

# DirectX Video Acceleration Specification for H.264/AVC Decoding

Gary J. Sullivan  
Microsoft Corporation  
December 2007  
Updated December 2010

Applies to:

- DirectX Video Acceleration

Summary: Defines extensions to DirectX Video Acceleration (DXVA) to support decoding of H.264/AVC video.

The information contained in this document represents the current view of Microsoft Corporation on the issues discussed as of the date of publication. Because Microsoft must respond to changing market conditions, it should not be interpreted to be a commitment on the part of Microsoft, and Microsoft cannot guarantee the accuracy of any information presented after the date of publication.

MICROSOFT MAKES NO WARRANTIES, EXPRESS OR IMPLIED, AS TO THE INFORMATION IN THIS DOCUMENT.

Complying with all applicable copyright laws is the responsibility of the user. Without limiting the rights under copyright, no part of this document may be reproduced, stored in or introduced into a retrieval system, or transmitted in any form or by any means (electronic, mechanical, photocopying, recording, or otherwise), or for any purpose, without the express written permission of Microsoft Corporation.

Microsoft may have patents, patent applications, trademarks, copyrights, or other intellectual property rights covering subject matter in this document. Except as expressly provided in any written license agreement from Microsoft, the furnishing of this document does not give you any license to these patents, trademarks, copyrights, or other intellectual property.

Unless otherwise noted, the example companies, organizations, products, domain names, e-mail addresses, logos, people, places and events depicted herein are fictitious, and no association with any real company, organization, product, domain name, e-mail address, logo, person, place or event is intended or should be inferred.

Microsoft does not make any representation or warranty regarding specifications in this document or any product or item developed based on these specifications. Microsoft disclaims all express and implied warranties, including but not limited to the implied warranties or merchantability, fitness for a particular purpose and freedom from infringement. Without limiting the generality of the foregoing, Microsoft does not make any warranty of any kind that any item developed based on these specifications, or any portion of a specification, will not infringe any copyright, patent, trade secret or other intellectual property right of any person or entity in any country. It is your responsibility to seek licenses for such intellectual property rights where appropriate. Microsoft shall not be liable for any damages arising out of or in connection with the use of these specifications, including liability for lost profit, business interruption, or any other damages whatsoever. Some states do not allow the exclusion or limitation of liability or consequential or incidental damages; the above limitation may not apply to you.

## Introduction

This specification defines extensions to DirectX® Video Acceleration (DXVA) to support decoding of H.264/AVC video, a video compression standard published jointly as ITU-T Recommendation H.264 and ISO/IEC 14496 (MPEG-4) Part 10.

This specification assumes that you are familiar with the H.264/AVC specification and with the basic design of DXVA.

DXVA consists of a DDI for display drivers and an API for software decoders. Version 1.0 of DXVA is supported in Windows 2000 or later. Version 2.0 is available starting in Windows Vista. The data structures used for decoding are the same in both versions, and the information in this specification applies to both. Any relevant differences between the two versions are noted.

In DXVA, some decoding operations are implemented by the graphics hardware driver. This set of functionality is termed the accelerator. Other decoding operations are implemented by user-mode application software, called the host decoder or software decoder. Processing performed by the accelerator is called off-host processing. Typically the accelerator uses the GPU to speed up some operations. Whenever the accelerator performs a decoding operation, the host decoder must convey to the accelerator buffers containing the information needed to perform the operation.

---

**Note** In this document, the term shall describes behavior that is required by the specification. The term should describes behavior that is encouraged but not required. The term note refers to observations about implications of the specification.

---

---

**Note** In this version of document, section 2.3 accelerator decoder specific support about format change and surface allocation is added to optimize video decoding latency and performance according to different accelerator capabilities. Display information about which field should be displayed first in the compressed picture is also specified in Reserved8BitsA of DXVA\_PicParams\_H264 for the scenario where downsampling of uncompressed picture happens right after decoding. Information to indicate whether the display information is set properly by the host decoder or should be ignored is specified in the section entitled "Accelerator Decoder Specific Support".

---

Send questions or comments about this specification to [askdxva@microsoft.com](mailto:askdxva@microsoft.com).

## 1.0 General Design Considerations

This section provides an overview of the design for DXVA decoding of H.264/AVC video. It is intended as background information, and might be helpful in understanding the sections that follow. In the case of conflicts, later sections of this document override this section. Unless otherwise noted, all references to the H.264/AVC specification are to the 2010 edition published

---

by the ITU-T, dated March 2010. This specification is available at <http://www.itu.int/rec/T-REC-H.264>.

The initial design is intended to be sufficient for decoding the High, Main, and Baseline profiles. To support other profiles would require incorporating some additional features into the design:

- SP and SI slices. SP slices can be handled at the picture level, with the exception of slice\_qs\_delta.
  - More than 8 bits per sample. This could be accomplished by increasing the precision of transform coefficients and I\_PCM macroblock samples.
  - Chroma sampling schemes other than 4:2:0. This could be accomplished by increasing the number of chroma blocks in a macroblock and indicating the format at the picture level.
- 6
- Transform-bypass mode. This could be accomplished by sending a flag for each macroblock. Residual blocks would be sent using 16 bits per sample.
  - Residual color transform. This could be accomplished using a flag at the picture level.

---

Note The use of the residual color transform in H.264/AVC has been deprecated by ITU-T and ISO/IEC since the 2005 edition of the standard. Therefore, the associated DXVA flag must equal 0 for uses relating to the current version of the standard.

---

The critical design considerations for DXVA decoding of H.264/AVC video include the following:

- Which basic modes of operation to support. The estimated order of priority, from highest to lowest, is:
  1. Off-host inverse transform with host-based entropy decoding.
  2. Raw bitstream format.
  3. Host-based inverse transform with off-host motion compensation and spatial prediction.
- How to incorporate the loop filter: Whether to put the loop filter control data in the same buffer as the macroblock control commands, or put them in a separate buffer. The current design supports both methods.
- How to handle slice-level data (for explicit weighted prediction, for example).
- The structure of macroblock control commands. Unlike MPEG-2, H.264/AVC requires supporting a highly variable number of motion vectors—in principle, up to 32 motion vectors per macroblock. This factor means the design must use either variable-length macroblock control commands, or separate motion vector buffers. The current design uses separate motion vector buffers. (Hypothetically, motion vector buffers could also be placed in the same buffer as the residual data.)
- How to perform macroblock skipping. Unlike MPEG-2, the motion for skipped macroblocks is not simple to infer. (It is not just the same as the macroblock to the left.) In the current design, every macroblock requires its own macroblock control command. Hypothetically, the design could specify an inference rule and allow macroblock skipping if the data fits the rule. However, the benefit of having a 1:1 correspondence between macroblock control commands and macroblocks might outweigh the benefits of supporting such an inference rule.

- How to send residual data when using host-based inverse transform or transform bypass. Considerations include whether to use 16 bits per sample; how to handle 4x4 and 8x8 inverse transforms; and how to handle extra DC transforms for chroma samples and for Intra\_16x16 macroblocks.
- When using off-host inverse transform, how to send coefficients; how to handle 4x4 and 8x8 inverse transforms; how to handle extra DC transforms; whether to send data as levels or as scaled coefficients; and how to handle I\_PCM sample values.
- Whether to support additional post-processing, such as film-grain synthesis.

## 1.1 Picture Data

The following data must be conveyed for each picture. For details, see section 4.0, Picture Parameters Data Structure.

- PicWidthInMbs
- PicHeightInMbs. (Useful primarily as a data validation check.)
- IntraPicFlag. (Not essential but possibly helpful.)
- MbaffFrameFlag
- field\_pic\_flag

- `bottom_field_flag`
- `chroma_format_idc`
- `BitDepthY` and `BitDepthC`
- `residual_colour_transform_flag`, if High 4:4:4 Profile is supported.
- `qpprime_y_zero_transform_bypass_flag`. (Might not be needed.)
- Scaling lists or scaling matrixes. Not required if inverse quantization is performed on the host CPU. If "flat" scaling lists are used, it might be possible to set a flag and not send the scaling lists to the accelerator.
- `CurrPic`. Indicates the current destination surface.
- `RefFrameList`. Contains a list of 16 reference frame surfaces.
- Flags for long-term reference frames. In the current design, these are included in `RefFrameList`.
- `weighted_pred_flag`
- `weighted_bipred_idc`
- `CurrFieldOrderCnt`. Contains the values of `TopFieldOrderCnt` and `BottomFieldOrderCnt`.
- `FieldOrderCntList`. Contains a list of 16 `PicOrderCnt` pairs for top and bottom fields, each 32 bytes. The accelerator should not assume these values are invariant on each picture, because random access issues might prevent the decoder from having the correct value. As a result, the value assigned to a picture might change after the picture has been decoded, especially in the most-significant bits (MSBs).
- `sp_for_switch_flag`. Required only if SP and SI slices are supported.

