printers, and cameras.

See also: infrared (IR)  infrared device  port

**infrastructure master**
A domain controller that holds the infrastructure operations master role in Active Directory. The infrastructure master updates the group-to-user reference whenever group memberships change and replicates these changes across the domain. At any time, the infrastructure master role can be assigned to only one domain controller in each domain.

See also: Active Directory  domain controller  operations master

**inheritance**
In security, a mechanism that allows a specific access control entry (ACE) to be copied from the container where it was applied to all children of the container. Inheritance can be used to manage access to a whole subtree of objects in a single update operation. In Active Directory, the ability to build new object classes from existing object classes. The new object is defined as a subclass of the original object class. The original object class becomes a superclass of the new object. A subclass inherits the attributes of the superclass, including structure rules and content rules. In Group Policy, a mechanism that allows policy settings in Group Policy objects (GPOs) that are linked to parent containers to be applied to objects in child containers.

See also: access control entry (ACE)  Active Directory  block inheritance  delegation  enforce  Group Policy Management console (GPMC)  Group Policy object (GPO)  object class  precedence

**inherited permissions**
Permissions on an object that are automatically inherited from its parent object. Inherited permissions cannot be modified.

See also: object  parent object  permission

**initialize**
In Disk Management, the process of detecting a disk or volume and assigning it a status (for example, healthy) and a type (for example, dynamic).

See also: basic disk  basic volume  dynamic disk  dynamic volume

**inode**
A file identifier in UNIX. Each inode is identified by a unique number and contains user and group ownership information, access settings, file type, size, links, and modification information.

**input language**
A setting that specifies the language in which you enter text. When you add a new input language, you also select a keyboard layout and other input methods for that language.

See also: Input Method Editor (IME)

**Input Method Editor (IME)**
A program used to enter the thousands of different characters in written Asian languages with a standard 101-key keyboard. An IME consists of both an engine that converts keystrokes into phonetic and ideographic characters and a dictionary of commonly used ideographic words. As the user enters keystrokes, the IME engine attempts to identify which character or characters that the keystrokes should be converted into.

**input/output (I/O) port**
A channel through which data is transferred between a device and the microprocessor. The port appears to the microprocessor as one or more memory addresses that it can use to send or receive data.

See also: device  memory address  port

**install**
When referring to software, to add program files and folders to your hard disk and related data to your registry so that the software runs properly. Installing contrasts with upgrading, where existing program files, folders, and registry entries are updated to a more recent version. When referring to hardware, to physically connect the device to your computer, to load device drivers onto your computer, and to configure device properties and settings.

See also: device driver  registry  uninstall  upgrade

**integrated device electronics (IDE)**
A type of disk-drive interface in which the controller electronics reside on the drive itself, eliminating the need for a separate adapter card. IDE offers advantages such as look-ahead caching to increase overall performance.

**integrated local management interface (ILMI)**
A limited set of Simple Network Management Protocol (SNMP) functions included in the asynchronous transfer mode (ATM) specification for the ATM user network interface (UNI).

See also: asynchronous transfer mode (ATM)  Simple Network Management Protocol (SNMP)  user-to-network interface (UNI)

**Integrated Services Digital Network (ISDN)**
A digital phone line used to provide higher bandwidth. ISDN in North America is typically available in two forms: Basic Rate Interface (BRI) consists of 2 B-channels at 64 kilobits per second (Kbps) and a D-channel at 16 Kbps; Primary Rate Interface (PRI) consists of 23 B-channels at 64 Kbps and a D-channel at 64 Kbps. An ISDN line must be installed by the phone company at both the calling site and the called site.

See also: B-channel  D-channel  multilink dialing  Service Profile Identifier (SPID)  switch type

**Integrated Services over Slow Links (ISSLOW)**
A queuing mechanism used to optimize slow (low-capacity) network interfaces by reducing latency. In particular, it is designed for interfaces that forward traffic to modem links, Integrated Services Digital Network (ISDN) B-channels, and sub-T1 links.

See also: B-channel  Integrated Services Digital Network (ISDN)

**Integrated Windows authentication**
A configuration setting that enables negotiation of authentication protocols in Internet Information Services (IIS).

See also: authentication protocol  Internet Information Services (IIS)

**IntelliMirror**
A set of change and configuration management features based on Active Directory that enables management of user and computer data and settings, including security data. IntelliMirror also provides limited ability to deploy software to Windows 2000 and later workstations or servers.

See also: Active Directory

**interactive dialog box**
A dialog box that requires a response from the user. Intermediary devices such as a security host require such a dialog box as an added layer of security between the client and the remote access server. In such dialog boxes, the user types an access code or a user name and password on the remote access terminal screen.

See also: intermediary device  remote access server  static dialog box

**interactive logon**

The process of logging on to a local computer by using a keyboard.

**interconnect**
A private network that connects nodes in a cluster.

See also: cluster  node

**intermediary device**
A device other than a modem or X.25 PAD, located between a network connection and the remote access server. This device is typically a modem-pool switch or security host and requires either a static or interactive dialog box between the client and itself.

See also: interactive dialog box  PAD (packet assembler/disassembler)  remote access server  static dialog box

**internal network number**
A 4-byte hexadecimal number used for addressing and routing purposes. The internal network number identifies a virtual network inside a computer. The internal network number must be unique to the IPX internetwork. Also called virtual network number.

See also: external network number  Internetwork Packet Exchange (IPX)

**internal private queue**
For Message Queuing, a queue that stores various types of administrative messages, or an interim queue for storing and forwarding messages in transit to a destination queue. Internal private queues are not displayed in Microsoft Management Console (MMC) snap-ins, and they cannot be deleted.

See also: Message Queuing  private queue  queue

**internal router**
A router for which all the networks that it is connected to belong in the same area.

See also: router

**international prefix**
Digits dialed before the country code to access the international phone service. The actual digits depend on the country or region in which you are dialing an international number. For example, in the United States of America, the prefix for international dialing is 011. To dial from the United States of America to Honduras, which has the country code 504, you would dial: (011) (504) (000) 000-0000

**International Telecommunication Union - Telecommunication [Standardization Sector] (ITU-T)**
The sector of the International Telecommunication Union (ITU) responsible for telecommunication standards. ITU-T replaces the Comite Consultatif International Telegraphique et Telephonique (CCITT). Its responsibilities include standardizing modem design and operations, and standardizing protocols for networks and facsimile transmission. ITU is an international organization within which governments and the private sector coordinate global telecom networks and services.

**Internet**
A worldwide network of computers. If you have access to the Internet, you can retrieve information from millions of sources, including schools, governments, businesses, and individuals.

See also: router  World Wide Web (WWW)

**Internet address**
An address for a resource on the Internet that is used by Web browsers to locate Internet resources. An Internet address typically starts with a protocol name, followed by the name of the organization that maintains the site; the suffix identifies the kind of organization it is. For example, the address http://www.yale.edu/ provides the following information: http: This Web server uses the Hypertext Transfer Protocol. www: This site is on the World Wide Web. edu: This is an educational institution. Internet address is also called Uniform Resource Locator (URL).

See also: protocol  Web server

**Internet Authentication Service (IAS)**
The Microsoft implementation of a Remote Authentication Dial-In User Service (RADIUS) server, which provides authentication and accounting for network access, and proxy, which provides forwarding of RADIUS messages.

See also: authentication  Certificate Services  Remote Access Service (RAS)  Remote Authentication Dial-In User Service (RADIUS)  service  virtual private network (VPN)

**Internet Control Message Protocol (ICMP)**
A required maintenance protocol in the TCP/IP suite that reports errors and provides simple diagnostic capabilities. ICMP is used by the Ping tool to perform TCP/IP troubleshooting.

See also: Internet Protocol (IP) protocol Transmission Control Protocol/Internet Protocol (TCP/IP)

**Internet Engineering Task Force (IETF)**
An open community of network designers, operators, vendors, and researchers concerned with the evolution of Internet architecture and the smooth operation of the Internet. Technical work is performed by working groups organized by topic areas (such as routing, transport, and security) and through mailing lists. Internet standards are developed in IETF Requests for Comments (RFCs), which are a series of notes that discuss many aspects of computing and computer communication, focusing on networking protocols, programs, and concepts.

See also: Request for Comments (RFC)

**Internet Group Management Protocol (IGMP)**
A protocol used by Internet Protocol version 4 (IPv4) hosts to report their multicast group memberships to any immediately neighboring multicast routers.

See also: Internet Protocol multicasting Multicast Listener Discovery (MLD) protocol

**Internet group name**
A name known by a DNS service that includes a list of the specific addresses of systems that have registered the name.

See also: Domain Name System (DNS)

**Internet Information Services (IIS)**
Software services that support Web site creation, configuration, and management, along with other Internet functions. Internet Information Services include Network News Transfer Protocol (NNTP), File Transfer Protocol (FTP), and Simple Mail Transfer Protocol (SMTP).

See also: File Transfer Protocol (FTP) Network News Transfer Protocol (NNTP) Simple Mail Transfer Protocol (SMTP)

**Internet Key Exchange (IKE)**
A protocol that establishes the security association and shared keys necessary for two parties to communicate by using Internet Protocol security (IPSec).

See also: Internet Protocol security (IPsec) protocol

**Internet Printing Protocol (IPP)**
The protocol that uses the Hypertext Transfer Protocol (HTTP) to send print jobs to printers throughout the world. Windows 2000, Windows XP, and the Windows Server 2003 family support Internet Printing Protocol (IPP) version 1.0.

See also: protocol

**Internet Protocol (IP)**
A routable protocol in the TCP/IP protocol suite that is responsible for IP addressing, routing, and the fragmentation and reassembly of IP packets.

See also: Compression Control Protocol (CCP) packet Transmission Control Protocol/Internet Protocol (TCP/IP) voluntary tunnel

**Internet Protocol multicasting**
The extension of local area network multicasting technology to a TCP/IP network. Hosts send and receive multicast datagrams, the destination fields of which specify IP host group addresses rather than individual IP addresses. A host indicates that it is a member of a group by means of the Internet Group Management Protocol (IGMP).

See also: Internet Group Management Protocol (IGMP) Transmission Control Protocol/Internet Protocol (TCP/IP)

**Internet Protocol security (IPsec)**
A set of industry-standard, cryptography-based protection services and protocols. IPsec protects all protocols in the TCP/IP protocol suite except Address Resolution Protocol (ARP). For virtual private network (VPN) connections, IPsec is used in conjunction with Layer Two Tunneling Protocol (L2TP).

See also: Address Resolution Protocol (ARP) Layer Two Tunneling Protocol (L2TP) protocol Transmission Control Protocol/Internet Protocol (TCP/IP) virtual private network (VPN)

**Internet SCSI (iSCSI)**
An industry standard developed to enable transmission of SCSI commands over the existing Internet Protocol (IP) network by using the TCP/IP protocol. iSCSI offers the possibility of delivering both messaging traffic and block-based storage over IP networks without installing a separate Fibre Channel network.

**Internet Server Application Programming Interface (ISAPI)**
An application programming interface (API) that resides on a server computer for initiating software services tuned for Windows operating systems. In Microsoft Provisioning System, ISAPI resides on the Web server.

See also: application programming interface (API)

**Internet service provider (ISP)**
A company that provides individuals or companies access to the Internet and the World Wide Web. An ISP provides a telephone number, a user name, a password, and other connection information so users can connect their computers to the ISP's computers. An ISP typically charges a monthly or hourly connection fee.

See also: Web server

**Internetwork Packet Exchange (IPX)**
A network protocol native to NetWare that controls addressing and routing of packets within and between local area networks (LANs). IPX does not guarantee that a message will be complete (no lost packets).

See also: Compression Control Protocol (CCP) Internetwork Packet Exchange/Sequenced Packet Exchange (IPX/SPX) local area network (LAN) Routing Information Protocol over IPX (RIPX)

**Internetwork Packet Exchange/Sequenced Packet Exchange (IPX/SPX)**
Transport protocols used in Novell NetWare networks, which together correspond to the combination of TCP and IP in the TCP/IP protocol suite. Windows implements IPX through NWLink.

See also: Internetwork Packet Exchange (IPX) NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) Transmission Control Protocol/Internet Protocol (TCP/IP)

**interrupt**
A request for attention from the processor. When the processor receives an interrupt, it suspends its current operations, saves the status of its work, and transfers control to a special routine known as an interrupt handler, which contains the instructions for dealing with the particular situation that caused the interrupt.

See also: interrupt request (IRQ)

**interrupt request (IRQ)**
A signal sent by a device to get the attention of the processor when the device is ready to accept or send information. Each device sends its interrupt requests over a specific hardware line. Each device must be assigned a unique IRQ number.

See also: interrupt

**interrupt request (IRQ) lines**
Hardware lines over which devices can send signals to get the attention of the processor when the device is ready to accept or send information. Each device must have a unique IRQ line.

See also: device interrupt request (IRQ)

**intersite messaging service (ISM)**
A service that supports transports for asynchronous, site-to-site messaging. Each transport serves two major roles: send/receive and topology queries (such as, what are the various sites connected by this transport, and at what cost?). The intersite messaging services shipped in Windows are remote procedure call (RPC) and Simple Mail Transfer Protocol (SMTP) (mail).

See also: remote procedure call (RPC) service Simple Mail Transfer Protocol (SMTP)

**intersite replication**
In Active Directory, the replication of directory partition updates between sites. Intersite replication occurs between bridgehead servers that store the same domain or application directory partition. One bridgehead server per domain or application directory partition and per replication transport is designated automatically in each site. If two sites have no domains or application directory partitions in common, a bridgehead server in each site replicates both the configuration and schema directory partitions between the two sites.

See also: Active Directory bridgehead server directory partition intrasite replication replication site

**Intersite Topology Generator**
An Active Directory process that runs on one domain controller in a site that considers the cost of intersite connections, checks if previously available domain controllers are no longer available, and checks if new domain controllers have been added. The Knowledge Consistency Checker (KCC) process then updates the intersite replication topology accordingly.

See also: Active Directory domain controller Knowledge Consistency Checker (KCC) replication topology site

**intersite topology generator (ISTG)**
A server in an Active Directory architecture that is responsible for managing the inbound replication connection objects for all the server contact points in the server's site.

**intrasite replication**
In Active Directory, the replication of directory partition updates that occurs between two or more domain controllers that store the same domain or application directory partition and that reside within the same site.

See also: Active Directory directory partition domain controller intersite replication site

**IP**
See other term: Internet Protocol (IP)

**IP address**
For Internet Protocol version 4 (IPv4), a 32-bit address used to identify an interface on a node on an IPv4 internetwork. Each interface on the IP internetwork must be assigned a unique IPv4 address, which is made up of the network ID, plus a unique host ID. This address is typically represented with the decimal value of each octet separated by a period (for example, 192.168.7.27). You can configure the IP address statically or dynamically by using Dynamic Host Configuration Protocol (DHCP). For Internet Protocol version 6 (IPv6), an identifier that is assigned at the IPv6 layer to an interface or set of interfaces and that can be used as the source or destination of IPv6 packets.

See also: Internet Protocol (IP) node scope

**IP Address resource**
A 32-bit number in dotted decimal format that represents an Internet Protocol (IP) address and is supported as a cluster resource by a Resource DLL provided with Windows.

See also: IP address Resource DLL

**IPP**
See other term: Internet Printing Protocol (IPP)

**IPsec**
See other term: Internet Protocol security (IPsec)

**IPsec policy**
Configuration policy that defines which traffic Internet Protocol security (IPsec) examines, how that traffic is secured and encrypted, and how IPsec peers are authenticated.

See also: authentication encryption Internet Protocol security (IPsec) policy

**IPX/SPX**
See other term: Internetwork Packet Exchange/Sequenced Packet Exchange (IPX/SPX)

**IR**
See other term: infrared (IR)

**IrDA**
See other term: Infrared Data Association (IrDA)

**IRQ**
See other term: interrupt request (IRQ)

**ISAM**
See other term: indexed sequential access method (ISAM)

**ISAPI**
See other term: Internet Server Application Programming Interface (ISAPI)

**iSCSI**

See other term: Internet SCSI (iSCSI)

**iSCSI initiator**
A logical entity that enables a server to communicate with an iSCSI device over an Internet Protocol (IP) network. Each iSCSI initiator can have one or more network adapters through which communication is established.

**iSCSI target**
A logical entity created in order to manage the connections between an iSCSI device and the servers that need to access it over an Internet Protocol (IP) network. A target defines the portals (IP addresses) that can be used to connect to the iSCSI device, as well as the security settings (if any) that the iSCSI device requires in order to authenticate the servers that are requesting access to its resources.

**ISDN**
See other term: Integrated Services Digital Network (ISDN)

**ISM**
See other term: intersite messaging service (ISM)

**ISP**
See other term: Internet service provider (ISP)

**ISTG**
See other term: intersite topology generator (ISTG)

**Itanium**
An Intel microprocessor that uses explicitly parallel instruction set computing and 64-bit memory addressing. "Itanium-based" refers to systems or platforms that are based on the Itanium processor. "Itanium 2-based" refers to systems or platforms that are based on the Itanium 2 processor. "Itanium architecture-based" refers to systems or platforms that are based on the Itanium and Itanium 2 processors.

**iteration**
See other term: iterative query

See also: DNS server  Domain Name System (DNS)  iterative query  recursive resolution  referral

**iterative query**
A query made to a DNS server for the best answer the server can provide without seeking further help from other DNS servers. Also called a nonrecursive query.

See also: DNS server  Domain Name System (DNS)  recursive query  referral

**ITU-T**
See other term: International Telecommunication Union - Telecommunication [Standardization Sector] (ITU-T)

**IXFR**
See other term: incremental zone transfer (IXFR)

# Windows Server 2003 Glossary - J

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - J**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**job object**
A system-level structure that allows processes to be grouped together and managed as a single unit.

See also: process

**join**
In Active Directory Application Mode (ADAM) or Active Directory Lightweight Directory Services (AD LDS), to create a replica of an existing ADAM or AD LDS instance in the same configuration set. When you create a replica of an existing ADAM or AD LDS instance, you join it to the same configuration set that hosts the original (existing) instance.

**journal**
For Message Queuing, a queue where journal messages are stored.

See also: journal quota  Message Queuing  queue  source journaling  target journaling

**journal quota**
For Message Queuing, a property that specifies the cumulative limit for journal messages in a journal queue. The limit is based on cumulative journal message size. When a journal queue`s quota is reached, messages are no longer stored.

See also: journal  Message Queuing  property

**junction point**
A physical location on a hard disk that points to data located at another location on your hard disk or another storage device. Junction points are created when you create a mounted drive. You can also create a junction point using the linkd command.

See also: mounted drive

# Windows Server 2003 Glossary - K

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - K**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**KDC**

See other term: Key Distribution Center (KDC)

**Kerberos V5 authentication protocol**

An authentication mechanism used to verify user or host identity. The Kerberos V5 authentication protocol is the default authentication service. Internet Protocol security (IPSec) can use the Kerberos protocol for authentication.

See also: Internet Protocol security (IPsec) Key Distribution Center (KDC) realm service ticket ticket-granting service (TGS) ticket-granting ticket (TGT)

**kernel mode**

A highly privileged mode of operation where program code has direct access to all memory, including the address spaces of all user-mode processes and applications, and to hardware. Also known as supervisor mode, protected mode, or Ring 0.

**key**

In Registry Editor, a folder that appears in the left pane of the Registry Editor window. A key can contain subkeys and entries. For example, Environment is a key of HKEY_CURRENT_USER. In IP security (IPSec), a value used in combination with an algorithm to encrypt or decrypt data. Key settings for IPSec are configurable to provide greater security.

See also: entry Internet Protocol security (IPsec) registry subkey

**Key Distribution Center (KDC)**

A network service that supplies session tickets and temporary session keys used in the Kerberos V5 authentication protocol.

See also: Kerberos V5 authentication protocol ticket-granting service (TGS) ticket-granting ticket (TGT)

**keyboard layout**

The arrangement that accommodates the special characters and symbols used in different languages. Keyboard layouts affect which characters appear when users press the keys on their keyboards. After the keyboard layout is changed, the characters that appear on the screen may no longer correspond to the characters that are printed on the keyboard keys.

**Knowledge Consistency Checker (KCC)**

A built-in process that runs on all domain controllers and generates the replication topology for the Active Directory forest. At specified intervals, the KCC reviews and makes modifications to the replication topology to ensure propagation of data either directly or transitively.

See also: Active Directory domain controller forest replication topology

# Windows Server 2003 Glossary - L

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - L**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**L2TP**

See other term: Layer Two Tunneling Protocol (L2TP)

**label**

In DNS, each part of a DNS domain name that represents a node in the domain namespace tree. For example, the three labels "example," "microsoft," and "com" make up the DNS domain name example.microsoft.com. Each label used in a DNS name cannot exceed 63 octets, 255 bytes including the terminating dot, for the fully qualified domain name (FQDN).

See also: domain name  Domain Name System (DNS)  fully qualified domain name (FQDN)  node

**LAN**

See other term: local area network (LAN)

**LAN emulation (LANE)**

A group of software components that allows asynchronous transfer mode (ATM) to work with legacy networks and applications. With LANE, you can run your traditional local area network (LAN)-aware applications and protocols on an ATM network without modification. LANE makes the ATM protocol layers appear to be an Ethernet or Token Ring LAN to overlying protocols and applications. LANE provides an intermediate step between fully exploiting ATM and not using ATM at all.

See also: asynchronous transfer mode (ATM)  local area network (LAN)  protocol  Token Ring

**LAN emulation client (LEC)**

The client on an emulated local area network (ELAN) that performs data forwarding, address resolution, and other control functions. The LEC resides on end stations in an ELAN.

See also: client  emulated local area network (ELAN)  LAN emulation (LANE)

**LAN emulation configuration server**

The service that assigns individual local area network emulation (LANE) clients to particular emulated local area networks (ELANs) by directing them to the LAN emulation server (LES).

See also: emulated local area network (ELAN)  LAN emulation (LANE)  LAN emulation server (LES)  service

**LAN emulation server (LES)**

The central control point for an emulated local area network (ELAN). LES enables LAN emulation (LANE) clients to join the ELAN, and it resolves local area network (LAN) addresses to asynchronous transfer mode (ATM) addresses.

See also: asynchronous transfer mode (ATM)  emulated local area network (ELAN)  LAN emulation (LANE)  local area network (LAN)

**LANE**

See other term: LAN emulation (LANE)

**Last Known Good Configuration**

A hardware configuration that is available by pressing F8 during startup. If the current hardware settings prevent the computer from starting, Last Known Good Configuration can allow you to start the computer and examine the configuration. When Last Known Good Configuration is used, later configuration changes are lost.

See also: Safe mode

**latency**

In Active Directory replication, the delay between the time an update is applied to a specific replica and the time it is applied to

some other replica. Also known as propagation delay.

See also: Active Directory replica replication

**Layer Two Tunneling Protocol (L2TP)**
An industry-standard Internet tunneling protocol that provides encapsulation for sending Point-to-Point Protocol (PPP) frames across packet-oriented media. For IP networks, L2TP traffic is sent as User Datagram Protocol (UDP) messages. In Microsoft operating systems, L2TP is used in conjunction with Internet Protocol security (IPSec) as a virtual private network (VPN) technology to provide remote access or router-to-router VPN connections. L2TP is described in RFC 2661.

See also: frame Internet Protocol security (IPsec) Point-to-Point Protocol (PPP) tunnel User Datagram Protocol (UDP)

**Layer Two Tunneling Protocol/Internet Protocol security (L2TP/IPsec)**
A virtual private network (VPN) connection method that provides session authentication, address encapsulation, and strong encryption of private data between remote access servers and clients. L2TP provides address encapsulation and user authentication, and Internet Protocol security (IPsec) provides computer authentication and encryption of the L2TP session.

See also: authentication encapsulation encryption Internet Protocol security (IPsec) Layer Two Tunneling Protocol (L2TP) virtual private network (VPN)

**LDAP**
See other term: Lightweight Directory Access Protocol (LDAP)

**LDAP Data Interchange Format (LDIF)**
A draft Internet standard for a file format that can be used to perform batch operations on directories that conform to Lightweight Directory Access Protocol (LDAP) standards.

See also: batch program Lightweight Directory Access Protocol (LDAP)

**LDIF**
See other term: LDAP Data Interchange Format (LDIF)

**lease**
The length of time for which a DHCP client can use a dynamically assigned IP address configuration. Before the lease time expires, the client must either renew or obtain a new lease with DHCP.

See also: DHCP client Dynamic Host Configuration Protocol (DHCP) IP address

**LEC**
See other term: LAN emulation client (LEC)

**LES**
See other term: LAN emulation server (LES)

**library**
A data-storage system, usually managed by Removable Storage. A library consists of removable media (such as tapes or discs) and a hardware device that can read from or write to the media. There are two major types of libraries: robotic libraries (automated multiple-media, multidrive devices) and stand-alone drive libraries (manually operated, single-drive devices). A robotic library is also called a jukebox or changer.

See also: Removable Storage

**Lightweight Directory Access Protocol (LDAP)**
The primary access protocol for Active Directory. LDAP is an industry-standard protocol, established by the Internet Engineering Task Force (IETF), that allows users to query and update information in a directory service. Active Directory supports both LDAP version 2 and LDAP version 3.

See also: Active Directory directory service Internet Engineering Task Force (IETF) protocol

**Line Printer Daemon (LPD)**
A service on a print server that receives print jobs from Line Printer Remote (LPR) tools that are running on client computers.

See also: Line Printer Remote (LPR) print job print server service

**Line Printer Remote (LPR)**
A connectivity tool that runs on client computers and that is used to print files to a computer running a Line Printer Daemon (LPD) server.

See also: Line Printer Daemon (LPD)

**link state database**
A map of an area maintained by Open Shortest Path First (OSPF) routers. It is updated after any change in the network topology. The link state database is used to compute Internet Protocol (IP) routes, which must be computed again after any change in the topology.

See also: adjacency  Internet Protocol (IP)  Open Shortest Path First (OSPF)

**linked object**
An object that is inserted into a document but still exists in the source file. When information is linked, the new document is updated automatically if the information in the original document changes. If you want to edit the linked information, double-click it. The toolbars and menus from the original program will appear. If the original document is on your computer, changes that you make to the linked information will also appear in the original document.

See also: embedded object  OLE  package  source document

**LIS**
See other term: logical IP subnet (LIS)

**Lmhosts file**
A local text file that maps network basic input/output (NetBIOS) names (commonly used for computer names) to IP addresses for hosts that are not located on the local subnet. In this version of Windows, this file is stored in the systemroot\System32\Drivers\Etc folder.

See also: host  IP address  network basic input/output system (NetBIOS)  systemroot

**load balancing**
A technique used by Windows Clustering to scale the performance of a server-based program (such as a Web server) by distributing its client requests across multiple servers within the cluster. Each host can specify the load percentage that it will handle, or the load can be equally distributed across all the hosts. If a host fails, Windows Clustering dynamically redistributes the load among the remaining hosts.

See also: cluster  host

**load weight**
A Network Load Balancing parameter that specifies the relative amount of load-balanced network traffic that the host handles for the associated port rule. Allowed values range from 0 (zero) to 100. To prevent a host from handling any network traffic, set the load weight to 0 (zero).

See also: Network Load Balancing  Network Load Balancing cluster

**local area network (LAN)**
A network of computers, printers, and other devices located within a relatively limited area (for example, a building). A LAN enables any connected device to interact with any other on the network.

See also: NetBIOS Extended User Interface (NetBEUI)  network basic input/output system (NetBIOS)  virtual local area network (VLAN)  workgroup

**local computer**
The computer that you are currently logged on to as a user. More generally, a local computer is a computer that you can access directly without using a communications line or a communications device, such as a network adapter or a modem.

See also: remote computer

**local group**
A security group that can be granted rights and permissions only to resources on the computer on which the group is created. Local groups can have any user accounts that are local to the computer as members, as well as users, groups, and computers from a domain to which the computer belongs.

See also: global group  member server  user account

**local printer**
A printer that is directly connected to one of the ports on a computer.

See also: port

**Local Security Authority (LSA)**
A protected subsystem that authenticates and logs users on to the local computer. In addition, the LSA maintains information about all aspects of local security on a computer (collectively known as the local security policy), and it provides various services for translation between names and identifiers.

See also: local security policy  security

**Local Security Authority Subsystem Service (LSASS)**
An interface for managing local security, domain authentication, and Active Directory processes. It handles authentication for the client and for the server. It also contains features that are used to support Active Directory utilities.

**local security policy**
Security information about all aspects of local security on a computer. The local security policy identifies who is assigned privileges and what security auditing is to be performed.

See also: auditing  security

**local service**
A service that performs a specific operating system function for other local processes on the computer.

See also: service

**Local Service account**
A predefined local account that is used to start a service and provide the security context for that service. The name of the account is NT AUTHORITY\LocalService. The Local Service account has limited access to the local computer and Anonymous access to network resources.

See also: access control list (ACL)  Local System account  Network Service account  service

**local storage**
For the Windows Server 2003 family, NTFS file system disk volumes used as primary data storage. Such disk volumes can be managed by Remote Storage by copying infrequently accessed files to remote (secondary) storage.

See also: NTFS file system  Remote Storage  volume

**Local System account**
A predefined local account that is used to start a service and provide the security context for that service. The name of the account is NT AUTHORITY\System. This account does not have a password, and any password information that you supply is ignored. The Local System account has full access to the system, including the directory service on domain controllers. Because the Local System account acts as a computer on the network, it has access to network resources.

See also: directory service  domain controller  Local Service account  Network Service account  service

**local user profile**
A computer-based record about an authorized user that is created automatically on the computer the first time a user logs on to a workstation or server computer.

**LocalTalk**
The Apple networking hardware built into every Macintosh computer. LocalTalk includes the cables and connector boxes that connect components and network devices that are part of the AppleTalk network system. Formerly known as AppleTalk Personal Network.

**log file**
A file that stores messages generated by an application, service, or operating system. These messages are used to track the operations performed. For example, Web servers maintain log files listing every request made to the server. Log files are usually plain text (ASCII) files and often have a .log extension. In Backup, a file that contains a record of the date the tapes were created and the names of files and directories successfully backed up and restored. The Performance Logs and Alerts service also creates log files.

See also: American Standard Code for Information Interchange (ASCII)  service

**logical drive**
A volume that you create within an extended partition on a basic master boot record (MBR) disk. Logical drives are similar to primary partitions, except that you are limited to four primary partitions per disk, whereas you can create an unlimited number of logical drives per disk. A logical drive can be formatted and assigned a drive letter.

See also: basic disk  basic volume  drive letter  extended partition  master boot record (MBR)  primary partition  volume

**logical IP subnet (LIS)**
A group of Internet Protocol (IP) hosts that belong to the same IP subnet.

See also: host  Internet Protocol (IP)  subnet

**logical printer**
The software interface between the operating system and the printer in Windows. While a printer is the device that does the actual printing, a logical printer is its software interface on the print server. This software interface determines how a print job is processed and how it is routed to its destination (to a local or network port, to a file, or to a remote print share). When you print a document, it is spooled (or stored) on the logical printer before it is sent to the printer itself.

See also: printer  spooling

**logical unit number (LUN)**
A logical reference to a portion of a storage subsystem. For example, in a disk storage subsystem, a LUN can comprise a disk, a section of a disk, a whole disk array, or a section of a disk array in the subsystem.

**logon event category**
In auditing, a group of events that are logged when a user attempts to log on to or log off from a computer.

See also: auditing  event

**logon rights**
User rights that are assigned to a user and that specify the ways in which a user can log on to a system. An example of a logon right is the right to log on to a system remotely.

See also: user rights

**logon script**
A file, typically a batch file, that runs automatically every time a user logs on to a computer or network. It can be used to configure a user`s working environment whenever a user logs on, and it allows an administrator to influence a user`s environment without managing all aspects of it. A logon script can be assigned to one or more user accounts.

See also: batch program  logon script path  user account

**logon script path**
A sequence of directory names that specifies the location of the logon script. When a user logs on, the authenticating computer locates the specified logon script (if one has been assigned to that user account) by following that computer`s local logon script path (usually systemroot\System32\Repl\Import\Scripts).

See also: logon script  systemroot  user account

**long distance operator**
Digits dialed before the area or city code to access a long distance phone service. For example, in the United States of America, you dial a 1 before the area or city code: (1) (206) 000-0000. The actual digits depend on the country/region or phone service. Area codes and long distance operators are not used in all countries/regions.

**long name**
A folder name or file name longer than the 8.3 file name standard (up to eight characters followed by a period and an extension of up to three characters) of the file allocation table (FAT) file system. This version of Windows supports file names up to 255 characters and automatically translates long names of files and folders to 8.3 names for MS-DOS and Windows 3.x users. In a Macintosh environment, users can assign names up to 31 characters, excluding colons, to files and folders.

See also: file allocation table (FAT)  MS-DOS (Microsoft Disk Operating System)

**loopback**
An advanced Group Policy setting that is useful in certain closely managed environments, such as laboratories, classrooms, public kiosks, and reception areas. You can find the setting and its description in the Group Policy console tree under Computer Configuration\Administrative Templates\System\Group Policy. The full name of this setting is User Group Policy loopback processing mode.

See also: console tree  Group Policy

**loose name checking**
A form of domain name checking DNS uses that examines characters in DNS names for valid American National Standards Institute (ANSI) character compliance. However, loose name checking does not check for compliance with DNS naming requirements and valid character usage for Internet host names, as specified in RFC 1123, Requirements for Internet Hosts -

Applications and Support. For RFC compliance, DNS domain names will use name labels made up only of valid uppercase and lowercase letters, number characters, and hyphens (A through Z, a through z, 0 through 9, and -) separated by periods.

See also: domain name  Domain Name System (DNS)  label  Request for Comments (RFC)

**LPD**
See other term: Line Printer Daemon (LPD)

**LPR**
See other term: Line Printer Remote (LPR)

**LSASS**
See other term: Local Security Authority Subsystem Service (LSASS)

**luminosity**
The brightness of a color based on a scale from black to white on your monitor.

**LUN**
See other term: logical unit number (LUN)

# Windows Server 2003 Glossary - M

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - M**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**machine-centric**
A service model that requires specific computers and services be used to complete a task. If a user must connect to a specific computer to access a service, then that service is considered machine-centric.

See also: service  service-centric

**Macintosh-accessible volume**
Storage space on the server used for folders and files of Macintosh users. A Macintosh-accessible volume is equivalent to a shared folder for Windows users. Each Macintosh-accessible volume on a computer running Services for Macintosh will correspond to a folder. Both Windows users and Macintosh users can be given access to files located in a folder that is designated as both a shared folder and a Macintosh-accessible volume.

See also: shared folder  volume

**Macintosh-style permissions**
Folder and volume permissions that are similar to the access privileges used on a Macintosh.

See also: permission  privilege  volume

**majority node set server cluster**
A cluster configuration that has two or more nodes and that is configured so that the nodes may or may not be attached to one or more cluster storage devices. The cluster configuration data is stored on multiple disks across the cluster, and the Cluster service makes sure that this data is kept consistent across the different disks. There are advantages and limitations for each cluster configuration (single node server cluster, single quorum device server cluster, and majority node set server cluster).

See also: cluster  cluster storage  node  single node server cluster  single quorum device server cluster

**Make Changes**
The Macintosh-style privilege that allows you to change the contents of folders for which you have this privilege. If you have the Make Changes privilege, you can modify, rename, move, create, and delete files in folders for which you have that privilege. When Services for Macintosh translates Macintosh-style privileges into Windows permissions, you are granted Write and Delete permissions for any folders for which you have the Make Changes privilege.

See also: privilege

**malicious program**
Any program that is created to do intentional harm to or compromise the security of a computer. Examples of malicious programs include trojan horses and computer viruses.

See also: Trojan horse  virus

**malicious user**
(1) A user who intentionally accesses a system with the intent to cause harm to the system or to use it in an unauthorized manner. (2) A person who has legitimate access to a system and poses a security threat to it, such as someone who tries to elevate their user rights to gain access to unauthorized data.

**managed volume**
A local NTFS file system 5.0 volume whose disk space is managed by Remote Storage. Remote Storage frees up disk space by automatically moving infrequently accessed files to a remote storage device.

See also: local storage  NTFS file system  Remote Storage  volume

**Management and Monitoring Tools**

Software components that include utilities for network management and monitoring, along with services that support client dialing and the updating of client phone books. Also included is the Simple Network Management Protocol (SNMP).

See also: Simple Network Management Protocol (SNMP)

**management information base (MIB)**
A set of objects that represent various types of information about a device, used by Simple Network Management Protocol (SNMP) to manage the device. Because different network management services are used for different types of devices and protocols, each service has its own set of objects.

See also: service  Simple Network Management Protocol (SNMP)

**management system**
A network-enabled host running Simple Network Management Protocol (SNMP) management software. This software requests information from SNMP agents. Also called a management console.

See also: host  Simple Network Management Protocol (SNMP)

**mandatory user profile**
A user profile that is not updated when the user logs off. It is downloaded to the user's desktop each time the user logs on, and it is created by an administrator and assigned to one or more users to create consistent or job-specific user profiles. Only members of the Administrators group can change profiles.

See also: roaming user profile  user profile

**man-in-the-middle attack**
A security attack in which an attacker intercepts and possibly modifies data that is transmitted between two users. The attacker pretends to be the other person to each user. In a successful man-in-the-middle attack, the users are unaware that there is an attacker between them, intercepting and modifying their data. Also referred to as a bucket brigade attack.

See also: security

**map**
To translate one value into another. In virtual memory systems, a computer might map a virtual address into a physical address.

See also: virtual memory

**MAPI**
See other term: Messaging API (MAPI)

**MARS**
See other term: multicast address resolution service (MARS)

**master boot record (MBR)**
The first sector on a hard disk, which begins the process of starting the computer. The MBR contains the partition table for the disk and a small amount of executable code called the master boot code.

See also: partition boot sector  Recovery Console

**master file table (MFT)**
An NTFS system file on NTFS-formatted volumes that contains information about each file and folder on the volume. The MFT is the first file on an NTFS volume.

See also: file allocation table (FAT)  NTFS file system  volume

**master server**
In Network Information Service (NIS), a server that provides periodic updates of NIS maps to subordinate servers. A Windows-based master server running Server for NIS can push periodic updates to both UNIX-based and Windows-based subordinate (also known as slave) servers. Master servers running Server for NIS update Server for NIS subordinate servers through an Active Directory database shared with the subordinate server.

**master server**
An authoritative DNS server for a zone. Master servers can vary and are one of two types (either primary or secondary masters), depending on how the server obtains its zone data.

See also: authoritative  DNS server  primary master  zone  zone transfer

**maximize**
To increase the size of a window as much as possible. To maximize a window, double-click the title bar, click the Maximize button (the middle button on the right side of the title bar), or press ALT+SPACEBAR and then press X.