## 1.2 Slice Data

The following data must be conveyed for slices in predicted (non-intra) pictures. Not all of this data is required under all circumstances. For more details, see section 6.0, Slice Control Data Structure.

- `slice_type`. Identifies I, P, B, SI, and SP slices.
- `num_ref_idx_l0_active_minus1`
- `num_ref_idx_l1_active_minus1`
- `slice_alpha_c0_offset_div2` or `FilterOffsetA`. (The current design uses `slice_alpha_c0_offset_div2`.)
- `slice_beta_offset_div2` or `FilterOffsetB`. (The current design uses `slice_beta_offset_div2`.)
- `RefPicList`. Contains two lists of indexes into the `RefFrameList` array, with up to 16 valid indexes for decoding frames, or 32 valid indexes for decoding fields. For decoding fields, an associated flag identifies the parity of the field within the uncompressed surface identified by the entry in the `RefFrameList` array.
- `luma_log2_weight_denom`
- `chroma_log2_weight_denom`
- `Weights`. Contains two lists of weight tables. Each entry in the list contains the weighting factor and additive offset for Y, Cb, and Cr.
- `QSY` and `QSC` values. Required only if SP and SI slices are supported.

## 1.3 Macroblock Data

The following data must be conveyed for each macroblock. For more information, see section 7.0, Macroblock Control Data Structure.

- Macroblock address.
- Macroblock type (`mb_type` or equivalent). The various macroblock types are listed in tables 7-11 through 7-14 of the H.264/AVC specification. These can be reduced to 30 distinct types:
- `I_NxN`, where the prediction mode is either 4x4 or 8x8, depending on the `transform_size_8x8` flag.
- `Intra_16x16`, with various values of `Intra16x16PredMode`, `CodedBlockPatternChroma`, and `CodedBlockPatternLuma` treated as a single type.
- `I_PCM`
- `SI`
- `P_L0_16x16`, including `P_Skip`.
- `P_L0_L0_16x8`
- `P_L0_L0_8x16`
- `P_8x8`, including `P_8x8ref0`.
- `B_xx_16x16`, where `xx` is `L0`, `L1`, or `Bi` (3 types).
- `B_xx_yy_16x8`, where `xx` and `yy` are `L0`, `L1`, or `Bi` (9 types).
- `B_xx_yy_8x16` (9 types).
- `B_8x8`, including `B_Skip` and `B_Direct_16x16`.

The list can be further reduced to 26 cases, because the macroblock types for `P` and `SP` slices (those starting with "P\_" in the previous list) have equivalents in the "B\_" types, so they can be omitted. In the current design, the macroblock type is defined by a 1-bit intra flag and 5 bits to distinguish the various cases within intra and nonintra types.

- `mb_field_decoding_flag` or equivalent
- `transform_size_8x8_flag` or equivalent
- Sub-macroblock partition shape. Needed for `P_8x8` and `B_8x8` macroblock types. Four sub-macroblock partitions are defined, requiring 2 bits to specify. For more information, see subclause 6.4.2 of the H.264/AVC specification.
- Sub-macroblock prediction modes (`Pred_L0`, `Pred_L1`, or `BiPred`). Needed for `B_8x8` macroblock types, for each of the four sub-macroblocks.
- Luma intra prediction information, for intra modes. For `Intra_4x4` sample prediction, there are 16 modes of 4 bits each. For `Intra_8x8` prediction, there are four modes of 4 bits each. For `Intra16x16` prediction, there is one mode (`Intra16x16PredMode`), requiring 2 bits.
- Flags to indicate the availability of neighboring macroblocks for intra prediction.

---

**Note** Some intra macroblocks must be processed after the left-neighboring and above-neighboring inter macroblocks in the same slice. Also, within the same row of macroblocks or macroblock pairs, it is not always possible to process two consecutive intra macroblocks in parallel. Parallel processing of different rows is feasible if a lag is introduced when processing lower rows relative to higher rows. Also, note that an entire picture might be composed of intra macroblocks.

- 
- Chroma prediction mode (`intra_chroma_pred_mode`), requiring 2 bits, for intra prediction modes.
  - Filtering control parameters: QP values, flags indicating which edges to filter, and flags indicating whether to filter in frame mode or field mode. (For more information, see section 9.0, Deblocking Filter Control Data Structure.)
  - Flags indicating which residual blocks contain residual data.
- 

Note The `CodedBlockPatternLuma` variable in the H.264/AVC specification does not include a bit flag to indicate the presence or absence of non-zero DC coefficients in an `Intra_16x16` macroblock. Therefore, either an additional bit flag must be defined, or the host decoder must send a zero-valued coefficient with the `endofblock` flag set to 1, to indicate the absence of a luma DC coefficient in the macroblock.

---

- Flag to specify whether transform bypass mode is used. As an alternative, the host decoder could provide the value of `qpprime_y_zero_transform_bypass_flag` at the picture level and the value of `QPY` at the macroblock level, which is sufficient for the accelerator to infer the transform bypass mode.
- The values of `QPY` and `QPC`, or `QP'Y` and `QP'C`, if the accelerator is performing inverse quantization or needs these values to control the deblocking filter.
- An offset into a slice parameters data buffer, which locates the slice-level data that applies to the macroblock (for example, for weighted prediction).
- An offset into a motion vector data buffer, which locates the motion vector data for the macroblock. Motion vector data includes:
  - Reference indexes: As many as two reference indexes for each of the four submacroblocks.
  - Motion vectors: As many as two motion vectors for each of four sub-macroblock partitions in each of the four sub-macroblocks. Each motion vector has two components (horizontal and vertical).
- An offset into a residual difference data buffer, which locates the residual difference data for the macroblock. Residual difference data may be in the coefficient domain or the spatial domain.

## 1.4 Buffer Types

The host decoder will send the following DXVA buffers to the accelerator:

- One picture parameters buffer.
- Zero or one quantization matrix buffer.
- Zero or more slice control buffers. Not required when `IntraPicFlag` is 1 and the host decoder parses the bitstream.
- Zero or more macroblock control command buffers. Not required when the accelerator parses the bitstream.
- Zero or more motion vector buffers, containing motion vectors for inter prediction. Not required if the macroblock control buffer indicates that all macroblocks are coded in intra modes, or when the accelerator parses the bitstream.

- Zero or more residual difference data buffers, containing one or more of the following: transform coefficients, I\_PCM macroblock data, or spatial-domain residual difference blocks. Used for transform-bypass mode or host-based transform. Not required when the accelerator parses the bitstream.
- Zero or more deblocking filter control data buffers. These control the deblocking filter inside the decoding feedback loop. In other configurations, this functionality is provided by the macroblock control command buffer.
- Zero or more bitstream data buffers. Not required when the accelerator parses the bitstream.
- Zero or one film-grain synthesis data buffer. Required only if film-grain synthesis is used.

These buffer types are defined in the DXVA specification, but new data structures have been defined for H.264/AVC decoding. The sequence of operations is described in section 1.5.

## 1.5 DXVA Decoding Operations

The basic sequence of operations for DXVA decoding consists of the following calls by the host decoder. In DXVA 1.0, these methods are part of the IAMVideoAccelerator interface. In DXVA 2.0, they are part of the IDirectXVideoDecoder interface and some parameters are changed.

1. **BeginFrame.** Signals the start of one or more decoding operations by the accelerator, which will cause the accelerator to write data into an uncompressed surface buffer.
2. **Execute.** Sends one or more compressed data buffers to the accelerator and specifies the operations to perform on the buffers. The accelerator might return status information from the call.

In DXVA 1.0, the decoder specifies the operations to perform by setting the `dwFunction` parameter in `IAMVideoAccelerator::Execute`. This parameter contains from one to four 8-bit commands packed into a 32-bit value. If there is only one command, it is placed in the 8 most significant bits (MSBs) of `dwFunction`, and the remaining bytes are set to zero. The 8-bit command is referred to as `BDXVA_Func`, although this is not a formal parameter name.

In DXVA 2.0, the command can be specified in the `Function` member of the optional `DXVA2_DecomposeExtensionData` structure passed to `IDirectXVideoDecoder::Execute`. In most cases, however, the command is implied by the type of buffer.

3. **EndFrame.** Signals that the host decoder has sent all of the data needed for this `BeginFrame` call. The accelerator can complete the operations.

For H.264/AVC decoding, the data passed to the `Execute` method includes a destination index to indicate which uncompressed surface buffer is affected by the operation. Each call to `Execute` affects one destination surface. Calling `BeginFrame` locks the buffer for writing, and calling `EndFrame` unlocks the buffer. The host decoder can call `Execute` more than once between each `BeginFrame/EndFrame` pair. The decoder shall not interleave calls to `BeginFrame`, `Execute`, and `EndFrame` that affect output to different uncompressed surfaces.

During the `BeginFrame/EndFrame` sequence, the accelerator might read from uncompressed surfaces other than the surface being written to. For example, decoding a picture might require data from one or more previously-decoded pictures. If the host decoder issues a command that requires writing to a buffer, and then issues a command that requires reading from the same buffer, it is the accelerator's responsibility to serialize the operations. In other words, the accelerator must complete the write operation before starting a read operation on the same buffer.

The DXVA design for H.264/AVC restricts the sequence of buffer types that can be sent to the accelerator. The following sets of buffer types are defined:

Type 1: Compressed picture decoded entirely by the host decoder. The host decoder sends the following buffer:

- One picture parameters data buffer, with IntraPicFlag set to 1.

Type 2: Compressed picture decoding with host-based bitstream parsing. The host decoder sends the following buffers:

- One picture parameters buffer.
- One quantization matrix buffer.
- One slice control buffer.
- One macroblock control buffer.
- Zero or one motion vector buffer.
- Zero or more residual difference data buffers.

Type 3: Compressed picture decoding with off-host parsing. The host decoder sends the following buffers:

- One picture parameters buffer.
- One quantization matrix buffer.
- One slice control buffer.
- One bitstream data buffer.

Type 4: Deblocking filter. The host decoder sends the following buffers:

- One picture parameters buffer.
- One deblocking filter control data buffer.

Type 5: Film-grain synthesis. The host decoder sends the following buffers:

- One film-grain synthesis data buffer.

Type 6: Status reporting feedback. The host decoder does not send any buffers.

For these six types, four values of `BDXVA_Func` are defined:

Value	Description
1	Compressed picture decoding, possibly including the deblocking filter (Types 1, 2, and 3).
5	Deblocking filter (Type 4).
6	Film-grain synthesis (Type 5).
7	Request for status reporting (Type 6).

If `dwFunction` is present, it shall contain exactly one of the values listed here. However, the correct function can be inferred from the types of buffer passed to the accelerator without knowing the value of `dwFunction`, as follows:

- If a slice control buffer is present, parts of a compressed picture are to be decoded. The operation is then controlled by either a macroblock control buffer or a bitstream buffer.
- If a deblocking filter control data buffer is present, the accelerator is to perform some part of the deblocking filter on the picture.
- If a film-grain synthesis data buffer is present, the accelerator is to perform film-grain synthesis.

- 

Function 7 (status reporting) is a special case, described in the next section.

Between a single pair of BeginFrame and EndFrame calls, the host decoder can combine different sets of buffers in the following combinations:

- One Type 1, or one or more Type 2, with bDXVA\_Func = 1.
- One Type 1, or one or more Type 2, with bDXVA\_Func = 1; followed by one or more Type 4 with bDXVA\_Func = 5.
- One Type 1, or one or more Type 2, with bDXVA\_Func = 1; followed by one Type 5 with bDXVA\_Func = 6.
- One Type 1, or one or more Type 2, with bDXVA\_Func = 1; followed by one or more Type 4 with bDXVA\_Func = 5; followed by one Type 5 with bDXVA\_Func = 6.
- One or more Type 3 with bDXVA\_Func = 1.
- One or more Type 3 with bDXVA\_Func = 1; followed by one Type 5 with bDXVA\_Func = 6.
- One or more Type 4 with bDXVA\_Func = 5.
- One Type 5 with bDXVA\_Func = 6.

Only the combinations listed here are valid. When bitstream data buffers (Type 3) are used, the total quantity of data in the buffer (and the amount of data reported by the host decoder) shall be an integer multiple of 128 bytes.

Whenever the host decoder calls Execute to pass a set of compressed buffers to the accelerator, the private output data pointer shall be NULL, as follows:

- DXVA 1.0: When dwNumBuffers is greater than zero, lpPrivateOutputData shall be NULL and cbPrivateOutputData shall be zero.
- DXVA 2.0: When the NumCompBuffers member of the DXVA2\_DecodeExecuteParams structure is greater than zero, pPrivateOutputData shall be NULL and PrivateOutputDataSize shall be zero.  
(Alternatively, the pExtensionData member of the DXVA2\_DecodeExecuteParams structure can be NULL.)

### 1.5.1 Status Reporting

After calling EndFrame for the uncompressed destination surfaces, the host decoder may call Execute with bDXVA\_Func = 7 to get a status report. The host decoder does not pass any compressed buffers to the accelerator in this call. Instead, the decoder provides a private output data buffer into which the accelerator will write status information. The decoder provides the output data buffer as follows:

- DXVA 1.0: The host decoder sets lpPrivateOutputData to point to the buffer. The cbPrivateOutputData parameter specifies the maximum amount of data that the accelerator should write to the buffer.
- DXVA 2.0: The host decoder sets the pPrivateOutputData member of the DXVA2\_DecodeExecuteParams structure to point to the buffer. The PrivateOutputDataSize member specifies the maximum amount of data that the accelerator should write to the buffer.

The value of cbPrivateOutputData or PrivateOutputDataSize shall be an integer multiple of sizeof(DXVA\_Status\_H264).

When the accelerator receives the Execute call for status reporting, it should not stall operation to wait for any prior operations to complete. Instead, it should immediately provide the available status information for all operations that have completed since the previous request for a status report, up to the maximum amount requested. Immediately after the Execute call returns, the host decoder can read the status report information from the buffer. The status report data structure is described in section 12.

## 1.6 Accelerator Internal Information Storage

The H.264/AVC decoding process requires storing some additional information along with the array of decoded pictures to be used as reference pictures for decoding B slices. Rather than have the host decoder collect this information and explicitly provide it to the accelerator, the accelerator must store this information as it decodes each picture, so that the information is available if the picture is later used as a reference picture.

Because of this requirement, the host decoder must use the DXVA interface to decode any non-intra pictures that are used as reference pictures for decoding subsequent B slices. For non-intra pictures, the host decoder cannot simply write a decoded picture into an uncompressed destination surface and then use that surface as a reference picture for decoding a B slice.

For intra pictures, the host decoder has the option of performing the entire decoding process and sending the decoded picture to the accelerator. To do so, the decoder calls BeginFrame, then Execute with a Type 1 buffer as described in section 1.5 (that is, a picture parameters buffer with the IntraPicFlag flag set to 1), followed by EndFrame. This sequence indicates that the host decoder has decoded the intra picture, and that the accelerator can use the picture as a reference for deblocking filter, film-grain synthesis, or decoding subsequent pictures.

The accelerator must store the following information for each macroblock of each decoded reference picture:

- A flag indicating whether the macroblock was predicted using intra or inter prediction.
- If the value of frame\_mbs\_only\_flag in the picture parameters buffer is 0, a flag indicating whether the macroblock or macroblock pair was coded in frame or field mode.
- For inter macroblocks, some form of reference picture identifier for each 8x8 region. It is recommended that accelerators use the combination of CurrPic and field\_pic\_flag from the picture parameters data structure for the reference picture.

---

Note The accelerator should not use the values TopFieldOrderCnt and BottomFieldOrderCnt as part of the identifier. For more information, see the remarks about these values that follow.

- 
- For inter macroblocks, the following data:
    - If direct\_8x8\_inference\_flag in the picture parameters buffer is 0, one motion vector for each 4x4 region; or a representation of the motion segmentation and the motion vector associated with each segmented region.
  - If direct\_8x8\_inference\_flag is 1, one motion vector for each 8x8 region; or a representation of the motion segmentation and the motion vector associated with each segmented region.