See also: minimize  title bar

**maximum password age**
The period of time a password can be used before the system requires the user to change it.

See also: password

**MBR**
See other term: master boot record (MBR)

**MCS**
See other term: multicast server (MCS)

**MD2**
A hash algorithm that creates a 128-bit hash value and was developed by RSA Data Security, Inc.

See also: hash algorithm

**MD4**
A hash algorithm that creates a 128-bit hash value and was developed by RSA Data Security, Inc.

See also: hash algorithm

**MD5**
An industry-standard one-way, 128-bit hashing scheme, developed by RSA Data Security, Inc., and used by various Point-to-Point Protocol (PPP) vendors for encrypted authentication. A hashing scheme is a method for transforming data (for example, a password) in such a way that the result is unique and cannot be changed back to its original form. The Challenge Handshake Authentication Protocol (CHAP) uses challenge-response with one-way MD5 hashing on the response. In this way, you can prove to the server that you know your password without actually sending the password over the network.

See also: Challenge Handshake Authentication Protocol (CHAP)  hash algorithm  MD5  message digest

**media**
Any fixed or removable objects that store computer data. Examples include hard disks, floppy disks, tapes, and compact discs.

**media access control (MAC) address**
The address that is used for communication between network adapters on the same subnet. Each network adapter has an associated MAC address.

See also: multicast media access control (MAC) address  network adapter  subnet

**media master**
The original set of files that are copied to a tape or disk from local storage. Remote Storage can make up to three copies of the media master on different storage media. Each copy of the media master is called a copy set.

See also: copy set  media  Remote Storage

**media pool**
A logical collection of removable media that have the same management policies. Media pools are used by applications to control access to specific tapes or discs within libraries managed by Removable Storage.

See also: backup media pool  media  Removable Storage

**media sensing**
A feature that, when it detects a network cable connection failure, removes the bound protocols from the failed network adapter until the cable connection is reestablished. Without these bound protocols, the network interface connected through the failed network adapter is not available for cluster communication.

See also: network adapter  protocol

**member**
For DFS Replication, a server that is part of a replication group.

**member server**

A server that is joined to a domain but is not a domain controller. Member servers typically function as file servers, application servers, database servers, Web servers, certificate servers, firewalls, or remote access servers.

See also: domain  domain controller  stand-alone server  Web server

**membership**
Defines the relationship between each replicated folder/member pair. Each membership has a status, either enabled or disabled.

**memory address**
A portion of computer memory that can be allocated to a device or used by a program or the operating system. Devices are usually allocated a range of memory addresses.

See also: device

**Memory Usage**
In Task Manager, the current working set of a process, in kilobytes. The current working set is the number of pages currently resident in memory. On the Task Manager Processes tab, the column heading is Mem Usage.

See also: Task Manager

**Memory Usage Delta**
In Task Manager, the change in memory, in kilobytes, used since the last update.

See also: Task Manager

**message**
For Message Queuing, a unit of information sent between computers running Message Queuing. The message can contain text or binary data as defined by the sending application. All messages, including status messages, are stored in queues on Message Queuing computers.

See also: Message Queuing

**Message Authentication Code (MAC)**
An algorithm that ensures the quality of a block of data.

**message digest**
See other term: hash

**Message Queuing**
A message queuing and routing system for Windows that enables distributed applications running at different times to communicate across heterogeneous networks and with computers that may be offline. Message Queuing provides guaranteed message delivery, efficient routing, security, and priority-based messaging. Formerly known as MSMQ.

See also: Microsoft Distributed Transaction Coordinator (MS DTC)  MSMQ

**Message Queuing resource**
A resource type that can use Message Queuing in a cluster.

See also: cluster  Message Queuing  resource types

**Message Queuing server**
For Message Queuing (formerly known as MSMQ), a computer that can provide message queuing, routing, and directory services to client computers. Message Queuing servers can be used to provide message routing and session concentration for independent clients, provide message routing between sites over routing links, create queues and store messages for dependent clients, and access information in Active Directory (if installed on a Windows domain controller).

See also: Active Directory  dependent client  independent client  MSMQ  routing link  routing services  session concentration

**Messaging API (MAPI)**
The application programming interface (API) for which Active Directory provides support for backward compatibility with Microsoft Exchange applications. New applications should use Active Directory Service Interfaces (ADSI) for accessing Active Directory.

See also: Active Directory  Active Directory Service Interfaces (ADSI)  application programming interface (API)

**Messenger service**
A service that sends and receives messages sent by administrators or by the Alerter service.

See also: Alerter service  performance alert  service

**metadata**
Data about data. For example, the title, subject, author, and size of a file constitute the file`s metadata.

**metric**
A number used to indicate the cost of a route in the Internet Protocol (IP) routing table that enables the selection of the best route among possible multiple routes to the same destination.

See also: Internet Protocol (IP)  routing

**MFT**
See other term: master file table (MFT)

**MIB**
See other term: management information base (MIB)

**Microcom Networking Protocol Five (MNP5)**
A data-compression standard that allows modems to increase throughput by compressing data before transmission. Data can be compressed with a ratio of up to 2:1. MNP5 sometimes expands data that has already been compressed, resulting in poorer performance in those cases. If you have an MNP5 modem, do not turn on modem compression and software compression at the same time. To turn on MNP5 compression, you must also turn on MNP4 error control.

See also: Microcom Networking Protocol Four (MNP4)

**Microcom Networking Protocol Four (MNP4)**
An industry-standard communication protocol that allows modems to automatically retransmit corrupted data, assuring that only error-free data passes through the modem. MNP2 and MNP3 standards are included in MNP4.

See also: Microcom Networking Protocol Five (MNP5)

**Microsoft Digest**
A security support provider (SSP) that implements the Digest Access protocol. Microsoft Digest provides a simple challenge response mechanism for authenticating clients, and it is intended for use by client/server applications that use communications that are based on Hypertext Transfer Protocol (HTTP) or Simple Authentication and Security Layer (SASL).

**Microsoft Distributed Transaction Coordinator (MS DTC)**
A transaction manager that coordinates transactions that span multiple resource managers, such as Message Queuing and Microsoft SQL Server. MS DTC is automatically installed when Message Queuing is installed.

See also: Message Queuing  transaction

**Microsoft Management Console (MMC)**
A framework for hosting administrative tools called snap-ins. A console might contain tools, folders or other containers, World Wide Web pages, and other administrative items. These items are displayed in the left pane of the console, called a console tree. A console has one or more windows that can provide views of the console tree. The main MMC window provides commands and tools for authoring consoles. The authoring features of MMC and the console tree itself might be hidden when a console is in User Mode.

See also: console tree  details pane  snap-in

**Microsoft Point-to-Point Encryption (MPPE)**
A 128-bit key or 40-bit key encryption algorithm using RSA RC4. MPPE provides for packet confidentiality between the remote access client and the remote access or tunnel server, and it is useful where Internet Protocol security (IPSec) is not available. MPPE 40-bit keys are used to satisfy current North American export restrictions. MPPE is compatible with Network Address Translation.

See also: remote access server  tunnel server

**Microsoft Reserved (MSR) partition**
A required partition on every GUID partition table (GPT) disk. System components can allocate portions of the MSR partition into new partitions for their own use. For example, when you convert a basic GPT disk to dynamic, the system allocates a portion of the MSR partition to be used as the Logical Disk Manager (LDM) metadata partition. The MSR partition varies in size based on the size of the GPT disk. For disks smaller than 16 GB, the MSR partition is 32 MB. For disks larger than 16 GB, the

MSR partition is 128 MB. The MSR partition is not visible in Disk Management, and you cannot store data on the MSR partition or delete it.

See also: GUID partition table (GPT)  partition

**MIDI**
See other term: Musical Instrument Digital Interface (MIDI)

**MIDI setup**
The setup that specifies the type of Musical Instrument Digital Interface (MIDI) device you are using, the channel settings needed to play MIDI files, and the port your device is using.

See also: Musical Instrument Digital Interface (MIDI)

**minimize**
To reduce a window to a button on the taskbar. To minimize a window, click the Minimize button (leftmost button on the right side of the title bar) or press ALT+SPACEBAR and then press N.

See also: maximize  title bar

**minimum password length**
The fewest characters a password can contain.

See also: password

**minimum TTL**
In DNS, a default Time to Live (TTL) value that is set in seconds and used with all resource records in a zone. This value is set in the start of authority (SOA) resource record for each zone. By default, the DNS server includes this value in query responses. It is used to inform recipients how long they can store and use resource records, which are provided in the query answer, before they must expire the stored records data. When TTL values are set for individual resource records, those values override the minimum TTL.

See also: DNS server  Domain Name System (DNS)  resource record (RR)  start-of-authority (SOA) resource record  Time to Live (TTL)  zone

**mirror**
One of the two volumes that make up a mirrored volume. Each mirror of a mirrored volume resides on a different disk. If one mirror becomes unavailable (due to a disk failure, for example), Windows can use the remaining mirror to gain access to the volume`s data.

See also: fault tolerance  mirrored volume  volume

**mirrored volume**
A fault-tolerant volume that duplicates data on two physical disks. A mirrored volume provides data redundancy by using two identical volumes, which are called mirrors, to duplicate the information contained on the volume. A mirror is always located on a different disk. If one of the physical disks fails, the data on the failed disk becomes unavailable, but the system continues to operate in the mirror on the remaining disk. You can create mirrored volumes only on dynamic disks on computers running the Windows 2000 Server or Windows Server 2003 families of operating systems. You cannot extend mirrored volumes.

See also: dynamic disk  dynamic volume  fault tolerance  RAID-5 volume  volume

**mixed mode**
In a Windows 2000 domain, the default domain mode setting. Mixed mode enables Windows NT-based backup domain controllers to coexist with Windows 2000-based domain controllers. Mixed mode does not support universal groups or the nesting of groups. You can change the domain mode setting to native mode when all Windows NT-based domain controllers are removed from a domain. In Windows Server 2003 domains, mixed mode is referred to as "Windows 2000 mixed," and it is one of three domain functional levels available.

See also: Active Directory  backup domain controller (BDC)  domain functionality  native mode  universal group

**MMC**
See other term: Microsoft Management Console (MMC)

**MNP4**
See other term: Microcom Networking Protocol Four (MNP4)

**MNP5**
See other term: Microcom Networking Protocol Five (MNP5)

**modem (modulator/demodulator)**
A device that enables computer information to be transmitted and received over a telephone line. The transmitting modem translates digital computer data into analog signals that can be carried over a telephone line. The receiving modem translates the analog signals back to digital form.

See also: modem compression  null modem cable  port  Telephony API (TAPI)  Waiting for Call

**modem compression**
A technique used to reduce the number of characters transmitted without losing data content. The transmitting modem compresses the data and the receiving computer or modem decompresses the data back to its original state.

See also: modem (modulator/demodulator)

**modulation standards**
Protocols that determine how modems convert digital data into analog signals that can be transmitted over telephone lines. Initially, Bell created modulation standards used in the United States, and the CCITT created international recommendations. The ITU-T (formerly called the CCITT) now makes recommendations generally adopted by modem manufacturers both internationally and in the United States. The ITU-T V series recommendations (such as V.34 and V.90) define data communication over the telephone network. The suffixes -bis and -ter (for example, V.32bis) indicate later versions.

See also: International Telecommunication Union - Telecommunication [Standardization Sector] (ITU-T)  modem (modulator/demodulator)  protocol  V.34  V.90

**mount**
To place a removable tape or disc into a drive.

See also: dismount  library  mounted drive

**mounted drive**
A drive attached to an empty folder on an NTFS volume. Mounted drives function the same as any other drive, but are assigned a label or name instead of a drive letter. The mounted drive`s name is resolved to a full file system path instead of just a drive letter. Members of the Administrators group can use Disk Management to create mounted drives or reassign drive letters.

See also: drive  mount  NTFS file system  volume

**MPIO**
See other term: Multipath I/O (MPIO)

**MPPE**
See other term: Microsoft Point-to-Point Encryption (MPPE)

**MPR**
See other term: MultiProtocol Routing (MPR)

**MS DTC**
See other term: Microsoft Distributed Transaction Coordinator (MS DTC)

**MS-DOS (Microsoft Disk Operating System)**
A Microsoft computer operating system with a command-line interface that is used to control many internal computer functions, such as running programs and organizing and maintaining files.

See also: Command Prompt window  MS-DOS-based program

**MS-DOS-based program**
A program that is designed to run with MS-DOS and therefore may not be able to take full advantage of all Windows features.

See also: MS-DOS (Microsoft Disk Operating System)  program information file (PIF)

**MSMQ**
The message queuing and routing system for Windows NT 4.0, Windows 95, and Windows 98. For Windows 2000, Windows XP, and the Windows Server 2003 family, this feature is called Message Queuing.

See also: Message Queuing

**multibyte**
A character set that may consist of both one-byte and two-byte characters. A multibyte-character string may contain a mixture of single-byte and double-byte characters. Windows Server 2003 DNS uses the Unicode Transformation Format 8 (UTF-8) encoding scheme described in RFC 2044 to interpret and transform multibyte characters into single-byte characters of 8-bit length.

See also: Domain Name System (DNS)  UCS Transformation Format 8 (UTF-8)

**multicast address resolution service (MARS)**
A service for resolving multicast IP addresses to the asynchronous transfer mode (ATM) addresses of the clients that have joined that multicast group. MARS can work in conjunction with the multicast server (MCS) and clients to distribute multicast data through point-to-multipoint connections.

See also: asynchronous transfer mode (ATM)  IP address  multicast server (MCS)  multicasting

**multicast datagram**
An Internet Protocol (IP) datagram sent to a select multicast group of hosts. Each datagram is sent from a single host source for transmission and delivery to multiple host destinations using the Class D IP address reserved for a specified multicast group.

See also: datagram  host  Internet Protocol (IP)  multicasting

**Multicast Listener Discovery (MLD)**
A protocol used by Internet Protocol version 6 (IPv6) hosts to report their multicast group memberships to any immediately neighboring multicast routers.

See also: multicasting  protocol

**multicast media access control (MAC) address**
A type of media access control address used by multiple, networked computers to receive the same incoming network frames concurrently. Network Load Balancing uses multicast MAC addresses to efficiently distribute incoming network traffic to cluster hosts.

See also: media access control (MAC) address  multicasting  Network Load Balancing

**multicast scope**
A range of multicast group IP addresses in the Class D address range that are available to be leased or assigned to multicast DHCP clients by DHCP.

See also: address class  Dynamic Host Configuration Protocol (DHCP)  IP address  lease  multicasting

**multicast server (MCS)**
A service that manages zero or more multicast groups and distributes multicast data sent to it by clients of those multicast groups through point-to-multipoint connections.

See also: multicasting  nonhubbed mode  service

**multicasting**
The process of sending a message simultaneously to more than one destination on a network.

See also: multicast server (MCS)

**multihomed computer**
A computer that has multiple network adapters or that has been configured with multiple IP addresses for a single network adapter.

See also: IP address  network adapter  virtual IP address

**multilink dialing**
The combination of two or more physical communications links` bandwidth into a single logical link to increase your remote access bandwidth and throughput by using remote access Multilink. Based on the Internet Engineering Task Force (IETF) standard RFC 1990, Multilink combines analog modem paths, Integrated Services Digital Network (ISDN) B-channels, and mixed analog and digital communications links on both your client and server computers. This increases your Internet and intranet access speed and decreases the amount of time you are connected to a remote computer.

See also: bandwidth  B-channel  Integrated Services Digital Network (ISDN)

**multimaster replication**
A replication model in which any domain controller accepts and replicates directory changes. This model differs from single-master replication models, in which one domain controller stores the single modifiable copy of the directory and other domain controllers store backup copies.

See also: domain controller  replication

**multimedia streaming**
Playing audio and video immediately as it is downloaded from a network, rather than storing it in a file first.

**Multipath I/O (MPIO)**
A Microsoft multipathing solution that enables more than one read/write path to a logical unit number (LUN). With MPIO, multipathing is achieved by assigning multiple Fibre Channel host bus adapter ports or multiple iSCSI initiator adapters on a server to the same LUN, and then configuring that server to use MPIO.

**multipathing**
In storage technologies, a solution that increases availability and path failover by providing multiple paths from a server or cluster to a storage subsystem. In the event that the path being used fails, multipathing logic uses an alternate path for I/O so that applications can still access their data.

**multiple boot**
A computer configuration that runs two or more operating systems.

See also: dual boot  startup environment

**MultiProtocol Routing (MPR)**
A protocol that enables routing over Internet Protocol (IP) and Internetwork Packet Exchange (IPX) networks by connecting local area networks (LANs) or by connecting LANs to wide area networks (WANs).

See also: Internet Protocol (IP)  Internetwork Packet Exchange (IPX)  local area network (LAN)  wide area network (WAN)

**Musical Instrument Digital Interface (MIDI)**
A serial interface standard that allows for the connection of music synthesizers, musical instruments, and computers. The MIDI standard is based partly on hardware and partly on a description of the way in which music and sound are encoded and communicated between MIDI devices. The information transmitted between MIDI devices is in a form called a MIDI message, which encodes aspects of sound, such as pitch and volume, as 8-bit bytes of digital information. MIDI devices can be used for creating, recording, and playing back music. Using MIDI, computers, synthesizers, and sequencers can communicate with each other, either keeping time or actually controlling the music created by other connected equipment.

See also: MIDI setup

**My Documents**
A folder that provides you with a convenient place to store documents, graphics, or other files you want to access quickly. When you save a file in a program such as WordPad or Paint, the file is automatically saved in My Documents, unless you choose a different folder.

See also: home folder

# Windows Server 2003 Glossary - N

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - N**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**name**
The identifier of your computer on the network.

**name resolution**
The process of having software translate between names that are easy for users to work with and numerical IP addresses, which are difficult for users but necessary for TCP/IP communications. Name resolution can be provided by software components such as DNS or WINS.

See also: Domain Name System (DNS)  Transmission Control Protocol/Internet Protocol (TCP/IP)  Windows Internet Name Service (WINS)

**name resolution service**
A service, such as that provided by WINS or DNS, that allows friendly names to be resolved to an address, or other specially defined resource data used to locate network resources of various types and purposes.

See also: Domain Name System (DNS)  service  Windows Internet Name Service (WINS)

**name server (NS) resource record**
A resource record used in a zone to designate the DNS domain names for authoritative DNS servers for the zone.

See also: DNS server  Domain Name System (DNS)  resource record (RR)  zone

**named pipe**
A portion of memory that can be used by one process to pass information to another process, so that the output of one is the input of the other. The second process can be local (on the same computer as the first) or remote (on a networked computer).

See also: shared resource

**namespace**
A naming convention that defines a set of unique names for resources in a network. For DNS, a hierarchical naming structure that identifies each network resource and its place in the hierarchy of the namespace. For WINS, a flat naming structure that identifies each network resource using a single, unique name. For DFS Namespaces, a virtual tree of folders that begins with \\ServerOrDomainName\RootName.

See also: Domain Name System (DNS)  Windows Internet Name Service (WINS)

**namespace path**
A Universal Naming Convention (UNC) path to the namespace root (\\ServerOrDomainName\RootName) or to a folder under the namespace root (\\ServerOrDomainName\RootName\Subfolder\Folder). The namespace path of a domain-based namespace begins with a domain name, whereas the namespace path of a stand-alone namespace begins with the name of the server that hosts the root target.

**namespace root**
The top-level folder in the namespace. For example, \\ServerOrDomainName\RootName is the namespace root.

**namespace server**
A server that hosts a namespace. A namespace server can be a domain controller or member server.

**naming context**
See other term: directory partition

**NAS**
See other term: network access server (NAS)

**native mode**
In Windows 2000 domains, the domain mode in which all domain controllers in a domain are running Windows 2000 and a domain administrator has switched the domain operation mode from mixed mode to native mode. Native mode supports universal groups and nesting of groups. In native mode, domain controllers running Windows NT 4.0 or earlier are not supported. In Windows Server 2003 domains, native mode is referred to as "Windows 2000 native," and it is one of three domain functional levels available.

See also: Active Directory  domain functionality  mixed mode  universal group

**NCP**
See other term: NetWare Core Protocol

**NDIS**
See other term: Network Driver Interface Specification (NDIS)

**NDS**
See other term: Novell Directory Services (NDS)

**negative caching**
In DNS, client caching of failed responses to a query. Negative caching improves the response time for successive queries for the same name.

See also: cache  Domain Name System (DNS)

**Net Logon service**
A user-mode service that runs in the Windows security subsystem. The Net Logon service passes the user`s credentials through a secure channel to the domain database and returns the domain security identifiers and user rights for the user. In addition, the Net Logon service performs a variety of other functions related to the user logon process, such as periodic password updates for computer accounts and domain controller discovery.

See also: user mode  user rights

**NetBEUI**
See other term: NetBIOS Extended User Interface (NetBEUI)

**NetBIOS**
See other term: network basic input/output system (NetBIOS)

**NetBIOS Extended User Interface (NetBEUI)**
A network protocol native to Microsoft Networking. It is usually used in small, department-size local area networks (LANs) of 1 to 200 clients. NetBEUI can use Token Ring source routing as its only method of routing. NetBEUI is the Microsoft implementation of the NetBIOS standard.

See also: Compression Control Protocol (CCP)  local area network (LAN)  network basic input/output system (NetBIOS)  protocol  Token Ring

**NetBIOS name**
A 16-byte name of a process using network basic input/output system (NetBIOS). The NetBIOS name is a name that is recognized by WINS, which maps the name to an IP address.

See also: IP address  network basic input/output system (NetBIOS)  Windows Internet Name Service (WINS)

**Netdom**
A tool that allows management of Windows domains and trust relationships from the command line.

See also: domain  trust relationship

**netmask ordering**
A method DNS uses to give ordering and preference to IP addresses on the same network when a requesting client queries for a host name that has multiple host address (A) type resource records. This is designed so that the client program will attempt to connect to a host using the closest (and fastest) IP address available.

See also: address (A) resource record  Domain Name System (DNS)  host  IP address

**NetWare Core Protocol**
The file-sharing protocol that governs communications about resources (such as disk and printer), bindery, and Novell Directory Services (NDS) operations between server and client computers on a Novell NetWare network.

See also: bindery  Internetwork Packet Exchange (IPX)  Novell Directory Services (NDS)  protocol

**network access server (NAS)**
The device that accepts Point-to-Point Protocol (PPP) connections and places clients on the network that the NAS serves.

See also: Point-to-Point Protocol (PPP)

**network adapter**
A device that connects your computer to a network. Sometimes called a network interface card (NIC).

See also: device

**network adapter driver**
A device driver that works directly with the network adapter, acting as an intermediary between the adapter and the protocol driver.

See also: device driver  network adapter

**network address translation (NAT)**
A process that translates the internal Internet Protocol (IP) address of each computer on a local area network (LAN) into an external IP address when that computer connects to the Internet. This process improves the security of the network because internal addresses are not made public.

See also: Internet Protocol (IP)

**network administrator**
A person responsible for planning, configuring, and managing the day-to-day operation of the network. Also called a system administrator.

See also: administrator

**network basic input/output system (NetBIOS)**
An application programming interface (API) that can be used by programs on a local area network (LAN). NetBIOS provides programs with a uniform set of commands for requesting the lower-level services required to manage names, conduct sessions, and send datagrams between nodes on a network.

See also: application programming interface (API)  basic input/output system (BIOS)  datagram  local area network (LAN)  node  service

**network bridge**
A device that connects networks using the same communications protocols so that information can be passed from one network to the other. Also, a device that connects two local area networks (LANs), whether or not they use the same protocols. A network bridge operates at the ISO/OSI data-link layer.

See also: local area network (LAN)  protocol

**Network Connections**
A component you can use to gain access to network resources and functionality, whether you are physically at the network location or in a remote location. By using the Network Connections folder you can create, configure, store, and monitor connections. Formerly called Network and Dial-up Connections or Dial-Up Networking.

**Network Control Protocol**
A protocol within the Point-to-Point Protocol (PPP) suite that negotiates the parameters of an individual local area network (LAN) protocol such as TCP/IP or Internetwork Packet Exchange (IPX).

See also: Internetwork Packet Exchange (IPX)  local area network (LAN)  Point-to-Point Protocol (PPP)  Transmission Control Protocol/Internet Protocol (TCP/IP)

**Network DDE service**
A service that provides network transport and security for dynamic data exchange (DDE) conversations.

See also: dynamic data exchange (DDE)  service

**Network Driver Interface Specification (NDIS)**
A Microsoft/3Com specification establishing a common shared interface for Microsoft operating systems to support protocol-independent transport of multiple network transport protocols (such as TCP/IP, NetBEUI, IPX/SPX, and AppleTalk). NDIS allows more than one transport protocol to be bound and to operate simultaneously over a single network adapter.

See also: Internetwork Packet Exchange (IPX) Internetwork Packet Exchange/Sequenced Packet Exchange (IPX/SPX) NetBIOS Extended User Interface (NetBEUI) Transmission Control Protocol/Internet Protocol (TCP/IP)

**Network File System (NFS)**
A service for distributed computing systems that provides a distributed file system, eliminating the need for keeping multiple copies of files on separate computers.

See also: service

**network gateway**
A device that connects networks using different communications protocols so that information can be passed from one network to the other. A network gateway both transfers information and converts it to a form that is compatible with the protocols being used by the receiving network.

See also: device protocol

**network ID**
A number used to identify the systems that are located on the same physical network bounded by routers. The network ID should be unique to the internetwork.

See also: router

**Network Information Service (NIS)**
A service for distributed computing systems that provides a distributed database system for common configuration files.

See also: service

**Network Information Service (NIS)**
A network naming and administration system that was developed by Sun Microsystems and is constructed on the client-server model of computing. Formerly known as Yellow Pages (yp), NIS provides a simple network look-up service that consists of databases and processes.

**Network Load Balancing**
A Windows network component that uses a distributed algorithm to load-balance Internet Protocol (IP) traffic across a number of hosts, helping to enhance the scalability and availability of mission-critical, IP-based services, such as Terminal Services, Web services, virtual private networking, and streaming media. It also provides high availability by detecting host failures and automatically redistributing traffic to the surviving hosts.

See also: availability cluster host scalability

**Network Load Balancing cluster**
Up to 32 Web servers from which Network Load Balancing presents a single IP address to Web clients and among which Network Load Balancing distributes incoming Web requests.

See also: IP address Network Load Balancing Web server

**network media**
The type of physical wiring and lower-layer protocols used for transmitting and receiving packets, for example, Ethernet, Fiber Distributed Data Interface (FDDI), and Token Ring.

See also: packet protocol Token Ring

**Network Name resource**
The name of a device that exists on a network and is supported as a cluster resource by a Resource DLL provided with Windows.

See also: Resource DLL

**Network News Transfer Protocol (NNTP)**
A member of the TCP/IP suite of protocols used to distribute network news messages to NNTP servers and clients (newsreaders) on the Internet. NNTP is designed so that news articles are stored on a server in a central database, thus enabling a user to select specific items to read.

See also: Transmission Control Protocol/Internet Protocol (TCP/IP)

**network number**
In the Macintosh environment, the routing address or range of addresses assigned to the physical network that AppleTalk

Phase 2 routers use to direct information to the appropriate network. Also called network range and cable range.

See also: router

**network partition**
A state in which one or more of the nodes in a cluster cannot communicate with the other cluster nodes.

See also: cluster  node

**network place**
A folder on a Web server. You can view files and folders on Web servers just as you would view files and folders on network servers. However, when you save a file to a network place, the file is saved on a Web server, not on your computer`s hard disk. You can create network places by using the Add Network Place Wizard, which is located in My Network Places. Network places are available only on Web servers that support Web Extender Client (WEC), FrontPage extensions, and Distributed Authoring and Versioning (DAV) protocols.

See also: Web server

**Network Service account**
A predefined local account that is used to start a service and provide the security context for that service. The name of the account is NT AUTHORITY\NetworkService. The Network Service account has limited access to the local computer and authenticated access (as the computer account) to network resources.

See also: access control list (ACL)  Local Service account  Local System account  service

**network/bit-masked identifier**
An IP address that includes a subnet bit-mask. Active Directory uses the subnet bit-mask to recognize sites and establish how replication of directory information will occur.

See also: Active Directory  IP address  replication  site  subnet

**network-to-network interface (NNI)**
An interface that defines how switches in a network communicate with each other.

**NFS**
See other term: Network File System (NFS)

**NFS client**
A computer running client software to access shared Network File System (NFS) resources.

**NFS server**
A computer providing Network File System (NFS) disk resources to NFS clients.

**NIS**
See other term: Network Information Service (NIS)

**NIS**
See other term: Network Information Service (NIS)

**NIS map**
A database served by Network Information Service (NIS). The NIS lookup calls require a map (database) name and an NIS domain name. An NIS domain consists of a collection of such maps.

**nis2ad**
A Windows command-line utility that transfers the entries in the Network Information Service (NIS) map source file specified by mapfile located in the UNIX NIS domain specified by NIS_domain to the Active Directory domain specified by AD_domain.

**nisadmin**
A Windows command-line utility that administers Server for NIS on the local computer or on a remote computer.

**nismap**
A Windows command-line utility that manages the map specified by mapname maintained by Server for NIS on a local computer or a remote computer.

**NNI**
See other term: network-to-network interface (NNI)

**NNTP**
See other term: Network News Transfer Protocol (NNTP)

**No Override**
In Group Policy in the Windows Server 2003 family, to force the Group Policy object (GPO) links of the parent container to take precedence over the GPO links of the child containers. By default, the GPO links that are closest to the user or computer (links to the child container) have higher precedence than GPO links higher up (links to the parent container). Enforcement causes GPOs that are linked in parent containers to take precedence instead. In Group Policy Management console (GPMC), Enforce is used instead of No Override.

See also: block inheritance  enforce  Group Policy  Group Policy Management console (GPMC)  Group Policy object link  inheritance  precedence

**node**
For tree structures, a location on the tree that can have links to one or more items below it. For local area networks (LANs), a device that is connected to the network and is capable of communicating with other network devices. For server clusters, a computer system that is an active or inactive member of a cluster.

See also: local area network (LAN)  server cluster

**nonauthoritative restore**
A restore operation performed on an Active Directory domain controller in which the objects in the restored directory are not treated as authoritative. The restored objects are updated with changes held on other domain controllers in the domain.

See also: Active Directory  authoritative restore

**noncontainer object**
An object that cannot logically contain other objects. For example, a file is a noncontainer object.

See also: container object  object

**noncontiguous namespace**
A namespace based on different DNS root domain names, such as that of multiple trees in the same forest.

See also: domain name  Domain Name System (DNS)  forest  namespace

**nonhubbed mode**
A mode in which asynchronous transfer mode (ATM) Address Resolution Protocol/multicast address resolution service (ARP/MARS) does not forward multicast and broadcast traffic for multicast group clients. In this mode, the service returns a dynamic listing of ATM hosts currently registered for the multicast group address to requesting clients. Clients then use this list to initiate and establish their own point-to-multipoint virtual connections with each of the members in the multicast list.

See also: Address Resolution Protocol (ARP)  asynchronous transfer mode (ATM)  hubbed mode  multicast address resolution service (MARS)  multicast server (MCS)

**nonpaged memory**
Memory that cannot be paged to disk. Paging is the moving of infrequently used parts of a program`s working memory from random access memory (RAM) to another storage medium, usually the hard disk.

See also: paging file  random access memory (RAM)

**nonpaged pool**
Operating system memory that is never paged to disk. Paging is the moving of infrequently used parts of a program`s working memory from RAM to another storage medium, usually the hard disk. In Task Manager, the amount of memory used by a process, in kilobytes.

See also: paging file  Task Manager

**nonrepudiation**
The use of cryptography to ensure that someone performing an action on a computer cannot falsely deny that they performed that action. A system with nonrepudiation provides undeniable proof that a user took a specific action such as transferring money, authorizing a purchase, or sending a message.

See also: cryptography

**nontransitive trust**
A trust relationship in a multiple-domain environment that is restricted to just two domains. For example, if domain A has a

nontransitive trust with domain B, and domain B trusts domain C, then there is no trust relationship between domain A and domain C. Nontransitive trusts can be one-way or two-way.

See also: forest  nontransitive trust  one-way trust  trust relationship  two-way trust

**non-Windows**
Operating systems that are not Windows-brand operating systems.

**normal backup**
A backup that copies all selected files and marks each file as having been backed up (in other words, the archive attribute is cleared). With normal backups, you need only the most recent copy of the backup file or tape to restore all of the files. You usually perform a normal backup the first time you create a backup set.

See also: copy backup  daily backup  differential backup  incremental backup

**notification area**
The area on the taskbar to the right of the taskbar buttons. The notification area displays the time and can also contain shortcuts that provide quick access to programs, such as Volume Control and Power Options. Other shortcuts can appear temporarily, providing information about the status of activities. For example, the printer shortcut icon appears after a document has been sent to the printer and disappears when printing is complete.

See also: taskbar

**notify list**
A list maintained by the primary master for a zone of other DNS servers that should be notified when zone changes occur. The notify list is made up of IP addresses for DNS servers configured as secondary masters for the zone. When the listed servers are notified of a change to the zone, they will initiate a zone transfer with another DNS server and update the zone.

See also: DNS server  IP address  primary master  zone  zone transfer

**Novell Directory Services (NDS)**
On networks running Novell NetWare 4.x and higher, a distributed database that maintains information about every resource on the network and that provides access to these resources.

See also: resource

**Nslookup**
A command-line tool used to diagnose DNS infrastructure.

See also: Domain Name System (DNS)

**NTFS file system**
An advanced file system that provides performance, security, reliability, and advanced features that are not found in any version of file allocation table (FAT). For example, NTFS guarantees volume consistency by using standard transaction logging and recovery techniques. If a system fails, NTFS uses its log file and checkpoint information to restore the consistency of the file system. NTFS also provides advanced features, such as file and folder permissions, encryption, disk quotas, and compression.

See also: file allocation table (FAT)  file system

**NTFS permissions**
The settings that administrators apply to access control entries (ACEs) for managing access to files and folders under the NTFS file system. Take Ownership is an example of an NTFS permission.

See also: access control entry (ACE)  access control list (ACL)  NTFS file system  permission

**NTGATEWAY**
A group of NetWare servers. Accounts used to create a gateway must belong to this group.

See also: gateway

**NTLM authentication protocol**
A challenge/response authentication protocol. The NTLM authentication protocol is supported in Windows 2000, Windows XP, and the Windows Server 2003 family, but it is not the default. It was the default authentication protocol for earlier versions of Windows.

See also: authentication  protocol

**null modem cable**
Special cabling that eliminates the modem`s need for asynchronous communications between two computers over short distances. A null modem cable emulates modem communication.

See also: modem (modulator/demodulator)

**null password**
See other term: blank password

**NWLink**
See other term: NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink)

**NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink)**
The Microsoft implementation of the Internetwork Packet Exchange/Sequenced Packet Exchange (IPX/SPX) protocol used on NetWare networks. NWLink allows connectivity between Windows-based computers and NetWare networks running IPX/SPX. NWLink also provides network basic input/output system (NetBIOS) functionality and the Routing Information Protocol (RIP).

See also: Internetwork Packet Exchange/Sequenced Packet Exchange (IPX/SPX) NetWare network basic input/output system (NetBIOS) Routing Information Protocol over IPX (RIPX)

# Windows Server 2003 Glossary - O

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - O**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**object**
An entity, such as a file, folder, shared folder, printer, or Active Directory object, described by a distinct, named set of attributes. For example, the attributes of a File object include its name, location, and size; the attributes of an Active Directory User object might include the user's first name, last name, and e-mail address. For OLE and ActiveX, an object can also be any piece of information that can be linked to, or embedded into, another object.

See also: Active Directory attribute attribute child object OLE parent object

**object access event category**
In auditing, a group of events that are logged when an object, such as a file or folder, is accessed by means of an action for which auditing has been enabled. For example, object access events might be logged when a file is opened, modified, or deleted.

See also: auditing event object

**object class**
A distinct, named set of attributes that represents a specific type of entity stored in the directory, such as users, printers, or applications. The attributes include data describing the thing that is identified by the directory object. Attributes of a user might include the user`s first name, last name, and e-mail address.

See also: directory

**object identifier**
A number that identifies an object class or attribute. Object identifiers (OIDs) are organized into an industry-wide global hierarchy. An object identifier is represented as a dotted decimal string, such as 1.2.3.4, with each dot representing a new branch in the hierarchy. National registration authorities issue root object identifiers to individuals or organizations, who manage the hierarchy below their root object identifier.

See also: attribute object class

**ODBC**
See other term: Open Database Connectivity (ODBC)

**offline**
A state that marks a component in a cluster as unavailable. A node in an offline state is either inactive or not running. Resources and groups also have an offline state.

See also: group node online pending resource

**offline mode**
For Message Queuing, a condition in which a computer that belongs to a domain is temporarily unable to communicate with a domain controller. This occurs when the computer itself is offline, all domain controllers in the site are offline, or when an attempt is made to access a remote computer and the remote computer is temporarily unable to query a domain controller for authentication.

See also: Message Queuing

**OID**
See other term: object identifier

**OLE**
A way to transfer and share information between applications by pasting information created in one application into a document created in another application, such as a spreadsheet or word processing file.

See also: embedded object  linked object  package

**on-disk catalog**
Information stored on a local disk drive. The on-disk catalog contains a list of files and folders that have been backed up in a backup set.

See also: backup set  on-media catalog

**one-way trust**
A trust relationship between two domains in which only one of the two domains trusts the other domain. For example, domain A trusts domain B, and domain B does not trust domain A. One-way trusts are often used to enable authenticated access to resource domains.

See also: authentication  domain  trust relationship  two-way trust

**online**
A state that marks a component in a cluster as available. When a node is online, it is an active member of the cluster and can own and run groups as well as honor cluster database updates, contribute votes to the quorum algorithm, and maintain heartbeats. Resources and groups also have an online state.

See also: cluster  group  heartbeat  node  offline  pending  resource

**on-media catalog**
Information stored on backup storage media. The on-media catalog contains a list of files and folders that have been backed up in a backup set.

See also: backup set  on-disk catalog

**Open Database Connectivity (ODBC)**
An application programming interface (API) that enables database applications to access data from a variety of existing data sources.

See also: application programming interface (API)

**Open Shortest Path First (OSPF)**
A routing protocol used in medium-sized and large networks. This protocol is more complex than Routing Information Protocol (RIP), but it allows better control and is more efficient in propagation of routing information.

See also: protocol  routing  Routing Information Protocol (RIP)

**Open Systems Interconnection (OSI) reference model**
A networking model introduced by the International Organization for Standardization (ISO) to promote multi-vendor interoperability. OSI is a seven-layered conceptual model consisting of the application, presentation, session, transport, network, data-link, and physical layers.

See also: Transmission Control Protocol/Internet Protocol (TCP/IP)

**OpenType font**
A type of computer font that can be rotated or scaled to any size. OpenType fonts are clear and readable in all sizes and can be sent to any printer or other output device that is supported by Windows.