---

Note The value of direct\_8x8\_inference\_flag must be 1 in all bitstreams of the Baseline and Extended profiles and in all bitstreams marked as level 3 or higher. This includes all bitstreams supporting standard definition (SD) picture sizes at SD frame rates (that is, all

- bitstreams having both 1,620 or more macroblocks per frame and 40,500 or more macroblocks per second). Nonetheless, it is important to remember that decoders designed for one level are required by the H.264/AVC specification to decode bitstreams of all lower levels. Therefore, accelerators must be designed to handle both cases.

---

The accelerator also needs the values of TopFieldOrderCnt and BottomFieldOrderCnt per picture, but these are provided by the host decoder in the CurrFieldOrderCnt and FieldOrderCntList members of the picture parameters data structure. The accelerator should not store these values on its own, as doing so could interfere with randomaccess functionality.

---

Note This design is intended to enable features such as random access and "trick mode" (smooth reverse or fast-forward playback with minimal picture storage).

---

## 2.0 Configuration Parameters

This section describes the configuration parameters for H.264/AVC decoding.

### 2.1 Syntax

The existing DXVA configuration structures are used for configuration:

- DXVA 1.0: Configuration uses the DXVA\_ConfigPictureDecode structure.
- DXVA 2.0: Configuration uses the DXVA2\_ConfigPictureDecode structure.

### 2.2 Semantics

The meaning of the structure members is documented in the DXVA 1.0 and 2.0 documentation, with the following modifications for H.264/AVC decoding.

bConfigBitstreamRaw

May be 0, 1, or 2.

Value	Description
0	Picture data will be sent using macroblock control command buffers. The DXVA_Slice_H264_Long structure is used for slice control data.
1	Picture data will be sent using raw bitstream buffers. The DXVA_Slice_H264_Long structure is used for slice control data.
2	Same as 1, but the DXVA_Slice_H264_Short structure is used for slice control data.

bConfigMBcontrolRasterOrder May be 0 or

1.

Value	Description
0	The order of macroblocks within each macroblock control buffer shall follow raster order with no gaps, unless the restricted-mode profile specifies otherwise.

1	<p>As with 0, the order of macroblocks within each macroblock control buffer shall follow raster order with no gaps.</p> <p>In addition, the order in which the decoder sends macroblock control buffers to the accelerator shall follow raster scan order for the first macroblock of each buffer. (The host decoder may send more than one macroblock control buffer at a time, but consecutive calls to send macroblock control buffers must not violate raster scan order.)</p>
---	---

When `bConfigBitstreamRaw` is 1 or 2, `bConfigMBcontrolRasterOrder` has no meaning and shall be 0.

Regardless of the value of `bConfigMBcontrolRasterOrder`, the order of macroblocks within each macroblock control buffer shall follow raster order, unless the decoder is using a restricted-mode profile that specifically includes the ability to remove this restriction. When `bConfigMBcontrolRasterOrder` is 0, the host decoder may ignore the second constraint listed for 1.

`bConfigResidDiffHost` May be 0  
or 1.

`bConfigSpatialResid8`

Shall be 0. In H.264/AVC, spatial-domain prediction is performed for intra pictures. Therefore, intra pictures require the same number of bits per sample to represent spatial residual data as are used for other picture types. The same is true for intra macroblocks of non-intra pictures. `bConfigResid8Subtraction` Shall be 0.

`bConfigSpatialHost8or9Clipping` Shall  
be 0. `bConfigSpatialResidInterleaved`  
Shall be 0. `bConfigIntraResidUnsigned`  
Shall be 0.

`bConfigResidDiffAccelerator` May be 0  
or 1.

`bConfigHostInverseScan`  
Shall be 1.

`bConfigSpecificIDCT`

Shall be 2 when `bConfigResidDiffAccelerator` is 1. Otherwise, shall be 0.

Value	Description
-------	-------------

0	Host-based residual difference decoding.
2	Indicates the use of the integer inverse transforms specified by H.264/AVC.

#### bConfig4GroupedCoefs

May be 0 or 1.

Value	Description
0	The host will not send deblocking filter control buffers. Instead, the deblocking filter process will be controlled by data found in other buffers.
1	The host will send deblocking filter control buffers to control the deblocking filter process.

If bConfigBitstreamRaw is 1, bConfig4GroupedCoefs shall be 0.

Zero is a higher-performance acceleration capability than 1, because it requires the host decoder to perform less work and send less data to the accelerator. Decoders should select this mode if possible.

## 2.3 Accelerator Decoder Specific Support

The **ConfigDecoderSpecific** member of the **DXVA2\_ConfigPictureDecode** structure contains information about some decoder accelerator specific support. **ConfigDecoderSpecific** has the type unsigned short, where the least-significant bit is considered bit 0 and the most significant bit is bit 15.

For purposes specified herein, a "format change" is defined as the detection by the host decoder that the number of surfaces to be used has increased or that the decoding resolution (picture width or height) has changed or that the accelerator capability requirements have changed, such as enabling or disabling downsampling of the output.

The semantics of bit 15 are as follows:

- 0b: in the event of a format change, some accelerators indicating this value may not be capable of continuing operation. The host decoder should therefore create a new video decoder device and destroy the old video decoder device when a format change occurs.
- 1b: in the event of a format change, the accelerator is indicated to be capable of continuing operation. The host decoder should not create a new video decoder device and proceed using the existing video decoder device instance.

When bit 15 of **ConfigDecoderSpecific** is set equal to 1 by the accelerator through the API **GetVideoDecoderConfig()**, the video decoder device can be reused after a format change and the host decoder should not create a new video decoder device in the event of a format change (thereby reducing latency relative to that experienced by recreating the decoder device).

---

Note Older accelerators use the value 0 for bit 15 of **ConfigDecoderSpecific**, as the use of the value 1 was not defined prior to late 2014.

---

The semantics of bit 14 are as follows:

- 0b: accelerator may only support a texture array, or supports both an array of textures or a texture array for uncompressed surfaces but the use of a texture array may have better performance than an array of textures. In this case, the host decoder should create a texture array for uncompressed surfaces to ensure proper operation.
- 1b: accelerator supports both array of textures and texture array for uncompressed surfaces but an array of textures may have better performance than a texture array. In this case, the host decoder should create an array of textures for uncompressed surfaces.

The performance of the use of a "texture array" versus an "array of textures" may be different for different accelerators. Bit 14 of **ConfigDecoderSpecific** indicates the recommended configuration for the uncompressed surfaces used for decoding. The recommended value for bit 14 of **ConfigDecoderSpecific** is set by the accelerator through the API `GetVideoDecoderConfig()`.

---

Note Older accelerators use the value 0 for bit 14 of **ConfigDecoderSpecific**, as the use of the value 1 was not defined prior to late 2014.

---

The semantics of bit 13 are as follows:

- 0b: the display information about which field of the decoded picture should be displayed first is not needed for the accelerator. **Reserved8BitsA** in **DXVA\_PicParams\_H264** structure should be ignored by the accelerator. In this case, the accelerator does not need to be prepared for the scenario in which downsampling of a decoded picture happens after decoding as enabled by the new APIs `CheckVideoDecoderDownsampling()` and `DecoderEnableDownsampling()`.

- 1b: the display information about which field of the decoded picture should be displayed first is needed. **Reserved8BitsA** in **DXVA\_PicParams\_H264** structure should be set properly by the host decoder with the display information accelerator needs for different scenarios, such as the scenario where downsampling of a decoded picture happens right after decoding as enabled by the new APIs `CheckVideoDecoderDownsampling()` and `DecoderEnableDownsampling()`. Accelerator should be prepared for the scenario where downsampling of a decoded picture happens right after decoding as enabled by the new APIs `CheckVideoDecoderDownsampling()` and `DecoderEnableDownsampling()`.

Bit 13 of **ConfigDecoderSpecific** is used to indicate whether host decoder properly sets the display information about which field of the decoded picture should be displayed first through **Reserved8BitsA** or not for various scenarios, and whether **Reserved8BitsA** in **DXVA\_PicParams\_H264** structure should be ignored or not. The value for bit 13 of **ConfigDecoderSpecific** is set by the host decoder through the API `CreateVideoDecoder()` as a hint to the accelerator.

Other bits of **ConfigDecoderSpecific** are reserved and shall be set to 0.

### 3.0 DXVA\_PicEntry\_H264 Structure

The `DXVA_PicEntry_H264` structure specifies a reference to an uncompressed surface. It is used in other data structures described in this document.

#### 3.1 Syntax

```
typedef struct _DXVA_PicEntry_H264 {
    union { struct {
        UCHAR Index7Bits : 7;
        UCHAR AssociatedFlag : 1;
    };
        UCHAR bPicEntry;
    };
} DXVA_PicEntry_H264, *LPDXVA_PicEntry_H264;
```

#### 3.2 Semantics

##### Index7Bits

An index that identifies an uncompressed surface for the `CurrPic` or `RefFrameList` member of the picture parameters structure (section 4.0) or the `RefPicList` member of the slice control data structure (section 6.0)

When `Index7Bits` is used in the `CurrPic` and `RefFrameList` members of the picture parameters structure, the value directly specifies the DXVA index of an uncompressed surface.

When `Index7Bits` is used in the `RefPicList` member of the slice control data structure, the value identifies the surface indirectly, as an index into the `RefFrameList` array of the associated picture parameters structure. For more information, see section 6.2.

In all cases, when Index7Bits does not contain a valid index, the value is 127.

#### AssociatedFlag

Optional 1-bit flag associated with the surface. The meaning of the flag depends on the context. For example, it can specify the top field or bottom field.

#### bPicEntry

Accesses the entire 8 bits of the union.

#### Requirements

Header: Include dxva.h.

## 4.0 Picture Parameters Data Structure

The DXVA\_PicParams\_H264 structure provides the picture-level parameters of a compressed picture for H.264/AVC decoding.

This structure is used when bDXVA\_Func is 1 and the buffer type is DXVA\_PICTURE\_DECODE\_BUFFER (DXVA 1.0) or DXVA2\_PictureParametersBufferType (DXVA 2.0).

### 4.1 Syntax

```
typedef struct _DXVA_PicParams_H264 { USHORT
wFrameWidthInMbsMinus1;
  USHORT wFrameHeightInMbsMinus1;
  DXVA_PicEntry_H264 CurrPic;  UCHAR
num_ref_frames; union { struct {
  USHORT field_pic_flag      : 1;
  USHORT MbaffFrameFlag     : 1;
  USHORT residual_colour_transform_flag : 1;
  USHORT sp_for_switch_flag : 1;
  USHORT chroma_format_idc  : 2;
  USHORT RefPicFlag         : 1;
  USHORT constrained_intra_pred_flag : 1;
  USHORT weighted_pred_flag : 1;
  USHORT weighted_bipred_idc : 2;
  USHORT MbsConsecutiveFlag : 1;
  USHORT frame_mbs_only_flag : 1;
  USHORT transform_8x8_mode_flag : 1;
  USHORT MinLumaBipredSize8x8Flag : 1;
  USHORT IntraPicFlag       : 1;
};
  USHORT wBitFields;
};
  UCHAR bit_depth_luma_minus8;
  UCHAR bit_depth_chroma_minus8;
  USHORT Reserved16Bits;
  UINT StatusReportFeedbackNumber;
  DXVA_PicEntry_H264 RefFrameList[16];
  INT CurrFieldOrderCnt[2];
  INT FieldOrderCntList[16][2];  CHAR
pic_init_qs_minus26;
```

```

CHAR  chroma_qp_index_offset;
CHAR  second_chroma_qp_index_offset;
UCHAR ContinuationFlag;
CHAR  pic_init_qp_minus26;
UCHAR num_ref_idx_l0_active_minus1;
UCHAR num_ref_idx_l1_active_minus1;
UCHAR Reserved8BitsA;
USHORT FrameNumList[16];
UINT  UsedForReferenceFlags;
USHORT NonExistingFrameFlags;
USHORT frame_num;
UCHAR log2_max_frame_num_minus4;
UCHAR pic_order_cnt_type;
UCHAR log2_max_pic_order_cnt_lsb_minus4;
UCHAR delta_pic_order_always_zero_flag;
UCHAR direct_8x8_inference_flag;
UCHAR entropy_coding_mode_flag;
UCHAR pic_order_present_flag;
UCHAR num_slice_groups_minus1;
UCHAR slice_group_map_type;
UCHAR deblocking_filter_control_present_flag;
UCHAR redundant_pic_cnt_present_flag;
UCHAR Reserved8BitsB;
USHORT slice_group_change_rate_minus1;
UCHAR SliceGroupMap[810];
} DXVA_PicParams_H264, *LPDXVA_PicParams_H264;

```

## 4.2 Semantics

### wFrameWidthInMbsMinus1

Width of the frame containing this picture, in units of macroblocks, minus 1. (The width in macroblocks is wFrameWidthInMbsMinus1 plus 1.)

### wFrameHeightInMbsMinus1

Height of the frame containing this picture, in units of macroblocks, minus 1. (The height in macroblocks is wFrameHeightInMbsMinus1 plus 1.) When the picture is a field, the height of the frame is twice the height of the picture and is an integer multiple of 2 in units of macroblocks.

### CurrPic

Specifies the uncompressed destination surface of the frame for the current decoded picture. If field\_pic\_flag is 1, the AssociatedFlag field in CurrPic is interpreted as follows:

Value	Description
0	The current picture is the top field of the uncompressed destination frame surface.
1	The current picture is the bottom field of the uncompressed destination frame surface.

If field\_pic\_flag is 0, AssociatedFlag has no meaning and shall be 0, and the accelerator shall ignore the value. num\_ref\_frames

Corresponds to the H.264/AVC syntax element named either `num_ref_frames` or `max_num_ref_frames`, and affects the decoding process accordingly.

---

**Note** Starting in late 2008, the name of the corresponding syntax element has been changed in the H.264/AVC specification from `num_ref_frames` to `max_num_ref_frames`, in order to clarify its use. The meaning of the syntax element is unchanged.

---

---

**Note** There is no obvious reason why an accelerator requires this information. However, it might be useful for some accelerator implementations. Regardless, the host decoder shall set the appropriate value, consistent with the other variables for the coded video sequence.

---

#### `field_pic_flag`

Corresponds to the H.264/AVC syntax element of the same name and affects the decoding process accordingly.

#### `MbaffFrameFlag`

Corresponds to the variable of the same name in the H.264/AVC specification and affects the decoding process accordingly.

#### `residual_colour_transform_flag`

Corresponds to the syntax element of the same name in the H.264/AVC specification and affects the decoding process accordingly. When `chroma_format_idc` does not equal 3 (specifying 4:4:4), `residual_colour_transform_flag` has no meaning and shall equal 0, and the accelerator shall ignore the value.

---

**Note** The use of the residual color transform in H.264/AVC has been deprecated by ITU-T and ISO/IEC since the 2005 edition of the standard. Therefore, this flag must equal 0 for uses relating to the current version of the standard.

---

#### `sp_for_switch_flag`

Corresponds to the H.264/AVC syntax element of the same name and affects the decoding process accordingly.

#### `chroma_format_idc`

Indicates the chroma format for the decoding process. The following values are defined:

Value	Description
0	4:0:0 sampling. (Luma-only monochrome.)
1	4:2:0 sampling.
2	4:2:2 sampling
3	4:4:4 sampling.

If the value is 0, the accelerator shall set all Cb and Cr samples to the constant value  $128 * (1 \ll \text{bit\_depth\_chroma\_minus}8)$ .

**RefPicFlag**

Specifies whether the current picture may be used as a reference picture.

Value	Description
0	The current picture will not be used as a reference for decoding any other pictures in the bitstream.
1	After the current picture is decoded, it may be used as a reference for decoding other pictures.

A decoder should ordinarily set the value to 0 when the `nal_ref_idc` syntax elements of the VCL NAL units are 0, and set the value to 1 otherwise. The accelerator does not have to do any particular processing in response to this value, but it might be useful information. For example, the accelerator can use it to determine whether the accelerator can start decoding a subsequent picture before the current picture has been completely decoded.

**constrained\_intra\_pred\_flag**

Corresponds to the H.264/AVC syntax element of the same name. If the value is 1 (constrained intra prediction), the results of decoding macroblocks that use inter prediction modes are not needed for decoding macroblocks that use intra prediction modes.

The accelerator may use this flag to determine whether it can decode intra and inter macroblocks in parallel. However, an accelerator is not required to use this flag. The `IntraPredAvailFlags` field in the macroblock control data structure provides enough information to determine whether each neighboring macroblock is available for intra prediction.

**weighted\_pred\_flag**

Corresponds to the H.264/AVC syntax element of the same name and affects the decoding process accordingly.