See also: font  TrueType font

**operations master**
A domain controller that has been assigned one or more special roles in an Active Directory domain. The domain controllers assigned these roles perform operations that are single-master (not permitted to occur at different places on the network at the same time). Examples of these operations include resource identifier allocation, schema modification, PDC emulation, adding and removing domains to and from the forest, and tracking changes to security principals across all domains in a forest.

See also: Active Directory  domain controller  domain naming master  infrastructure master  PDC emulator master  schema master

**operator**
In mathematics and in programming and computer applications, a symbol or other character indicating an operation that acts on one or more elements. You can use the following four operators in standard calculations: / (divide); * (multiply); - (subtract); and + (add). For Indexing Service, a word or character that specifies a relationship in a query.

See also: Indexing Service

**ordering method**
The order in which targets are listed in a referral. Targets in a client's site are always listed first in a referral (unless a target priority setting overrides this). Targets outside of a client's site can be listed in order of lowest cost or in random order, or they can be excluded altogether from the referral.

**organization claims**
Claims in intermediate or normalized form within an organization's namespace.

**organizational unit**
An Active Directory container object used within domains. An organizational unit is a logical container into which users, groups, computers, and other organizational units are placed. It can contain objects only from its parent domain. An organizational unit is the smallest scope to which a Group Policy object (GPO) can be linked, or over which administrative authority can be delegated.

See also: Active Directory  container object  Group Policy object (GPO)  parent domain

**original equipment manufacturer (OEM)**
A company that typically purchases computer components from other manufacturers, uses the components to build a personal computer, preinstalls Windows onto that computer, and then sells the computer to the public.

**orphan**
A member of a mirrored volume or a RAID-5 volume that has failed due to a severe cause, such as a loss of power or a complete hard-disk head failure. When this happens, the fault-tolerant driver determines that it can no longer use the orphaned member and directs all new reads and writes to the remaining members of the fault-tolerant volume.

See also: fault tolerance  mirrored volume  RAID-5 volume

**orphan file**
A file that is stored inside My Briefcase and not linked to any file outside My Briefcase. When you update files, the orphan file is not synchronized with any other file.

**OS/2**
A protected-mode, virtual memory, multitasking operating system for personal computers based on the Intel 80286, 80386, i486, and Pentium processors. OS/2 can run most MS-DOS-based programs and can read all MS-DOS disks.

See also: MS-DOS-based program

**OSChooser**
The client-side wizard that walks a user through the installation of an operating system or provides access to maintenance and troubleshooting utilities.

See also: client

**OSI**
See other term: Open Systems Interconnection (OSI) reference model

**OSPF**
See other term: Open Shortest Path First (OSPF)

**out-of-band connection**
A connection between two computers that relies on a nonstandard network connection, such as a serial port connection, and nonstandard remote administration tools, such as Special Administration Console (SAC). An out-of-band connection is usually used only when a remote computer cannot access a network or is not in a functional state because of hardware or software failure.

See also: in-band connection  remote computer  serial port

**owner**
In a Windows environment, the person who controls how permissions are set on objects and can grant permissions to others. In the Macintosh environment, an owner is the user responsible for setting permissions for a folder on a server. A Macintosh user who creates a folder on the server automatically becomes the owner of the folder, and can then transfer ownership to someone else. Each Macintosh-accessible volume on the server also has an owner.

See also: permission

**owner category**
In the Macintosh environment, the user category to which you assign permissions for the owner of a folder or a Macintosh volume.

See also: permission  volume

# Windows Server 2003 Glossary - P

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - P**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**package**
An icon that represents embedded or linked information. That information may consist of a complete file, such as a Paint bitmap, or part of a file, such as a spreadsheet cell. When you choose the package, the application used to create the object either plays the object (for example, a sound file) or opens and displays the object. If you change the original information, linked information is automatically updated. However, you must manually update embedded information.

See also: embedded object  linked object  OLE

**packet**
An Open Systems Interconnection (OSI) network layer transmission unit that consists of binary information representing both data and a header containing an identification number, source and destination addresses, and error-control data.

See also: Open Systems Interconnection (OSI) reference model

**packet filtering**
Prevents certain types of network packets from either being sent or received. This can be employed for security reasons (to prevent access from unauthorized users) or to improve performance by disallowing unnecessary packets from going over a slow connection.

See also: packet

**packet header**
In network protocol communications, a specially reserved field of a defined bit length that is attached to the front of a packet for carry and transfer of control information. When the packet arrives at its destination, the field is then detached and discarded as the packet is processed and disassembled in a corresponding reverse order for each protocol layer.

See also: packet

**packet switching**
A technology for breaking data into packets and then sending the packets over a network. Each packet has a header containing its source and destination, a sequence number to reassemble the information, a block of data content, and an error-checking code. The data packets may take different routes to their destination, where the original information is reassembled after the packets arrive. The international standard for packet switching networks is X.25.

See also: packet

**PAD (packet assembler/disassembler)**
A device that connects a non-X.25 device such as a modem to an X.25 packet switching network.

See also: packet

**PAE**
See other term: Physical Address Extension (PAE)

**page**
In virtual memory systems, a unit of data storage that is brought into random access memory (RAM), typically from a hard drive, when a requested item of data is not already in RAM.

See also: virtual memory

**page fault**
The interrupt that occurs when software attempts to read from or write to a virtual memory location that is marked not present. In Task Manager, page fault is the number of times data has to be retrieved from disk for a process because it was not

found in memory. The page fault value accumulates from the time the process started.

See also: Page Faults Delta  Task Manager  virtual memory

**Page Faults Delta**
In Task Manager, the change in the number of page faults since the last update.

See also: page fault  Task Manager

**paged pool**
The system-allocated virtual memory that has been charged to a process and that can be paged. Paging is the moving of infrequently used parts of a program`s working memory from random access memory (RAM) to another storage medium, usually the hard disk. In Task Manager, the amount of system-allocated virtual memory, in kilobytes, used by a process.

See also: registry size limit (RSL)  Task Manager  virtual memory

**page-description language (PDL)**
A computer language that describes the arrangement of text and graphics on a printed page.

See also: PostScript  PostScript fonts  Printer Control Language (PCL)  Printer Job Language (PJL)

**paging file**
A hidden file or files on the hard disk that Windows uses to hold parts of programs and data files that do not fit in memory. The paging file and physical memory, or random access memory (RAM), comprise virtual memory. Windows moves data from the paging file to memory as needed and moves data from memory to the paging file to make room for new data. Also known as a swap file.

See also: Peak Memory Usage  registry size limit (RSL)  virtual memory

**PAP**
See other term: Password Authentication Protocol (PAP)

**paper source**
The location (such as Upper Paper Tray or Envelope Feeder) of the paper at the printer.

See also: printer

**parallel port**
The input/output connector for a parallel interface device. Printers are generally plugged into a parallel port.

See also: port  serial port

**parent domain**
For DNS and Active Directory, domains that are located in the namespace tree directly above other derivative domain names (child domains). For example, microsoft.com would be the parent domain for example.microsoft.com, a child domain.

See also: Active Directory  child domain  domain  Domain Name System (DNS)

**parent object**
An object in which another object resides. For example, a folder is a parent object in which a file, or child object, resides. An object can be both a parent and a child object. For example, a subfolder that contains files is both the child of the parent folder and the parent folder of the files.

See also: child object  object

**parent-child trust**
A trust that is automatically established when a new domain (the child domain) is added, or becomes subordinate, to an existing domain (the parent domain). Parent-child trusts are transitive and two-way.

See also: child domain  parent domain  transitive trust  two-way trust

**parity**
A calculated value that is used to reconstruct data after a failure. RAID-5 volumes stripe data and parity intermittently across a set of disks. When a disk fails, some server operating systems use the parity information together with the data on good disks to recreate the data on the failed disk.

See also: fault tolerance  RAID-5 volume  striped volume

**parity bit**
In asynchronous communications, an extra bit used in checking for errors in groups of data bits transferred within or between computer systems. In modem-to-modem communications, a parity bit is often used to check the accuracy with which each character is transmitted.

See also: parity

**partition**
A portion of a physical disk that functions as though it were a physically separate disk. After you create a partition, you must format it and assign it a drive letter before you can store data on it. On basic disks, partitions are known as basic volumes, which include primary partitions and logical drives. On dynamic disks, partitions are known as dynamic volumes, which include simple, striped, spanned, mirrored, and RAID-5 volumes.

See also: basic disk  basic volume  drive letter  dynamic volume  extended partition  primary partition  system partition

**partition boot sector**
A portion of a hard disk partition that contains information about the disk`s file system and a short machine language program that loads the Windows operating system.

See also: partition

**passive client**
A Hypertext Transfer Protocol (HTTP) browser, capable of broadly supported HTTP, that can make use of cookies. Active Directory Federation Services (ADFS) in Windows Server 2003 R2 supports only passive clients, and it adheres to the WS-Federation Passive Requestor Profile (WS-F PRP) specification.

**passport authentication**
A user authentication mechanism that uses standard Web technologies to enable single sign-on access to multiple Web resources.

See also: .NET Passport  authentication

**password**
A security measure used to restrict logon names to user accounts and access to computer systems and resources. A password is a string of characters that must be provided before a logon name or an access is authorized. A password can be made up of letters, numbers, and symbols, and it is case-sensitive.

See also: maximum password age  minimum password length  user account

**Password Authentication Protocol (PAP)**
A simple, plaintext authentication scheme for authenticating Point-to-Point Protocol (PPP) connections. The user name and password are requested by the remote access server and returned by the remote access client in plaintext.

See also: authentication  password  plaintext  Point-to-Point Protocol (PPP)  remote access server

**password policy**
A collection of policy settings that define the password requirements for a Group Policy object (GPO).

See also: Group Policy object (GPO)  password

**Password Synchronization**
A feature of Windows that helps integrate Windows and UNIX networks by simplifying the process of maintaining secure passwords in both environments.

**path**
A sequence of directory (or folder) names that specifies the location of a directory, file, or folder within the Windows directory tree. Each directory name and file name within the path must be preceded by a backslash (\). For example, to specify the path of a file named Readme.doc located in the Windows directory on drive C, type C:\Windows\Readme.doc.

See also: directory

**paused**
A state that applies to a node in a cluster. The node is a fully active member in the cluster but cannot accept new resource groups (for example, a resource group cannot fail over or fail back to a paused node). You can administer and maintain a paused node.

See also: cluster  failback  failover  node  offline

**PC Card**
A removable device, approximately the size of a credit card, that can be plugged into a Personal Computer Memory Card International Association (PCMCIA) slot in a portable computer. PCMCIA devices can include modems, network cards, and hard disk drives.

See also: modem (modulator/demodulator)

**PCL**
See other term: Printer Control Language (PCL)

**PDC**
See other term: primary domain controller (PDC)

**PDC emulator master**
A domain controller that holds the PDC emulator operations master role in Active Directory. The PDC emulator services network clients that do not have Active Directory client software installed, and it replicates directory changes to any Windows NT backup domain controllers (BDCs) in the domain. The PDC emulator handles password authentication requests involving passwords that have recently changed and not yet been replicated throughout the domain. At any time, the PDC emulator master role can be assigned to only one domain controller in each domain.

See also: Active Directory  backup domain controller (BDC)  domain controller  operations master  primary domain controller (PDC)

**PDL**
See other term: page-description language (PDL)

**Peak Memory Usage**
In Task Manager, the peak amount of physical memory resident in a process since it started.

See also: Task Manager

**pending**
A state that refers to a resource in a cluster when the resource is in the process of being brought online or taken offline.

See also: offline  online  resource

**Per Device or Per User Licensing**
A licensing mode that requires a separate device-based or user-based Client Access License (CAL) for each device or user that accesses a server running Windows Server 2003, regardless of the number of concurrent connections.

See also: client  device  Per Server Licensing

**Per Server Licensing**
A licensing mode that requires a separate device-based or user-based Client Access License (CAL) for each concurrent connection to a server running Windows Server 2003.

See also: client  device  Per Device or Per User Licensing

**performance alert**
A feature that detects when a predefined counter value rises above or falls below the configured threshold and notifies a user by means of the Messenger service.

See also: Messenger service

**performance counter**
In System Monitor, a data item that is associated with a performance object. For each counter selected, System Monitor presents a value corresponding to a particular aspect of the performance that is defined for the performance object.

See also: performance object

**performance object**
In System Monitor, a logical collection of counters that is associated with a resource or service that can be monitored.

See also: performance counter

**performance object instance**
In System Monitor, a term used to distinguish between multiple performance objects of the same type on a computer.

See also: performance object

**perimeter network**
An Internet Protocol (IP) network segment that contains resources, such as Web servers and virtual private network (VPN) servers, that are available to Internet users. Also known as screened subnet.

See also: Internet Authentication Service (IAS)  Internet Protocol (IP)  virtual private network (VPN)

**permanent virtual circuit (PVC)**
A virtual circuit assigned to a preconfigured static route.

See also: static routes

**permission**
A rule associated with an object to regulate which users can gain access to the object and in what manner. Permissions are assigned or denied by the object`s owner.

See also: object  privilege

**personal identification number (PIN)**
A secret identification code that is used to protect smart cards from misuse. The PIN is similar to a password and is known only to the owner of the card. The smart card can be used only by someone who possesses the smart card and knows the PIN.

See also: smart card

**Physical Address Extension (PAE)**
A feature of x86-based servers that allows computers running Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, to support more than 4 gigabytes (GB) of physical memory. Physical Address Extension (PAE) allows up to 64 GB of physical memory to be used as regular 4-kilobyte (KB) pages and expands the number of bits that can be used by the kernel to address physical memory from 32 to 36.

See also: x86

**Physical Disk resource**
A disk on a cluster storage device. Physical disks are supported as cluster resources by a Resource DLL.

See also: Resource DLL

**physical security**
The protection of critical data repositories and paths through the use of physical barriers. Physical barriers range in effectiveness and complexity from locked doors to multilayer access control systems involving proof of identity and explicit access permissions.

See also: security

**PID**
See other term: process identifier (PID)

**PIF**
See other term: program information file (PIF)

**ping**
A utility that verifies connections to one or more remote hosts. The ping command uses Internet Control Message Protocol (ICMP) echo request and echo reply packets to determine whether a particular Internet Protocol (IP) system on a network is functional. Ping is useful for diagnosing IP network or router failures.

See also: host  Internet Control Message Protocol (ICMP)  Internet Protocol (IP)  packet

**pixel**
Short for picture element, one spot in a rectilinear grid of thousands of such spots that form an image produced on the screen by a computer or on paper by a printer. A pixel is the smallest element that display or print hardware and software can manipulate to create letters, numbers, or graphics. Also called a pel.

See also: screen resolution

**PJL**
See other term: Printer Job Language (PJL)

**PKCS #10**
The Certification Request Syntax Standard, developed and maintained by RSA Data Security, Inc.

See also: Public Key Cryptography Standards (PKCS)  Rivest-Shamir-Adleman (RSA) cryptographic algorithms

**PKCS #12**
Personal Information Exchange Syntax Standard, developed and maintained by RSA Data Security, Inc. This standard primarily provides a format for storing keys or a certificate in a file.

See also: Public Key Cryptography Standards (PKCS)  Rivest-Shamir-Adleman (RSA) cryptographic algorithms

**PKCS #7**
The Cryptographic Message Syntax Standard. It is a general syntax, developed and maintained by RSA Data Security, Inc., for data to which cryptography may be applied, such as digital signatures and encryption. It also provides a syntax for disseminating certificates or certificate revocation lists.

See also: certificate revocation list (CRL)  encryption  Public Key Cryptography Standards (PKCS)

**PKI**
See other term: public key infrastructure (PKI)

**plaintext**
Data in its unencrypted or decrypted form. Sometimes also called cleartext.

See also: encryption

**plotter font**
A font created by a series of dots connected by lines. Plotter fonts can be scaled to any size and are most often printed on plotters. Some dot-matrix printers also support plotter fonts.

See also: font

**Plug and Play**
A set of specifications developed by Intel Corporation that enables a computer to detect and configure a device automatically and install the appropriate device drivers.

See also: universal serial bus (USB)

**PNNI**
See other term: private or public network-to-network interface (PNNI)

**p-node**
A network basic input/output system (NetBIOS) implementation that uses point-to-point communication with a WINS server to resolve names as IP addresses.

See also: IP address  network basic input/output system (NetBIOS)  Windows Internet Name Service (WINS)

**point of presence (POP)**
The local access point for a network provider. Each POP provides a telephone number that allows users to make a local call for access to online services.

**point of termination station (POTS)**
Basic dial telephone connections to the public switched network, without any added features or functions. Also called plain old telephone service.

**pointer (PTR) resource record**
A DNS resource record used in a reverse lookup zone to map an IP address to a DNS name.

See also: Domain Name System (DNS)  in-addr.arpa domain  IP address  resource record (RR)  reverse lookup  zone

**Point-to-Point Protocol (PPP)**
An industry standard suite of protocols for the use of point-to-point links to transport multiprotocol datagrams. PPP is documented in RFC 1661.

See also: Compression Control Protocol (CCP)  remote access  Request for Comments (RFC)  Transmission Control Protocol/Internet Protocol (TCP/IP)  voluntary tunnel

**Point-to-Point Tunneling Protocol (PPTP)**

Networking technology that supports multiprotocol virtual private networks (VPNs), enabling remote users to access corporate networks securely across the Internet or other networks by dialing into an Internet service provider (ISP) or by connecting directly to the Internet. PPTP tunnels, or encapsulates, Internet Protocol (IP) or Internetwork Packet Exchange (IPX) traffic inside IP packets. This means that users can remotely run applications that depend on particular network protocols. PPTP is described in RFC 2637.

See also: Internet Protocol (IP) Internetwork Packet Exchange (IPX) NetBIOS Extended User Interface (NetBEUI) packet Request for Comments (RFC) tunnel virtual private network (VPN)

**poison reverse**
A process that, used with split horizon, improves Routing Information Protocol (RIP) convergence over simple split horizon by advertising all network IDs. However, the network IDs learned in a given direction are advertised with a hop count of 16, indicating that the network is unavailable.

See also: hop count Routing Information Protocol (RIP) split horizon

**policy**
The mechanism by which computer settings are configured automatically, as defined by the administrator. Depending on context, this can refer to Group Policy or Windows NT 4.0 System Policy.

See also: Group Policy Group Policy object (GPO) System Policy

**polling intervals**
The frequency the Resource Monitor checks that the resource is available and operating. There are two levels of polling: Looks Alive and Is Alive. The server cluster requests a more thorough check of the resource`s state at each Is Alive interval than it does at each Looks Alive interval; therefore, the Is Alive polling interval is typically longer than the Looks Alive polling interval. You can specify the two polling intervals and a time-out value for resources.

See also: resource Resource Monitor

**POP**
See other term: point of presence (POP)

**POP3 (Post Office Protocol 3)**
A popular protocol used for receiving e-mail messages. This protocol is often used by Internet service providers (ISPs). POP3 servers allow access to a single Inbox in contrast to Internet Message Access Protocol (IMAP) servers, which provide access to multiple server-side folders.

See also: Internet service provider (ISP) Simple Mail Transfer Protocol (SMTP)

**port**
A connection point on your computer where you can connect devices that pass data into and out of a computer. For example, a printer is typically connected to a parallel port (also called an LPT port), and a modem is typically connected to a serial port (also called a COM port).

See also: parallel port serial port universal serial bus (USB)

**port based network access control**
A form of network access control that uses the physical characteristics of a switched local area network (LAN) infrastructure to authenticate devices that are attached to a LAN port and to prevent access to that port if the authentication process fails. This form of network access control is used in 802.1X authentication.

See also: 802.1X authentication access control authentication local area network (LAN) port

**port ID**
The method that Transmission Control Protocol (TCP) and User Datagram Protocol (UDP) use to specify which program running on the system is sending or receiving the data.

See also: User Datagram Protocol (UDP)

**port rule**
For Network Load Balancing, a set of configuration parameters that determine the filtering mode to be applied to a range of ports.

See also: filtering mode Network Load Balancing port

**port scanning**

A method that is used to identify services or programs that respond to service requests that are made over a network port.

See also: port  service

**Portable Operating System Interface for UNIX (POSIX)**
An Institute of Electrical and Electronics Engineers (IEEE) standard that defines a set of operating-system services. Programs that adhere to the POSIX standard can be easily ported from one system to another. POSIX was based on UNIX system services, but it was created in a way that allows it to be implemented by other operating systems.

See also: service

**POSIX**
See other term: Portable Operating System Interface for UNIX (POSIX)

**possible owner**
A node in a cluster that can run a specific resource. By default, all nodes appear as possible owners, so the resource can run on any node. In most cases, it is appropriate to use this default setting. If you want the resource to be able to fail over, at least two nodes must be designated as possible owners.

See also: cluster  failover  node  resource

**PostScript**
A page-description language (PDL), developed by Adobe Systems for printing on laser printers. PostScript offers flexible font capability and high-quality graphics. It is the standard for desktop publishing because it is supported by imagesetters, the high-resolution printers used by printing services for commercial typesetting.

See also: page-description language (PDL)  PostScript fonts  PostScript printer  Printer Control Language (PCL)  Printer Job Language (PJL)  service  Type 1 fonts

**PostScript fonts**
Fonts that are defined in terms of the PostScript page-description language (PDL) rules and are intended to be printed on a PostScript-compatible printer. When a document displayed in a screen font is sent to a PostScript printer, the printer uses the PostScript version if the font exists. If the font doesn`t exist but a version is installed on the computer, that font is downloaded to the printer. If there is no PostScript font installed in either the printer or the computer, the bit-mapped (raster) font is translated into PostScript and the printer produces text using the bit-mapped font. PostScript fonts are distinguished from bit-mapped fonts by their smoothness, detail, and faithfulness to standards of quality established in the typographic industry.

See also: downloadable fonts  font  page-description language (PDL)  PostScript  raster fonts

**PostScript printer**
A printer that uses the PostScript page-description language (PDL) to create text and graphics on the output medium, such as paper or overhead transparency. Examples of PostScript printers include the Apple LaserWriter, the NEC LC-890, and the QMS PS-810.

See also: page-description language (PDL)  PostScript  virtual printer memory

**POTS**
See other term: point of termination station (POTS)

**power conditioning**
A feature of an uninterruptible power supply (UPS) that removes spikes, surges, sags, and noise from the power supply.

See also: uninterruptible power supply (UPS)

**Power Users group**
A group whose members can manage accounts, resources, and applications that are installed on a workstation, stand-alone server, or member server. This group does not exist on domain controllers. Administrative tasks that can be performed by members of this group include creating local users and groups; modifying and deleting accounts that they have created; removing users from the Power Users, Users, and Guests groups; installing most applications; and creating and deleting file shares.

See also: domain controller  group  member server  stand-alone server

**PPP**
See other term: Point-to-Point Protocol (PPP)

**PPTP**

See other term: Point-to-Point Tunneling Protocol (PPTP)

**precedence**
In Group Policy, the application hierarchy, based on the order in which Group Policy objects (GPOs) are applied. The GPO that is applied last takes precedence over all other objects.

See also: Group Policy Management console (GPMC)  Group Policy object (GPO)  Group Policy object link  inheritance

**predefined key**
A key that represents one of the main divisions of the registry. Each predefined key is displayed in a separate Registry Editor window, with the key's name appearing in the window`s title bar. For example, HKEY_CLASSES_ROOT is a predefined key.

See also: hive  key  registry

**preferred owner**
The node on which you prefer each group to run. For example, the static load balancing model performs best when groups are appropriately balanced between two nodes. When a node fails, the remaining node takes over the groups from the failed node, but performance is diminished. By setting those groups to fail back to their preferred server (the failed node), you automatically restore maximum performance when failback occurs. A group does not fail back if a preferred owner is not selected. You will not always choose a preferred owner because it may not matter where the group resides; all that matters is that the group is still running on one of the two nodes. Or, the nodes may be equally capable of handling the load required to use some or all of the resources.

See also: failback  group  node  resource

**preferred server**
The NetWare server that you connect to by default when you log on to your computer. The preferred server validates your user credentials and is queried when you request information about resources available on the NetWare network.

See also: credentials  resource

**preset-to callback**
A form of security in which a remote access server verifies users by calling them back at numbers supplied by the network administrator at the time user privileges are granted. Only a network administrator can change a preset callback number. This ensures that no one can borrow a user`s password and connect to the server from a location other than the user`s normal one.

See also: callback number  connected, user authenticated  remote access server

**preshared key**
An Internet Protocol security (IPSec) technology in which a shared, secret key is used for authentication in IPSec policy.

See also: authentication  Internet Protocol security (IPsec)  IPsec policy  key

**prestage**
To create a computer account in Active Directory before an operating system has been installed on the computer that will use the account. Prestaging is a part of supporting Remote Installation Services (RIS) for the client computer, and it ensures smooth client installations because the newly installed client computer is immediately recognized as having an account in Active Directory. The computer account information must include the globally unique identifier (GUID), which RIS uses to identify the client computer. An administrator can also use prestaging to control which computers can be installed through RIS.

See also: Active Directory  computer account  globally unique identifier (GUID)  Remote Installation Services (RIS)

**Primary disk**
The hard disk drive that contains the system and boot partitions used to start Windows.

See also: boot partition  system partition

**primary domain controller (PDC)**
In a Windows NT domain, a domain controller running Windows NT Server 4.0 or earlier that authenticates domain logon attempts and updates user, computer, and group accounts in a domain. The PDC contains the master read-write copy of the directory database for the domain. A domain has only one PDC. In a Windows 2000 or Windows Server 2003 domain, the PDC emulator master supports compatibility with client computers that are not running Windows 2000 or Windows XP Professional.

See also: Active Directory  backup domain controller (BDC)  mixed mode  PDC emulator master

**primary group**

The group with which a Macintosh user usually shares documents stored on a server. You specify a user`s primary group in the user`s account. When a user creates a folder on the server, the user`s primary group is set by default as the folder`s associated group.

See also: group

**primary master**
An authoritative DNS server for a zone that can be used as a point of update for the zone. Only primary masters have the ability to be updated directly to process zone updates, which include adding, removing, or modifying resource records that are stored as zone data. Primary masters are also used as the first sources for replicating the zone to other DNS servers.

See also: DNS server  replication  resource record (RR)  zone

**primary partition**
A type of partition that you can create on basic disks. A primary partition is a portion of a physical disk that functions as though it were a physically separate disk. On basic master boot record (MBR) disks, you can create up to four primary partitions on a basic disk, or three primary partitions and an extended partition with multiple logical drives. On basic GUID partition table (GPT) disks, you can create up to 128 primary partitions. Also known as a volume.

See also: basic disk  extended partition  GUID partition table (GPT)  logical drive  master boot record (MBR)  partition  volume

**primary zone**
A copy of the zone that is administered locally.

See also: secondary zone  zone

**principle of least privilege**
The security guideline that a user should have the minimum privileges necessary to perform a specific task. This helps to ensure that, if a user is compromised, the impact is minimized by the limited privileges held by that user. In practice, a user runs within the security context of a normal user. When a task requires additional privileges, the user can use a tool such as Run as to start a specific process with those additional privileges or to log on as a user with the necessary privileges.

See also: privilege  security

**print job**
The source code that contains both the data to be printed and the commands for print. Print jobs are classified into data types based on what modifications, if any, the spooler must make to the job for it to print correctly.

See also: print spooler  Printer window  printing pool

**print processor**
The component that, working in conjunction with the printer driver, receives and alters print jobs, as necessary, according to their data type to ensure that the jobs print correctly.

See also: print job  printer driver

**print server**
A computer that is dedicated to managing the printers on a network. The print server can be any computer on the network.

See also: printer

**Print Server for Macintosh**
A service that enables Macintosh clients to send and spool documents to printers attached to a computer running Windows NT Server; Windows 2000 Server; or an operating system in the Windows Server 2003 family, excluding 64-bit editions, and that enables clients to send documents to printers anywhere on an AppleTalk network. Also known as MacPrint.

See also: service

**print spooler**
Software that accepts a document sent to a printer and then stores it on disk or in memory until the printer is ready for it.

See also: printer  spooling

**Print Spooler resource**
Printer queues providing access to a network printer connected to the network by an IP address rather than by an individual

name. Print spoolers are supported as cluster resources by a Resource DLL.

See also: IP address  print spooler  Resource DLL

**printer**
A device that puts text or images on paper or other print media. Examples are laser printers or dot-matrix printers.

See also: logical printer  print spooler  printing pool

**Printer Control Language (PCL)**
The page-description language (PDL) developed by Hewlett-Packard for their laser and inkjet printers. Because of the widespread use of laser printers, this command language has become a standard in many printers.

See also: page-description language (PDL)  PostScript  Printer Job Language (PJL)

**printer driver**
A program designed to allow other programs to work with a particular printer without concerning themselves with the specifics of the printer`s hardware and internal language. By using printer drivers that handle the subtleties of each printer, programs can communicate properly with a variety of printers.

See also: device driver

**printer fonts**
Fonts residing in or intended for a printer. A printer font, usually located in the printer`s read-only memory (ROM), can be internal, downloaded, or on a font cartridge.

See also: device fonts  downloadable fonts  font  font cartridge

**Printer Job Language (PJL)**
The printer command language developed by Hewlett Packard that provides printer control at the print-job level. Using PJL commands, you can change default printer settings such as number of copies to print. PJL commands also permit switching printer languages between print jobs without action by the user. If bi-directional communication is supported, a PJL-compatible printer can send information such as printer model and job status to the print server.

See also: page-description language (PDL)  PostScript  Printer Control Language (PCL)

**printer permissions**
Permissions that specify the type of access that a user or group has to a printer. The printer permissions are Print, Manage Printers, and Manage Documents.

See also: permission

**Printer window**
A window that shows information about any pending print jobs for the printer. For each printer you have installed or to which you are connected, you can view information such as how many documents are waiting to be printed, who owns them, and how large they are. Also called the queue view.

See also: print job

**Printers and Faxes**
The folder in Control Panel that contains the Add Printer Wizard and icons for all the printers installed on your computer.

See also: printer

**printing pool**
Two or more identical printers that are connected to one print server and act as a single printer. In this case, when you print a document, the print job will be sent to the first available printer in the pool.

See also: print job  printer

**private branch exchange (PBX)**
An automatic telephone switching system that enables users within an organization to place calls to each other without going through the public telephone network. Users can also place calls to outside numbers.

**private key**
The secret half of a cryptographic key pair that is used with a public key algorithm. Private keys are typically used to decrypt a symmetric session key, digitally sign data, or decrypt data that has been encrypted with the corresponding public key.

See also: public key  public key encryption

**private network**
A cluster network that supports only node-to-node communication.

See also: cluster  node

**private or public network-to-network interface (PNNI)**
The ATM Forum standard that defines the interface between asynchronous transfer mode (ATM) switches in a private network or a public network.

See also: asynchronous transfer mode (ATM)

**private queue**
For Message Queuing, a queue that is not published in Active Directory and that can be accessed only by applications that have access to the full format name of the queue.

See also: Active Directory  internal private queue  Message Queuing  public queue

**private volume**
A Macintosh-accessible volume that is accessible by only one Macintosh user. For a volume to be a private volume, the permissions on its root directory must give the volume`s owner all three permissions (Make Changes, See Files, and See Folders), while giving the primary group and everyone categories no permissions at all. When a private volume`s owner uses the Chooser to view the volumes available on the server, the private volume is listed; however, no other users can see the private volume when viewing the volumes available on the server.

See also: Chooser  permission  volume

**privilege**
A user's right to perform a specific task, usually one that affects an entire computer system rather than a particular object. Privileges are assigned by administrators to individual users or groups of users as part of the security settings for the computer.

See also: object  user rights

**process**
The virtual address space and the control information necessary for the execution of a program.

See also: socket

**process identifier (PID)**
A numerical identifier that uniquely distinguishes a process while it runs. Use Task Manager to view PIDs.

See also: process  Task Manager

**program**
A set of instructions that a computer uses to perform a specific task, such as word processing, accounting, or data management. Also called an application.

**program information file (PIF)**
A file that provides information to Windows about how best to run MS-DOS-based programs. When you start an MS-DOS-based program, Windows looks for a PIF to use with it. PIFs contain such items as the name of the file, a start-up directory, and multitasking options.

See also: MS-DOS-based program

**property**
A characteristic or parameter of a class of objects or devices. For example, properties of Microsoft Word files include Size, Created, and Characters.

See also: device  object  property cache  property value  tag

**property cache**
For Indexing Service, a file that stores values for document properties.

See also: document  Indexing Service  property

**property value**

A specific characteristic or parameter that defines a property. For example, property values of a specific Microsoft Word document could include Size = 10,000 bytes, Created = Jan 2, 1999, and Characters = 5,250.

See also: property

**Protective MBR**
The first sector of a GUID partition table (GPT) disk that is structured like the first sector of a master boot record (MBR) disk to prevent x86-based disk utilities from destroying GPT partitions. The Protective MBR contains one partition that reserves the entire space used on the disk by GPT partitions.

See also: Extensible Firmware Interface (EFI)  GUID partition table (GPT)  master boot record (MBR)  x86

**protocol**
A set of rules and conventions for sending information over a network. These rules govern the content, format, timing, sequencing, and error control of messages exchanged among network devices.

See also: Internet Protocol (IP)  Transmission Control Protocol/Internet Protocol (TCP/IP)

**protocol parser**
A dynamic-link library (DLL) that identifies the protocols used to send a frame onto the network.

See also: dynamic-link library (DLL)  frame  protocol

**proxy server**
A firewall component that manages Internet traffic to and from a local area network (LAN) and that can provide other features, such as document caching and access control. A proxy server can improve performance by supplying frequently requested data, such as a popular Web page, and it can filter and discard requests that the owner does not consider appropriate, such as requests for unauthorized access to proprietary files.

See also: local area network (LAN)

**psadmin**
A Windows command-line utility that manages the Password Synchronization component of Identity Management for UNIX, either on a specified computer, or globally.

**PSTN**
See other term: public switched telephone network (PSTN)

**public key**
The nonsecret half of a cryptographic key pair that is used with a public key algorithm. Public keys are typically used when encrypting a session key, verifying a digital signature, or encrypting data that can be decrypted with the corresponding private key.

See also: key  private key  Public Key Cryptography Standards (PKCS)  public key encryption  recovery agent

**public key cryptography**
See other term: public key encryption

**Public Key Cryptography Standards (PKCS)**
A family of standards for public key cryptography that includes RSA encryption, Diffie-Hellman key agreement, password-based encryption, extended-syntax, cryptographic message syntax, private key information syntax, and certificate request syntax, as well as selected attributes. Developed, owned, and maintained by RSA Data Security, Inc.

See also: public key cryptography

**public key encryption**
A method of encryption that uses two encryption keys that are mathematically related. One key is called the private key and is kept confidential. The other is called the public key and is freely given out to all potential correspondents. In a typical scenario, a sender uses the receiver's public key to encrypt a message. Only the receiver has the related private key to decrypt the message. The complexity of the relationship between the public key and the private key means that, provided the keys are long enough, it is computationally infeasible to determine one from the other. Also called asymmetric encryption.

See also: encryption  private key  public key  symmetric encryption

**public key infrastructure (PKI)**
The laws, policies, standards, and software that regulate or manipulate certificates and public and private keys. In practice, it is a system of digital certificates, certification authorities, and other registration authorities that verify and authenticate the validity

of each party involved in an electronic transaction. Standards for PKI are still evolving, even though they are being widely implemented as a necessary element of electronic commerce.

See also: certification authority (CA)  public key

**public network**
A cluster network that supports client-to-cluster communication (either with or without supporting node-to-node communication).

See also: cluster  node

**public queue**
For Message Queuing, a queue that is published in Active Directory and replicated throughout a Windows enterprise. Public queues can, therefore, be located by any computer running Message Queuing within the enterprise.

See also: Active Directory  Message Queuing  private queue  queue

**public switched telephone network (PSTN)**
Standard analog telephone lines, available worldwide.

**pull partner**
A WINS component that requests replication of updated WINS database entries from its push partner.

See also: push partner  replica  Windows Internet Name Service (WINS)

**pulse dialing**
A form of dialing that enters a phone number by means of pulse frequencies. The user typically hears a series of clicking sounds when dialing. Old-fashioned rotary dial phones use pulse dialing.

See also: touch-tone dialing

**push partner**
A WINS component that notifies its pull partner when updated WINS database entries are available for replication.

See also: pull partner  replica  Windows Internet Name Service (WINS)

**PVC**
See other term: permanent virtual circuit (PVC)

# Windows Server 2003 Glossary - Q

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - Q**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**QoS**
See other term: Quality of Service (QoS)

**qualified subordination**
An extension of a standard certification authority (CA) that allows you to place certificate issuance constraints on subordinate CAs and to place usage constraints on the certificates that are issued by subordinate CAs.

See also: certification authority (CA)  public key infrastructure (PKI)

**Quality of Service (QoS)**
A set of quality assurance standards and mechanisms for data transmission, implemented in this version of Windows.

**query**
For Indexing Service, a structured statement that specifies the documents you want to find. The simplest query is a single word.

See also: Indexing Service  tag  vector  wildcard character

**queue**
A list of programs or tasks waiting for execution. In Windows printing terminology, a queue refers to a group of documents waiting to be printed. In NetWare and OS/2 environments, queues are the primary software interface between the application and print device; users submit documents to a queue. With Windows, however, the printer is that interface; the document is sent to a printer, not a queue.

See also: printer  transactional message

**queue quota**
For Message Queuing, the storage size limit for messages in public queues. When a queue quota is reached, Message Queuing can no longer send messages to that queue until one or more messages are removed from the queue. Message Queuing enforces the computer quota before it enforces the queue quota on a computer.

See also: computer quota  Message Queuing  queue

**queue type**
For Message Queuing, a globally unique identifier (GUID) specified by the application that created the queue.

See also: globally unique identifier (GUID)  Message Queuing  queue

**quiet answer**
A telephone-answering protocol in which incoming calls are answered with silence instead of a tone signal. Some telephone-switching systems use quiet answering. These switching systems expect the caller to provide another phone number, code, or extension after the quiet answer.

See also: protocol

**quorum log**
The log where the quorum resource stores data. This data is maintained by the clustering software. Also known as the recovery log or change log.

See also: quorum resource  server cluster

**quorum resource**
The quorum-capable resource selected to maintain the configuration data necessary for recovery of the cluster. This data contains details of all of the changes that have been applied to the cluster database. The quorum resource is generally accessible to other cluster resources so that any cluster node has access to the most recent database changes. By default there

is only one quorum resource per cluster.

See also: node  server cluster

**quorum traffic**
In a majority node set server cluster, the replication traffic between nodes in a cluster. This replication traffic contains the cluster configuration data and ensures that the cluster quorum information is kept in sync across all nodes.

See also: cluster  majority node set server cluster  node  quorum resource  replication

**quota limit**
The amount of disk space available to a user.

See also: warning level

**quota template**
A template that defines a space limit on the physical drive, the type of quota (hard or soft), and a set of notifications to be generated when the quota limit is being approached.

# Windows Server 2003 Glossary - R

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - R**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**RA**
See other term: registration authority (RA)

**RADIUS**
See other term: Remote Authentication Dial-In User Service (RADIUS)

**RAID-5 volume**
A fault-tolerant volume with data and parity striped intermittently across three or more physical disks. Parity is a calculated value that is used to reconstruct data after a failure. If a portion of a physical disk fails, Windows recreates the data that was on the failed portion from the remaining data and parity. You can create RAID-5 volumes only on dynamic disks on computers running the Windows 2000 Server or Windows Server 2003 families of operating systems. You cannot mirror or extend RAID-5 volumes. In Windows NT 4.0, a RAID-5 volume was known as a striped set with parity.

See also: dynamic disk  dynamic volume  fault tolerance  parity  volume

**RAM**
See other term: random access memory (RAM)

**random access memory (RAM)**
Memory that can be read from or written to by a computer or other devices. Information stored in RAM is lost when the computer is turned off.

See also: virtual memory

**raster fonts**
Fonts that are stored as bitmaps. Raster fonts are designed with a specific size and resolution for a specific printer and cannot be scaled or rotated. If a printer does not support raster fonts, it will not print them. The five raster fonts are Courier, MS Sans Serif, MS Serif, Small, and Symbol. Also called bit-mapped fonts.

See also: font  printer

**raw socket**
A socket that provides direct access to lower-level network protocols.

See also: socket

**read-only memory (ROM)**
A semiconductor circuit that contains information that cannot be modified.

**realm**
A set of security principles, in a non-Windows networked environment, that are subject to Kerberos authentication.

See also: Kerberos V5 authentication protocol

**realm name**
An identifying prefix or suffix appended to a user name to enable appropriate routing and authentication during a remote logon process.

See also: authentication  routing  user name

**realm trust**
A trust between non-Windows Kerberos V5 realms, such as a UNIX realm, and Active Directory domains. Realm trusts can be transitive, nontransitive, one-way, or two-way.

See also: Active Directory  domain  Kerberos V5 authentication protocol  nontransitive trust  one-way trust  realm  transitive trust  two-way trust

**Real-Time Transport Protocol (RTP)**
An Internet protocol for transporting real-time traffic over multicast and unicast network services.

See also: protocol  unicast

**rebinding state**
A state used by DHCP clients to extend and renew their address lease when the current lease is close to expiring. In this state, the client broadcasts to the network to locate any DHCP server that can either renew or replace its currently leased configuration. The rebinding state begins when 87.5 percent of the client's lease time has elapsed.

See also: Dynamic Host Configuration Protocol (DHCP)  lease

**receiving member**
Between a pair of replicating servers, the member that is receiving replicated content over a connection.

**reconciliation**
The process of making the client lease information stored in the DHCP server database consistent with a duplicate copy of this same information stored in the Windows registry. Using the DHCP Microsoft Management Console (MMC), reconciliation helps restore or recover the contents of the DHCP server database file, Dhcp.mdb, located by default in the %Systemroot%\System32\Dhcp folder.

See also: Dynamic Host Configuration Protocol (DHCP)  lease  Microsoft Management Console (MMC)  systemroot

**recoverable message**
For Message Queuing, a message that can be recovered no matter which computer fails, but that uses more resources and is slower than an express message.

See also: express message  Message Queuing

**recovery agent**
A person who is issued a public key certificate for the purpose of recovering user data that is encrypted with Encrypting File System (EFS).

See also: Encrypting File System (EFS)  public key

**Recovery Console**
A command-line interface that provides a limited set of administrative commands that are useful for repairing a computer.

See also: NTFS file system

**recovery policy**
A type of public key Group Policy object (GPO) used by Encrypting File System (EFS) that provides for one or more user accounts to be designated as recovery agents.

See also: Encrypting File System (EFS)  Group Policy object (GPO)  public key  recovery agent  user account

**recursive query**
A query made to a DNS server in which the requester asks the server to assume the full workload and responsibility for providing a complete answer to the query. The DNS server will then use separate iterative queries to other DNS servers on behalf of the requester to assist in completing an answer for the recursive query.

See also: DNS server  iterative query  recursive resolution

**recursive resolution**
One of the two process types (iterative and recursive) for DNS name resolution. In this process, a resolver (a DNS client) will request that a DNS server provide a complete answer to a query that does not include pointers to other DNS servers. When a client makes a query and requests that the server use recursive resolution to answer, it effectively shifts the workload of resolving the query from the client to the DNS server. If the DNS server supports and uses recursive resolution, it contacts other DNS servers as necessary (using iterative queries on behalf of the client) until it obtains a definitive answer to the query. This type of resolution allows the client resolver to be small and simple.

See also: DNS server  Domain Name System (DNS)  iteration  iterative query  recursive query

**Recycle Bin**

The place in which Windows stores deleted files. You can retrieve files you deleted in error, or you can empty the Recycle Bin to create more disk space.

**Redundant Array of Independent Disks (RAID)**
A method used to standardize and categorize fault-tolerant disk systems. RAID levels provide various mixes of performance, reliability, and cost. Some servers provide three of the RAID levels: Level 0 (striping), Level 1 (mirroring), and Level 5 (RAID-5).

See also: fault tolerance  RAID-5 volume

**referral**
An ordered list of targets that a client computer receives from a domain controller or namespace server when the user accesses a namespace root or folder with targets in the namespace.

See also: DFS namespace  Distributed File System (DFS)  iteration

**referral server**
A server that responds to requests for service from remote installation clients. It refers clients to other remote installation servers where they can install Windows desktop operating systems. The referral server does not directly host client computers for installing the operating system.

**refresh**
In PerformancePoint Planning, to update displayed information with current data. In PerformancePoint Monitoring, the activity of synchronizing dashboards and dashboard elements between the local workspace and Monitoring Server.

See also: refresh rate

**refresh interval**
An interval of time used by secondary masters of a zone to determine how often to check if their zone data needs to be refreshed. When the refresh interval expires, the secondary master checks with its source for the zone to see if its zone data is still current or if it needs to be updated using a zone transfer. This interval is set in the start-of-authority (SOA) resource record for each zone.

See also: start-of-authority (SOA) resource record  zone  zone transfer

**refresh rate**
The frequency with which the video screen is retraced to prevent the image from flickering. The entire image area of most monitors is refreshed approximately 60 times per second.

See also: refresh

**region**
Contiguous chunks of storage on a disk.

See also: disk

**registered file type**
File types that are tracked by the system registry and are recognized by the programs you have installed on your computer.

See also: file type  registry

**registration authority (RA)**
A computer that is configured for an administrator to request and retrieve issued certificates on behalf of other users. An RA does not require that a certification authority be installed on the same computer.

See also: certification authority (CA)

**registry**
A database repository for information about a computer's configuration. The registry contains information that Windows continually references during operation, such as: profiles for each user; the programs installed on the computer and the types of documents that each can create; property settings for folders and program icons; what hardware exists on the system; which ports are being used. The registry is organized hierarchically as a tree, and it is made up of keys and their subkeys, hives, and entries.

See also: entry  hive  key  registry size limit (RSL)  subkey

**registry boot**
The default boot option used by most Windows DNS servers. When registry boot is used, DNS is started and initialized using

DNS parameters and their values as they are stored in the Windows registry. You can use a Berkeley Internet Name Domain (BIND) boot file as an alternative to this method of boot configuration for DNS.

See also: BIND boot file  DNS server  Domain Name System (DNS)

**registry size limit (RSL)**
A universal maximum for the space that registry files (hives) can consume in the paged pool. This maximum prevents an application from filling the paged pool with registry data.

See also: hive  paged pool  registry

**relative distinguished name**
The part of the object name that identifies the object as unique from its siblings at its level in the naming hierarchy. For example, in the distinguished name CN=My Name,CN=Users,DC=Microsoft,DC=Com the relative distinguished name of the user object is My Name. The relative distinguished name of the user object`s parent object is Users.

See also: object

**relative ID (RID)**
The part of a security ID (SID) that uniquely identifies an account or group within a domain.

See also: domain  forest  group  RID master  security ID (SID)

**relative name**
The partial DNS domain name configured in individual resource records to locate and qualify the record within a zone. The relative name is joined to the front of the parent domain (domain of origin) for each resource record to form a fully qualified domain name (FQDN) within the zone. In DNS Manager, the relative name will correspond to fields that use record-specific name properties, such as the Host computer name field used in an address (A) resource record.

See also: address (A) resource record  Domain Name System (DNS)  fully qualified domain name (FQDN)  resource record (RR)  zone

**remote access**
Part of the integrated Routing and Remote Access service that provides remote networking for telecommuters, mobile workers, and system administrators who monitor and manage servers at multiple branch offices. Users can use Network Connections to dial in to remotely access their networks for services such as file and printer sharing, electronic mail, scheduling, and SQL database access.

See also: remote access server  response  Serial Line Internet Protocol (SLIP)  service

**remote access policy**
A set of conditions and connection parameters that define the characteristics of the incoming connection and the set of constraints imposed on it. Remote access policy determines whether a specific connection attempt is authorized to be accepted.

**remote access server**
A Windows-based computer running the Routing and Remote Access service and configured to provide remote access.

See also: remote access  set-by-caller callback

**Remote Access Service (RAS)**
A Windows NT 4.0 service that provides remote networking for telecommuters, mobile workers, and system administrators who monitor and manage servers at multiple offices.

**remote administration**
The management of one computer by an administrator working at another computer that is connected to the first computer across a network.

See also: remotely administered server

**Remote Authentication Dial-In User Service (RADIUS)**
A security authentication protocol based on a client/server model and widely used by Internet service providers (ISPs). RADIUS is the most popular means of authenticating and authorizing dial-up, virtual private network (VPN), wireless, and authenticating switch clients today. A RADIUS client is included in the Routing and Remote Access service that ships with the Windows Server 2003 family. A RADIUS server and proxy, named Internet Authentication Service (IAS), is included in Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows

Server 2003, Datacenter Edition.

See also: authentication  authorization  Internet Authentication Service (IAS)  tunnel  virtual private network (VPN)

**remote computer**
A computer that you can access only by using a communications line or a communications device, such as a network card or a modem.

See also: local computer

**remote differential compression (RDC)**
A protocol that can be used to efficiently update files over a limited-bandwidth network. RDC detects insertions, removals, and re-arrangements of data in files.

**Remote Installation Services (RIS)**
Software services that allow an administrator to set up new client computers remotely, without having to visit each client. The target clients must support remote booting.

See also: Single Instance Store (SIS)

**remote procedure call (RPC)**
A message-passing facility that allows a distributed application to call services that are available on various computers on a network. Used during remote administration of computers.

See also: service

**Remote Storage**
A data management service used to migrate infrequently accessed files from local storage to remote storage. Migrated files are recalled transparently when the user opens the file.

See also: local storage  service  validation

**remotely administered server**
A server that you can administer by using a different computer. You typically access this type of server by using a network connection. A remotely administered server can have a local keyboard, mouse, or video card and monitor. If it does not have these peripherals attached, it is also known as a headless server. Such servers are often housed in a physically secure location.

See also: physical security  remote administration  server

**Removable Storage**
A service used for managing removable media (such as tapes and discs) and storage devices (libraries). Removable Storage allows applications to access and share the same media resources.

See also: library  service

**rendering intent**
In color management, the approach used to map the colors specified in an image file to the color gamut of your monitor or printer. The color gamut is the range of color that a device can produce.

See also: color gamut

**rendezvous**
Client service referral behavior performed using a DNS query to resolve domain names to locate host computers that are service providers for well-known TCP/IP-based network services. Rendezvous for clients uses queries for resource record types such as mail exchanger (MX) or service (SRV) records.

See also: Domain Name System (DNS)  resource record (RR)  service

**reparse points**
NTFS file system objects that have a definable attribute containing user-controlled data and that are used to extend functionality in the input/output (I/O) subsystem.

See also: attribute  NTFS file system  object

**replica**
In Active Directory replication, one instance of a logical Active Directory partition that is synchronized by means of replication between domain controllers that hold copies of the same directory partition. <i>Replica</i> can

also refer to an instance of an object or attribute in a distributed directory. In the File Replication service (FRS), a computer that has been included in the configuration of a specific replica set.

See also: Active Directory File Replication service (FRS) replica set replication topology

**replica set**
One or more shared folders that participates in replication.

See also: replication shared folder

**replicated folder**
A folder that is kept synchronized on members of a replication group. A replicated folder has an associated local path on each member.

**replication**
The process of copying updated data from a data store or file system on a source computer to a matching data store or file system on one or more destination computers to synchronize the data.

See also: Active Directory DFS root directory partition Distributed File System (DFS) File Replication service (FRS) multimaster replication replica replication policy topology

**replication group**
A set of servers that participates in the replication of one or more replicated folders.

**replication latency**
In Active Directory replication, the delay between the time an update is applied to a given replica of a directory partition and the time it is applied to some other replica of the same directory partition. A server receives changes no sooner than either it is notified of a change from its neighbor in the same site or its periodic replication timer expires. Sometimes referred to as propagation delay.

See also: Active Directory replication directory partition replica

**replication partner**
A domain controller that acts as a replication source for a given domain controller. The Knowledge Consistency Checker (KCC) determines which servers are best suited to replicate with each other, and it generates the list of domain controllers that are candidates for replication partners from the list of domain controllers in the site on the basis of connectivity, history of successful replication, and matching of full and partial replicas. A domain controller has some number of direct replication partners with which it replicates for a given directory partition. The other domain controllers in the site replicate transitively with this domain controller.

See also: directory partition domain controller Knowledge Consistency Checker (KCC) site

**replication policy**
Rules that define how and when replication is performed.

See also: replication

**replication topology**
In Active Directory replication, the set of physical connections that domain controllers use to replicate directory updates among domain controllers within sites and between sites. In the File Replication service (FRS), the interconnections between replica set members. These interconnections determine the path that data takes as it replicates to all replica set members.

See also: Active Directory Distributed File System (DFS) domain controller File Replication service (FRS) replica replica set replication

**report message**
For Message Queuing, a message that contains status information and is sent to report queues on the source computer. Examples include test messages and route tracking messages.

See also: Message Queuing report queue

**report queue**
For Message Queuing, a queue on the source computer that contains report messages. Report queues can be used when sending test messages and tracking message routes.

See also: Message Queuing report message

**Request for Comments (RFC)**
An official document of the Internet Engineering Task Force (IETF) that specifies the details for protocols included in the TCP/IP family.

See also: Internet Engineering Task Force (IETF) protocol Transmission Control Protocol/Internet Protocol (TCP/IP)

**reservation**
A specific IP address within a scope permanently reserved for leased use to a specific DHCP client. Client reservations are made in the DHCP database using DHCP Manager and based on a unique client device identifier for each reserved entry.

See also: Dynamic Host Configuration Protocol (DHCP) IP address lease scope

**resolver**
DNS client programs used to look up DNS name information. Resolvers can be either a small stub (a limited set of programming routines that provide basic query functionality) or larger programs that provide additional lookup DNS client functions, such as caching.

See also: caching caching resolver Domain Name System (DNS)

**resource**
Generally, any part of a computer system or network, such as a disk drive, printer, or memory, that can be allotted to a running program or a process. For Device Manager, any of four system components that control how the devices on a computer work. These four system resources are interrupt request (IRQ) lines, direct memory access (DMA) channels, input/output (I/O) ports, and memory addresses. For server clusters, a physical or logical entity that is capable of being managed by a cluster, brought online and taken offline, and moved between nodes. A resource can be owned only by a single node at any point in time.

See also: direct memory access (DMA) input/output (I/O) port interrupt request (IRQ) lines memory address node offline online server cluster

**resource allocation**
The process of distributing a computer system's facilities to different components of a job in order to perform the job.

**Resource DLL**
A dynamic-link library (DLL) containing an implementation of the Resource application programming interface (API) for a specific type of resource. The Resource DLL is loaded into the address space of its Resource Monitor.

See also: application programming interface (API) dynamic-link library (DLL)

**resource fork**
One of two forks (resource fork and data fork) that make up each Macintosh file. The resource fork holds Macintosh operating system resources, such as code, menu, font, and icon definitions. Resource forks have no relevance to personal computers, so the resource forks of files on the server are never accessed by personal computer clients.

See also: data fork

**resource group**
In a server cluster, a defined collection of resources. Resources that are dependent on each other are typically placed within the same resource group.

See also: node resource server cluster

**Resource Monitor**
A cluster software component that facilitates communication between a node`s server cluster and one or more of its resources.

See also: node resource server cluster

**resource partner**
A federation partner that trusts the Federation Service to issue claims-based security tokens. The resource partner contains published Web-based applications that users in the account partner can access.

**resource record (RR)**
A standard DNS database structure containing information used to process DNS queries. For example, an address (A) resource record contains an IP address corresponding to a host name. Most of the basic resource record types are defined in RFC 1035, but additional RR types have been defined in other RFCs and approved for use with DNS.

See also: Domain Name System (DNS) Request for Comments (RFC) retry interval zone

**resource record set (RRset)**
A collection of more than one resource record returned in a query response by a DNS server. RRsets are used in responses where more than one record is part of the answer.

See also: DNS server  resource record (RR)

**resource types**
Classes of resources, such as print spooler, physical disk, and file share, organized by the server cluster. Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, provide Resource DLL files for the most common types of resources. Using the application programming interface (API) provided in the Microsoft Platform Software Development Kit (SDK), other vendors can add support for other resource types.

See also: print spooler  Resource DLL  server cluster  storage-class resource

**response**
In Windows remote access, strings expected from the device, which can contain macros.

See also: remote access  string

**response message**
For Message Queuing, a message sent by a receiving application to the response queue specified by a sending application. Any available queue can be specified as a response queue.

See also: Message Queuing  queue  response queue

**response queue**
For Message Queuing, a queue that is created by the sending application and used by the receiving application to reply to messages. For example, an application might send a response message to a response queue every time the application receives a message.

See also: Message Queuing  queue  response message

**restricted token**
An access token with restricted access to securable objects or performing privileged tasks.

See also: access token  object  privilege  security ID (SID)

**Resultant Set of Policy (RSoP)**
A feature that simplifies Group Policy implementation and troubleshooting. RSoP uses Windows Management Instrumentation (WMI) to determine how policy settings are applied to users and computers. RSoP has two modes: logging mode and planning mode. Logging mode determines the resultant effect of policy settings that have been applied to an existing user and computer based on a site, domain, and organizational unit. Planning mode simulates the resultant effect of policy settings that are applied to a user and computer.

See also: Group Policy  Group Policy Management console (GPMC)  Microsoft Management Console (MMC)  Windows Management Instrumentation (WMI)

**retry interval**
The time, in seconds after the refresh interval expires, used by secondary masters of a zone to determine how often to try and retry contacting its source for zone data to see if its replicated zone data needs to be refreshed. This interval is set in the start-of-authority (SOA) resource record for each zone.

See also: refresh interval  replication  start-of-authority (SOA) resource record  zone

**reverse lookup**
A DNS query for a pointer (PTR) resource record that resolves an IP address to its corresponding fully qualified domain name (FQDN).

See also: Domain Name System (DNS)  fully qualified domain name (FQDN)  IP address  pointer (PTR) resource record

**reversible encryption**
A mechanism that stores an encrypted password in such a way that the original password can be unencrypted and retrieved. Some applications require the unencrypted password so that they can perform certain tasks.

See also: encrypted password

**RFC**

See other term: Request for Comments (RFC)

**RGB color space**
Multidimensional color space consisting of the red, green, and blue intensities that make up a given color. This system is typically used in scanners, digital cameras, computer monitors, and computer printers.

See also: color management  color space

**RID**
See other term: relative ID (RID)

**RID master**
A domain controller that holds the RID operations master role in Active Directory. The RID master is assigned to allocate unique sequences of relative IDs to each domain controller in its domain. As the domain controllers use the IDs allocated, they contact the RID master and are allocated additional sequences as needed. At any time, the RID master role can be assigned to only one domain controller in each domain.

See also: Active Directory  domain controller  operations master  relative ID (RID)  security ID (SID)  security principal

**RIP**
See other term: Routing Information Protocol (RIP)

**RIPX**
See other term: Routing Information Protocol over IPX (RIPX)

**RIS**
See other term: Remote Installation Services (RIS)

**Rivest-Shamir-Adleman (RSA) cryptographic algorithms**
A widely used set of public key algorithms that were published by RSA Data Security, Inc. The RSA cryptographic algorithms are supported by the Microsoft Base Cryptographic Service Provider and the Microsoft Enhanced Cryptographic Service Provider.

See also: cryptographic service provider (CSP)  public key cryptography

**roaming user profile**
A server-based user profile that is downloaded to the local computer when a user logs on and that is updated both locally and on the server when the user logs off. A roaming user profile is available from the server when logging on to a workstation or server computer. When logging on, the user can use the local user profile if it is more current than the copy on the server.

See also: local user profile  mandatory user profile  user profile

**role-based administration**
A management technique that is characterized by the use of collections of settings that are based on an object's role within an organization. Role-based administration can be used to manage users, computers, and other file system and directory service objects.

See also: access control entry (ACE)  authorization  object

**rolling upgrade**
In a cluster, the process of systematically upgrading cluster nodes one node at a time. During the upgrade, the remaining cluster nodes continue to provide service.

See also: cluster  node

**ROM**
See other term: read-only memory (ROM)

**root**
The highest or uppermost level in a hierarchically organized set of information. The root is the point from which further subsets are branched in a logical sequence that moves from a broad or general focus to narrower perspectives.

See also: DFS root  root certificate  root certification authority  root hints  root servers  root target

**root certificate**
A self-signed certification authority certificate. It is called a root certificate because it is the certificate for the root authority. The root authority must sign its own certificate because by definition there is no higher certifying authority in the certification

hierarchy.

See also: certification authority (CA)  certification hierarchy  root certification authority

**root certification authority**
The most trusted certification authority (CA), which is at the top of a certification hierarchy. The root CA has a self-signed certificate. Also called the root authority.

See also: certification authority (CA)  certification hierarchy  root

**root directory**
The top-level directory (or folder) on a computer, partition or volume, or Macintosh-accessible volume.

See also: Macintosh-accessible volume  partition  volume

**root domain**
The beginning of the DNS namespace. In Active Directory, the initial domain in an Active Directory tree. Also, the initial domain of a forest.

See also: Active Directory  domain  Domain Name System (DNS)  forest  namespace

**root hints**
DNS data stored on a DNS server that identifies the authoritative DNS servers for the root zone of the DNS namespace. The root hints are stored in the file Cache.dns, located in the systemroot\System32\Dns folder.

See also: DNS server  Domain Name System (DNS)  root servers  systemroot

**root servers**
DNS servers that are authoritative for the root of the namespace.

See also: authoritative  DNS server  root

**root target**
A Universal Naming Convention (UNC) path of a shared folder that is associated with the namespace root. A domain-based namespace can have multiple root targets, whereas a stand-alone namespace can have a single root target only.

See also: DFS root  target

**round robin**
A simple mechanism used by DNS servers to share and distribute loads for network resources. Round robin is used to rotate the order of resource records (RRs) returned in a response to a query when multiple RRs of the same type exist for a queried DNS domain name.

See also: DNS server  resource record (RR)

**Routemon utility**
A scripting utility for the Routing and Remote Access service that is a command-line alternative to the router administration user interface available through the Routing and Remote Access Manager.

**router**
A device or computer that forwards packets between interfaces based on a network layer destination address. For example, an Internet Protocol (IP) router forwards IP packets based on the destination IP address in the IP header. Routers typically use a routing table, which contains a series of entries for destinations and the corresponding next-hop address and interface to use to forward a packet to its eventual destination.

See also: local area network (LAN)  packet header  routing  Routing Information Protocol over IPX (RIPX)  static routes  Token Ring  wide area network (WAN)

**routing**
The process of forwarding a packet through an internetwork from a source host to a destination host.

See also: host  packet

**Routing Information Protocol (RIP)**
An industry standard, distance vector routing protocol used in small- to medium-sized Internet Protocol (IP) and Internetwork Packet Exchange (IPX) internetworks.

See also: Internet Protocol (IP)  Internetwork Packet Exchange (IPX)  protocol

**Routing Information Protocol over IPX (RIPX)**
A protocol used by routers to exchange information between routers on an Internetwork Packet Exchange (IPX) network and by hosts to determine the best router to use when forwarding IPX traffic to a remote IPX network.

See also: host Internetwork Packet Exchange (IPX) NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) protocol router

**routing link**
For Message Queuing, a communications link established between Windows sites for routing messages. Specially configured Message Queuing servers with routing services enabled are used to create a routing link between sites.

See also: Message Queuing routing services routing-link cost site

**routing protocol**
Any of several protocols that enable the exchange of routing table information between routers. Typically, medium- to large-sized TCP/IP internetworks implement routing protocols to simplify the administration of routing tables.

See also: router routing

**routing services**
For Message Queuing, a service on a Message Queuing server that provides message routing services. If so configured, this feature can be used on a Message Queuing server to enable computers that use different network protocols to communicate, reduce the number of sessions by acting as a gateway for all incoming or outgoing messages for independent clients, and route messages between sites over a routing link.

See also: gateway independent client Message Queuing Message Queuing server routing link service session concentration site

**routing-link cost**
For Message Queuing, a number used to determine the route messages can take between two sites. This number represents the relative monetary cost of communication over a link. A routing link has a default routing-link cost of 1 and should not be changed unless you have multiple routing links between two sites and you want to enforce message routing over a specific routing link.

See also: Message Queuing routing link site

**RPC**
See other term: remote procedure call (RPC)

**RR**
See other term: resource record (RR)

**RRset**
See other term: resource record set (RRset)

**RS-232-C standard**
An accepted industry standard for serial communication connections. Adopted by the Electric Industries Association, this Recommended Standard (RS) defines the specific lines and signal characteristics used by erial communications controllers to standardize the transmission of serial data between devices. The letter C signifies the third in a series.

See also: device

**RSA**
See other term: Rivest-Shamir-Adleman (RSA) cryptographic algorithms

**RSL**
See other term: registry size limit (RSL)

**RSoP**
See other term: Resultant Set of Policy (RSoP)

**RTP**
See other term: Real-Time Transport Protocol (RTP)

**Run as**
A feature that provides users with a secondary logon capability. By using Run as, users can run applications or commands in a different security context without having to log off. Run as prompts the user for different credentials before running the

application or command.

See also: secondary logon  security context

**runaway recall limit**
In Remote Storage, the setting that prohibits a user or an application from recalling files from Remote Storage more than the specified number of times in succession with less than 10 seconds between each recall. Otherwise, applications such as those for virus checking, data backup, indexing, and searching typically read all files on your computer and can cause excessive file recalls and slow performance.

See also: Remote Storage

# Windows Server 2003 Glossary - S

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - S**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**S/MIME**
See other term: Secure/Multipurpose Internet Mail Extensions (S/MIME)

**SA**
See other term: security association (SA)

**SACL**
See other term: system access control list (SACL)

**Safe mode**
A method of starting Windows using only basic files and drivers. Safe mode is available by pressing the F8 key during startup. This allows you to start the computer when a problem prevents it from starting correctly.

See also: Safe Mode with Command Prompt  Safe Mode with Networking

**Safe Mode with Command Prompt**
A method of starting Windows using basic files and drivers only, without networking, and with only a command prompt displayed. This mode is available by pressing the F8 key when prompted during startup. This allows you to start your computer when a problem prevents it from starting normally.

See also: Safe mode  Safe Mode with Networking

**Safe Mode with Networking**
A method of starting Windows using only basic files, drivers, and networking. This mode is available by pressing the F8 key when prompted during startup. This allows you to start your computer when a problem prevents it from starting normally.

See also: Safe mode  Safe Mode with Command Prompt

**SAM**
See other term: Security Accounts Manager (SAM)

**SAM account name**
A domain-unique security principal name in Windows NT 4.0 and earlier.

See also: Security Accounts Manager (SAM)  security principal name

**SAN**
See other term: system area network (SAN)

**SAP**
See other term: Service Advertising Protocol (SAP)

**SASL**
See other term: Simple Authentication and Security Layer (SASL)

**saturation**
In color management, the purity of a color's hue, moving from gray to the pure color.

See also: hue

**SBM**
See other term: subnet bandwidth management (SBM)

**scalability**

A measure of how well a computer, service, or application can grow to meet increasing performance demands. For server clusters, the ability to incrementally add one or more systems to an existing cluster when the overall load of the cluster exceeds its capabilities.

See also: server cluster

**scavenging**
The process of cleaning and removing extinct or outdated names data from the WINS database.

See also: Windows Internet Name Service (WINS)

**Schannel**
See other term: secure channel (Schannel)

**schema**
The set of definitions for the universe of objects that can be stored in a directory. For each object class, the schema defines which attributes an instance of the class must have, which additional attributes it can have, and which other object classes can be its parent object class.

See also: attribute  directory partition  object  object class  parent object

**schema master**
A domain controller that holds the schema operations master role in Active Directory. The schema master performs write operations to the directory schema and replicates updates to all other domain controllers in the forest. At any time, the schema master role can be assigned to only one domain controller in the forest.

See also: Active Directory  domain controller  operations master  schema

**scope**
A range of IP addresses that are available to be leased or assigned to DHCP clients by the DHCP service.

See also: Dynamic Host Configuration Protocol (DHCP)  IP address  lease

**scope of influence**
In a domain environment, a site, domain, or organizational unit; in a workgroup environment, the local disk.

See also: domain  organizational unit  site

**scope of management (SOM)**
In Group Policy, any Active Directory container to which you can link a Group Policy object (GPO). These containers can be sites, domains, or organizational units.

See also: Active Directory  Group Policy  Group Policy object (GPO)

**screen font**
A typeface designed for display on a computer monitor screen. A screen font often has an accompanying PostScript font for printing to PostScript-compatible printers.

See also: font  PostScript

**screen resolution**
The setting that determines the amount of information that appears on your screen, measured in pixels. Low resolution, such as 640 x 480, makes items on the screen appear large, although the screen area is small. High resolution, such as 1024 x 768, makes the overall screen area large, although individual items appear small.

See also: pixel

**screen saver**
A moving picture or pattern that appears on a computer screen when the mouse or keyboard has not been used for a specified period of time.

**SCSI**
See other term: small computer system interface (SCSI)

**SDP**
See other term: Session Description Protocol (SDP)

**secondary cluster**
A specific virtual IP address assigned to a Network Load Balancing cluster (the "primary cluster"). The secondary cluster`s virtual IP address is different than the primary cluster`s virtual IP address. Secondary clusters allow you to configure an independent set of port rules for each virtual IP address in your Network Load Balancing (primary) cluster. Also known as a virtual cluster.

See also: cluster  Network Load Balancing  virtual IP address

**secondary logon**
The practice of logging on by using one security context and then, within the initial logon session, authenticating and using a second account. In Windows 2000, Windows XP Professional, and the Windows Server 2003 family, secondary logon is enabled by the RunAs.exe program and service.

See also: authentication

**secondary zone**
A read-only copy of a DNS zone that is transferred from an authoritative DNS server to another DNS server to provide redundancy.

See also: authoritative  DNS server  DNS zone  Domain Name System (DNS)  primary zone  zone

**second-level domain**
A DNS domain name that is rooted hierarchically at the second tier of the domain namespace, directly beneath the top-level domain names. Top-level domain names include .com and .org. When DNS is used on the Internet, second-level domains are names that are registered and delegated to individual organizations and businesses.

See also: domain name  Domain Name System (DNS)  parent domain  top-level domains

**sector**
A 512-byte unit of physical storage on a hard disk. Windows file systems allocate storage in clusters, where a cluster is one or more contiguous sectors.

See also: cluster  file system

**secure channel (Schannel)**
A Security Support Provider (SSP) that implements the Secure Sockets Layer (SSL) and Transport Layer Security (TLS) Internet standard authentication protocols.

See also: authentication protocol  Secure Sockets Layer (SSL)  Transport Layer Security (TLS)

**secure dynamic update**
The process in which a DNS client submits a dynamic update request to a DNS server and the DNS server performs the update only if the client is authenticated.

See also: authentication  DNS client  DNS server  dynamic update

**Secure Hash Algorithm (SHA-1)**
An algorithm that generates a 160-bit hash value from an arbitrary amount of input data. SHA-1 is used with the Digital Signature Algorithm (DSA) in the Digital Signature Standard (DSS), among other places.

See also: Digital Signature Standard (DSS)  hash algorithm

**Secure Hypertext Transfer Protocol**
A protocol that provides a secure Hypertext Transfer Protocol (HTTP) connection.

See also: Hypertext Transfer Protocol (HTTP)  protocol

**Secure Sockets Layer (SSL)**
A proposed open standard for establishing a secure communications channel to prevent the interception of critical information, such as credit card numbers. Primarily, it enables secure electronic financial transactions on the World Wide Web, although it is designed to work on other Internet services as well.

See also: Internet

**secure zone**
A DNS zone that is stored in Active Directory and to which access control list (ACL) security features are applied.

See also: access control list (ACL)  Active Directory  DNS zone  Domain Name System (DNS)

**Secure/Multipurpose Internet Mail Extensions (S/MIME)**
An extension of MIME that supports secure mail. It enables message originators to digitally sign e-mail messages to provide proof of message origin and data integrity. It also enables messages to be transmitted in encrypted format to provide confidential communications.

See also: public key encryption

**security**
On a network, protection of a computer system and its data from harm or loss, implemented especially so that only authorized users can gain access to shared files.

See also: authorization

**Security Accounts Manager (SAM)**
A Windows service used during the logon process. SAM maintains user account information, including groups to which a user belongs.

See also: group  service  user account

**security association (SA)**
A combination of identifiers, which together define Internet Protocol security (IPSec) that protects communication between sender and receiver. An SA is identified by the combination of a Security Parameters Index (SPI), destination IP address, and security protocol (Authentication Header (AH) or Encapsulating Security Payload (ESP)). An SA must be negotiated before secured data can be sent.

See also: Authentication Header (AH)  Encapsulating Security Payload (ESP)  Internet Protocol security (IPsec)  IP address  Security Parameters Index (SPI)

**security context**
The security attributes or rules that are currently in effect. For example, the rules that govern what a user can do to a protected object are determined by security information in the user`s access token and in the object`s security descriptor. Together, the access token and the security descriptor form a security context for the user`s actions on the object.

See also: access token  object  security descriptor

**security descriptor**
A data structure that contains security information associated with a protected object. Security descriptors include information about who owns the object, who can access it and in what way, and what types of access are audited.

See also: discretionary access control list (DACL)  group  object  permission  security context  system access control list (SACL)

**security event**
An event that is logged in the security log in Event Viewer. All events that are logged in the security log are auditing events, and they can be divided into the following event categories: account logon, account management, directory service access, logon, object access, policy change, privilege use, process tracking, or system.

See also: auditing  event  Event Viewer  security log

**security filtering**
A method of applying the settings of a Group Policy object (GPO) based on security principals.

See also: Group Policy object (GPO)  security principal

**security group**
A group that can be listed in discretionary access control lists (DACLs) used to define permissions on resources and objects. A security group can also be used as an e-mail entity. Sending an e-mail message to the group sends the message to all the members of the group.

See also: discretionary access control list (DACL)  group

**security host**
An authentication device, supplemental to standard Windows and remote access server security, that verifies whether a caller from a remote client is authorized to connect to the remote access server.

See also: authentication  remote access  remote access server

**security ID (SID)**
A data structure of variable length that identifies user, group, and computer accounts. Every account on a network is issued a unique SID when the account is first created. Internal processes in Windows refer to an account`s SID rather than the account's user or group name.

See also: group account  user account  user name

**security log**
An event log containing information about security events that are specified in the audit policy.

See also: audit policy  event

**security package**
The software implementation of a security protocol. Security packages are contained in security support provider dynamic-link libraries (DLLs) or in security support provider/authentication package DLLs.

**Security Parameters Index (SPI)**
A unique, identifying value in the security association (SA) used to distinguish among multiple SAs existing at the receiving computer.

See also: security association (SA)

**security principal**
In Windows-based computers, an account (such as a user, security group, device, or computer) that can be granted or denied access to resources.

See also: group  resource  security ID (SID)  service

**security principal name**
A name that uniquely identifies a user, group, or computer within a single domain. This name is not guaranteed to be unique across domains.

See also: domain  group  security principal

**security protocol**
A specification that defines security-related data objects and rules about how the objects are used to maintain security on a computer system.

**security support provider (SSP)**
A dynamic-link library (DLL) that implements the Security Support Provider Interface (SSPI) by making one or more security packages available to applications. Each security package provides mappings between an application`s SSPI function calls and an actual security model`s functions. Security packages support security protocols such as Kerberos and NTLM.

**Security Support Provider Interface (SSPI)**
A common interface between transport-level applications, such as Microsoft Remote Procedure Call (RPC), and security support providers (SSPs), such as Windows Distributed Security. SSPI allows a transport application to call one of the SSPs to obtain an authenticated connection. These calls do not require extensive knowledge of the security protocol`s details.

**security template**
A physical file representation of a security configuration that can be applied to a local computer or imported to a Group Policy object (GPO) in Active Directory. When you import a security template to a GPO, Group Policy processes the template and makes the corresponding changes to the members of that GPO, which can be users or computers.

See also: Active Directory  Group Policy  Group Policy object (GPO)

**security token**
A cryptographically signed data unit that expresses one or more claims.

**security token service**
A Web service that issues security tokens. A security token service makes assertions based on evidence that it trusts to whoever trusts it. To communicate trust, this service requires proof, such as a security token or set of security tokens, and it issues a security token with its own trust statement. (Note that for some security token formats, this can simply be a reissuance or cosignature.) In Active Directory Federation Services (ADFS), the Federation Service is a security token service.

**See Files**

The Macintosh-style privilege that allows you to see any files in the folders for which you have this privilege. When Services for Macintosh translates Macintosh-style privileges into Windows permissions, you are granted Read permission for any folders for which you have the See Files and See Folders privileges.

See also: See Folders

**See Folders**
The Macintosh-style privilege that allows you to see folders for which you have this privilege but not any files those folders might contain. When Services for Macintosh translates Macintosh-style privileges into Windows permissions, you are granted Read permission for any folders for which you have the See Files and See Folders privileges.

See also: See Files

**seed router**
A router that initializes and broadcasts network numbers and zones about one or more physical AppleTalk networks. Servers that are running the AppleTalk protocol can function as seed routers. You can also use hardware routers from other companies as seed routers.

See also: router  zone

**sending member**
Between a pair of replicating servers, the member that is sending replicated content over a connection.

**Serial Line Internet Protocol (SLIP)**
An older industry standard that is part of Windows remote access client to ensure interoperability with other remote access software.

See also: remote access

**serial port**
An interface on the computer that allows asynchronous transmission of data characters one bit at a time. Also called a communication port or COM port.

See also: communication port  port

**server**
A computer that provides shared resources, such as files or printers, to network users.

See also: client  shared resource

**server application**
Application software running on a cluster node, regardless of whether it does service registration.