**weighted\_bipred\_idc**

Corresponds to the H.264/AVC syntax element of the same name and affects the decoding process accordingly.

**MbsConsecutiveFlag**

Specifies whether the macroblocks of the picture are required to be consecutive without gaps, in order of `CurrMbAddr`, within each macroblock control buffer.

If the value is 1, the value of `CurrMbAddr` for the  $(i + 1)$ th macroblock shall equal  $1 + \text{CurrMbAddr}_i$ , where  $\text{CurrMbAddr}_i$  is the value of `CurrMbAddr` for the  $i$ th macroblock, for all macroblocks present in the macroblock control buffer. If `MbsConsecutiveFlag` is 0, this constraint may be disregarded.

The value shall be 1 unless the restricted-mode profile in use explicitly supports the value 0.

This flag corresponds to the need for the accelerator to support the H.264/AVC capabilities generally known as multiple slice groups or flexible macroblock ordering. `frame_mbs_only_flag`

Corresponds to the H.264/AVC syntax element of the same name and affects the decoding process accordingly.

**transform\_8x8\_mode\_flag**

Corresponds to the H.264/AVC syntax element of the same name and affects the decoding process accordingly.

**MinLumaBipredSize8x8Flag**

The value 1 indicates that, within the current picture, the functions

SubMbPartWidth() and SubMbPartHeight() must equal 8 whenever the bSubMbPredModes flag in the macroblock control buffer indicates a BiPred prediction mode for a sub-macroblock. (These two functions give the width and height of the sub-macroblock partitions.) If 0, this constraint does not apply.

An accelerator might operate faster when this flag is set to 1, so the host decoder should set this flag whenever the stated condition is true—for example, for bitstreams that conform to the Main, High, High 10, High 4:2:2, or High 4:4:4 profile at level 3.1 or higher.

#### IntraPicFlag

Specifies whether all macroblocks in the current picture have intra prediction modes.

Value	Description
0	Some macroblocks of the current picture might have inter macroblock prediction modes. (The IntraMbFlag in the macroblock control command buffer might be 0 for some macroblocks.)
1	All macroblocks of the current picture have intra macroblock prediction modes. (The IntraMbFlag is 1 for all macroblocks.)

#### wBitFields

Provides an alternate way to access the previous bit fields.

#### bit\_depth\_luma\_minus8

Corresponds to the H.264/AVC syntax element of the same name and affects the decoding process accordingly.

#### bit\_depth\_chroma\_minus8

Corresponds to the H.264/AVC syntax element of the same name and affects the decoding process accordingly.

#### Reserved16Bits

May be 0, 1, 2, or 3, as follows:

Software decoders should be implemented, as soon as feasible, to set the value of Reserved16Bits to 3. The value 0 was previously assigned for uses prior to July 20, 2007. The value 1 was previously assigned for uses prior to October 12, 2007. The value 2 was previously assigned for uses prior to January 15, 2009. Software decoders shall not set Reserved16Bits to any value other than those listed here.

---

**Note** Software decoders that set Reserved16Bits to 3 should ensure that any aspects of software decoder operation that were previously not in conformance with this version of the specification have been corrected in the current implementation.

One particular aspect of conformance that should be checked is the ordering of quantization scaling list data, as specified in section 5.2. In addition, the ReservedIntraBit flag in the macroblock control buffer must use the semantics described in section 7.2 (this flag was previously reserved). The semantics of Index7Bits and RefPicList have also been clarified in updates to this specification.

The goal of changing the values allowed for Reserved16Bits is to enable accelerators to detect the value of 3 as an indication of a higher degree of assurance of conformance with this specification, relative to the previously specified value 0, and to indicate conformance with the updated semantics of ReservedIntraBit and RefFrameList.

Accelerators may use the four least-significant bits of Reserved16Bits to identify the software decoder generation, such that a lower value indicates an older generation of software decoder.

The 12 most-significant bits of Reserved16Bits currently have no specified meaning and shall be ignored by accelerators.

#### StatusReportFeedbackNumber

Arbitrary number set by the host decoder to use as a tag in the status report feedback data. The value should not equal 0, and should be different in each call to Execute. For more information, see section 12.0, Status Report Data Structure.

#### RefFrameList

Contains a list of 16 uncompressed frame buffer surfaces. Entries that will not be used for decoding the current picture, or any subsequent pictures, are indicated by setting bPicEntry to 0xFF. If bPicEntry is not 0xFF, the entry may be used as a reference surface for decoding the current picture or a subsequent picture (in decoding order). All uncompressed surfaces that correspond to pictures currently marked as "used for reference" must appear in the RefFrameList array. Nonreference surfaces (those which only contain pictures for which the value of RefPicFlag was 0 when the picture was decoded) shall not appear in RefFrameList for a subsequent picture. In addition, surfaces that contain only pictures marked as "unused for reference" shall not appear in RefFrameList for a subsequent picture.

For each entry whose value is not 0xFF, the value of AssociatedFlag is interpreted as follows:

Value	Description
0	Not a long-term reference frame.
1	Long-term reference frame. The uncompressed frame buffer contains a reference frame or one or more reference fields marked as "used for longterm reference."

If field\_pic\_flag is 1, the current uncompressed frame surface may appear in the list for the purpose of decoding the second field of a complementary reference field pair.

#### CurrFieldOrderCnt

Contains the picture order counts.

If field\_pic\_flag is 1 and the value of AssociatedFlag for CurrPic is 1, CurrFieldOrderCnt[1] contains BottomFieldOrderCnt for the current picture; CurrFieldOrderCnt[0] shall be 0, and its value shall be ignored by the accelerator.

If field\_pic\_flag is 1 and the value of AssociatedFlag for CurrPic is 0, CurrFieldOrderCnt[0] contains TopFieldOrderCnt for the current picture; CurrFieldOrderCnt[1] shall be 0, and its value shall be ignored by the accelerator.

If field\_pic\_flag is 0, CurrFieldOrderCnt[0] contains TopFieldOrderCnt for the current picture, and CurrFieldOrderCnt[1] contains BottomFieldOrderCnt for the current picture.

#### FieldOrderCntList

Contains the picture order counts for the reference frames listed in RefFrameList. For each entry *i* in the RefFrameList array, FieldOrderCntList[*i*][0] contains the value of TopFieldOrderCnt for entry *i*, and FieldOrderCntList[*i*][1] contains the value of BottomFieldOrderCnt for entry *i*.

---

Note This section was modified in June, 2007. These values are needed in the derivation process for co-located 4x4 sub-macroblock partitions, when the current picture has MbaffFrameFlag equal to 1 and contains B\_Skip, B\_Direct16x16, or B\_Direct8x8 macroblocks in macroblock pairs with mb\_field\_decoding\_flag equal to 0 in B slices for which the first entry in L1 is a complementary field pair marked as "used for long-term reference." (For details, see subclause 8.4.1.2.1 of the H.264/AVC specification.)

---

If an element of the list is not relevant (for example, if the corresponding entry in RefFrameList is empty or is marked as "not used for reference"), the value of TopFieldOrderCnt or BottomFieldOrderCnt in FieldOrderCntList shall be 0. Accelerators can rely on this constraint being fulfilled.

The following structure members correspond to the H.264/AVC syntax elements of the same name and affect the decoding process accordingly. If the syntax element is not present in the bitstream and has no inferred value according to the H.264/AVC specification, the host decoder shall set the value to 0. Accelerators can rely on this constraint being fulfilled:

- pic\_init\_qs\_minus26
- chroma\_qp\_index\_offset
- second\_chroma\_qp\_index\_offset

#### ContinuationFlag

If this flag is 1, the remainder of this structure is present in the buffer and contains valid values. If this flag is 0, the structure might be truncated at this point in the buffer, or the remaining fields may be set to 0 and shall be ignored by the accelerator.

The remaining members of this structure are needed only for off-host bitstream parsing. If the host decoder parses the bitstream, the decoder can truncate the picture parameters data structure buffer after the ContinuationFlag or set the remaining members to zero.

#### Reserved8BitsA

The 2 least-significant bits of **Reserved8BitsA** are used to indicate which field of a decoded picture should be displayed first when bit 13 of **ConfigDecoderSpecific** as set by the host decoder is equal to 1. The 6 most-significant bits of **Reserved8BitsA** currently have no specified meaning, shall be set to 0 (always), and their value shall be ignored by accelerators (so that some backward-compatible use for these bits may be specified in the future).