See also: node

**server cluster**
A group of computers, known as nodes, working together as a single system to ensure that mission-critical applications and resources remain available to clients. A server cluster presents the appearance of a single server to a client.

See also: cluster  node

**server farm**
In Active Directory Federation Services (ADFS), a collection of load-balanced federation servers, federation server proxies, or Web servers hosting the ADFS Web Agent.

**Server for NIS**
A feature of Windows that enables a Windows–based Active Directory domain controller to administer Network Information Service (NIS) networks.

**Server Message Block (SMB)**
A file-sharing protocol designed to allow networked computers to transparently access files that reside on remote systems over a variety of networks. The SMB protocol defines a series of commands that pass information between computers. SMB uses four message types: session control, file, printer, and message.

See also: protocol

**Server Operators group**

A group whose members can manage all domain controllers in a single domain. This group does not exist on workstations, stand-alone servers, or member servers. Administrative tasks that can be performed by members of this group include logging on locally, creating and deleting network shared resources, starting and stopping services, backing up and restoring files, formatting the hard disk of the computer, and shutting down the computer.

See also: domain  domain controller  group  member server  service  stand-alone server

**server zone**
The AppleTalk zone on which a server appears. On a Phase 2 network, a server appears in the default zone of the server`s default network.

See also: server  zone

**Server-Gated Cryptography (SGC)**
An extension of Secure Sockets Layer (SSL) that enables organizations, such as financial institutions, that have export versions of Internet Information Services (IIS) to use strong encryption (for example, 128-bit encryption).

See also: cryptography  Internet Information Services (IIS)  Secure Sockets Layer (SSL)

**service**
A program, routine, or process that performs a specific system function to support other programs, particularly at a low (close to the hardware) level. When services are provided over a network, they can be published in Active Directory, facilitating service-centric administration and usage. Some examples of services are the Security Accounts Manager service, File Replication Service (FRS), and Routing and Remote Access service.

See also: File Replication service (FRS)  Security Accounts Manager (SAM)

**service (SRV) resource record**
A DNS resource record used to identify computers that host specific services, specified in RFC 2782. SRV resource records are used to locate domain controllers for Active Directory.

See also: Active Directory  domain controller  Domain Name System (DNS)  Request for Comments (RFC)  resource record (RR)

**Service Advertising Protocol (SAP)**
A NetWare protocol used to identify the services and addresses of servers attached to the network. When a server starts, it uses the protocol to advertise its service. When the same server goes offline, it uses the protocol to announce that it is no longer available. NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink) uses SAP to locate NetWare servers and services.

See also: NWLink IPX/SPX/NetBIOS Compatible Transport Protocol (NWLink)  protocol

**Service Pack**
A software upgrade to an existing software distribution that contains updated files consisting of patches and hot fixes.

**Service Principal Name (SPN)**
A way of referring to a service principal. SPN structures generally follow Internet Engineering Task Force (IETF) naming conventions, and they often include the name of the computer on which the service is running. SPNs may be used to request Kerberos tickets, and they are required for mutual authentication.

See also: authentication  Internet Engineering Task Force (IETF)  service  ticket

**Service Profile Identifier (SPID)**
An 8-digit to 14-digit number that identifies the services that you order for each B-channel. For example, when you order Primary Rate ISDN, you obtain two phone numbers and two SPIDs from your Integrated Services Digital Network (ISDN) provider. Typical ISDN adapters cannot operate without configuring SPIDs.

See also: B-channel  Integrated Services Digital Network (ISDN)  service

**Service Provider Interface**
Calling conventions that back-end services use to make themselves accessible to front-end applications.

See also: service

**service ticket**
A ticket issued by the Kerberos V5 ticket-granting service (TGS) that allows a user to authenticate to a specific service in the domain.

See also: Kerberos V5 authentication protocol ticket ticket-granting service (TGS)

**service-centric**
A service model that does not require that a specific computer be used to complete a task. In a service-centric environment, users need to know only what service they want to use. They do not need to know what computer that service resides on to use it successfully.

See also: machine-centric service

**session**
A logical connection created between two hosts to exchange data. Typically, sessions use sequencing and acknowledgments to send data reliably. In the context of load balancing TCP/IP traffic, a set of client requests directed to a server. These requests can be invoked with multiple, possibly concurrent, TCP connections. The server program sometimes maintains state information between requests. To preserve access to the server state, Network Load Balancing needs to direct all requests within a session to the same cluster host when load balancing.

See also: client request host load balancing Network Load Balancing server Transmission Control Protocol/Internet Protocol (TCP/IP)

**session concentration**
For Message Queuing, a feature that typically reduces network bandwidth within a site and the number of sessions between sites. Specially configured Message Queuing servers with routing services provide session concentration.

See also: bandwidth Message Queuing Message Queuing server routing services session site

**Session Description Protocol (SDP)**
A protocol that Telephony API (TAPI) uses to advertise Internet Protocol (IP) multicast conferences. This protocol describes multimedia sessions for the purposes of session announcement, session invitation, and other forms of session initiation. SDP descriptors are stored in Active Directory. SDP is described in RFC 2327 of the Internet Engineering Task Force (IETF).

See also: Active Directory Internet Engineering Task Force (IETF) protocol Request for Comments (RFC) Telephony API (TAPI)

**session key**
In Internet Protocol security (IPSec), a value that is used in combination with an algorithm to encrypt or decrypt data that is transferred between computers. A session key is created for every pair of computers to provide enhanced security on computers that have multiple simultaneous active sessions.

See also: algorithm encryption Internet Protocol security (IPsec) key session

**set-by-caller callback**
In Network Connections, a form of callback in which the user supplies the telephone number that the remote access server uses for callback. This setting spares the user any long-distance telephone charges.

See also: Network Connections remote access server

**Setup**
The program that installs Windows. Also known as unattended installation, Winnt32.exe, and Winnt.exe.

**SGC**
See other term: Server-Gated Cryptography (SGC)

**SHA-1**
See other term: Secure Hash Algorithm (SHA-1)

**share**
To make resources, such as folders and printers, available to others.

See also: resource shared folder

**shared folder**
A folder on another computer that has been made available for other people to use on the network.

See also: share

**shared folder permissions**
Permissions that restrict a shared resource`s availability over the network to only certain users.

See also: permission  shared resource

**shared printer**
A printer that receives input from more than one computer. For example, a printer attached to another computer on the network can be shared so that it is available for you to use. Also called a network printer.

See also: printer  share

**shared resource**
Any device, data, or program that is used by more than one program or one other device. For Windows, shared resource refers to any resource that is made available to network users, such as folders, files, printers, and named pipes. Shared resource can also refer to a resource on a server that is available to network users.

See also: device  named pipe  resource  server  share

**shortcut**
A link to any item accessible on your computer or on a network, such as a program, file, folder, disk drive, printer, or another computer. You can put shortcuts in various areas, such as on the desktop, on the Start menu, or in specific folders.

See also: desktop

**shortcut trust**
A trust that is manually created between two domains in the same forest. The purpose of a shortcut trust is to optimize the interdomain authentication process by shortening the trust path. Shortcut trusts are transitive and can be one-way or two-way.

See also: Active Directory  domain  forest  one-way trust  trust path  trust relationship  two-way trust

**SID**
See other term: security ID (SID)

**signaling protocol**
A protocol that uses signaling to request, route, accept, and tear down virtual circuits.

See also: protocol

**signed driver**
A driver that meets the criteria of the Windows Logo Program. For performance and stability, Microsoft strongly recommends that you use only signed drivers for new or updated drivers.

See also: unsigned driver  Windows Logo Program

**Simple Authentication and Security Layer (SASL)**
An open framework, described in Request for Comments (RFC) 2222, for adding authentication support to connection-based protocols.

**Simple Mail Transfer Protocol (SMTP)**
A member of the TCP/IP suite of protocols that governs the exchange of electronic mail between message transfer agents.

See also: protocol  Transmission Control Protocol/Internet Protocol (TCP/IP)

**Simple Network Management Protocol (SNMP)**
A network protocol used to manage TCP/IP networks. In Windows, the SNMP service is used to provide status information about a host on a TCP/IP network.

See also: agent  protocol  service  Transmission Control Protocol/Internet Protocol (TCP/IP)

**Simple Object Access Protocol (SOAP)**
An XML/HTTP-based protocol for platform-independent access to objects and services on the Web. SOAP defines a message format in XML that travels over the Internet using Hypertext Transfer Protocol (HTTP). By using existing Web protocols (HTTP) and languages (XML), SOAP runs over the existing Internet infrastructure without being tied to any operating system, language, or object model.

See also: Extensible Markup Language (XML)  Hypertext Transfer Protocol (HTTP)  object  service

**Simple TCP/IP Services**
Four TCP/IP services: Character Generator, Daytime Discard, Echo, and Quote of the Day.

See also: service  Transmission Control Protocol/Internet Protocol (TCP/IP)

**simple volume**
A dynamic volume made up of disk space from a single dynamic disk. A simple volume can consist of a single region on a disk or multiple regions of the same disk that are linked together. If the simple volume is not a system volume or boot volume, you can extend it within the same disk or onto additional disks. If you extend a simple volume across multiple disks, it becomes a spanned volume. You can create simple volumes only on dynamic disks. Simple volumes are not fault tolerant, but you can mirror them to create mirrored volumes on computers running the Windows 2000 Server or Windows Server 2003 families of operating systems.

See also: dynamic disk  dynamic volume  fault tolerance  mirrored volume  spanned volume  volume

**single affinity**
Specifies that Network Load Balancing should direct multiple requests from the same client IP address to the same cluster host. This is the default setting for affinity.

See also: affinity  Class C affinity  Network Load Balancing

**Single Instance Store (SIS)**
A component that saves disk space on the server by maintaining a single physical copy of all identical files found. If SIS finds a duplicate file on the server, it copies the original file into the SIS store and leaves a link where the original resided. This technology is used only with Remote Installation Services.

See also: Remote Installation Services (RIS)

**single node server cluster**
A cluster configuration that has one node and that can be configured with or without external cluster storage devices. For a single node cluster without an external cluster storage device, the local disk is configured as the cluster storage device. There are advantages and limitations for each cluster configuration (single node server cluster, single quorum device server cluster, and majority node set server cluster).

See also: cluster  cluster storage  majority node set server cluster  node  single quorum device server cluster

**single quorum device server cluster**
A cluster configuration that has two or more nodes and that is configured so that every node is attached to one or more cluster storage device. The cluster configuration data is stored on a single cluster storage device. There are advantages and limitations for each cluster configuration (single node server cluster, single quorum device server cluster, and majority node set server cluster).

See also: cluster  cluster storage  majority node set server cluster  node  single node server cluster

**single sign-on**
A process that enables a user with a domain account to log on to a network once, using a password or smart card, and to gain access to any computer in the domain.

See also: domain  smart card

**single sign-on (SSO)**
An optimization of the authentication sequence to remove the burden of repeated logon actions by an end user

**single sign-on daemon (SSOD)**
A daemon on a Windows-based computer that receives an encrypted password and decrypts it before requesting a password change on the UNIX host.

**SIS**
See other term: Single Instance Store (SIS)

**site**
One or more well-connected (highly reliable and fast) TCP/IP subnets. A site allows administrators to configure Active Directory access and replication topology to take advantage of the physical network.

See also: Active Directory  replication topology  subnet  Transmission Control Protocol/Internet Protocol (TCP/IP)

**site link**
An Active Directory object that represents a set of sites that can communicate at uniform cost through some intersite transport. For Internet Protocol (IP) transport, a typical site link connects just two sites and corresponds to an actual wide area network (WAN) link. An IP site link connecting more than two sites might correspond to an asynchronous transfer mode (ATM) backbone connecting more than two clusters of buildings on a large campus or several offices in a large metropolitan area

connected via leased lines and IP routers.

See also: Active Directory  asynchronous transfer mode (ATM)  Internet Protocol (IP)  site  site link bridge  wide area network (WAN)

**site link bridge**
An Active Directory object that represents a set of site links, all of whose sites can communicate via some transport. Typically, a site link bridge corresponds to a router (or a set of routers) in an Internet Protocol (IP) network. By default, the Knowledge Consistency Checker (KCC) may form a route through any and all site links in a transitive manner. If this behavior is turned off, each site link represents its own distinct and isolated network. Sets of site links that can be treated as a single route are expressed through a site link bridge. Each bridge represents an isolated communication environment for network traffic.

See also: Active Directory  Internet Protocol (IP)  Knowledge Consistency Checker (KCC)  site  site link

**sleep mode**
An energy-saving mode in which the Windows operating system shuts down all unnecessary components, such as the display screen and the disk drive. The computer returns to its former operating status when it is awakened.

See also: wake-on-LAN

**SLIP**
See other term: Serial Line Internet Protocol (SLIP)

**small computer system interface (SCSI)**
A standard high-speed parallel interface defined by the American National Standards Institute (ANSI). A SCSI interface is used for connecting microcomputers to peripheral devices, such as hard disks and printers, and to other computers and local area networks (LANs).

See also: device  local area network (LAN)

**smart card**
A credit card–sized device that is used with an access code to enable certificate-based authentication and single sign-on to the enterprise. Smart cards securely store certificates, public and private keys, passwords, and other types of personal information. A smart card reader attached to the computer reads the smart card.

See also: authentication  single sign-on  smart card reader

**smart card reader**
A device that is installed in computers to enable the use of smart cards for enhanced security features.

See also: smart card

**SMS**
See other term: Systems Management Server (SMS)

**SMTP**
See other term: Simple Mail Transfer Protocol (SMTP)

**snap-in**
A type of tool that you can add to a console supported by Microsoft Management Console (MMC). A stand-alone snap-in can be added by itself; an extension snap-in can be added only to extend the function of another snap-in.

See also: Microsoft Management Console (MMC)

**sniffer**
An application or device that can read, monitor, and capture network data exchanges and read network packets. If the packets are not encrypted, a sniffer provides a full view of the data inside the packet.

See also: device  packet

**SNMP**
See other term: Simple Network Management Protocol (SNMP)

**socket**
An identifier for a particular service on a particular node on a network. The socket consists of a node address and a port number, which identifies the service. For example, port 80 on an Internet node indicates a Web server. There are two kinds of sockets: streams (bidirectional) and datagrams.

See also: datagram  node  port  process  raw socket

**software decoder**
A type of digital video disc (DVD) decoder that allows a DVD drive to display movies on your computer screen. A software decoder uses only software to display movies.

See also: DVD decoder  DVD drive  hardware decoder

**software restriction policies**
A collection of policy settings that define what software can run on a computer, based on the default security level for a Group Policy object (GPO). Exceptions to that default security level can then be defined by certificate rules, hash rules, path rules, registry path rules, and Internet zone rules.

See also: default security level  Group Policy  Group Policy object (GPO)  software restriction policies rule

**software restriction policies rule**
A rule that creates an exception to the default security level that is defined by software restriction policies. The following types of rules can be created: certificate rules, which recognize software that is digitally signed by an Authenticode software publisher certificate; hash rules, which recognize specific software based on a hash of the software; path rules, which recognize software based on the location in which the software is stored; registry path rules, which recognize software based on the location of the software as it is stored in the registry; and Internet zone rules, which recognize software based on the zone of the Internet from which the software is downloaded.

See also: default security level  hash  path  registry  software restriction policies

**SOM**
See other term: scope of management (SOM)

**source document**
The document where a linked or embedded object was originally created.

See also: embedded object  linked object

**source journaling**
For Message Queuing, the process of storing a copy of an outgoing message. Source journaling is configured on a message basis, and it is set by the sending application. When source journaling is enabled, a copy of the message is put in the source journal of the source computer when the message arrives at the destination (target) queue.

See also: journal  Message Queuing  target journaling

**spanned volume**
A dynamic volume consisting of disk space on more than one physical disk. You can increase the size of a spanned volume by extending it onto additional dynamic disks. You can create spanned volumes only on dynamic disks. Spanned volumes are not fault tolerant and cannot be mirrored.

See also: dynamic disk  dynamic volume  fault tolerance  mirrored volume  simple volume  volume

**sparse file**
A file that is handled in a way that requires much less disk space than would otherwise be needed. Sparse support allows an application to create very large files without committing disk space for those regions of the file that contain only zeros. For example, you can use sparse support to work with a 42-GB file in which you need to write data only to the first 64 KB (the rest of the file is zeroed).

**special permissions**
On NTFS volumes, a custom set of permissions. You can customize permissions on files and directories by selecting the individual components of the standard sets of permissions.

See also: NTFS file system  permission  volume

**SPID**
See other term: Service Profile Identifier (SPID)

**split horizon**
A route-advertising algorithm that prevents the advertising of routes in the same direction in which they were learned. Split horizon helps prevent routing loops.

See also: poison reverse  routing

**splitting**
A Briefcase command that separates the copy of the file inside Briefcase from the copy outside Briefcase.

**spooling**
A process on a server in which print documents are stored on a disk until a printer is ready to process them. A spooler accepts each document from each client, stores it, then sends it to a printer when the printer is ready.

See also: print spooler

**SQL**
See other term: structured query language (SQL)

**SSL**
See other term: Secure Sockets Layer (SSL)

**SSP**
See other term: security support provider (SSP)

**SSPI**
See other term: Security Support Provider Interface (SSPI)

**stand-alone certification authority**
A certification authority (CA) that is not integrated with Active Directory.

See also: Active Directory  certification authority (CA)

**stand-alone root**
A DFS namespace, the configuration information for which is stored locally on the host server. The path to access the root or a link starts with the host server name. A stand-alone root has only one root target. There is no root-level fault tolerance. Therefore, when the root target is unavailable, the entire DFS namespace is inaccessible.

See also: DFS namespace  root target

**stand-alone server**
A server that runs Windows 2000 or Windows Server 2003, but does not participate in a domain. A stand-alone server has only its own database of users, and it processes logon requests by itself. A stand-alone server does not share account information with other computers and cannot provide access to domain accounts, but it can participate in a workgroup.

See also: domain  member server  workgroup

**standard NIS map**
In Network Information Service (NIS), a map that consists of aliases, bootparams, ethers, hosts, group, netgroup, netid, netmasks, networks, passwd, protocols, rpc, services, pservers, and shadow; all other maps are nonstandard.

**start-of-authority (SOA) resource record**
A record that indicates the starting point or original point of authority for information stored in a zone. The SOA resource record (RR) is the first RR created when adding a new zone. It also contains several parameters used by other computers that use DNS to determine how long they will use information for the zone and how often updates are required.

See also: authoritative  Domain Name System (DNS)  resource record (RR)  zone

**Startrom.com**
A program used by Remote Installation Services (RIS) that is the first file downloaded to the client using Trivial File Transfer Protocol (TFTP). Startrom.com is a small program that displays the Press F12 for Network Service Boot prompt. If F12 is pressed within three seconds, the Client Installation Wizard (OSChooser) is downloaded to begin the remote installation process.

See also: Remote Installation Services (RIS)  Trivial File Transfer Protocol (TFTP)

**startup environment**
In dual-boot or multiple-boot systems, the configuration settings that specify which system to start and how each system should be started.

See also: dual boot  multiple boot

**stateless**

As related to servers, not involving the update of a server-side database based on a client request. As related to the handling of files, the content of the file is not modified or noticed. For Web servers, a stateless client request, which members of a Network Load Balancing cluster can process, is one that returns a static Web page to the client.

See also: Network Load Balancing cluster

**static dialog box**
A scripted dialog box between the client computer and an intermediary device. This kind of dialog box requires no response from the user.

See also: client

**static load balancing**
The process of manually moving a group between nodes to balance the load across the nodes.

See also: group  node

**static routes**
Routes in a routing table that are permanent until changed by a network administrator or by an automatically scheduled auto-static update.

See also: router  routing

**status area**
See other term: notification area

**status bar**
A line of information related to the current program. The status bar is usually located at the bottom of a window. Not all windows have a status bar.

**Stop error**
A serious error that affects the operating system and that could place data at risk. The operating system generates an obvious message, a screen with the Stop error, rather than continuing on and possibly corrupting data. Also called a fatal system error.

See also: Stop screen

**Stop screen**
A blue character-mode screen that appears when Windows encounters a condition that compromises safe system operation and the system stops. Commonly referred to as a blue screen or bug check.

See also: Stop error

**storage report**
A reporting tool that alerts administrators to current disk use trends, as well as to attempts by certain users or groups to save unauthorized files.

**storage subsystem**
A stand-alone hardware appliance that hosts one or more storage devices (such as disk drives, tape drives, optical drives), and is peripheral to the server or servers that control access to it. Storage subsystems are used to create centralized data repositories, while freeing computing and storage resources on servers.

**storage-class resource**
A required dependency for many resource types. Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, provide one storage-class resource: Physical Disk. However, your vendor or reseller might supply other storage-class resource types.

See also: dependency  resource types

**strict RFC checking**
For DNS, a form of domain name checking that examines characters used in DNS names for compliance with DNS naming requirements and valid character usage as specified in RFC 1123, Requirements for Internet Hosts - Applications and Support. For strict RFC compliance, DNS domain names will use name labels made up only of valid uppercase and lowercase letters, number characters, and hyphens (A through Z, a through z, 0 through 9, -), separated by periods.

See also: domain name  Domain Name System (DNS)  label  loose name checking  Request for Comments (RFC)

**string**

A group of characters or character bytes handled as a single entity. Computer programs use strings to store and transmit data and commands. Most programming languages consider strings (such as 2674:gstmn) as distinct from numeric values (such as 470924).

See also: transmitting station ID (TSID) string

**striped volume**
A dynamic volume that stores data in stripes on two or more physical disks. Data in a striped volume is allocated alternately and evenly (in stripes) across the disks. Striped volumes offer the best performance of all the volumes that are available in Windows, but they do not provide fault tolerance. If a disk in a striped volume fails, the data in the entire volume is lost. You can create striped volumes only on dynamic disks. Striped volumes cannot be mirrored or extended.

See also: dynamic disk  dynamic volume  fault tolerance  mirrored volume  volume

**strong password**
A password that cannot be easily guessed or cracked. A strong password is at least six characters long, does not contain all or part of the user's account name, and contains at least three of the four following categories of characters: uppercase characters, lowercase characters, numbers, and symbols found on the keyboard (such as !, @, #).

See also: password  password policy  weak password

**structured query language (SQL)**
A widely accepted standard database sublanguage used in querying, updating, and managing relational databases.

**stub area**
An Open Shortest Path First (OSPF) area that does not advertise individual external networks. A stub area blocks external routes and therefore reduces the amount of memory required on the internal routers located in the stub area. To keep the topology database size small, routing to all external networks in a stub area is done through a default route (destination 0.0.0.0 with the subnet mask of 0.0.0.0). In OSPF, any destination that you cannot reach through an intra-area or inter-area router is reachable through the default route.

See also: Open Shortest Path First (OSPF)  routing

**stub zone**
A copy of a zone that contains only the resource records required to identify the authoritative DNS servers for that zone. A DNS server that hosts a parent zone and a stub zone for one of the parent zone`s delegated child zones can receive updates from the authoritative DNS servers for the child zone.

See also: authoritative  DNS server  resource record (RR)  zone

**subdomain**
A DNS domain located directly beneath another domain name (the parent domain) in the namespace tree. For example, example.microsoft.com would be a subdomain of the domain microsoft.com. Also called child domain.

See also: child domain  domain  Domain Name System (DNS)  parent domain

**subject**
In public key cryptography, an entity that requests or holds a certificate. A subject can be a user, a computer, or any other device capable of requesting or using a certificate.

See also: public key cryptography

**subkey**
An element of the registry that contains entries or other subkeys. A tier of the registry that is immediately below a key or a subtree (if the subtree has no keys).

See also: descendent key  entry  key  registry  subtree

**subnet**
A subdivision of an Internet Protocol (IP) network. Each subnet has its own unique subnetted network ID.

See also: Internet Protocol (IP)  network ID

**subnet bandwidth management (SBM)**
An Internet Engineering Task Force (IETF) standard that enables administrative control at the subnet level.

See also: Internet Engineering Task Force (IETF)

**subordinate server**
A server that does not attempt to resolve queries on its own. Instead, it sends all queries to forwarders. Formerly known as slave server.

**subtree**
Any node within a tree, along with any selection of connected descendant nodes. The highest level of the registry (for example, HKEY_LOCAL_MACHINE).

See also: key  node  registry  subkey

**superscope**
An administrative grouping feature that supports a DHCP server`s ability to use more than scope for each physical interface and subnet. Superscopes are useful under the following conditions: If more DHCP clients must be added to a network than were originally planned, if an Internet Protocol (IP) network is renumbered, or if two or more DHCP servers are configured to provide scope redundancy and fault-tolerant design DHCP service for a single subnet. Each superscope can contain one or more member scopes (also known as child scopes).

See also: DHCP client  DHCP server  fault tolerance  scope  subnet

**SVC**
See other term: switched virtual circuit (SVC)

**switch type**
The type of interface to which your Integrated Services Digital Network (ISDN) device is being attached. Also called switch.

See also: B-channel  D-channel  Integrated Services Digital Network (ISDN)

**switched virtual circuit (SVC)**
A connection established dynamically between devices on an asynchronous transfer mode (ATM) network through the use of signaling.

See also: asynchronous transfer mode (ATM)

**switching hub**
A central network device (multiport hub) that forwards packets to specific ports rather than, as in conventional hubs, broadcasting every packet to every port. In this way, the connections between ports deliver the full bandwidth available.

See also: hub  packet  port

**symmetric encryption**
An encryption algorithm that requires the same secret key to be used for both encryption and decryption. Because of its speed, symmetric encryption is typically used when a message sender needs to encrypt large amounts of data. Also called secret key encryption.

See also: public key encryption

**symmetric key**
A single key that is used with symmetric encryption algorithms for both encryption and decryption.

See also: encryption  key  symmetric encryption

**synchronous**
Each application or command runs in the order listed, and each item must finish before the next command is run.

**syntax**
The order in which a command must be typed, and the elements that follow the command.

See also: Command Prompt window

**Syskey**
A tool used to configure the startup key, a random, 128-bit, symmetric cryptographic key created at system startup and used to encrypt all of the user`s symmetric cryptographic keys.

See also: encryption  symmetric key

**system access control list (SACL)**
The part of an object`s security descriptor that specifies which events are to be audited per user or group. Examples of auditing

events are file access, logon attempts, and system shutdowns.

See also: auditing  discretionary access control list (DACL)  event  object  security descriptor

**system area network (SAN)**
A network configuration, usually on a separate Internet Protocol (IP) subnet, that gives data a direct path to system hardware.

See also: Internet Protocol (IP)  subnet

**system default profile**
The user profile that is loaded when Windows is running and no user is logged on. When the Begin Logon dialog box is visible, the system default profile is loaded.

See also: user profile

**system disk**
A disk that contains the MS-DOS system files necessary to start MS-DOS.

See also: MS-DOS (Microsoft Disk Operating System)

**system files**
Files used by Windows to load, configure, and run the operating system. Generally, system files must never be deleted or moved.

**System menu**
A menu that contains commands you can use to manipulate a window or close a program. You click the program icon at the left of the title bar to open the System menu.

**system partition**
The partition that contains the hardware-specific files needed to load Windows (for example, Ntldr, Osloader, Boot.ini, Ntdetect.com). The system partition can be, but does not have to be, the same as the boot partition.

See also: boot partition  partition

**System Policy**
A Windows NT 4.0-style policy based on registry settings made using Poledit.exe, the System Policy Editor.

See also: policy  registry

**System State**
In Backup, a collection of system-specific data maintained by the operating system that must be backed up as a unit. It is not a backup of the entire system. The System State data includes the registry, COM+ Class Registration database, system files, boot files, and files under Windows File Protection. For servers, the System State data also includes the Certificate Services database (if the server is a certificate server). If the server is a domain controller, the System State data also includes the Active Directory database and the SYSVOL directory. If the server is a node in a cluster, it includes the Cluster database information. The IIS Metabase is included if Internet Information Services (IIS) is installed.

See also: Active Directory  cluster  domain controller  Internet Information Services (IIS)  node  registry  SYSVOL

**system variables**
Storage locations for data that are defined by the operating system and that are the same regardless of who is logged on at the computer. (Users who are also members of the Administrators group can add new variables or change the values.)

See also: Administrators group

**system volume**
The volume that contains the hardware-specific files that are needed to load Windows on x86-based computers with a basic input/output system (BIOS). The system volume can be, but does not have to be, the same volume as the boot volume.

See also: basic input/output system (BIOS)  boot volume  volume  x86

**systemroot**
The path and folder name where the Windows system files are located. Typically, this is C:\Windows, although you can designate a different drive or folder when you install Windows. You can use the value %systemroot% to replace the actual location of the folder that contains the Windows system files. To identify your systemroot folder, click Start, click Run, type %systemroot%, and then click OK.

**Systems Management Server (SMS)**
A Microsoft product that includes inventory collection, software deployment, and diagnostic tools. SMS automates the task of upgrading software, allows remote problem solving, provides asset management information, and monitors software usage, computers, and networks.

**SYSVOL**
A shared directory that stores the server copy of the domain`s public files, which are replicated among all domain controllers in the domain.

See also: directory  domain  domain controller

# Windows Server 2003 Glossary - T

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - T**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**T.120**
The International Telecommunication Union - Telecommunication [Standardization Sector] (ITU-T) standard for multipoint data conferencing. T.120 provides the protocols for establishing and managing data flow, connections, and conferences. Support for T.120 enables data transfer from conferencing applications, such as file transfer and application sharing, to operate in conjunction with H.323 connections.

See also: H.323  International Telecommunication Union - Telecommunication [Standardization Sector] (ITU-T)

**tag**
For Indexing Service, one or more terms that identify an element in a query, such as weight, phrase, property, or regular expression. For example, the tag {prop name=created} specifies the Created property in a query.

See also: property  query

**TAPI**
See other term: Telephony API (TAPI)

**TAPI server security file**
A file that stores information about the telephony devices for each installed telephony service provider, including the addresses that are assigned to each device and the users who are authorized to use each device.

See also: Telephony API (TAPI)

**target**
A Universal Naming Convention (UNC) path that corresponds to a namespace root or folder.

See also: DFS link  DFS root  Distributed File System (DFS)

**target journaling**
For Message Queuing, the process of storing copies of incoming messages. Target journaling is configured on a queue basis. When target journaling is enabled, a copy of each incoming message is placed in the target journal when the message is retrieved (read) from the destination queue.

See also: journal  Message Queuing  source journaling

**target priority**
A setting that specifies whether a specific target in a referral should be listed first or last, or first or last among targets of equal cost.

**Task Manager**
A tool that provides information about programs and processes running on the computer. Using Task Manager, you can end or run programs, end processes, and display a dynamic overview of your computer`s performance.

See also: process  program

**taskbar**
The bar that contains the Start button and appears by default at the bottom of the desktop. You can click the taskbar buttons to switch between programs. You can also hide the taskbar, move it to the sides or top of the desktop, and customize it in other ways.

See also: desktop  notification area

**taskpad**
A details pane view that displays shortcuts to commands that are available for the selected snap-in in the console tree. Users

can run a command by clicking a task.

See also: console tree  details pane  snap-in

**TCP/IP**
See other term: Transmission Control Protocol/Internet Protocol (TCP/IP)

**TDI**
See other term: Transport Driver Interface (TDI)

**teaming network adapters**
A configuration method that provides fault tolerance by grouping network adapters on multiple ports to a single physical network segment. For example, if connections through one port fail (due to failure of the adapter, cable, switch port, or switch), another port is activated automatically. Teaming network adapters work transparently to the operating system and other devices on the network.

See also: device  fault tolerance  network adapter  port

**Telephony API (TAPI)**
An application programming interface (API) used by communications programs to work with telephony and network services.

See also: application programming interface (API)  Internet Protocol (IP)  modem (modulator/demodulator)  service

**telephony switch**
A computer or electromechanical device that controls the routing and operation of a signal path.

**Telnet**
A protocol that enables an Internet user to log on to and enter commands on a remote computer linked to the Internet, as if the user were using a text-based terminal directly attached to that computer. Telnet is part of the TCP/IP suite of protocols. The term telnet also refers to the software (client or server component) that implements this protocol.

See also: protocol  Transmission Control Protocol/Internet Protocol (TCP/IP)

**temporary address**
An Internet Protocol version 6 (IPv6) address that uses an interface identifier that changes over time and that is not derived from a hardware property, such as a media access control (MAC) address. A temporary address makes it difficult to track the identity of a computer on the Internet across sessions.

See also: Internet Protocol (IP)  media access control (MAC) address

**Terminal Services**
The underlying technology that enables Remote Desktop, Remote Assistance, and Terminal Server.

See also: Terminal Services Licensing

**Terminal Services Licensing**
Software that provides the ability to register and track licenses for Terminal Services clients.

See also: Terminal Services

**terminate-and-stay-resident (TSR) program**
A program running under MS-DOS that remains loaded in memory even when it is not running, so that it can be quickly invoked for a specific task performed while any other application is operating.

See also: MS-DOS (Microsoft Disk Operating System)

**test queue**
For Message Queuing, a queue that stores sent test messages.

See also: Message Queuing  queue

**text box**
In a dialog box, a box in which you type information needed to carry out a command. The text box may be blank or may contain text when the dialog box opens.

**text mode**
The portion of Setup that uses a text-based interface.

See also: GUI mode  Setup

**TFTP**
See other term: Trivial File Transfer Protocol (TFTP)

**TGS**
See other term: ticket-granting service (TGS)

**TGT**
See other term: ticket-granting ticket (TGT)

**Thread Count**
In Task Manager, the number of threads running in a process.

See also: process  Task Manager

**thumbnail**
A miniature version of an image that is often used for quick browsing through multiple images.

**ticket**
A set of identification data for a security principal, issued by a domain controller for purposes of user authentication. Two forms of tickets in Windows are ticket-granting tickets (TGTs) and service tickets.

See also: authentication  domain controller  service ticket  ticket-granting ticket (TGT)

**ticket-granting service (TGS)**
A Kerberos V5 service provided by the Kerberos V5 Key Distribution Center (KDC) service that issues service tickets that allow users to authenticate to services in a domain.

See also: Kerberos V5 authentication protocol  Key Distribution Center (KDC)  service ticket  ticket-granting ticket (TGT)

**ticket-granting ticket (TGT)**
A credential issued to a user by the Kerberos Key Distribution Center (KDC) when the user logs on. The user must present the TGT to the KDC when requesting session tickets for services. Because a TGT is normally valid for the life of the user`s logon session, it is sometimes called a user ticket.

See also: Kerberos V5 authentication protocol  Key Distribution Center (KDC)  ticket-granting service (TGS)

**time server**
A computer that periodically synchronizes the time on all computers within a network. This ensures that the time used by network services and local functions remains accurate.

See also: server

**time slice**
A brief period of time during which a particular task is given control of the microprocessor in a time-sharing multitasking environment. A computer`s processor is allocated to an application, usually measured in milliseconds. Also called quantum.

**time stamp**
A certification specifying that a particular message existed at a specific time and date. In a digital context, trusted third parties generate a trusted time stamp for a particular message by having a time stamping service append a time value to a message and then digitally signing the result.

See also: service

**Time to Live (TTL)**
For Internet Protocol (IP), a field in the IP header of an IP packet that indicates the maximum number of links over which the packet can travel before being discarded by a router. For DNS, TTL values are used in resource records within a zone to determine how long requesting clients should cache and use this information when it appears in a query response answered by a DNS server for the zone.

See also: DNS server  Domain Name System (DNS)  Internet Protocol (IP)  packet  resource record (RR)  Transmission Control Protocol/Internet Protocol (TCP/IP)  zone

**time-out error**
A condition where an expected character is not received in time. When this condition occurs, the software assumes that the data has been lost and requests that it be resent.

**title bar**
The horizontal bar at the top of a window that contains the name of the window. On many windows, the title bar also contains the program icon, the Maximize, Minimize, and Close buttons, and the optional ? button for context-sensitive Help. To display a menu with commands such as Restore and Move, right-click the title bar.

See also: maximize  minimize

**TLS**
See other term: Transport Layer Security (TLS)

**token**
Any nonreducible textual element in data that is being parsed. For example, the use in a program of a variable name, a reserved word, or an operator. Storing tokens as short codes shortens program files and speeds execution. For networking, a unique structured data object or message that circulates continuously among the nodes of a token ring and describes the current state of the network. Before any node can send a message on the network, it must first wait to control the token.

See also: Token Ring

**Token Ring**
The Institute of Electrical and Electronics Engineers (IEEE) 802.5 standard that uses a token-passing technique for media access control (MAC). Token Ring supports media of both shielded and unshielded twisted pair wiring for data rates of 4 megabits per second (Mbps) and 16 megabits per second.

See also: client  token

**token-signing certificate**
An X.509 certificate whose associated public/private key pair is used to provide integrity for security tokens.

**tombstone**
In Active Directory, an object that is removed from the directory but not yet deleted.

See also: Active Directory  directory  object

**tombstone lifetime**
The length of time that an object lives as a tombstone in the directory before being collected as garbage.

See also: directory  object  tombstone

**top-level domains**
Domain names that are rooted hierarchically at the first tier of the domain namespace directly beneath the root (.) of the DNS namespace. On the Internet, top-level domain names such as .com and .org are used to classify and assign second-level domain names (such as microsoft.com) to individual organizations and businesses according to their organizational purpose.

See also: domain  domain name  Domain Name System (DNS)  domain namespace  root  second-level domain

**topological database**
An overview of networks and how they relate to routers. Routers in the same area have the same topological database.

See also: router

**topology**
The physical layout of computers, cables, switches, routers, and other components of a network. Topology also refers to the underlying network architecture, such as Ethernet or Token Ring. In Active Directory replication, the set of connections that domain controllers use to replicate information among themselves.

See also: Active Directory replication  domain controller

**touch-tone dialing**
A form of dialing that uses multiple-tone signaling. The user hears a series of tones (beeps) when dialing. Push-button telephones usually use touch-tone dialing.

See also: pulse dialing

**trace log**
A type of log generated when the user selects a trace data provider using the Performance tool. Trace logs differ from counter-data logs in that they measure data continuously rather than taking periodic samples.

**transaction**
For Message Queuing, the pairing of two or more actions that are performed together as a single action; the action succeeds or fails as a whole. Using Microsoft Distributed Transaction Coordinator (MS DTC) ensures that either both actions succeed or neither is executed.

See also: Message Queuing  Microsoft Distributed Transaction Coordinator (MS DTC)  transactional dead-letter queue  transactional message

**transactional dead-letter queue**
For Message Queuing, a queue that stores transactional messages that cannot reach their destination queue. Transactional dead-letter queues store failed messages on the computer on which the message expired. Messages in these queues are written to disk and are therefore recoverable.

See also: dead-letter queue  Message Queuing  queue  transaction

**transactional message**
For Message Queuing, a message that can be sent and received only from within a transaction. This type of message returns to its prior state when a transaction is terminated abruptly. A transactional message is removed from a queue only when the transaction is committed; otherwise, it remains in the queue and can be subsequently read during another transaction.