When bit 13 of **ConfigDecoderSpecific** as set by the host decoder is equal to 0, the 2 least-significant bits of **Reserved8BitsA** shall be set to 0 and any value set should be ignored.

When bit 13 of **ConfigDecoderSpecific** as set by the host decoder is equal to 1 to indicate that the display information about which field of the decoded picture should be displayed first is needed, as in the scenario where downsampling of a decoded picture happens after decoding as enabled by the new APIs CheckVideoDecoderDownsampling() and DecoderEnableDownsampling(), the 2 least-significant bits of **Reserved8BitsA** shall be set as follows.

- When the compressed picture is a coded field, the 2 least-significant bits of **Reserved8BitsA** shall be set to equal to 0. In this case, the accelerator shall

determine which field should be displayed first by using CurrFieldOrderCnt in the top field and bottom field picture parameters data structures when both fields are present, or through the CurrFieldOrderCnt in an unpaired field picture parameters data structure and the CurrFieldOrderCnt in the next picture parameters data structure in decoding order.

- When the compressed picture is a coded frame and the top field of the coded frame should be displayed first, the 2 least-significant bits of **Reserved8BitsA** shall be set to equal to 1.
- When the compressed picture is a coded frame and the bottom field of the coded frame should be displayed first, the 2 least-significant bits of **Reserved8BitsA** shall be set to equal to 2.
- When the compressed picture is a coded frame and the coded frame should be displayed as a progressive frame, the 2 least-significant bits of **Reserved8BitsA** shall be set to equal to 3.

#### FrameNumList

For each entry in RefFrameList, the corresponding entry in FrameNumList contains the value of FrameNum or LongTermFrameIdx, depending on the value of AssociatedFlag in the RefFrameList entry. (FrameNum is assigned to short-term reference pictures, and LongTermFrameIdx is assigned to long-term reference pictures.)

If an element in the list of frames is not relevant (for example, if the corresponding entry in RefFrameList is empty or is marked as "not used for reference"), the value of the FrameNumList entry shall be 0. Accelerators can rely on this constraint being fulfilled.

#### UsedForReferenceFlags

Contains two 1-bit flags for each entry in RefFrameList. For the  $i$ th entry in RefFrameList, the two flags are accessed as follows:

- $\text{Flag1}_i = (\text{UsedForReferenceFlags} \gg (2 * i)) \& 1$
- $\text{Flag2}_i = (\text{UsedForReferenceFlags} \gg (2 * i + 1)) \& 1$

If  $\text{Flag1}_i$  is 1, the top field of frame number  $i$  is marked as "used for reference," as defined by the H.264/AVC specification. If  $\text{Flag2}_i$  is 1, the bottom field of frame number  $i$  is marked as "used for reference." (Otherwise, if either flag is 0, that field is not marked as "used for reference.")

If an element in the list of frames is not relevant (for example, if the corresponding entry in RefFrameList is empty), the value of both flags for that entry shall be 0. Accelerators may rely on this constraint being fulfilled.

#### NonExistingFrameFlags

Contains a bit flag for each entry in RefFrameList. For the  $i$ th entry in RefFrameList, the flag is accessed as follows:

- $\text{Flag}_i = (\text{NonExistingFrameFlags} \gg i) \& 1$

If  $\text{Flag}_i$  is 1, frame number  $i$  is marked as "non-existing," as defined by the H.264/AVC specification. (Otherwise, if the flag is 0, the frame is not marked as "non-existing.")

If an element in the list of frames is not relevant (for example, if the corresponding entry in RefFrameList is empty or is marked as "not used for reference"), the flag for that entry shall be 0. Accelerators may rely on this constraint being fulfilled. See Remarks for more information.

The following structure members correspond to the H.264/AVC syntax elements of the same name and affect the decoding process accordingly. If the syntax element is not present in the bitstream and has no inferred value according to the H.264/AVC specification, the host decoder shall set the value to 0. Accelerators can rely on this constraint being fulfilled:

```
pic_init_qp_minus26 num_ref_idx_l0_active_minus1 num_ref_idx_l1_active_minus1
frame_num log2_max_frame_num_minus4 pic_order_cnt_type
log2_max_pic_order_cnt_lsb_minus4 delta_pic_order_always_zero_flag
direct_8x8_inference_flag entropy_coding_mode_flag pic_order_present_flag
num_slice_groups_minus1 slice_group_map_type deblocking_filter_control_present_flag
redundant_pic_cnt_present_flag slice_group_change_rate_minus1
```

---

**Note** The `num_ref_idx_l0_active_minus1` and `num_ref_idx_l1_active_minus1` members correspond to variables in the picture parameter set in the H.264/AVC specification, which may be overridden in the slice-level syntax.

---

#### Reserved8BitsB

This structure member has no meaning. The value shall be 0, and accelerators shall ignore the value.

#### SliceGroupMap

Contains the `mapUnitToSliceGroupMap` array defined in the H.264/AVC specification. Each entry in the array is represented using 4 bits in `SliceGroupMap`, such that `mapUnitToSliceGroupMap[i]` is represented in bits  $j*4$  to  $j*4+3$  of `SliceGroupMap[i>>1]`, where  $j = i \& 1$ .

This array is needed only for off-host bitstream parsing where `num_slice_groups_minus1` is not 0. If the host decoder parses the bitstream, or if `num_slice_groups_minus1` is 0, the decoder can truncate the picture parameters data buffer before this array, or else set the array members to zero, and the accelerator shall ignore the contents of the array.

The `DXVA_PicParams_H264` structure prototype defines `SliceGroupMap` with 810 entries. This is large enough for pictures up to the size of standard-definition television—that is, up to 720 x 576 pixels for an ITU-R BT.601 frame coded with `MbaffFrameFlag` equal to 0. The actual size of the array provided by the host decoder may differ, as determined by the size of the coded picture and the definition of the slice group map unit (single-macroblock units or two-macroblock units) as given in the H.264/AVC specification.

#### Remarks

The values in `RefFrameList` and `UsedForReferenceFlags` are the primary way that the accelerator can determine whether the entries in `RefFrameList`, `FieldOrderCntList`, `FrameNumList`, and `NonExistingFrameFlags` are valid for decoding the current picture. When `RefFrameList[i]` is 0xFF, the following values must all be zero:

- `FieldOrderCntList[i][0]`
- `FieldOrderCntList[i][1]`
- `FrameNumList[i]`
- `(UsedForReferenceFlags >> (2 * i)) & 3`
- `(NonExistingFrameFlags >> i) & 1`

When `(UsedForReferenceFlags >> (2 * i)) & 3` equals zero, `RefFrameList[i]` must be 0xFF.

## Requirements

Header: Include dxva.h.

## 5.0 Quantization Matrix Data Structure

The DXVA\_Qmatrix\_H264 structure contains quantization matrix data, which is sent on a per-picture basis.

This structure is used when bDXVA\_Func is 1 and the buffer type is DXVA\_INVERSE\_QUANTIZATION\_MATRIX\_BUFFER (DXVA 1.0) or DXVA2\_InverseQuantizationMatrixBufferType (DXVA 2.0).

### 5.1 Syntax

```
typedef struct _DXVA_Qmatrix_H264 {
    UCHAR
    bScalingLists4x4[6][16];
    UCHAR bScalingLists8x8[2][64];
} DXVA_Qmatrix_H264, *LPDXVA_Qmatrix_H264;
```

### 5.2 Semantics

#### bScalingLists4x4

Contains the scaling lists for the 4x4 scaling process. Each scaling list is ordered in zig-zag scan order. When applicable, default or "flat" scaling lists are handled by the host decoder filling in the appropriate values.

#### bScalingLists8x8

Contains the scaling lists for the 8x8 scaling process. Each scaling list is ordered in zig-zag scan order. When applicable, default or "flat" scaling lists are handled by the host decoder filling in the appropriate values.

---

**Note** The scaling lists are supplied in zig-zag scan order. This is the same ordering shown for the default matrix values in tables 7-3 and 7-4 of the H.264/AVC specification. It is the ordering used prior to the application of the inverse scanning process defined in subclauses 8.5.5 and 8.5.6 of the H.264/AVC specification, which converts the scaling list into a 2-dimensional weight scale matrix.