See also: Message Queuing  queue  transaction

**transitive trust**
A trust relationship that flows throughout a set of domains, such as a domain tree, and forms a relationship between a domain and all domains that trust that domain. For example, if domain A has a transitive trust with domain B, and domain B trusts domain C, then domain A trusts domain C. Transitive trusts can be one-way or two-way, and they are required for Kerberos-based authentication and Active Directory replication.

See also: Active Directory  Active Directory replication  domain tree  Kerberos V5 authentication protocol  nontransitive trust  one-way trust  trust relationship  two-way trust

**Transmission Control Protocol/Internet Protocol (TCP/IP)**
A set of networking protocols widely used on the Internet that provides communications across interconnected networks of computers with diverse hardware architectures and various operating systems. TCP/IP includes standards for how computers communicate and conventions for connecting networks and routing traffic.

See also: Internet Protocol (IP)  protocol

**transmitting station ID (TSID) string**
A string that specifies the transmitter subscriber ID sent by the fax machine when sending a fax to a receiving machine. This string is usually a combination of the fax or telephone number and the name of the business. It is often the same as the called subscriber ID.

See also: called subscriber ID (CSID) string  string

**Transport Driver Interface (TDI)**
A common set of routines for network layer components that communicate with the session layer of the Open Systems Interconnection (OSI) model. These routines allow software components above and below the transport layer to be mixed and matched without reprogramming.

See also: Open Systems Interconnection (OSI) reference model

**Transport Layer Security (TLS)**
A protocol that provides communications privacy and security between two applications communicating over a network. TLS encrypts communications and enables clients to authenticate servers and, optionally, servers to authenticate clients. TLS is a more secure version of the Secure Sockets Layer (SSL) protocol.

See also: authentication  protocol  Secure Sockets Layer (SSL)

**transport provider**
The driver and support files that provide transport services in a networking environment.

**trap**
In Simple Network Management Protocol (SNMP), a message sent by an agent to a management system indicating that an event has occurred on the host running the agent.

See also: agent  event  host  Simple Network Management Protocol (SNMP)

**tree root trust**
A trust that is automatically established when you add a new domain tree (the tree root domain) to an Active Directory forest (the forest root domain). Tree root trusts are transitive and two-way.

See also: Active Directory domain tree forest root domain transitive trust trust relationship two-way trust

**tree view**
A hierarchical representation of the folders, files, disk drives, and other resources connected to a computer or network. For example, Windows Explorer uses a tree view to display the resources that are attached to a computer or a network.

See also: resource

**triggered update**
A type of Routing Information Protocol (RIP) announcement that occurs when network topology changes. With triggered updates, the update announcing network topology changes is sent almost immediately rather than waiting for the next periodic announcement. Triggered updates improve the convergence time (the time it takes for a router to update its routing tables) of RIP internetworks, but at the cost of additional broadcast traffic while the triggered updates are propagated.

See also: routing Routing Information Protocol (RIP)

**Triple DES (3DES)**
An implementation of Data Encryption Standard (DES) encryption that employs three iterations of cryptographic operations on each segment of data. Each iteration uses a 56-bit key for encryption, which yields 168-bit encryption for the data. Although 3DES is slower than DES because of the additional cryptographic calculations, its protection is far stronger than DES.

See also: cryptography Data Encryption Standard (DES) encryption

**Trivial File Transfer Protocol (TFTP)**
A protocol used to download the initial files needed to begin the installation process.

See also: protocol

**Trojan horse**
A program that appears to be useful or harmless but that contains hidden code designed to exploit or damage the system on which it is run. Trojan horse programs are most commonly delivered to users through e-mail messages that misrepresent the program's purpose and function. Also called Trojan code.

See also: virus

**TrueType font**
A type of computer font that can be scaled to any size. TrueType fonts are clear and readable in all sizes and can be sent to any printer or other output device that is supported by Windows.

See also: font

**trust path**
A series of trust relationships that authentication requests must follow between domains. Domain controllers determine the trust path for all authentication requests between a domain controller in the trusting domain and a domain controller in the trusted domain.

See also: authentication domain domain controller trust relationship

**trust relationship**
A logical relationship established between domains to allow pass-through authentication, in which a trusting domain honors the logon authentications of a trusted domain. User accounts and global groups defined in a trusted domain can be given rights and permissions in a trusting domain, even though the user accounts or groups don`t exist in the trusting domain`s directory.

See also: authentication domain global group group permission user account

**trusted domain object (TDO)**
An object that represents one direction of a trust relationship. When trust relationships are established, unique TDOs are created and stored in the domain. For example, when a two-way trust is established, two TDOs are created.

See also: domain object trust relationship two-way trust

**TTL**

See other term: Time to Live (TTL)

**TTY**
A communications device that consists of a keyboard and a printer. Each keystroke on the sending machine generates a character code that is sent to the receiving machine, which prints the character. TTY is usually associated with a video display that is treated like a teletypewriter or that emulates one.

**tunnel**
A logical connection over which data is encapsulated. Typically, both encapsulation and encryption are performed, and the tunnel is a private, secure link between a remote user or host and a private network.

See also: encryption  host  tunnel server  voluntary tunnel

**tunnel server**
A server or router that terminates tunnels and forwards traffic to the hosts on the target network.

See also: host  router  server  tunnel

**tunneling protocol**
A communication standard used to manage tunnels and encapsulate private data. Data that is tunneled must also be encrypted to be a virtual private network (VPN) connection. Two commonly used tunneling protocols are the Point-to-Point Tunneling Protocol (PPTP) and Layer Two Tunneling Protocol (L2TP).

See also: Layer Two Tunneling Protocol (L2TP)  Point-to-Point Tunneling Protocol (PPTP)  virtual private network (VPN)

**two-way trust**
A trust relationship between two domains in which both domains trust each other. For example, domain A trusts domain B, and domain B trusts domain A. All parent-child trusts are two-way.

See also: domain  one-way trust  parent-child trust  trust relationship

**Type 1 fonts**
Scalable fonts designed to work with PostScript devices.

See also: font  PostScript

# Windows Server 2003 Glossary - U

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - U**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**UAM**
See other term: user authentication module (UAM)

**UBR**
See other term: unspecified bit rate (UBR)

**UCS**
See other term: Universal Character Set (UCS)

**UCS Transformation Format 8 (UTF-8)**
A character set for protocols evolving beyond the use of ASCII. The UTF-8 protocol provides for support of extended ASCII characters and translation of UCS-2, an international 16-bit Unicode character set. UTF-8 enables a far greater range of names than can be achieved using ASCII or extended ASCII encoding for character data.

See also: American Standard Code for Information Interchange (ASCII) Unicode Universal Character Set (UCS)

**UDDI**
See other term: Universal Description, Discovery, and Integration (UDDI)

**UDP**
See other term: User Datagram Protocol (UDP)

**UDP socket**
A socket that transmits datagrams over the User Datagram Protocol (UDP).

See also: datagram socket User Datagram Protocol (UDP)

**UID**
See other term: user identifier (UID)

**unallocated space**
Available disk space that is not allocated to any volume. The type of volume that you can create on unallocated space depends on the disk type. On basic disks, you can use unallocated space to create primary or extended partitions. On dynamic disks, you can use unallocated space to create dynamic volumes.

See also: basic disk dynamic disk extended partition logical drive object partition primary partition volume

**unattended Setup**
An automated, hands-free method of installing Windows. During installation, unattended Setup uses an answer file to supply data to Setup instead of requiring that an administrator or end user interactively provide the answers.

See also: Setup

**UNC**
See other term: Universal Naming Convention (UNC)

**UNC (Universal Naming Convention) name**
The full name of a resource on a network. It conforms to the \\servername\sharename syntax, where servername is the name of the server and sharename is the name of the shared resource. UNC names of directories or files can also include the directory path under the share name, with the following syntax: \\servername\sharename\directory\filename

See also: resource

**UNI**

See other term: user-to-network interface (UNI)

**unicast**
An address that identifies a specific, globally unique host.

See also: host

**Unicode**
A character encoding standard developed by the Unicode Consortium that represents almost all of the written languages of the world. The Unicode character repertoire has multiple representation forms, including UTF-8, UTF-16, and UTF-32. Most Windows interfaces use the UTF-16 form.

See also: American Standard Code for Information Interchange (ASCII) UCS Transformation Format 8 (UTF-8) Universal Character Set (UCS)

**Uniform Resource Identifier (URI)**
A compact string of characters that identifies an abstract resource or physical resource. URIs are explained in RFC 2396. In Active Directory Federation Services (ADFS), URIs are used to uniquely identify partners and account stores.

**uninstall**
When referring to software, the act of removing program files and folders from your hard disk and removing related data from your registry so the software is no longer available. When referring to a device, the act of removing the corresponding device drivers from your hard disk and physically removing the device from your computer.

See also: device device driver install

**uninterruptible power supply (UPS)**
A device that connects a computer and a power source to ensure that electrical flow is not interrupted. UPS devices use batteries to keep the computer running for a period of time after a power failure. UPS devices usually provide protection against power surges and brownouts as well.

**Universal Asynchronous Receiver/Transmitter (UART)**
An integrated circuit (silicon chip) that is commonly used in microcomputers to provide asynchronous communication. The UART provides parallel-to-serial conversion of data to be transmitted and serial-to-parallel conversion of data received.

See also: asynchronous communication

**Universal Character Set (UCS)**
An international standard character set reference that is part of the Unicode standard. The most widely held existing version of the UCS standard is UCS-2, which specifies 16-bit character values currently accepted and recognized for use to encode most of the world`s languages.

See also: American Standard Code for Information Interchange (ASCII) UCS Transformation Format 8 (UTF-8) Unicode

**Universal Description, Discovery, and Integration (UDDI)**
An industry specification for publishing and locating information about Web services. UDDI defines a standards-based way to store and retrieve information about Web services, Web service providers, binding information, and technical interface definitions—all classified using a set of standard or custom classification schemes.

See also: service

**universal group**
A security or distribution group that can contain users, groups, and computers from any domain in its forest as members. Universal security groups can be granted rights and permissions on resources in any domain in the forest.

See also: distribution group domain forest security group

**Universal Naming Convention (UNC)**
A convention for naming files and other resources beginning with two backslashes (\), indicating that the resource exists on a network computer. UNC names conform to the \\%SERVERNAME%\%SHARENAME% syntax, where %SERVERNAME% is the server's name and %SHARENAME% is the name of the shared resource. The UNC name of a directory or file can also include the directory path after the share name, by using the following syntax: \\%SERVERNAME%\%SHARENAME\%DIRECTORY%\%FILENAME%.

**universal serial bus (USB)**
An external bus that supports Plug and Play installation. Using USB, you can connect and disconnect devices without shutting

down or restarting your computer. You can use a single USB port to connect up to 127 peripheral devices, including speakers, telephones, CD-ROM drives, joysticks, tape drives, keyboards, scanners, and cameras. A USB port is usually located on the back of your computer near the serial port or parallel port.

See also: bus  Plug and Play  port

**UNIX file permissions**
A set of permissions that describes the access rights to a UNIX file or directory for the file owner, the group owner, and other users. Every UNIX file and directory possesses a set of permissions, and each user can have any combination of read, write, or execute access.

**unsigned driver**
A driver that is not supported and that is not certified to work with a particular version of Windows.

See also: signed driver  Windows Logo Program

**unspecified bit rate (UBR)**
An asynchronous transfer mode (ATM) service type that does not include any service guarantees.

See also: asynchronous transfer mode (ATM)

**upcasing**
The method of case-insensitive handling for network basic input/output system (NetBIOS) names. Upcasing is used by Windows to convert any lowercase letters entered in NetBIOS names to equivalent uppercase letters. For example, the name host1 is case-converted to HOST1.

See also: downcasing  network basic input/output system (NetBIOS)

**upgrade**
When referring to software, to update existing program files, folders, and registry entries to a more recent version. Upgrading, unlike performing a new installation, leaves existing settings and files in place.

See also: install  registry

**UPN**
See other term: user principal name (UPN)

**UPS**
See other term: uninterruptible power supply (UPS)

**UPS service**
A service that manages an uninterruptible power supply (UPS) connected to a computer.

See also: service  uninterruptible power supply (UPS)

**USB**
See other term: universal serial bus (USB)

**user account**
In Active Directory, an object that consists of all the information that defines a domain user, which includes user name, password, and groups in which the user account has membership. User accounts can be stored in either Active Directory or on your local computer. For computers running Windows XP Professional and member servers running Windows Server 2003, use Local Users and Groups to manage local user accounts. For domain controllers running Windows Server 2003, use Active Directory Users and Computers to manage domain user accounts.

See also: Active Directory  group  member server  object  password  user name

**user authentication module (UAM)**
A software component that prompts clients for their user names and passwords.

See also: password  user name

**user class**
An administrative feature that allows DHCP clients to be grouped logically according to a shared or common need. For example, a user class can be defined and used to allow similar DHCP leased configuration for all client computers in a specific building or site location.

See also: DHCP client  Dynamic Host Configuration Protocol (DHCP)  lease

**User Datagram Protocol (UDP)**
A transport layer protocol that offers a connectionless datagram service that guarantees neither delivery nor correct sequencing of delivered packets (much like Internet Protocol (IP)), but provides a payload checksum and upper layer protocol identification that uses source and destination ports.

See also: datagram  Internet Protocol (IP)  packet  service  Transmission Control Protocol/Internet Protocol (TCP/IP)

**user identifier (UID)**
An identifier assigned to a user within UNIX. A user can only have one UID.

**user mode**
The processing mode in which applications run.

**user name**
A unique name identifying a user account to Windows. An account's user name must be unique among the other group names and user names within its own domain or workgroup.

See also: domain  user account  workgroup

**USER object**
An object from Window Manager, which includes windows, menus, cursors, icons, hooks, accelerators, monitors, keyboard layouts, and other internal objects. In Task Manager, the number of USER objects currently being used by a process.

See also: Task Manager

**user password**
The password stored in each user's account. Each user generally has a unique user password and must type that password when logging on or accessing a server.

See also: password  user account

**user principal name (UPN)**
A user account name (sometimes referred to as the user logon name) and a domain name identifying the domain in which the user account is located. This is the standard usage for logging on to a Windows domain. The format is as follows: someone@example.com (as for an e-mail address).

See also: domain  domain name  user principal name (UPN) suffix

**user principal name (UPN) suffix**
The part of the user principal name (UPN) to the right of the @ character. The default UPN suffix for a user account is the DNS domain name of the domain that contains the user account. Alternative UPN suffixes may be added to simplify administration and user logon processes by providing a single UPN suffix for all users. The UPN suffix is only used within the Active Directory forest, and it is not required to be a valid DNS domain name.

See also: Active Directory  domain  domain name  Domain Name System (DNS)  forest  user account  user principal name (UPN)

**user profile**
A file that contains configuration information for a specific user, such as desktop settings, persistent network connections, and application settings. Each user's preferences are saved to a user profile that Windows uses to configure the desktop each time that a user logs on.

See also: desktop

**user rights**
Tasks that a user is permitted to perform on a computer system or domain. There are two types of user rights: privileges and logon rights. An example of a privilege is the right to shut down the system. An example of a logon right is the right to log on to a computer locally. Both types are assigned by administrators to individual users or groups as part of the security settings for the computer.

See also: domain  group  logon rights  privilege

**user rights policy**
Security settings that manage the assignment of rights to groups and user accounts.

See also: group  user account  user rights

**user-to-network interface (UNI)**
The interface between asynchronous transfer mode (ATM) users or end stations and an ATM switch or network. The UNI is defined in the ATM Forum UNI documents.

See also: asynchronous transfer mode (ATM)

**UTF-8**
See other term: UCS Transformation Format 8 (UTF-8)

# Windows Server 2003 Glossary - V

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - V**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**V.34**
A data transmission standard that provides for up to 33,600 bits per second (bps) communications over telephone lines. It defines a full-duplex (two-way) modulation technique and includes error-correcting and negotiation.

See also: bits per second (bps) full-duplex modulation standards V.90

**V.90**
A data transmission standard that provides for up to 56,000 bits per second (bps) communications over telephone lines. The transmission speed from the client-side modem is 33,600 bps, the same as for V.34. The transmission speed from the host-side modem, such as an Internet service provider (ISP) or corporate network, is up to 56,000 bps, with an average speed of 40,000 to 50,000 bps. When the host-side modem does not support this standard, the alternative is V.34.

See also: bits per second (bps) client host Internet service provider (ISP) modem (modulator/demodulator) modulation standards V.34

**validation**
The process of comparing files on local volumes with their associated data in secondary storage by Remote Storage. Volumes that are validated ensure that the correct data is recalled from remote storage when a user attempts to open the file from a local volume.

See also: Remote Storage volume

**variable**
In programming, a named storage location capable of containing a certain type of data that can be modified during program execution. System environment variables are defined by the operating systems in the Windows Server 2003 family, and they are the same no matter who is logged on to the computer. Administrator group members can add new variables or change the values, however. User environment variables can be different for each user of a particular computer. They include any environment variables you want to define or variables defined by your applications, such as the path where application files are located.

See also: environment variable

**variable bit rate (VBR)**
An asynchronous transfer mode (ATM) service type that guarantees service based on average and peak traffic rates. VBR is used for traffic that requires little or no cell loss. It transmits data in spurts, or bursts, rather than in a continuous stream.

See also: asynchronous transfer mode (ATM) service

**VBR**
See other term: variable bit rate (VBR)

**VCI**
See other term: virtual channel identifier (VCI)

**VDM**
See other term: virtual DOS machine (VDM)

**VDS**
See other term: Virtual Disk Service (VDS)

**vector**
For Indexing Service, an ordered series of words or numbers used in a query. For example, a single document can have (Scott Cooper; Don Hall; Amy Egert) as a vector of coauthors.

See also: Indexing Service  query

**vector font**
A font rendered from a mathematical model, in which each character is defined as a set of lines drawn between points. Vector fonts can be cleanly scaled to any size or aspect ratio.

See also: font  plotter font

**vendor class**
An administrative feature that allows DHCP clients to be identified and leased according to their vendor and hardware configuration type. For example, assigning a vendor class of HP to a printer vendor such as Hewlett-Packard would allow all Hewlett-Packard printers to be managed as a single unit so they could all obtain a similar DHCP leased configuration.

See also: DHCP client  Dynamic Host Configuration Protocol (DHCP)  lease

**video adapter**
An expansion board that plugs into a personal computer to give it display capabilities. A computer`s display capabilities depend on both the logical circuitry (provided in the video adapter) and the monitor. Each adapter offers several different video modes. The two basic categories of video modes are text and graphics. Within the text and graphics modes, some monitors also offer a choice of resolutions. At lower resolutions a monitor can display more colors. Modern adapters contain memory, so that the computer`s random access memory (RAM) is not used for storing displays. In addition, most adapters have their own graphics coprocessor for performing graphics calculations. These adapters are often called graphics accelerators.

See also: graphics mode

**virtual address**
In a virtual memory system, the address the application uses to reference memory. The kernel and the memory management unit (MMU) translate this address into a physical address before the memory is actually read or written.

See also: virtual memory

**virtual channel identifier (VCI)**
A section of the asynchronous transfer mode (ATM) cell header that contains the virtual channel address over which the cell is to be routed.

See also: asynchronous transfer mode (ATM)

**virtual cluster**
A Network Load Balancing cluster that you create by assigning specific port rules to specific virtual IP addresses. With virtual clusters, you can use different port rules for different Web sites or applications hosted on the cluster, provided each Web site or application has a different virtual IP address.

See also: Network Load Balancing  Network Load Balancing cluster  port rule  virtual IP address

**virtual container**
A container that allows any Lightweight Directory Access Protocol (LDAP)-compliant directory to be accessed through Active Directory.

See also: Active Directory  directory  Lightweight Directory Access Protocol (LDAP)

**Virtual Disk Service (VDS)**
A set of application programming interfaces (APIs) that provides a single interface for managing disks. VDS uses two sets of providers to manage storage devices. The built-in VDS software providers enable the management of disks and volumes at the operating system level. The VDS hardware providers enable the management of disk storage subsystems and are supplied by the hardware vendor.

**virtual DOS machine (VDM)**
A protected environment subsystem that emulates MS-DOS and 16-bit Windows within 32-bit versions of the Windows Server 2003 family. A VDM is created whenever a user starts an MS-DOS program in 32-bit versions of the Windows Server 2003 family. Note that 64-bit versions of the Windows Server 2003 family cannot run MS-DOS and 16-bit Windows programs.

See also: MS-DOS (Microsoft Disk Operating System)

**virtual IP address**
An IP address that is shared among the hosts of a Network Load Balancing cluster. A Network Load Balancing cluster might

also use multiple virtual IP addresses, for example, in a cluster of multihomed Web servers.

See also: host  IP address  multihomed computer  Network Load Balancing cluster

**virtual link**
A logical link between a backbone area border router and an area border router that is not connected to the backbone.

See also: area border router (ABR)  backbone router

**virtual local area network (VLAN)**
A logical grouping of hosts on one or more local area networks (LANs) that allows communication to occur between hosts as if they were on the same physical LAN.

See also: host  local area network (LAN)

**virtual memory**
Temporary storage used by a computer to run programs that need more memory than it has. For example, programs could have access to 4 gigabytes (GB) of virtual memory on a computer`s hard drive, even if the computer has only 32 megabytes (MB) of random access memory (RAM). The program data that does not currently fit in the computer`s memory is saved into paging files.

See also: paging file  random access memory (RAM)  Virtual Memory Size  virtual printer memory

**Virtual Memory Size**
In Task Manager, the amount of virtual memory, or address space, committed to a process.

See also: Task Manager  virtual memory

**virtual network**
A logical network that exists inside Novell NetWare and NetWare-compatible servers and routers but that is not associated with a physical adapter. The virtual network appears to a user as a separate network. On a computer running Windows 2000 Server or on an operating system in the Windows Server 2003 family, programs advertise their location on a virtual network, not a physical network. The internal network number identifies a virtual network inside a computer.

See also: external network number  internal network number

**virtual path identifier (VPI)**
A section of the asynchronous transfer mode (ATM) cell header that contains the virtual path address over which the cell is to be routed.

See also: asynchronous transfer mode (ATM)

**virtual printer memory**
In a PostScript printer, a part of memory that stores font information. The memory in PostScript printers is divided into two areas: banded memory and virtual memory. The banded memory contains graphics and page-layout information needed to print your documents. The virtual memory contains any font information that is sent to your printer either when you print a document or when you download fonts.

See also: PostScript printer  virtual memory

**virtual private network (VPN)**
The extension of a private network that encompasses encapsulated, encrypted, and authenticated links across shared or public networks. VPN connections typically provide remote access and router-to-router connections to private networks over the Internet.

See also: authentication  encryption  remote access  routing  tunnel

**virtual server**
In a server cluster, a collection of services that appear to clients as a physical Windows-based server but are not associated with a specific server. A virtual server is typically a resource group that contains all of the resources needed to run a particular application and that can be failed over like any other resource group. All virtual servers must include a Network Name resource and an IP Address resource.

See also: failover  IP Address resource  Network Name resource  resource  server cluster

**virus**

A malicious computer program designed specifically to replicate itself and spread from computer to computer. A virus may damage hardware, software, or data.

See also: Trojan horse

**VLAN**
See other term: virtual local area network (VLAN)

**VoIP (Voice over Internet Protocol)**
A method for sending voice over a local area network (LAN), a wide area network (WAN), or the Internet using TCP/IP packets.

See also: local area network (LAN)  Transmission Control Protocol/Internet Protocol (TCP/IP)  wide area network (WAN)

**volume**
An area of storage on a hard disk. A volume is formatted by using a file system, such as file allocation table (FAT) or NTFS, and has a drive letter assigned to it. You can view the contents of a volume by clicking its icon in Windows Explorer or in My Computer. A single hard disk can have multiple volumes, and volumes can also span multiple disks.

See also: disk  drive letter  file allocation table (FAT)  NTFS file system  simple volume  spanned volume

**volume password**
An optional, case-sensitive password you can assign to a Macintosh-accessible volume when you configure the volume. To access the volume, a user must type the volume password.

See also: password  volume

**volume set**
A volume that consists of disk space on one or more physical disks. A volume set is created by using basic disks and is supported only in Windows NT 4.0 or earlier. Volume sets were replaced by spanned volumes, which use dynamic disks.

See also: basic disk  dynamic disk  partition  spanned volume  volume

**volume shadow copy**
A volume that represents a duplicate of the original volume taken at the time the copy began.

See also: crash consistency  differential data  volume

**voluntary tunnel**
A tunnel that is initiated by the client. A voluntary tunnel tunnels Point-to-Point Protocol (PPP) over Internet Protocol (IP) from the client to the tunnel server, and then the data is forwarded to the target host by the tunnel server.

See also: client  host  Internet Protocol (IP)  Point-to-Point Protocol (PPP)  tunnel  tunnel server

**VPI**
See other term: virtual path identifier (VPI)

**VPN**
See other term: virtual private network (VPN)

**VPN server**
A computer that accepts virtual private network (VPN) connections from VPN clients. A VPN server can provide a remote access VPN connection or a router-to-router VPN connection.

See also: client  router  server  virtual private network (VPN)

# Windows Server 2003 Glossary - W

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - W**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**Waiting for Call**
A telephony signal that Network Connections has put the modem in Listen mode and is waiting for incoming calls.

See also: modem (modulator/demodulator)  Network Connections

**wake-on-LAN**
A power management feature that allows a device to bring the operating system out of standby or sleep mode if there is network activity.

See also: sleep mode

**WAN**
See other term: wide area network (WAN)

**warning level**
The point at which users are nearing their quota limit.

See also: quota limit

**weak password**
A password that does not provide an effective defense against unauthorized access to a resource. A weak password can be less than six characters long, contain all or part of a users account name, or contain less than three of the four following categories of characters: uppercase characters, lowercase characters, base 10 digits, and symbols found on the keyboard (such as !, @, #).

See also: password  password policy  strong password

**Web Distributed Authoring and Versioning (WebDAV)**
An application protocol related to Hypertext Transfer Protocol (HTTP) 1.1 that allows clients to transparently publish and manage resources on the World Wide Web.

See also: Hypertext Transfer Protocol (HTTP)  protocol

**Web server**
A computer that is maintained by a system administrator or Internet service provider (ISP) and that responds to requests from a user's browser.

See also: Internet service provider (ISP)

**Web Services (WS-*)**
The specifications for a Web Services Architecture that is based on industry standards such as Simple Object Access Protocol (SOAP); XML; Web Service Description Language (WSDL); and Universal Description, Discovery, and Integration (UDDI). WS-* provides a foundation for delivering complete, interoperable business solutions for the extended enterprise, including the ability to manage federated identity and security.

**Web Services Security (WS-Security)**
A series of specifications that describe how to attach signature and encryption headers to Simple Object Access Protocol (SOAP) messages. In addition, WS-Security describes how to attach security tokens, including binary security tokens such as X.509 certificates and Kerberos tickets, to messages. In Active Directory Federation Services (ADFS), WS-Security is used when Kerberos signs security tokens.

**WebDAV**
See other term: Web Distributed Authoring and Versioning (WebDAV)

**well-connected**

Sufficient connectivity to make your network and Active Directory useful to clients on your network. The precise meaning of well-connected is determined by your particular needs.

See also: Active Directory  client

**well-known services**
Services that are so pervasive in the computer industry that standard bindings are universally recognized. These services often maintain a machine-centric status and are frequently legacy services such as those developed for use in TCP/IP networks, for example, Telnet and File Transfer Protocol (FTP). Well-known services can published in Active Directory, but because their bindings are widely known, the information is superfluous.

See also: Active Directory  File Transfer Protocol (FTP)  machine-centric  service  Transmission Control Protocol/Internet Protocol (TCP/IP)

**wide area network (WAN)**
A network that connects geographically separated locations by using telecommunications services.

See also: device  local area network (LAN)

**wildcard character**
A keyboard character that can be used to represent one or many characters when conducting a query. The question mark (?) represents a single character, and the asterisk (*) represents one or more characters.

**wildcarding**
In DNS, the supported use of wildcard characters such as the asterisk (*) in domain names for DNS queries that resolve to multiple names. When wildcarding is used, DNS servers must support resolving name queries that use wildcard characters, and resolvers must be able to parse multiple records from any resource record sets (RRsets) issued in wildcard query responses.

See also: DNS server  domain name  Domain Name System (DNS)  resource record set (RRset)  wildcard character

**Windows Catalog**
A Web site that lists hardware and software that is designed for use with Windows XP, Windows 2000 Server products, and products in the Windows Server 2003 family. You can use this site to help you decide whether to purchase a particular device or program, to help you evaluate whether a particular computer would support an upgraded operating system, or for similar decisions about hardware and software.

See also: device  Hardware Compatibility List (HCL)

**Windows Clustering**
A feature of Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, that provides the complementary clustering technologies, Network Load Balancing clusters, and server clusters.

See also: cluster  Network Load Balancing cluster  server cluster

**Windows Hardware Quality Labs (WHQL)**
Provides compatibility testing services to test hardware and drivers for Windows operating systems.

**Windows Internet Name Service (WINS)**
A Windows name resolution service for network basic input/output system (NetBIOS) names. WINS is used by hosts running NetBIOS over TCP/IP (NetBT) to register NetBIOS names and to resolve NetBIOS names to Internet Protocol (IP) addresses.

See also: IP address  network basic input/output system (NetBIOS)  resource  service  WINS proxy  WINS resource

**Windows Logo Program**
A certification program to help customers identify systems, hardware, and software that meet a baseline definition of platform features and quality goals and ensure a good user experience of Windows.

See also: signed driver  unsigned driver

**Windows Management Instrumentation (WMI)**
A management infrastructure in Windows that supports monitoring and controlling system resources through a common set of interfaces and provides a logically organized, consistent model of Windows operation, configuration, and status.

See also: resource

**Windows Management Instrumentation filter**

A query that is based on Windows Management Instrumentation (WMI) and used to filter the effect of a Group Policy object (GPO). WMI filters are written in WMI Query Language (WQL) and are evaluated on the target computer or user. If the filter evaluates to true, then the GPO is applied. Otherwise, the GPO is not applied. WMI filters are useful for exception management.

See also: Group Policy Management console (GPMC)  Group Policy object (GPO)  Group Policy object link

**Windows Media Services**
Software that provides multimedia support, allowing you to deliver content using Advanced Streaming Format over an internet or the Internet.

See also: multimedia streaming

**Windows Open Services Architecture (WOSA)**
A common set of interfaces that connect front-end applications with back-end services.

See also: service

**Windows Support Tools**
Tools that administrators, developers, or support personnel can use to diagnose and troubleshoot operating system configuration problems. Although Windows Support Tools are included on the operating system CD, they are not guaranteed or supported by Microsoft, and they must be installed separately from the operating system.

**Windows NT token–based application**
A Windows application that relies on a Windows NT token to perform authorization of users.

**WINS**
See other term: Windows Internet Name Service (WINS)

**WINS proxy**
A computer that listens to name query broadcasts and responds for those names not on the local subnet. The proxy communicates with a WINS server to resolve names and then caches them for a specific time period.

See also: subnet  Windows Internet Name Service (WINS)

**WINS resource**
A resource type that provides Windows Internet Name Service (WINS) from a cluster.

See also: cluster  resource types  Windows Internet Name Service (WINS)

**Winsock**
Windows Sockets. An application programming interface (API) standard for software that provides a TCP/IP interface under Windows.

See also: application programming interface (API)  Transmission Control Protocol/Internet Protocol (TCP/IP)

**wireless communication**
Communication between a computer and another computer or device without wires. The form of wireless communication provided as part of the Windows operating system uses infrared (IR) light to transmit files. Radio frequencies, as used by cellular and cordless telephones, are another form of wireless communication.

See also: infrared (IR)  infrared device  infrared port

**WMI**
See other term: Windows Management Instrumentation (WMI)

**WMI filter**
See other term: Windows Management Instrumentation filter

**workgroup**
A simple grouping of computers, intended only to help users find such things as printers and shared folders within that group. Workgroups in Windows do not offer the centralized user accounts and authentication offered by domains.

See also: authentication  domain  user account

**working set**
For a process, the amount of physical memory assigned to the process by the operating system.

See also: process

**World Wide Web (WWW)**
A system for exploring the Internet by using hyperlinks. When you use a Web browser, the Web appears as a collection of text, pictures, sounds, and digital movies.

See also: Internet

**WOSA**
See other term: Windows Open Services Architecture (WOSA)

**WS-Federation**
A specification that defines a model and set of messages for brokering trust and the federation of identity and authentication information across different trust realms. The WS-Federation specification identifies two sources of identity and authentication requests across trust realms: active requestors, such as Simple Object Access Protocol (SOAP)-enabled applications, and passive requestors, which are defined as HTTP browsers capable of supporting broadly supported HTTP, for example, HTTP 1.1.

**WS-Federation Passive Requestor Profile (WS-F PRP)**
An implementation of the WS-Federation specification that proposes a standard protocol for how passive clients (such as Web browsers) apply the federation framework. Within this protocol, Web service requestors are expected to understand the new security mechanisms and be capable of interacting with Web service providers.

# Windows Server 2003 Glossary - X

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - X**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**X.500**
A set of standards defining a distributed directory service, developed by the International Standards Organization (ISO).

See also: directory service

**X.509 v3 certificate**
Version 3 of the International Telecommunication Union - Telecommunication [Standardization Sector] (ITU-T) recommendation X.509 for certificate syntax and format. This is the standard certificate format used by Windows certificate-based processes. An X.509 certificate includes the public key and information about the person or entity to whom the certificate is issued, information about the certificate, plus optional information about the certification authority (CA) issuing the certificate.

See also: certification authority (CA)  International Telecommunication Union - Telecommunication [Standardization Sector] (ITU-T)  public key

**x86**
Refers to microprocessors that have or emulate the 32-bit Intel processor architecture.

**XML**
See other term: Extensible Markup Language (XML)

**XOR (exclusive OR)**
A Boolean operation that yields true if and only if one of its operands is true and the other is false. For some server operating systems, the exclusive OR is a Boolean operation in which the RAID-5 volume form of fault tolerance maintains an XOR of the total data to provide data redundancy. This is used to reconstruct missing data on a failed disk or sector from the remaining disks in the RAID-5 volume.

See also: fault tolerance  RAID-5 volume

# Windows Server 2003 Glossary - Y

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - Y**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**ypcat**
A Windows command-line utility that prints the values of all keys from the Network Information Service (NIS) database specified by mapname, which can be a map name or a map nickname.

**ypclear**
A Windows command-line utility that tells the specified Network Information Service (NIS) server in a specified domain that a map has changed and that the server should clear its cache.

**ypmatch**
A Windows command-line utility that displays the values of one or more keys from the Network Information Service (NIS) map specified by mapname, which may be a map name or a map nickname.

**yppush**
A Windows command-line utility that sends a request to a UNIX-based subordinate (also known as slave) Network Information Service (NIS) server to transfer a new version of the NIS map specified by mapname from the master NIS server.

# Windows Server 2003 Glossary - Z

Updated: March 7, 2008

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For more Windows Server terms, see the Windows Server 2008 Glossary.

**Glossary - Z**

# A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**zone**

In the Macintosh environment, a logical grouping that simplifies browsing the network for resources, such as servers and printers. In a DNS database, a manageable unit of the DNS database that is administered by a DNS server. A zone stores the domain names and data of the domain with a corresponding name, except for domain names stored in delegated subdomains.

See also: DNS server  domain  Domain Name System (DNS)  partition  resource

**zone list**

In the Macintosh environment, a list that includes all of the zones associated with a particular network. A zone list is not to be confused with a DNS zone.

See also: DNS zone  Domain Name System (DNS)  zone

**zone transfer**

The synchronization of authoritative DNS data between DNS servers. A DNS server configured with a secondary zone periodically queries the master DNS servers to synchronize its zone data.

See also: authoritative  DNS server  primary zone  secondary zone  zone

# IIS 6.0 Glossary

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1

A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

**Symbols**

**3DES** See definition for Triple DES (3DES).

**A**

**abstract classes** Templates used only to derive new Structural classes. Abstract classes cannot be instantiated in the directory.

**access control** A security mechanism that determines which operations a user, group, service, or computer is authorized to perform on a computer or on a particular object, such as a file, printer, registry subkey, or directory service object. See also group; object; permission; registry.

**access control list (ACL)** A list of security protections that apply to an entire object, a set of the objects properties, or an individual property of an object. There are two types of access control lists: discretionary and system. See also object.

**Active Directory** The Windows-based directory service. Active Directory stores information about objects on a network and makes this information available to users and network administrators. Active Directory gives network users access to permitted resources anywhere on the network using a single logon process. It provides network administrators with an intuitive, hierarchical view of the network and a single point of administration for all network objects. See also directory partition; directory service; domain; forest; object.

**Active Directory Service Interfaces (ADSI)** A directory service model and a set of Component Object Model (COM) interfaces. ADSI enables Windows applications and Active Directory clients to access several network directory services, including Active Directory. ADSI is supplied as a software development kit (SDK). See also Active Directory; Component Object Model (COM); directory service.

**ActiveX** A set of technologies that allows software components to interact with one another in a networked environment, regardless of the language in which the components were created.

**Address Resolution Protocol (ARP)** In TCP/IP, a protocol that uses broadcast traffic on the local network to resolve a logically assigned Internet Protocol version 4 (IPv4) address to its physical hardware or media access control (MAC) layer address. In asynchronous transfer mode (ATM), ARP is used two different ways. For classical IPv4 over ATM (CLIP), ARP is used to resolve addresses to ATM hardware addresses. For ATM LAN emulation (LANE), ARP is used to resolve Ethernet/802.3 or Token Ring addresses to ATM hardware addresses. See also asynchronous transfer mode (ATM); Internet Protocol (IP); IP address; packet; Transmission Control Protocol/Internet Protocol (TCP/IP).

**administrative credentials** Logon information that is used to identify a member of an administrative group. Groups that use administrative credentials include Administrators, Domain Admins, and DNS Admins. Most system-wide or domain-wide tasks require administrative credentials. See also Administrators group; group.

**Administrators group** On a local computer, a group whose members have the highest level of administrative access to the local computer. Examples of administrative tasks that can be performed by members of this group include installing programs; accessing all files on the computer; auditing access control; and creating, modifying, and deleting local user accounts. In an Active Directory domain, a group whose members have the highest level of administrative access in the domain. Examples of administrative tasks that can be performed by members of this group include setting domain policy; assigning and resetting domain user account passwords; setting up and managing domain controllers; and creating, modifying, and deleting domain user accounts. See also access control; Active Directory; auditing; domain; domain controller; group; object.

**ADSI** See definition for Active Directory Service Interfaces (ADSI).

**ADSI provider** COM objects that implement ADSI for a particular namespace (for example, an LDAP namespace such as Active Directory).

**agent** An application that runs on a Simple Network Management Protocol (SNMP) managed device. The agent application is the object of management activities. A computer running SNMP agent software is also sometimes referred to as an agent.

**aggregation** A composition technique for implementing component objects in which a new object can be built by using one or more existing objects that support some or all of the new objects required interfaces.

**American Standard Code for Information Interchange (ASCII)** A standard single-byte character encoding scheme used

for text-based data. ASCII uses designated 7-bit or 8-bit number combinations to represent either 128 or 256 possible characters. Standard ASCII uses 7 bits to represent all uppercase and lowercase letters, the numbers 0 through 9, punctuation marks, and special control characters used in U.S. English. Most current x86-based systems support the use of extended (or high) ASCII. Extended ASCII allows the eighth bit of each character to identify an additional 128 special symbol characters, foreign-language letters, and graphic symbols.

**Anonymous access** An authentication mechanism by which users who are able to connect to an Internet site without credentials are assigned to the IUSR_*ComputerName* account and granted the access rights that are assigned to that account. See also access control; Anonymous authentication; authentication.

**Anonymous authentication** An authentication mechanism that does not require user accounts and passwords. Anonymous authentication grants remote users the identity IUSR_*ComputerName*. Anonymous authentication is used on the Internet to grant visitors restricted access to predefined public resources. See also Anonymous access; authentication.

**Anonymous FTP authentication** A protocol that makes it possible for a user to retrieve documents, files, programs, and other archived data from anywhere on the Internet without having to establish a logon name and password.

**apartment-threaded** A threading model in which each method of a component will execute on a thread that is associated with that component. See also multithreaded apartment (MTA); single-threaded apartment (STA).

**API** See definition for application programming interface (API).

**application** A computer program, such as a word processor or electronic spreadsheet, or a group of Active Server Pages (ASP) scripts and components that perform such tasks.

**application isolation** The separation of applications by process boundaries that prevent the applications from affecting one another. Application isolation is configured differently for each of the two Internet Information Services (IIS) isolation modes. See also IIS 5.0 isolation mode; worker process isolation mode.

**application pool** A grouping of one or more URLs served by a worker process.

**application programming interface (API)** A set of routines that an application uses to request and carry out lower-level services performed by a computers operating system. These routines usually carry out maintenance tasks such as managing files and displaying information.

**application root** The root directory for an application. All directories and files contained within the application root are considered part of the application. Also called an application starting-point directory.

**application scope** A way of making data available to all users of an application from all pages of a Web application. A variable or an object instance is given application scope by being stored in the Active Server Pages (ASP) application object. Application scope is useful for global data, such as a global counter.

**argument** A constant, variable, or expression that is passed to a procedure.

**array** A list of data values—all of the same type—any element of which can be referenced by an expression that consists of the array name followed by an indexing expression. Arrays are part of the fundamentals of data structures, which, in turn, are a major fundamental of computer programming.

**ASCII (American Standard Code for Information Interchange)** See definition for American Standard Code for Information Interchange (ASCII).

**ASP buffering** Functionality of Active Server Pages (ASP) that temporarily stores all output that is generated by a script until script execution is complete and then sends the output to a client.

**association** In file name extension mapping, the linking of a file extension, such as .asp, to an application, such as asp.dll. In Windows Management Instrumentation (WMI), an association class represents a relationship between two specific WMI classes. The properties of an association class include pointers, or references, to the two classes or instances.

**asymmetric key algorithm** See definition for public-key algorithm.

**asynchronous transfer mode (ATM**) A high-speed, connection-oriented, virtual circuit-based packet switching protocol used to transport many different types of network traffic. ATM packages data in 53-byte, fixed-length cells that can be switched quickly between logical connections on a network. See also protocol.

**ATM** See definition for asynchronous transfer mode (ATM).

**attribute** For files, information that indicates whether a file is read-only, hidden, ready for archiving (backing up), compressed, or encrypted, and whether the file contents should be indexed for fast file searching. In Active Directory, a

property of an object. For each object class, the schema defines which attributes an instance of the class must have and which additional attributes it might have. See also Active Directory; class; object.

**auditing** The process that tracks the activities of users by recording selected types of events in the security log of a server or a workstation.

**authentication** The process for verifying that an entity or object is who or what it claims to be. Examples include confirming the source and integrity of information, such as verifying a digital signature or verifying the identity of a user or computer. See also cryptography; Kerberos V5 authentication protocol.

**authorization** The process that determines what a user is permitted to do on a computer system or network. See also authentication.

**Automation** A Component Object Model (COM) based technology that allows for interoperability among ActiveX components, including OLE components. Formerly referred to as *OLE Automation*.

**availability** A level of service provided by applications, services, or systems. Highly available systems have minimal downtime, whether planned or unplanned. Availability is often expressed as the percentage of time that a service or system is available, for example, 99.9 percent for a service that is down for 8.75 hours a year.

**B**

**bandwidth** The data transfer capacity of a transmission medium. In digital communications, the transfer capacity expressed in bits per second (bps) or megabits per second (Mbps). For example, Ethernet accommodates a bandwidth of 10,000,000 bps or 10 Mbps. In analog communications, the difference between the highest and lowest frequencies in a specific range. For example, an analog telephone line accommodates a bandwidth of 3,000 hertz (Hz), the difference between the lowest (300 Hz) and highest (3,300 Hz) frequencies that it can carry. See also bits per second (bps).

**bandwidth throttling** Setting the maximum portion of total network capacity that a service is allowed to use. An administrator can deliberately limit a servers Internet workload by not allowing it to receive requests at full capacity, thus saving resources for other programs, such as e-mail.

**baseline** A range of measurements derived from performance monitoring that represents acceptable performance under typical operating conditions.

**Basic authentication** An authentication mechanism that is supported by most browsers, including Internet Explorer. Basic authentication encodes user name and password data before transmitting it over the network. Note that *encoding* is not the same as *encryption*. Also known as *plaintext authentication*. See also Anonymous authentication; authentication; Digest authentication; encryption.

**baud rate** The speed at which a modem communicates. Baud rate refers to the number of times the condition of the line changes. This is equal to bits per second only if each signal corresponds to one bit of transmitted data. Modems must operate at the same baud rate in order to communicate with each other. If the baud rate of one modem is set higher than that of the other, the faster modem usually alters its baud rate to match that of the slower modem. See also bits per second (bps); modem (modulator/demodulator).

**Berkeley Internet Name Domain (BIND)** An implementation of Domain Name System (DNS) written and ported to most available versions of the UNIX operating system. The Internet Software Consortium maintains the BIND software. See also Domain Name System (DNS).

**binary** A base-2 number system in which values are expressed as combinations of two digits, 0 and 1.

**BIND** See definition for Berkeley Internet Name Domain (BIND).

**binding** A process by which software components and layers are linked together. When a network component is installed, the binding relationships and dependencies for the components are established. Binding allows components to communicate with each other.

**bitmask** A value that is used with bit-wise operators (And, Eqv, Imp, Not, Or, Xor) to test the state of individual bits in a particular bit-field value. See also bitmask identifier.

**bitmask identifier** For the metabase, a name assigned to a bitmask to help identify its purpose. For example, In IIS 6.0, bitmask 512 is assigned the identifier MD_ACCESS_SCRIPT. See also bitmask.

**bits per second (bps)** The number of bits transmitted every second, used as a measure of the speed at which a device, such as a modem, can transfer data. See also modem (modulator/demodulator).

**Boolean data type** A data type with only two passable values, True (-1) or False (0). Boolean variables are stored as 16-bit

(2-byte) numbers.

**both-threaded** A threading model in which the object has the characteristics of an apartment-threaded object as well as a free-threaded object. See also apartment-threaded.

**bps** See definition for bits per second (bps).

**browser** Software that interprets the markup of files in HTML, formats them into Web pages, and displays them to the end user. Some browsers also permit end users to send and receive e-mail, read newsgroups, and play sound or video files embedded in Web documents.

**built-in groups** The default security groups installed with the operating system. Built-in groups have been granted useful collections of rights and built-in abilities. In most cases, built-in groups provide all the capabilities needed by a particular user. For example, members of the built-in Backup Operators group can back up and restore files and folders. To provide a needed set of capabilities to a user account, assign it to the appropriate built-in group. See also group.

**bulk encryption** A process in which large amounts of data, such as files, e-mail messages, or online communications sessions, are encrypted for confidentiality. It is usually done with a symmetric key algorithm. See also encryption.

**C**

**CA** See definition for certification authority (CA).

**cache** A special memory subsystem in which frequently used data values are duplicated for quick access.

**call** To transfer program execution to some section of code (usually a subroutine) while saving the necessary information to allow execution to resume at the calling point when the called section has completed execution. When a subroutine call occurs, one or more values (known as arguments or parameters) are often passed to the subroutine, which can then use and sometimes modify these values.

**callback function** A function provided by Internet Information Services (IIS) that allows an Internet Server API (ISAPI) extension or filter to access IIS services.

**certificate** A digital document that is commonly used for authentication and to secure information on open networks. A certificate securely binds a public key to the entity that holds the corresponding private key. Certificates are digitally signed by the issuing certification authority (CA), and they can be issued for a user, a computer, or a service. See also certification authority (CA); private key; public key.

**certificate revocation list (CRL)** A document maintained and published by a certification authority that lists certificates that have been revoked. See also certificate; certification authority (CA).

**certificate trust list (CTL)** A signed list of root certification authority certificates that an administrator considers reputable for designated purposes, such as client authentication or secure e-mail. See also certificate; certification authority (CA).

**certificate, client** See definition for client certificate.

**certification authority (CA)** An entity responsible for establishing and vouching for the authenticity of public keys belonging to subjects (usually users or computers) or other certification authorities. Activities of a certification authority can include binding public keys to distinguished names through signed certificates, managing certificate serial numbers, and certificate revocation. See also certificate; public key.

**CGI** See definition for common gateway interface (CGI).

**class** A category of objects that share a common set of characteristics. Each object in the directory is an instance of one or more classes in the schema. See also object.

**client** Any computer or program connecting to, or requesting the services of, another computer or program. Client can also refer to the software that enables the computer or program to establish the connection. For a local area network (LAN) or the Internet, a computer that uses shared network resources provided by another computer (called a *server*).See also server.

**client certificate** A digital certificate that functions in a manner that is similar to a driver's license or passport. Client certificates can contain detailed identification information about the user and organization that issued the certificate.

**client tier** In the three-tier Web application model, the application or process that requests services from the middle tier, which typically includes a Web server and business processes. See also data source tier; middle tier.

**client/server architecture** A model of computing in which client applications running on a desktop or personal computer access information on remote servers or host computers. The client portion of the application is typically optimized for user

interaction, whereas the server portion provides centralized, multi-user functionality.

**cluster** In data storage, the smallest amount of disk space that can be allocated to hold a file. All file systems used by Windows organize hard disks based on clusters, which consist of one or more contiguous sectors. The smaller the cluster size, the more efficiently a disk stores information. If no cluster size is specified during formatting, Windows picks defaults based on the size of the volume. These defaults are selected to reduce the amount of space that is lost and the amount of fragmentation on the volume. Also called an *allocation unit*. In computer networking, a group of independent computers that work together to provide a common set of services and present a single-system image to clients. The use of a cluster enhances the availability of the services and the scalability and manageability of the operating system that provides the services. See also availability; client; scalability.

**code page** A means of providing support for character sets and keyboard layouts for different countries or regions. A code page is a table that relates the binary character codes used by a program to keys on the keyboard or to characters on the display.

**COM** See definition for Component Object Model (COM).

**COM+** An extension of the COM (Component Object Model) programming architecture that includes a runtime or execution environment and extensible services, including transaction services, security, load balancing, and automatic memory management. See also Component Object Model (COM).

**common gateway interface (CGI)** A server-side interface for initiating software services. For example a set of interfaces that describe how a Web server communicates with software on the same computer. Any software can be a CGI program if it handles input and output according to the CGI standard.

**Component Object Model (COM)** An object-based programming model designed to promote software interoperability; it allows two or more applications or components to easily cooperate with one another, even if they were written by different vendors, at different times, in different programming languages, or if they are running on different computers running different operating systems. OLE technology and ActiveX are both built on top of COM. See also ActiveX.

**concrete class** In Windows Management Instrumentation (WMI), a class from which you can create an instance because it has a full implementation.

**concurrency** The appearance of simultaneous execution of processes or transactions by interleaving the execution of multiple pieces of work.

**connected user** A user who has access to a computer or a resource across the network.

**console tree** The left pane in Microsoft Management Console (MMC) that displays the items contained in the console. The items in the console tree and their hierarchical organization determine the capabilities of a console. See also details pane.

**cookie** A block of data that a Web server stores on a client system. When a user returns to the same Web site, the browser sends a copy of the cookie back to the server. Cookies identify users, instruct the server to send a customized version of the requested Web page, and submit account information for the user.

**credentials** A set of information that includes identification and proof of identification that is used to gain access to local and network resources. Examples of credentials are user names and passwords, smart cards, and certificates. See also certificate.

**CRL** See definition for certificate revocation list (CRL).

**CryptoAPI** An application programming interface (API) that is provided as part of Microsoft Windows. CryptoAPI provides a set of functions that allows applications to encrypt or digitally sign data in a flexible manner while providing protection for the user's sensitive private key data. Actual cryptographic operations are performed by independent modules known as *cryptographic service providers (CSPs)*. See also application programming interface (API); cryptographic service provider (CSP); private key.

**cryptographic service provider (CSP)** The code that performs authentication, encoding, and encryption services that Windows-based applications access through CryptoAPI. A CSP is responsible for creating keys, destroying them, and using them to perform a variety of cryptographic operations. Each CSP provides a different implementation of the CryptoAPI. Some provide stronger cryptographic algorithms, while others use hardware components, such as smart cards. See also authentication; CryptoAPI; encryption.

**cryptography** The processes, art, and science of keeping messages and data secure. Cryptography is used to enable and ensure confidentiality, data integrity, authentication (entity and data origin), and nonrepudiation. See also authentication.

**CSP** See definition for cryptographic service provider (CSP).

**CTL** See definition for certificate trust list (CTL).

**custom property** A metabase property that is not predefined in the metabase schema (MBSchema.xml) and is created programmatically to meet a specific need. See also schema.

**cycle** In logging, to close an existing log file and start a new one.

**D**

**daemon** A networking program, usually associated with UNIX systems, that runs in the background performing tool functions such as housekeeping or maintenance without user intervention or awareness. Pronounced demon.

**Data Encryption Standard (DES)** An encryption algorithm that uses a 56-bit key and maps a 64-bit input block to a 64-bit output block. The key appears to be a 64-bit key, but one bit in each of the eight bytes is used for odd parity, resulting in 56 bits of usable key. See also key.

**data source tier** A logical layer that represents a computer running a Database Management System (DBMS), such as a SQL Server database. See also client tier; middle tier.

**datagram** One packet, or unit, of information that includes relevant delivery information, such as the destination address, that is sent through a packet-switching network. See also packet.

**DCOM** See definition for Distributed Component Object Model (DCOM).

**deadlock** A situation in which a thread will not relinquish its exclusive access to a critical section.

**debugger** A program designed to aid in detecting, locating, and correcting errors in another program by allowing the programmer to step through the program, examine the data, and monitor conditions such as the values of variables.

**decryption** The process of making encrypted data readable again by converting ciphertext to plaintext. See also encryption; plaintext.

**default document** The file that is sent by a Web server when it receives a request for a Uniform Resource Locator (URL) that does not specify a file name. This document can be generated automatically by the server, or it can be a custom file that is placed in that directory by the administrator. Sometimes called a default home page.

**default gateway** A configuration item for the TCP/IP protocol that is the IP address of a directly reachable IP router. Configuring a default gateway creates a default route in the IP routing table. See also Internet Protocol (IP); IP address; Transmission Control Protocol/Internet Protocol (TCP/IP).

**DES** See definition for Data Encryption Standard (DES).

**details pane** The right pane in Microsoft Management Console (MMC) that displays details for the selected item in the console tree. The details can be a list of items or they can be administrative properties, services, and events that are acted on by a snap-in. See also console tree; snap-in.

**DHCP** See definition for Dynamic Host Configuration Protocol (DHCP).

**dial-up connection** The connection to your network if you use a device that uses the telephone network. This includes modems with a standard telephone line, ISDN cards with high-speed ISDN lines, or X.25 networks. If you are a typical user, you might have one or two dial-up connections, for example, to the Internet and to your corporate network. In a more complex server situation, multiple network modem connections might be used to implement advanced routing. See also Integrated Services Digital Network (ISDN); modem (modulator/demodulator).

**dial-up networking (DUN)** Connecting to a remote network or the Internet through a dial-up connection, such as a modem.

**Digest authentication** An authentication mechanism that hashes user name, password, and other data before transmitting it over the network. See also authentication; Basic authentication; encryption; hash.

**digital certificate** An electronic certification issued by certification authorities that shows where a program comes from and proves that the installation package has not been altered. Administrators should sign their code with a digital certificate if planning to distribute an Internet Explorer package over the Internet. See also certification authority (CA).

**digital signature** The part of a digital certificate that contains an encryption key that uniquely identifies the holder of the certificate. See also certificate; client; key pair.

**directory** An information source that contains information about users, computer files, or other objects. In a file system, a directory stores information about files. In a distributed computing environment (such as a Windows domain), the directory stores information about objects such as printers, fax servers, applications, databases, and other users. See also domain; object.

**directory browsing** A feature that automatically provides a default Web page of available directories and files to browsers that submit a Uniform Resource Locator (URL) that does not specify a particular file.

**directory partition** A contiguous subtree of Active Directory that is replicated as a unit to other domain controllers in the forest that contain a replica of the same subtree. In Active Directory, a single domain controller always holds at least three directory partitions: schema (class and attribute definitions for the directory), configuration (replication topology and related metadata), and domain (subtree that contains the per-domain objects for one domain). Domain controllers running Windows Server 2003 can also store one or more application directory partitions. See also Active Directory; attribute; domain.

**directory replication** The copying of a master set of directories from a server (called an export server) to specified servers or workstations (called import computers) in the same or other domains. Replication simplifies the task of maintaining identical sets of directories and files on multiple computers because only a single master copy of the data must be maintained. Files are replicated when they are added to an exported directory and every time a change is saved to the file.

**directory service** Both the directory information source and the service that makes the information available and usable. A directory service enables the user to find an object when given any one of its attributes. See also Active Directory; attribute; directory; object.

**Distributed Component Object Model (DCOM)** The Microsoft Component Object Model (COM) specification that defines how components communicate over Windows-based networks. Use the DCOM Configuration tool to integrate client/server applications across multiple computers. DCOM can also be used to integrate robust Web browser applications. See also Component Object Model (COM).

**distributed processing** A computing environment that contains a client and a server. This structure allows the workload to be divided into parts yet appear as a single process.

**DLL** See definition for dynamic-link library (DLL).

**DNS** See definition for Domain Name System (DNS).

**domain** In Active Directory, a collection of computer, user, and group objects defined by the administrator. These objects share a common directory database, security policies, and security relationships with other domains. In DNS, any tree or subtree within the DNS namespace. Although the names for DNS domains often correspond to Active Directory domains, DNS domains should not be confused with Active Directory domains. See also Active Directory; Domain Name System (DNS); object.

**domain controller** In an Active Directory forest, a server that contains a writable copy of the Active Directory database, participates in Active Directory replication, and controls access to network resources. Administrators can manage user accounts, network access, shared resources, site topology, and other directory objects from any domain controller in the forest. See also Active Directory; authentication; directory; forest; shared resource.

**domain name** The name given by an administrator to a collection of networked computers that share a common directory. Part of the DNS naming structure, domain names consist of a sequence of name labels separated by periods. See also domain; Domain Name System (DNS).

**Domain Name System (DNS)** A hierarchical, distributed database that contains mappings of DNS domain names to various types of data, such as IP addresses. DNS enables the location of computers and services by user-friendly names, and it also enables the discovery of other information stored in the database. See also domain name; IP address; ping; Transmission Control Protocol/Internet Protocol (TCP/IP).

**DWORD** A data type that is composed of hexadecimal data with a maximum allotted space of 4 bytes.

**dynamic binding** Binding (converting symbolic addresses in the program to storage-related addresses) that occurs during program execution. The term often refers to object-oriented applications that determine, during run time, which software routines to call for particular data objects. Also called late binding.

**Dynamic Host Configuration Protocol (DHCP)** A TCP/IP service protocol that offers dynamic leased configuration of host IP addresses and distributes other configuration parameters to eligible network clients. DHCP provides safe, reliable, and simple TCP/IP network configuration, prevents address conflicts, and helps conserve the use of client IP addresses on the network. DHCP uses a client/server model where the DHCP server maintains centralized management of IP addresses that are used on the network. DHCP-supporting clients can then request and obtain lease of an IP address from a DHCP server as part of their network boot process. See also IP address; Transmission Control Protocol/Internet Protocol (TCP/IP).

**Dynamic HTML** A collection of features that extends the capabilities of traditional HTML, giving Web authors more flexibility, design options, and creative control over the appearance and behavior of Web pages.

**dynamic page** A Hypertext Markup Language (HTML) document that contains animated GIFs, Java applets, ActiveX Controls, or dynamic HTML (DHTML). Also, a Web page that is created automatically, based on information that is provided by the user, or that is generated on the fly with Active Server Pages (ASP).

**dynamic-link library (DLL)** An operating system feature that allows executable routines (generally serving a specific function or set of functions) to be stored separately as files with .dll extensions. These routines are loaded only when needed by the program that calls them.

**E**

**early binding** Occurs when an object is assigned to a variable that is declared to be of a specific object type. Early bound objects allow the compiler to allocate memory and perform other optimizations before an application executes.

**encapsulation** The method used to pass data from one protocol over a network within a different protocol. Data from one protocol is wrapped with the header of a different protocol. Encapsulation is described in RFC 1483. See also protocol.

**encryption** The process of disguising a message or data in such a way as to hide its substance. See also public key encryption; symmetric encryption.

**encryption key** A bit string that is used in conjunction with an encryption algorithm to encrypt and decrypt data. See also private key; public key.

**Ethernet** The IEEE 802.3 standard that uses Carrier Sense Multiple Access with Collision Detection (CSMA/CD) as the medium access control. Ethernet supports different mediums, such as coaxial cable, fiber-optic cable, and twisted-pair wiring, and different data rates, such as 10 megabits per second (Mbps).

**event** Any significant occurrence in the system or an application that requires users to be notified or an entry to be added to a log.

**Event Log service** A service that records events in the system, security, and application logs. The Event Log service is located in Event Viewer. See also event; event logging; Event Viewer.

**event logging** The process of recording an audit entry in the audit trail whenever certain events occur, such as services starting and stopping or users logging on and off and accessing resources. See also auditing; event; Event Viewer.

**Event Viewer** A component you can use to view and manage event logs, gather information about hardware and software problems, and monitor security events. Event Viewer maintains logs about program, security, and system events. See also event; event logging.

**extended partition** A type of partition that you can create only on basic master boot record (MBR) disks. Extended partitions are useful if you want to create more than four volumes on a basic MBR disk. Unlike primary partitions, you do not format an extended partition with a file system and then assign a drive letter to it. Instead, you create one or more logical drives within the extended partition. After you create a logical drive, you format it and assign it a drive letter. An MBR disk can have up to four primary partitions or three primary partitions, one extended partition, and multiple logical drives. See also logical drive; partition.

**Extensible Markup Language (XML)** A meta-markup language that provides a format for describing structured data. This facilitates more precise declarations of content and more meaningful search results across multiple platforms. In addition, XML enables a new generation of Web-based data viewing and manipulation applications. See also Hypertext Markup Language (HTML).

**extranet** A limited subset of computers or users on a public network, typically the Internet, that can access an organizations internal network. For example, the computers or users might belong to a partner organization.

**F**

**failback** The process of moving resources, either individually or in a group, back to their preferred node after the node has failed and come back online. See also node.

**failover** In server clusters, the process of taking resource groups offline on one node and bringing them online on another node. When failover occurs, all resources within a resource group fail over in a predefined order; resources that depend on other resources are taken offline before, and are brought back online after, the resources on which they depend. See also node; server cluster.

**FAT** See definition for file allocation table (FAT).

**fat server** In a client/server architecture, a server that performs most of the processing, with the client performing little or no processing.

**FAT32** A derivative of the file allocation table (FAT) file system. FAT32 supports smaller cluster sizes and larger volumes than FAT, which results in more efficient space allocation on FAT32 volumes. See also file allocation table (FAT).

**fault tolerance** The ability of computer hardware or software to ensure data integrity when hardware failures occur. Fault-tolerant features appear in many server operating systems and include mirrored volumes, RAID-5 volumes, and server clusters. See also cluster.

**file allocation table (FAT)** A file system used by MS-DOS and other Windows operating systems to organize and manage files. The file allocation table is a data structure that Windows creates when you format a volume by using FAT or FAT32 file systems. Windows stores information about each file in the file allocation table so that it can retrieve the file later. See also FAT32; NTFS file system.

**File Transfer Protocol (FTP)** A member of the TCP/IP suite of protocols, used to copy files between two computers on the Internet. Both computers must support their respective FTP roles: one must be an FTP client and the other an FTP server. See also Transmission Control Protocol/Internet Protocol (TCP/IP).

**filter** For Indexing Service, software that extracts content and property values from a document to index them. For Internet Protocol security (IPsec), a specification of Internet Protocol (IP) traffic that provides the ability to trigger security negotiations for a communication based on the source, destination, and type of IP traffic. For Internet Information Services (IIS), a feature of Internet Server Application Programming Interface (ISAPI) that allows preprocessing of requests and postprocessing of responses, permitting site-specific handling of Hypertext Transfer Protocol (HTTP) requests and responses. In IP and Internetwork Packet Exchange (IPX) packet filtering, a definition in a series of definitions that indicates to the router the type of traffic allowed or disallowed on each interface. See also Internet Information Services (IIS); Internet Protocol (IP); Internet Protocol security (IPsec); Internet Server Application Programming Interface (ISAPI).

**firewall** A combination of hardware and software that provides a security system for the flow of network traffic, usually to prevent unauthorized access from outside to an internal network or intranet. Also called a *security-edge gateway*. See also proxy server.

**forest** One or more Active Directory domains that share the same class and attribute definitions (schema), site and replication information (configuration), and forest-wide search capabilities (global catalog). Domains in the same forest are linked with two-way, transitive trust relationships. See also Active Directory; domain.

**FORTEZZA** A family of security products including PCMCIA-based cards, compatible serial port devices, combination cards (such as FORTEZZA/Modem and FORTEZZA/Ethernet), server boards, and others. FORTEZZA is a registered trademark held by the U.S. National Security Agency.

**frame** In synchronous communication, a package of information transmitted as a single unit from one device to another.

**FTP** See definition for File Transfer Protocol (FTP).

**G**

**gateway** A dedicated device (or a set of services running on a dedicated computer) that routes network traffic and enables communication between different networking protocols. A gateway is a multiprotocol Internet Protocol (IP) router that translates between different transport protocols or data formats. See also Internet Protocol (IP).

**globally unique identifier (GUID)** A 16-byte value generated from the unique identifier on a device, the current date and time, and a sequence number. A GUID is used to identify a particular device or component.

**graphical user interface (GUI)** A display format, like that of Windows, that represents a program's functions with graphic images such as buttons and icons. GUIs enable a user to perform operations and make choices by pointing and clicking with a mouse.

**group** A collection of users, computers, contacts, and other groups. Groups can be used as security or as e-mail distribution collections. Distribution groups are used only for e-mail. Security groups are used both to grant access to resources and as e-mail distribution lists. See also domain; local group.

**group account** A collection of user accounts. By making a user account a member of a group, you give the related user all the rights and permissions granted to the group. See also group.

**Group Policy** The infrastructure within Active Directory directory service that enables directory-based change and configuration management of user and computer settings, including security and user data. You use Group Policy to define configurations for groups of users and computers. With Group Policy, you can specify policy settings for registry-based policies, security, software installation, scripts, folder redirection, remote installation services, and Internet Explorer maintenance. The Group Policy settings that you create are contained in a Group Policy object (GPO). By associating a GPO with selected Active Directory system containers—sites, domains, and organizational units—you can apply the GPOs policy

settings to the users and computers in those Active Directory containers. To create an individual GPO, use the Group Policy Object Editor. To manage Group Policy objects across an enterprise, you can use the Group Policy Management console. See also Active Directory.

**Guest account** A built-in account used to log on to a computer running Windows when a user does not have an account on the computer or domain or in any of the domains trusted by the computers domain. See also domain.

**GUID** See definition for globally unique identifier (GUID).

**H**

**hash** A fixed-size result that is obtained by applying a one-way mathematical function (sometimes called a *hash algorithm*) to an arbitrary amount of data. If there is a change in the input data, the hash changes. The hash can be used in many operations, including authentication and digital signing. Also called a *message digest*. See also authentication; hash algorithm.

**hash algorithm** An algorithm that produces a hash value of some piece of data, such as a message or session key. With a good hash algorithm, changes in the input data can change every bit in the resulting hash value; for this reason, hashes are useful in detecting any modification in a data object, such as a message. Furthermore, a good hash algorithm makes it computationally infeasible to construct two independent inputs that have the same hash. Typical hash algorithms include MD2, MD4, MD5, and SHA-1. Also called a *hash function*. See also MD5; Secure Hash Algorithm (SHA-1).

**headless server** See definition for remotely administered server.

**heaps** A portion of memory reserved for a program to use for the temporary storage of data structures whose existence or size cannot be determined until the program is running.

**Help and Support Center** A unified place where a user can access all Help and Support content and services from both Microsoft and the OEM.

**hexadecimal** A base-16 number system represented by the digits 0 through 9 and the uppercase or lowercase letters A (equivalent to decimal 10) through F (equivalent to decimal 15).

**home directory** The root directory for a Web site, where the content files are stored. Also called a document root or Web root. In Internet Information Services (IIS), the home directory and all its subdirectories are available to users by default. Also, the root directory for an IIS service. Typically, the home directory for a site contains the home page. See also home page.

**home page** In the context of Internet Explorer, the home page is the first page users see when they start the browser. Home page is also a more general term for the main page of a Web site, which usually contains a main menu or table of contents with links to other pages within the site.

**host** Any device on a TCP/IP network that has an Internet Protocol (IP) address. Examples of hosts include servers, workstations, network-interface print devices, and routers. Sometimes used to refer to a specific network computer that is running a service used by network or remote clients. For Network Load Balancing, a cluster consists of multiple hosts connected over a local area network (LAN).See also client; cluster; local area network (LAN); Network Load Balancing; server; Transmission Control Protocol/Internet Protocol (TCP/IP).

**host name** The DNS name of a device on a network. These names are used to locate computers on the network. To find another computer, its host name must either appear in the Hosts file or be known by a DNS server. For most Windows-based computers, the host name and the computer name are the same. See also Domain Name System (DNS).

**hotfix** An update to address an issue identified after a software product has been distributed. Hotfix distribution is limited by its licensing terms.

**HTML** See definition for Hypertext Markup Language (HTML).

**HTTP** See definition for Hypertext Transfer Protocol (HTTP).

**HTTP header** An informational listing at the top of a Hypertext Transfer Protocol (HTTP) request or response.

**HTTPS** See definition for Secure Hypertext Transfer Protocol.

**Hypertext Markup Language (HTML)** A simple markup language used to create hypertext documents that are portable from one platform to another. HTML files are simple ASCII text files with codes embedded (indicated by markup tags) to denote formatting and hypertext links. See also American Standard Code for Information Interchange (ASCII).

**Hypertext Transfer Protocol (HTTP)** The protocol used to transfer information on the World Wide Web. An HTTP address (one kind of Uniform Resource Locator (URL)) takes the following form: http://www.microsoft.com. See also protocol.

**I**

**ICMP** See definition for Internet Control Message Protocol (ICMP).

**identities, multiple** See definition for multiple identities.

**identity** A person or entity that must be verified by means of authentication, based on criteria such as a password or a certificate. See also authentication; certificate.

**IEEE** Institute of Electrical and Electronics Engineers, founded in 1963. IEEE is an organization composed of engineers, scientists, and students, best known for developing standards for the computer and electronics industry.

**IETF** See definition for Internet Engineering Task Force (IETF).

**IIS** See definition for Internet Information Services (IIS).

**IIS 5.0 isolation mode** Internet Information Services (IIS) 6.0 isolation mode that simulates the IIS 5.0 Web process model.

**IIS Admin Objects** A set of methods, provided by Internet Information Services (IIS), that allow applications to access and modify configuration settings in the metabase.

**IIS Server Instance resource** A server-instance designation used with Internet Information Services (IIS) that supports the WWW and FTP services. IIS server instances are supported as cluster resources by a Resource DLL. IIS Server Instance resources can have dependencies on IP Address resources, Network Name resources, and Physical Disk resources. Access information for server instances does not fail over. See also failover; Internet Information Services (IIS).

**impersonation** A circumstance that occurs when Windows allows one process to take on the security attributes of another. See also attribute; security.

**impersonation token** An access token that captures the security information of a client process, allowing a service to impersonate the client process in security operations.

**in-memory metabase** An image of the Internet Information Services (IIS) metabase that has been loaded from disk into the computers RAM memory and is used while IIS is running. See also metabase.

**in-process** Internet Server API (ISAPI) extensions that are hosted in the worker process address space. See also Internet Server Application Programming Interface (ISAPI).

**in-schema property** A metabase property predefined in the metabase schema (MBSchema.xml) file. See also metabase schema.

**inheritance** In security, a mechanism that allows a specific access control entry (ACE) to be copied from the container where it was applied to all children of the container. Inheritance can be used to manage access to a whole subtree of objects in a single update operation. In Active Directory, the ability to build new object classes from existing object classes. The new object is defined as a subclass of the original object class. The original object class becomes a superclass of the new object. A subclass inherits the attributes of the superclass, including structure rules and content rules. In Group Policy, a mechanism that allows policy settings in Group Policy objects (GPOs) that are linked to parent containers to be applied to objects in child containers. See also Active Directory.

**input/output (I/O) port** A channel through which data is transferred between a device and the microprocessor. The port appears to the microprocessor as one or more memory addresses that it can use to send or receive data.

**Integrated Services Digital Network (ISDN)** A digital phone line used to provide higher bandwidth. ISDN in North America is typically available in two forms: Basic Rate Interface (BRI) consists of 2 B-channels at 64 kilobits per second (Kbps) and a D-channel at 16 Kbps; Primary Rate Interface (PRI) consists of 23 B-channels at 64 Kbps and a D-channel at 64 Kbps. An ISDN line must be installed by the phone company at both the calling site and the called site.

**Integrated Windows authentication** A configuration setting that enables negotiation of authentication protocols in Internet Information Services (IIS). See also Internet Information Services (IIS).

**internet** Two or more network segments connected by routers. Another term for *internetwork*.

**Internet** A worldwide network of computers. If you have access to the Internet, you can retrieve information from millions of sources, including schools, governments, businesses, and individuals.

**Internet Control Message Protocol (ICMP)** A required maintenance protocol in the TCP/IP suite that reports errors and provides simple diagnostic capabilities. ICMP is used by the Ping tool to perform TCP/IP troubleshooting. See also Internet Protocol (IP); protocol; Transmission Control Protocol/Internet Protocol (TCP/IP).

**Internet Engineering Task Force (IETF)** An open community of network designers, operators, vendors, and researchers concerned with the evolution of Internet architecture and the smooth operation of the Internet. Technical work is performed by working groups organized by topic areas (such as routing, transport, and security) and through mailing lists. Internet standards are developed in IETF Requests for Comments (RFCs), which are a series of notes that discuss many aspects of computing and computer communication, focusing on networking protocols, programs, and concepts.

**Internet Information Services (IIS)** Software services that support Web site creation, configuration, and management, along with other Internet functions. Internet Information Services include Network News Transfer Protocol (NNTP), File Transfer Protocol (FTP), and Simple Mail Transfer Protocol (SMTP). See also File Transfer Protocol (FTP).

**Internet Protocol (IP)** A routable protocol in the TCP/IP protocol suite that is responsible for IP addressing, routing, and the fragmentation and reassembly of IP packets. See also packet; Transmission Control Protocol/Internet Protocol (TCP/IP).

**Internet Protocol security (IPsec)** A set of industry-standard, cryptography-based protection services and protocols. IPsec protects all protocols in the TCP/IP protocol suite except Address Resolution Protocol (ARP). For virtual private network (VPN) connections, IPsec is used in conjunction with Layer Two Tunneling Protocol (L2TP). See also Address Resolution Protocol (ARP); protocol; Transmission Control Protocol/Internet Protocol (TCP/IP).

**Internet Server Application Programming Interface (ISAPI)** An application programming interface (API) that resides on a server computer, that initiates software services tuned for Windows operating systems. In Microsoft Provisioning System, ISAPI resides on the Web server. See also application programming interface (API).

**Internet service** One of any of a number of technologies for making information accessible to users over the Internet. Each Internet service is defined by a protocol, such as Hypertext Transfer Protocol (HTTP), and each is enabled using client/server applications, such as Web browsers and Web servers. Internet protocols are defined in the Request for Comments (RFC) documents that are published by the Internet Engineering Task Force (IETF).

**Internet service provider (ISP)** A company that provides individuals or companies access to the Internet and the World Wide Web. An ISP provides a telephone number, a user name, a password, and other connection information so users can connect their computers to the ISP's computers. An ISP typically charges a monthly or hourly connection fee.

**intranet** A network within an organization that uses Internet technologies and protocols, but is available only to certain people, such as employees of a company. Also called a *private network*. See also internet.

**IP** See definition for Internet Protocol (IP).

**IP address** For Internet Protocol version 4 (IPv4), a 32-bit address used to identify an interface on a node on an IPv4 internetwork. Each interface on the IP internetwork must be assigned a unique IPv4 address, which is made up of the network ID, plus a unique host ID. This address is typically represented with the decimal value of each octet separated by a period (for example, 192.168.7.27). You can configure the IP address statically or dynamically by using Dynamic Host Configuration Protocol (DHCP). For Internet Protocol version 6 (IPv6), an identifier that is assigned at the IPv6 layer to an interface or set of interfaces and that can be used as the source or destination of IPv6 packets. See also Dynamic Host Configuration Protocol (DHCP); Internet Protocol (IP); node; octet.

**IPsec** See definition for Internet Protocol security (IPsec).

**ISAPI** See definition for Internet Server Application Programming Interface (ISAPI).

**ISDN** See definition for Integrated Services Digital Network (ISDN).

**ISP** See definition for Internet service provider (ISP).

**J**

**JIT** See definition for just-in-time (JIT) activation.

**just-in-time (JIT) activation** The ability of a Component Object Model (COM) object to be activated only as needed for executing requests from its client. Objects can be deactivated even while clients hold references to them, allowing otherwise idle server resources to be used more productively.

**K**

**Keep-Alive connection** A Hypertext Transfer Protocol (HTTP) connection that is not closed after an exchange is completed.

**Kerberos V5 authentication protocol** An authentication mechanism used to verify user or host identity. The Kerberos V5 authentication protocol is the default authentication service. Internet Protocol security (IPsec) can use the Kerberos protocol for authentication. See also Internet Protocol security (IPsec).

**kernel** The core of layered architecture that manages the most basic operations of the operating system and the computer's

processor. The kernel schedules different blocks of executing code, called threads, for the processor; this efficiently keeps the processor as busy as possible and coordinates multiple processors to optimize performance. The kernel also synchronizes activities among executive-level subcomponents, such as I/O Manager and Process Manager, and handles hardware exceptions and other hardware-dependent functions. The kernel works closely with the hardware abstraction layer.

**kernel mode** A highly privileged mode of operation where program code has direct access to all memory, including the address spaces of all user-mode processes and applications, and to hardware. Also known as *supervisor mode*, *protected mode*, or *Ring 0*.

**key** In Registry Editor, a folder that appears in the left pane of the Registry Editor window. A key can contain subkeys and entries. For example, Environment is a key of **HKEY_CURRENT_USER**. In IP security (IPsec), a value used in combination with an algorithm to encrypt or decrypt data. Key settings for IPsec are configurable to provide greater security. See also Internet Protocol security (IPsec); registry; subkey.

**key pair** A private key and its related public key. See also private key; public key.

**L**

**late binding** See definition for dynamic binding.

**LCID** See definition for Locale Identifier (LCID).

**LDAP** See definition for Lightweight Directory Access Protocol (LDAP).

**Lightweight Directory Access Protocol (LDAP)** The primary access protocol for Active Directory. LDAP is an industry-standard protocol, established by the Internet Engineering Task Force (IETF), that allows users to query and update information in a directory service. Active Directory supports both LDAP version 2 and LDAP version 3. See also Active Directory; directory service; Internet Engineering Task Force (IETF); protocol.

**load balancing** A technique used by Windows Clustering to scale the performance of a server-based program (such as a Web server) by distributing its client requests across multiple servers within the cluster. Each host can specify the load percentage that it will handle, or the load can be equally distributed across all the hosts. If a host fails, Windows Clustering dynamically redistributes the load among the remaining hosts. See also cluster; host.

**local area network (LAN)** A communications network connecting a group of computers, printers, and other devices located within a relatively limited area (for example, a building). A LAN enables any connected device to interact with any other on the network.

**local group** A security group that can be granted rights and permissions on only resources on the computer on which the group is created. Local groups can have any user accounts that are local to the computer as members, as well as users, groups, and computers from a domain to which the computer belongs.

**Locale Identifier (LCID)** A unique integer that represents a locale for the formatting style of dates, times, currencies and other values, which is different for each geographical location. In Internet Information Services (IIS), the default LCID is the same as the system locale. See also LOCALE_SYSTEM_DEFAULT.

**LOCALE_SYSTEM_DEFAULT** The default system locale. There is also a default user locale. See also Locale Identifier (LCID).

**LocalHost** A placeholder for the name of the computer on which a program is running. LocalHost uses the reserved loopback IP address (127.0.0.1 in IPv4 and ::1 in IPv6).

**log file** A file that stores messages generated by an application, service, or operating system. These messages are used to track the operations performed. For example, Web servers maintain log files listing every request made to the server. Log files are usually plain text (ASCII) files and often have a .log extension. In Backup, a file that contains a record of the date the tapes were created and the names of files and directories successfully backed up and restored. The Performance Logs and Alerts service also creates log files. See also American Standard Code for Information Interchange (ASCII).

**logical drive** A volume that you create within an extended partition on a basic master boot record (MBR) disk. Logical drives are similar to primary partitions, except that you are limited to four primary partitions per disk, whereas you can create an unlimited number of logical drives per disk. A logical drive can be formatted and assigned a drive letter. See also extended partition.

**M**

**Mail or Messaging Application Programming Interface (MAPI)** An open and comprehensive messaging interface that is used by developers to create messaging and workgroup applications, such as e-mail, scheduling, calendars, and document management. In a distributed client/server environment, MAPI provides enterprise messaging services within Windows Open Services Architecture (WOSA).

**malicious user** A person who has legitimate access to a system and poses a security threat to it, such as someone who tries to elevate their user rights to gain access to unauthorized data. See also security; user rights.

**Management Information Base (MIB)** Information about aspects of a network that can be managed by using the Simple Network Management Protocol (SNMP). This information is formatted in MIB files that are provided for each service that can be monitored. Most third-party monitors (clients) use SNMP and MIB files to monitor Web, File Transfer Protocol (FTP), and other Windows services. Using SNMP, developers or system administrators can write their own custom monitoring applications.

**MAPI** See definition for Mail or Messaging Application Programming Interface (MAPI).

**master properties** In Internet Information Services (IIS), properties that are set at the computer level that become default settings for all Web or File Transfer Protocol (FTP) sites on that computer. See also inheritance.

**MD5** An industry-standard one-way, 128-bit hashing scheme, developed by RSA Data Security, Inc., and used by various Point-to-Point Protocol (PPP) vendors for encrypted authentication. A hashing scheme is a method for transforming data (for example, a password) in such a way that the result is unique and cannot be changed back to its original form. The Challenge Handshake Authentication Protocol (CHAP) uses challenge-response with one-way MD5 hashing on the response. In this way, you can prove to the server that you know your password without actually sending the password over the network. See also hash algorithm; MD5.

**MDAC** See definition for Microsoft Data Access Components (MDAC).

**Message Queuing** A message queuing and routing system for Windows that enables distributed applications running at different times to communicate across heterogeneous networks and with computers that may be offline. Message Queuing provides guaranteed message delivery, efficient routing, security, and priority-based messaging. Formerly known as *MSMQ*.

**metabase** A hierarchical store of configuration information and schema that is used to configure Internet Information Services (IIS). The metabase performs some of the same functions as the system registry, but it uses less disk space. In physical terms, the metabase is a combination of the MetaBase.xml and MBSchema.xml files and the in-memory metabase.

**metabase configuration file** A file that stores Internet Information Services (IIS) configuration settings to disk. This file is named MetaBase.xml by default. When IIS is started or restarted, the configuration settings are read from MetaBase.xml into the IIS cache in memory, which is called the in-memory metabase.

**metabase schema** The master configuration file (MBSchema.xml) supplied with Internet Information Services (IIS) that contains all of the predefined properties from which metabase entries are derived.

**metadata** Data that is used to describe other data. For example, Indexing Service must maintain data that describes the data in the content index.

**method** A procedure (function) that acts on an object.

**MIB** See definition for Management Information Base (MIB).

**Microsoft Data Access Components (MDAC)** Consists of ActiveX Data Objects (ADO), the Remote Data Service (RDS), Microsoft OLE DB Provider for ODBC, Open Database Connectivity (ODBC), ODBC drivers for Microsoft SQL Server, Microsoft Access and other desktop databases, as well as Oracle databases.

**middle tier** The logical layer between a user interface or Web client and the database. This is typically where the Web server resides and where business objects are instantiated. Also known as *application server tier*. See also client tier; data source tier.

**modem (modulator/demodulator)** A device that enables computer information to be transmitted and received over a telephone line. The transmitting modem translates digital computer data into analog signals that can be carried over a telephone line. The receiving modem translates the analog signals back to digital form.

**MSMQ** See definition for Message Queuing.

**MTA** See definition for multithreaded apartment (MTA).

**multiple identities** Multiple Web sites that are hosted on one computer. Also called virtual servers.

**Multipurpose Internet Mail Extensions mapping (MIME mapping)** A method of configuring browsers to view files that are in multiple formats. An extension of the Internet mail protocol that enables the sending of 8-bit-based e-mail messages, which are used to support extended character sets, voice mail, facsimile images, and so on.

**multithreaded apartment (MTA)** A form of multithreading that is supported by Component Object Model (COM). In a multithreaded apartment model, all of the threads in the process that have been initialized as free-threaded reside in a single

apartment.

**multithreading** Running several processes in rapid sequence within a single program, regardless of which logical method of multitasking is being used by the operating system. Because the user's sense of time is much slower than the processing speed of a computer, multitasking appears to be simultaneous, even though only one task at a time can use a computer processing cycle.

**N**

**name resolution** The process of having software translate between names that are easy for users to work with and numerical IP addresses, which are difficult for users but necessary for TCP/IP communications. Name resolution can be provided by software components such as DNS or WINS. See also Domain Name System (DNS); Transmission Control Protocol/Internet Protocol (TCP/IP); Windows Internet Name Service (WINS).

**namespace** A naming convention that defines a set of unique names for resources in a network. For DNS, a hierarchical naming structure that identifies each network resource and its place in the hierarchy of the namespace. For WINS, a flat naming structure that identifies each network resource using a single, unique name. See also Domain Name System (DNS); Windows Internet Name Service (WINS).

**Network File System (NFS)** A service for distributed computing systems that provides a distributed file system, eliminating the need for keeping multiple copies of files on separate computers.

**network latency** The time it takes for information to be transferred between computers in a network.

**Network Load Balancing** A Windows network component that uses a distributed algorithm to load-balance Internet Protocol (IP) traffic across a number of hosts, helping to enhance the scalability and availability of mission-critical, IP-based services, such as Terminal Services, Web services, virtual private networking, and streaming media. It also provides high availability by detecting host failures and automatically redistributing traffic to the surviving hosts. See also availability; cluster; host; scalability.

**Network News Transfer Protocol (NNTP)** A protocol that is used to distribute network news messages to NNTP servers and to NNTP clients (news readers) on the Internet. NNTP provides for the distribution, inquiry, retrieval, and posting of news articles by using a reliable, stream-based transmission of news on the Internet. NNTP is designed in such a way that news articles are stored on a server in a central database, so that users can select specific items to read. Indexing, cross-referencing, and expiration of old messages are also provided. NNTP is defined in RFC 977.

**NNTP** See definition for Network News Transfer Protocol (NNTP).

**node** For tree structures, a location on the tree that can have links to one or more items below it. For local area networks (LANs), a device that is connected to the network and is capable of communicating with other network devices. For server clusters, a computer system that is an active or inactive member of a cluster. See also local area network (LAN); server cluster.

**NTFS file system** An advanced file system that provides performance, security, reliability, and advanced features that are not found in any version of file allocation table (FAT). For example, NTFS guarantees volume consistency by using standard transaction logging and recovery techniques. If a system fails, NTFS uses its log file and checkpoint information to restore the consistency of the file system. NTFS also provides advanced features, such as file and folder permissions, encryption, disk quotas, and compression. See also FAT32; file allocation table (FAT).

**O**

**object** An entity, such as a file, folder, shared folder, printer, or Active Directory object, described by a distinct, named set of attributes. For example, the attributes of a File object include its name, location, and size; the attributes of an Active Directory User object might include the user's first name, last name, and e-mail address. For OLE and ActiveX, an object can also be any piece of information that can be linked to, or embedded into, another object. See also Active Directory; attribute.

**object identifier (OID)** An extensible, unique identification number for attributes and classes. Performance counter names have their own object identifiers, which are listed in Management Information Base (MIB) files, to provide performance monitoring applications with access to the counters. See also Management Information Base (MIB); Simple Network Management Protocol (SNMP).

**Object Linking and Embedding (OLE)** A set of integration standards for transferring and sharing information among client applications. Also, a protocol that enables the creation of compound documents with embedded links to applications, so that a user does not have to switch among applications to make revisions. OLE is based on the Component Object Model (COM), and it enables the development of reusable objects that operate across multiple applications.

**Object Linking and Embedding Database (OLE DB)** Data-access interfaces that provide consistent access to Structured Query Language (SQL) data sources and non-SQL data sources across an organization and the Internet. See also structured query language (SQL).

**object-cache scavenger** The code that periodically scans the cache for objects to be discarded. It deletes files that have not been used recently and therefore are unlikely to be used again in the near future.

**octet** In programming, an octet refers to eight bits or one byte. IP addresses, for example, are typically represented in dotted-decimal notation; that is, with the decimal value of each octet of the address separated by a period.

**ODBC** See definition for Open Database Connectivity (ODBC).

**OID** See definition for object identifier (OID).

**OLE** See definition for Object Linking and Embedding (OLE).

**OLE DB** See definition for Object Linking and Embedding Database (OLE DB).

**Open Database Connectivity (ODBC)** An application programming interface (API) that enables applications to access data from a variety of existing data sources. A standard specification for cross-platform database access.

**out-of-process** For IIS 5.0 isolation mode, ISAPI extensions that are hosted in a surrogate process called DLLHOST.exe, which is managed by COM+. See also IIS 5.0 isolation mode.

**out-of-process component** A Component Object Model (COM) component that runs in a separate process space from its client. See also process isolation.

**out-of-process, pooled** See definition for pooled out-of-process.

**P-Q**

**packet** An Open Systems Interconnection (OSI) network layer transmission unit that consists of binary information representing both data and a header containing an identification number, source and destination addresses, and error-control data.

**page** See definition for Web page.

**parameter** A value that is passed in a function call.

**partition** A portion of a physical disk that functions as though it were a physically separate disk. After you create a partition, you must format it and assign it a drive letter before you can store data on it. On basic disks, partitions are known as basic volumes, which include primary partitions and logical drives. On dynamic disks, partitions are known as dynamic volumes, which include simple, striped, spanned, mirrored, and RAID-5 volumes. See also extended partition.

**password authentication** See definition for authentication.

**path, physical** See definition for physical path.

**path, relative** See definition for relative path.

**performance counter** In System Monitor, a data item that is associated with a performance object. For each counter selected, System Monitor presents a value corresponding to a particular aspect of the performance that is defined for the performance object.

**Perl (Practical Extraction and Report Language)** An interpreted language that is based on C and several UNIX utilities. Perl has powerful string-handling features for extracting information from text files. Perl can assemble a string and send it to the shell as a command; therefore, it is often used for system administration tasks. A program in Perl is known as a script. Perl was devised by Larry Wall at the NASA Jet Propulsion Laboratory. See also script.

**permission** A rule associated with an object to regulate which users can gain access to the object and in what manner. Permissions are assigned or denied by the objects owner. See also object.

**physical path** A universal naming convention (UNC) directory path. See also relative path.

**ping** A utility that verifies connections to one or more remote hosts. The ping command uses Internet Control Message Protocol (ICMP) echo request and echo reply packets to determine whether a particular Internet Protocol (IP) system on a network is functional. **Ping** is useful for diagnosing IP network or router failures. See also host; Internet Control Message Protocol (ICMP); Internet Protocol (IP); packet.

**plaintext** Data that is not encrypted. Sometimes also called *cleartext*. See also encryption.

**Point-to-Point Protocol (PPP)** A set of industry-standard framing and authentication protocols that are included with Windows to ensure interoperability with other remote access software. PPP negotiates configuration parameters for multiple

layers of the Open Systems Interconnection (OSI) model. The Internet standard for serial communications, PPP defines how data packets are exchanged with other Internet-based systems using a modem connection.

**Point-to-Point Tunneling Protocol (PPTP)** A specification for virtual private networks (VPNs) in which some nodes of a local area network (LAN) are connected through the Internet. PPTP is an open industry standard that supports widely used networking protocols: Internet Protocol (IP), Internetwork Packet Exchange (IPX), and Microsoft NetBIOS Extended User Interface (NetBEUI). Organizations can use PPTP to outsource their remote dial-up needs to an Internet service provider or to other carriers to reduce cost and complexity.

**policies** Conditions that are set by the system administrator, for example, how quickly account passwords expire and how many unsuccessful logon attempts are allowed before a user is locked out. Policies manage accounts to help prevent exhaustive or random password attacks.

**pooled out-of-process** For IIS 5.0 isolation mode, a special Web Application Manager (WAM) package that hosts all out-of-process ISAPI extensions that are set to medium isolation within the same DLLHOST.exe process. See also IIS 5.0 isolation mode; out-of-process; Web Application Manager (WAM).

**port number** A number that identifies a certain Internet application. For example, the default port number for the WWW service is 80.

**PPP** See definition for Point-to-Point Protocol (PPP).

**PPTP** See definition for Point-to-Point Tunneling Protocol (PPTP).

**private key** The secret half of a cryptographic key pair that is used with a public key algorithm. Private keys are typically used to decrypt a symmetric session key, digitally sign data, or decrypt data that has been encrypted with the corresponding public key. See also public key; public key encryption.

**process** An operating system object that consists of an executable program, a set of virtual memory addresses, and one or more threads. When a program runs, a process is created.

**process accounting** A feature of Internet Information Services (IIS) that administrators can use to monitor and log resource consumption of Common Gateway Interface (CGI) scripts and out-of-process applications.

**process isolation** Running an application or component out of process. See also out-of-process component.

**property inheritance** See definition for inheritance.

**protocol** A set of rules and conventions for sending information over a network. These rules govern the content, format, timing, sequencing, and error control of messages exchanged among network devices. See also Internet Protocol (IP); Transmission Control Protocol/Internet Protocol (TCP/IP).

**provider** See definition for WMI provider.

**proxy** A software program that connects a user to a remote destination through an intermediary gateway.

**proxy server** A firewall component that manages Internet traffic to and from a local area network (LAN) and that can provide other features, such as document caching and access control. A proxy server can improve performance by supplying frequently requested data, such as a popular Web page, and it can filter and discard requests that the owner does not consider appropriate, such as requests for unauthorized access to proprietary files. See also firewall; local area network (LAN).

**public key** The non-secret half of a cryptographic key pair that is used with a public key algorithm. Public keys are typically used when encrypting a session key, verifying a digital signature, or encrypting data that can be decrypted with the corresponding private key. See also key; private key; public key encryption.

**public key encryption** A method of encryption that uses two encryption keys that are mathematically related. One key is called the *private key* and is kept confidential. The other is called the *public key* and is freely given out to all potential correspondents. In a typical scenario, a sender uses the receiver's public key to encrypt a message. Only the receiver has the related private key to decrypt the message. The complexity of the relationship between the public key and the private key means that, provided the keys are long enough, it is computationally infeasible to determine one from the other. Also called *asymmetric encryption*. See also encryption; private key; public key; symmetric encryption.

**public-key algorithm** An asymmetric cipher that uses two keys, one for encryption, the public key, and the other for decryption, the private key. See also asymmetric key algorithm; decryption; encryption; private key; public key.

**R**

**RAID** See definition for Redundant Array of Independent Disks (RAID).

**random access memory (RAM)** Memory that can be read from or written to by a computer or other devices. Information stored in RAM is lost when the computer is turned off.

**realm** A term that is sometimes used for domain, in this case to refer to user domains that are established for security reasons, not Internet domains. For password-protected files, the name of the protected resource or area on the server. If the user tries to access the protected resource while browsing, the name of the realm usually appears in the dialog box that asks for a user name and password.

**redirection** Redirection can be used to automatically send a user from an outdated Uniform Resource Locator (URL) to a new URL.

**Redundant Array of Independent Disks (RAID)** A data storage method in which data, along with information used for error correction, such as parity bits, is distributed among two or more hard disk drives to improve performance and reliability. The hard disk array is governed by array management software and a disk controller, which handles the error correction. RAID is generally used on network servers. Several defined levels of RAID offer differing trade-offs among access speed, reliability, and cost. Windows includes three of the RAID levels: Level 0, Level 1, and Level 5.

**registry** A database repository for information about a computer's configuration. The registry contains information that Windows continually references during operation, such as:

- Profiles for each user.
- The programs installed on the computer and the types of documents that each can create.
- Property settings for folders and program icons.
- What hardware exists on the system.
- Which ports are being used.

The registry is organized hierarchically as a tree, and it is made up of keys and their subkeys, hives, and entries. See also key; subkey.

**relative path** A universal naming convention (UNC) directory path with placeholders, or wildcards, at some levels. Also, the physical path that corresponds to a Uniform Resource Locator (URL). See also physical path.

**remote procedure call (RPC)** In programming, a call by one program to a second program on a remote system. The second program usually performs a task and returns the results of that task to the first program.

**remotely administered server** A server that you can administer by using a different computer. You typically access this type of server by using a network connection. A remotely administered server can have a local keyboard, mouse, or video card and monitor. If it does not have these peripherals attached, it is also known as a *headless server*. Such servers are often housed in a physically secure location. See also server.

**replication** The copying from one server node to another of either content or the configuration metabase, or both. This copying can be done either manually or automatically by using replication software. Replication is a necessary function of clustering that ensures fault tolerance. See also fault tolerance.

**Request for Comments (RFC)** The document series, begun in 1969, that describes the Internet suite of protocols and related experiments. Not all (in fact, very few) RFCs describe Internet standards, but all Internet standards are written up as RFCs. The RFC series of documents is unusual in that the proposed protocols are forwarded by the Internet research and development community, acting on its own behalf, as opposed to the formally reviewed and standardized protocols that are promoted by organizations such as the American National Standards Institute (ANSI).

**router** An intermediary device on a communications network that expedites message delivery. On a single network linking many computers through a mesh of possible connections, a router receives transmitted messages and forwards them to their correct destinations over the most efficient available route. On an interconnected set of local area networks (LANs) using the same communications protocols, a router serves the somewhat different function of acting as a link between LANs, enabling messages to be sent from one LAN to another.

**RPC** See definition for remote procedure call (RPC).

**RSA** A public-key encryption standard for Internet security. This acronym derives from the last names of the inventors of the technology: Rivest, Shamir, and Adleman.

**S**

**scalability** A measure of how well a computer, service, or application can grow to meet increasing performance demands. For server clusters, the ability to incrementally add one or more systems to an existing cluster when the overall load of the cluster exceeds its capabilities. See also server cluster.

**schema** A representation of the structure of something. Classes in Visual Basic and C++ can be said to be schemas of objects, and objects are instances of classes. In Internet Information Services (IIS), the metabase schema represents the structure of the metabase configuration file.

**scope** In programming, the extent to which an identifier, such as a constant, data type, variable, or routine, can be referenced within a program. Scope can be global or local. Scope can also be affected by the redefinition of identifiers, for example, by giving the same name to both a global variable and a local variable.

**script** A kind of program that consists of a set of instructions for an application or utility program. A script can be embedded in a Web page. See also ActiveX; common gateway interface (CGI).

**scripting engine** A program that interprets and executes a script. See also script.

**search expression** See Other Definition

**search interface** See Other Definition

**search string** See Other Definition

**Secure Hash Algorithm (SHA-1)** An algorithm that generates a 160-bit hash value from an arbitrary amount of input data. SHA-1 is used with the Digital Signature Algorithm (DSA) in the Digital Signature Standard (DSS), among other places. See also hash algorithm.

**Secure Hypertext Transfer Protocol** A protocol that provides a secure Hypertext Transfer Protocol (HTTP) connection. See also Hypertext Transfer Protocol (HTTP); protocol.

**Secure Sockets Layer (SSL)** A protocol that supplies secure data communication through data encryption and decryption. SSL uses RSA public-key encryption for specific TCP/IP ports. It is intended for handling commerce payments. An alternative method is Secure-HTTP (S-HTTP), which is used to encrypt specific Web documents, rather than the entire session. SSL is a general-purpose encryption standard. SSL can also be used for Web applications that require a secure link, such as e-commerce applications, or for controlling access to Web-based subscription services.

**security** On a network, protection of a computer system and its data from harm or loss, implemented especially so that only authorized users can gain access to shared files. See also authorization.

**security context** The security attributes or rules that are currently in effect. For example, the rules that govern what a user can do to a protected object are determined by security information in the user's access token and in the object's security descriptor. Together, the access token and the security descriptor form a security context for the user's actions on the object. See also object.

**Selectable Cryptographic Service Provider** See definition for cryptographic service provider (CSP).

**server** In general, a computer that provides shared resources to network users. See also client; shared resource.

**server certificate** A unique digital identification that forms the basis of a Web server's Secure Sockets Layer (SSL) security features. Server certificates are obtained from a mutually trusted, third-party organization, and they provide a way for users to authenticate the identity of a Web site.

**server cluster** A group of computers, known as *nodes*, working together as a single system to ensure that mission-critical applications and resources remain available to clients. A server cluster presents the appearance of a single server to a client. See also cluster; node.

**server node** An individual computer in a server cluster.

**server process** A process that hosts Component Object Model (COM) components. A COM component can be loaded into a surrogate server process, either on the client computer (local) or on another computer (remote). It can also be loaded into a client application process (in-process).

**server-side include** (SSI) A mechanism for including dynamic text in World Wide Web documents. Server-side includes are special command codes that are recognized and interpreted by the server; their output is placed in the document body before the document is sent to the browser. Server-side includes can be used, for example, to include the Date and Time stamp in the text of the file.

**session key** A digital key that is created by a client, encrypted, and then sent to a server. This key is used to encrypt data that is sent by the client.

**shared resource** Any device, data, or program that is used by more than one program or one other device. For Windows, *shared resource* refers to any resource that is made available to network users, such as folders, files, printers, and named pipes. *Shared resource* can also refer to a resource on a server that is available to network users. See also server.

**Simple Mail Transfer Protocol (SMTP)** A TCP/IP protocol for sending messages from one computer to another on a network. This protocol is used on the Internet to route e-mail.

**Simple Network Management Protocol (SNMP)** The network management protocol of TCP/IP. In SNMP, agents or clients monitor the activity of various devices on the network and report to the network console workstation. The agents or clients can be hardware as well as software. Control information about each device or service is maintained in a structure known as a management information block. One way to access this information is with Performance Counters. See also Management Information Base (MIB).

**single-threaded apartment (STA)** A form of threading that is supported by Component Object Model (COM). In a single-threaded apartment model, all objects are executed on a single thread and each thread resides within its own apartment.

**SMTP** See definition for Simple Mail Transfer Protocol (SMTP).

**snap-in** A type of tool that you can add to a console supported by Microsoft Management Console (MMC). A stand-alone snap-in can be added by itself; an extension snap-in can be added only to extend the function of another snap-in.

**sniffer** An application or device that can read, monitor, and capture network data exchanges and read network packets. If the packets are not encrypted, a sniffer provides a full view of the data inside the packet. See also packet.

**SNMP** See definition for Simple Network Management Protocol (SNMP).

**socket** An identifier for a particular service on a particular node on a network. The socket consists of a node address and a port number, which identifies the service. For example, port 80 on an Internet node indicates a Web server. There are two kinds of sockets: streams (bidirectional) and datagrams. See also datagram; node.

**SSI** See definition for server-side include (SSI).

**SSL** See definition for Secure Sockets Layer (SSL).

**STA** See definition for single-threaded apartment (STA).

**stateful object** An object that holds private state accumulated from the execution of one or more client calls.

**stateless object** An object that does not hold private state accumulated from the execution of one or more client calls.

**static page** A Hypertext Markup Language (HTML) page that is prepared in advance of a request for it and that is sent to the client upon request. This page takes no special action when it is requested. See also dynamic page.

**structured query language (SQL)** A widely accepted standard database sublanguage used in querying, updating, and managing relational databases.

**subkey** An element of the registry that contains entries or other subkeys. A tier of the registry that is immediately below a key or a subtree (if the subtree has no keys). See also key; registry.

**subnet mask** A 32-bit value that enables the recipient of Internet Protocol version 4 (IPv4) packets to distinguish the network ID and host ID portions of the IPv4 address. Typically, subnet masks use the format 255.x.x.x. IPv6 uses network prefix notations rather than subnet masks. See also IP address.

**symmetric encryption** An encryption algorithm that requires the same secret key to be used for both encryption and decryption. Because of its speed, symmetric encryption is typically used when a message sender needs to encrypt large amounts of data. Also called *secret key encryption*. See also public key encryption.

**System Data Source Name (DSN)** A name that can be used by any process on the computer. Internet Information Services (IIS) uses system DSNs to access Open Database Connectivity (ODBC) data sources.

**systemroot** The path and folder name where the Windows system files are located. Typically, this is C:\Windows, although you can designate a different drive or folder when you install Windows. You can use the value *%systemroot%* to replace the actual location of the folder that contains the Windows system files. To identify your systemroot folder, click **Start**, click **Run**, type **%systemroot%**, and then click **OK**.

**Systems Network Architecture (SNA)** A communications framework developed by IBM to define network functions and establish standards for enabling computers to share and process data.

**T**

**T1** A U.S. telephone standard for a transmission facility at digital signal level 1 (DS1) with 1.544 megabits per second in North America and 2.048 megabits per second in Europe. The bit rate is the equivalent bandwidth of approximately twenty-four 56-kilobits-per-second lines. A T1 circuit is capable of serving a minimum of 48 modems at 28.8 kilobits per second or 96 modems at 14.4 kilobits per second. T1 circuits are also used for voice telephone connections. A single T1 line carries 24 telephone connections with 24 telephone numbers. When it is used for voice transmission, a T1 connection must be split into 24 separate circuits.

**T3** A U.S. telephone standard for a transmission facility at digital signal level 3 (DS3). T3 is equivalent in bandwidth to 28 T1s, and the bit rate is 44.736 megabits per second. T3 is sometimes called a 45-meg circuit.

**TCP/IP** See definition for Transmission Control Protocol/Internet Protocol (TCP/IP).

**Telnet** A protocol that enables an Internet user to log on to and enter commands on a remote computer linked to the Internet, as if the user were using a text-based terminal directly attached to that computer. Telnet is part of the TCP/IP suite of protocols. The term *telnet* also refers to the software (client or server component) that implements this protocol. See also protocol; Transmission Control Protocol/Internet Protocol (TCP/IP).

**thread** A type of object within a process that runs program instructions. Using multiple threads allows concurrent operations within a process and enables one process to run different parts of its program on different processors simultaneously. A thread has its own set of registers, its own kernel stack, a thread environment block, and a user stack in the address space of its process. See also kernel.

**throttling** Controlling the maximum amount of bandwidth that is dedicated to Internet traffic on a server. This feature is useful if there are other services (such as e-mail) sharing the server over a busy link.

**time-out** A setting that automatically cancels an unanswered client request after a certain period of time.

**TP** See definition for transaction processing (TP).

**transaction processing (TP)** The real-time handling of computerized business transactions as they are received by the system. Also called online transaction processing (OLTP).

**Transmission Control Protocol/Internet Protocol (TCP/IP)** A set of networking protocols widely used on the Internet that provides communications across interconnected networks of computers with diverse hardware architectures and various operating systems. TCP/IP includes standards for how computers communicate and conventions for connecting networks and routing traffic. See also Internet Protocol (IP); protocol.

**Transport Layer Security (TLS) encryption** A generic security protocol similar to Secure Sockets Layer (SSL), used with Simple Mail Transfer Protocol (SMTP). See also Secure Sockets Layer (SSL).

**Triple DES (3DES)** An implementation of Data Encryption Standard (DES) encryption that employs three iterations of cryptographic operations on each segment of data. Each iteration uses a 56-bit key for encryption, which yields 168-bit encryption for the data. Although 3DES is slower than DES because of the additional cryptographic calculations, its protection is far stronger than DES. See also cryptography; Data Encryption Standard (DES); encryption.

**two-tier architecture** See definition for client/server architecture.

**type library** A binary file that describes a components methods, properties, and data structure.

**U**

**UNC (Universal Naming Convention) name** The full name of a resource on a network. It conforms to the *servername**sharename* syntax, where *servername* is the name of the server and *sharename* is the name of the shared resource. UNC names of directories or files can also include the directory path under the share name with the following syntax: *servername**sharename**directory**filename*

**Uniform Resource Locator (URL)** A naming convention that uniquely identifies the location of a computer, directory, or file on the Internet. A URL also specifies the appropriate Internet protocol, such as Hypertext Transfer Protocol (HTTP) or File Transfer Protocol (FTP). An example of a URL is http://www.microsoft.com.

**Universal Naming Convention (UNC)** A convention for naming files and other resources beginning with two backslashes (\), indicating that the resource exists on a network computer. UNC names conform to the *servername**sharename* syntax, where *servername* is the server's name and *sharename* is the name of the shared resource. The UNC name of a directory or file can also include the directory path after the share name by using the following syntax:

*\\servername\sharename\directory\filename*.

**upload** In communications, the process of transferring a copy of a file from a local computer to a remote computer by means of a modem or network. With a modem-based communications link, the process generally involves instructing the remote computer to prepare to receive the file on its disk and then wait for the transmission to begin.

**URL** See definition for Uniform Resource Locator (URL).

**URL directory** See definition for virtual directory.

**URL mapping** The process of associating a Uniform Resource Locator (URL) with a physical directory. See also virtual directory.

**usage data** Information that an administrator can use to learn how other people access and use a site. By analyzing this data, an administrator can identify a site's most popular (or unpopular) areas and clarify the most common navigational paths through the site.

**user rights** Tasks that a user is permitted to perform on a computer system or domain. There are two types of user rights: privileges and logon rights. An example of a privilege is the right to shut down the system. An example of a logon right is the right to log on to a computer locally. Both types are assigned by administrators to individual users or groups as part of the security settings for the computer. See also domain; group.

**user type** A DWORD that specifies how data is used. A user type is assigned to an identifier in the metabase.

**UTF-8** A method of character encoding that allows for both single and multibyte characters in one string. UTF-8 files take up more space than files that are stored in an American National Standards Institute (ANSI) format. Internet Information Services (IIS) supports Web files that are saved in UTF-8 format or in ANSI format. See also code page.

**V**

**virtual directory** A directory name, used in an address, that corresponds to a physical directory on the server. Sometimes called URL mapping.

**virtual server** A virtual computer that resides on a Hypertext Transfer Protocol (HTTP) server but appears to the user as a separate HTTP server. Several virtual servers can reside on one computer, each capable of running its own programs and each with individualized access to input and peripheral devices. Each virtual server has its own domain name and IP address, and each appears to the user as an individual Web site or File Transfer Protocol (FTP) site. Some Internet service providers (ISPs) use virtual servers for those clients who want to use their own domain names. Also called a Web site.

**volatile objects** Typically, files that a Web site administrator updates frequently.

**W-Z**

**W3C** See definition for World Wide Web Consortium (W3C).

**W3SVC** See definition for World Wide Web Publishing Service (WWW service).

**WAM** See definition for Web Application Manager (WAM).

**WBEM** See definition for Web-Based Enterprise Management (WBEM).

**Web application** A software program that uses Hypertext Transfer Protocol (HTTP) for its core communication protocol and that delivers Web-based information to the user in the Hypertext Markup Language (HTML) language. Also called a Web-based application.

**Web Application Manager (WAM)** For IIS 5.0 isolation mode, a COM+ application package that works with DLLHOST.exe to host out-of-process ISAPI extensions. Provides communication between DLLHOST.exe and INETINFO.exe. See also IIS 5.0 isolation mode.

**Web Distributed Authoring and Versioning (WebDAV)** An extension to the Hypertext Transfer Protocol (HTTP) 1.1 standard that facilitates access to files and directories through an HTTP connection. Remote authors can add, search, delete, or change directories and documents and their properties.

**Web farm** A Network Load Balancing cluster of IIS servers that support client Web site requests.

**Web garden** An application pool served by more than one worker process.

**Web page** A World Wide Web document. A Web page typically consists of a Hypertext Markup Language (HTML) file, with associated files for graphics and scripts, in a particular directory on a particular computer. It is identified by a Uniform Resource Locator (URL).

**Web server** In general, a computer that is equipped with server software that uses Internet protocols such as Hypertext Transfer Protocol (HTTP) and File Transfer Protocol (FTP) to respond to Web client requests on a TCP/IP network.

**Web service extensions** ISAPIs and CGIs that extend Internet Information Services (IIS) functionality beyond serving static pages.

**Web-Based Enterprise Management (WBEM)** An industry initiative to develop a standard technology for accessing management information about systems in an enterprise environment. The Microsoft implementation of Web-based Enterprise Management is Windows Management Instrumentation (WMI).

**WebDAV** See definition for Web Distributed Authoring and Versioning (WebDAV).

**wide area network (WAN)** A communications network connecting geographically separated locations that uses long-distance links of third-party telecommunications vendors. See also local area network (LAN).

**wildcard character** A keyboard character that can be used to represent one or many characters when conducting a query. The question mark (?) represents a single character, and the asterisk (*) represents one or more characters.

**Windows Internet Name Service (WINS)** A Windows name resolution service for network basic input/output system (NetBIOS) names. WINS is used by hosts running NetBIOS over TCP/IP (NetBT) to register NetBIOS names and to resolve NetBIOS names to Internet Protocol (IP) addresses. See also IP address.

**Windows Management Instrumentation (WMI)** The Microsoft implementation of Web-Based Enterprise Management (WBEM), which is an industry-wide standard technology for accessing management information about systems in an enterprise environment. WMI uses the Common Information Model (CIM) industry standard to represent managed components in a system. A system developer can develop a WMI interface that allows programmatic access to a system, so that users can write command-line administration scripts and tools. See also Web-Based Enterprise Management (WBEM).

**Windows Script Host (WSH)** A language-independent scripting host for ActiveX scripting engines on 32-bit Windows platforms.

**WMI** See definition for Windows Management Instrumentation (WMI).

**WMI provider** In Windows Management Instrumentation (WMI), a set of interfaces that provide programmatic access to management information in a system. Internet Information Services (IIS) implements a WMI provider in the namespace called MicrosoftIISv2to provide programmatic access to metabase properties and system settings.

**worker process** The implementation of the core Web server in Internet Information Services (IIS). Worker processes run in W3wp.exe.

**worker process isolation mode** The new Web process model for Internet Information Services (IIS) 6.0.

**worker thread** A thread that is created by a component, Internet Server API (ISAPI) extension, or filter to perform asynchronous processing. Using worker threads frees up Internet Information Services (IIS) I/O threads to process additional requests.

**working directory** The directory in which Web server software is installed. The RAM that is allocated to a process in the Windows operating system.

**World Wide Web (WWW)** A set of services that run on top of the Internet and provide a cost-effective way of publishing information, supporting collaboration and workflow, and delivering business applications to connected users all over the world. The Web is a collection of Internet host systems that make these services available on the Internet, using the Hypertext Transfer Protocol (HTTP). Web-based information is usually delivered in the form of hypertext and hypermedia, using Hypertext Markup Language (HTML). The most graphical service on the Internet, the Web also has the most sophisticated linking abilities.

**World Wide Web Consortium (W3C)** An international industry consortium that is jointly hosted by the Massachusetts Institute of Technology Laboratory for Computer Science (MIT/CS) in North America, by the Institut National de Recherche en Informatique et en Automatique (INRIA) in Europe, and by the Keio University Shonan Fujisawa Campus in Asia. W3C was founded in 1994 to develop common standards for the World Wide Web. Initially, the W3C was established in collaboration with CERN, where the Web originated, with support from the Defense Advanced Research Projects Agency (DARPA) and the European Commission.

**World Wide Web Publishing Service (WWW service)** The service that manages the Internet Information Services (IIS) core components that process HTTP requests and configure and manage Web applications. Formerly known as W3SVC.

**WSH** See definition for Windows Script Host (WSH).

**WWW** See definition for World Wide Web (WWW).

**WWW Service Administration and Monitoring component** A component of the World Wide Web Publishing Service (WWW service) in Internet Information Services (IIS) that is responsible for configuration, by means of the metabase, and for worker process management.

**XML** See definition for Extensible Markup Language (XML).