---

#### Remarks

Hypothetically, this structure could have been included in the picture parameters data structure, but DXVA already defines a buffer type for quantization matrixes. For consistency with previous DXVA designs, therefore, a separate quantization matrix data structure is used in H.264/AVC. Unlike previous DXVA designs, however, the quantization matrix data is required whenever the accelerator performs the inverse transform process, and not just when the accelerator parses the slice bitstream. This requirement arises because the accelerator must perform the inverse quantization scaling process whenever it performs the inverse transform.

#### Requirements

Header: Include dxva.h.

## 6.0 Slice Control Data Structure

Two structures are defined for slice control data. The choice of structure depends on the value of `bConfigBitstreamRaw` in the configuration parameters structure:

<code>bConfigBitstreamRaw</code>	Slice control data structure
0 or 1	<code>DXVA_Slice_H264_Long</code>
2	<code>DXVA_Slice_H264_Short</code>

These structures are used when `bDXVA_Func` is 1 and the buffer type is `DXVA_SLICE_CONTROL_BUFFER` (DXVA 1.0) or `DXVA2_SliceControlBufferType` (DXVA 2.0).

The `DXVA_Slice_H264_Short` structure is a subset of the `DXVA_Slice_H264_Long` structure.

When `bConfigBitstreamRaw` is 0, the slice control buffer is accompanied by a macroblock control data buffer, plus zero or more motion vector data buffers and zero or more residual difference data buffers. Otherwise, when `bConfigBitstreamRaw` is 1 or 2, the slice control buffer is accompanied by a raw bitstream data buffer. The total quantity of data in the bitstream buffer (and the amount of data reported by the host decoder) shall be an integer multiple of 128 bytes.

## 6.1 Syntax

```
typedef struct _DXVA_Slice_H264_Long {
    UINT  BSNALunitDataLocation;
    UINT  SliceBytesInBuffer;
    USHORT wBadSliceChopping;
    USHORT first_mb_in_slice;
    USHORT NumMbsForSlice;
    USHORT BitOffsetToSliceData;
    UCHAR slice_type;
    UCHAR luma_log2_weight_denom;
    UCHAR chroma_log2_weight_denom;
    UCHAR num_ref_idx_l0_active_minus1;
    UCHAR num_ref_idx_l1_active_minus1;
    CHAR  slice_alpha_c0_offset_div2;
    CHAR  slice_beta_offset_div2;
    UCHAR Reserved8Bits;
    DXVA_PicEntry_H264 RefPicList[2][32];
    SHORT Weights[2][32][3][2];
    CHAR  slice_qs_delta;
    CHAR  slice_qp_delta;
    UCHAR redundant_pic_cnt;
    UCHAR direct_spatial_mv_pred_flag;
    UCHAR cabac_init_idc;
    UCHAR disable_deblocking_filter_idc;
    USHORT slice_id;
} DXVA_Slice_H264_Long, *LPDXVA_Slice_H264_Long;

typedef struct _DXVA_Slice_H264_Short {
    UINT  BSNALunitDataLocation;
```

```

    UINT  SliceBytesInBuffer;
    USHORT wBadSliceChopping;
} DXVA_Slice_H264_Short, *LPDXVA_Slice_H264_Short;

```

## 6.2 Semantics

### BSNALunitDataLocation

If `wBadSliceChopping` is 0 or 1, this member locates the NAL unit with `nal_unit_type` equal to 1, 2, or 5 for the current slice. The value is the byte offset, from the start of the bitstream data buffer, of the first byte of the start code prefix in the byte stream NAL unit that contains the NAL unit with `nal_unit_type` equal to 1, 2, or 5. (The start code prefix is the `start_code_prefix_one_3bytes` syntax element. The byte stream NAL unit syntax is defined in Annex B of the H.264/AVC specification. The current slice is the slice associated with this slice control data structure.)

The bitstream data buffer shall not contain a byte stream NAL unit with `nal_unit_type` equal to 2 unless support for this NAL unit type is explicitly required for the DXVA restricted-mode profile in use. When `BSNALunitDataLocation` refers to a NAL unit having `nal_unit_type` equal to 2, the associated byte stream NAL units having `nal_unit_type` equal to 3 and 4 (when necessary) shall also be present in the bitstream data. They shall appear after the byte stream NAL unit whose location is given by `BSNALunitDataLocation`, and prior to the location given by the value of `BSNALunitDataLocation` in the next slice control buffer. Byte stream NAL units with `nal_unit_type` equal to 3 or 4 shall not be present unless they are preceded in the bitstream data by a byte stream NAL unit with `nal_unit_type` equal to 2.

The bitstream data buffer shall not contain NAL units with values of `nal_unit_type` outside the range [1...5]. However, the accelerator shall allow any such NAL units to be present and should ignore their content if present.

---

Note The bitstream data buffer might or might not contain `leading_zero_8bits`, `zero_byte`, and `trailing_zero_8bits` syntax elements. If present, the accelerator shall ignore these elements.

---

If `wBadSliceChopping` is not 0 or 1, `BSNALunitDataLocation` shall be 0.

### SliceBytesInBuffer

Number of bytes in the bitstream data buffer that are associated with this slice control data structure, starting with the byte at the offset given in `BSNALunitDataLocation`. When `BSNALunitDataLocation` refers to a NAL unit having `nal_unit_type` not equal to 2, the bitstream data buffer shall not contain additional byte stream NAL units in the bytes following `BSNALunitDataLocation` up to the location `BSNALunitDataLocation + SliceBytesInBuffer`.

### wBadSliceChopping

When off-host bitstream parsing is used, contains one of the following values:

Value	Description
0	All bits for the slice are located within the corresponding bitstream data buffer.
1	The bitstream data buffer contains the start of the slice, but not the entire slice, because the buffer is full.

2	The bitstream data buffer contains the end of the slice. It does not contain the start of the slice, because the start of the slice was located in the previous bitstream data buffer.
3	The bitstream data buffer does not contain the start of the slice (because the start of the slice was located in the previous bitstream data buffer), and it does not contain the end of the slice (because the current bitstream data buffer is also full).

Generally the host decoder should avoid using values other than 0.

The size of the data in the bitstream data buffer (and the amount of data reported by the host decoder) shall be an integer multiple of 128 bytes. When `wBadSliceChopping` is 0 or 2, if the end of the slice data is not an even multiple of 128 bytes, the decoder should pad the end of the buffer with zeroes. If off-host bitstream parsing is not used, the value of `wBadSliceChopping` shall be 0.

#### NumMbsForSlice

If `wBadSliceChopping` is 0, specifies the number of macroblocks in the accompanying macroblock control buffer or bitstream data buffer that are associated with the current slice control buffer. If the host decoder cannot readily determine this number, it may set the value to 0, to indicate that the actual number is unknown (for example, when the accelerator is parsing the slice bitstream and the `MbsConsecutiveFlag` flag in the picture parameters data structure is 0).

If `wBadSliceChopping` is not 0 and `NumMbsForSlice` is not 0, `NumMbsForSlice` specifies the number of macroblocks the bitstream data buffer would contain if the data buffer contained the entire slice.

The remaining elements of this structure enable off-host bitstream parsing. When offhost parsing is used, each slice control buffer is accompanied by one associated bitstream data buffer. The buffer contains a segment of a valid bitstream in the byte stream format specified in Annex B of the H.264/AVC specification.

---

Note In particular, this means that the buffer will contain `emulation_prevention_three_byte` syntax elements where those elements are required to be present in a NAL unit, as defined in the H.264/AVC specification.

---

#### BitOffsetToSliceData

When `wBadSliceChopping` is 0 or 1, specifies a bit offset to the location of the bit specified as follows:

- If `entropy_coding_mode_flag` is 0, `BitOffsetToSliceData` is the bit offset to the first bit of the `slice_data()` data structure for the first slice in the bitstream data buffer.
- If `entropy_coding_mode_flag` is 1, `BitOffsetToSliceData` is the bit offset to the first bit following all `cabac_alignment_one_bit` syntax elements in the `slice_data()` data structure for the first slice in the bitstream data buffer. In this case, `BitOffsetToSliceData % 8` shall be 0.

If `wBadSliceChopping` is 1, the referenced bit shall reside in the bitstream data buffer that is associated with this slice control buffer. (In other words, the decoder must not put the beginning of the `start_code_prefix_one_3bytes` syntax element in one bitstream data buffer, and the bit referenced by `BitOffsetToSliceData` in the next bitstream data buffer.)

This bit offset is the offset within the RBSP data for the slice, relative to the starting position of the slice\_header() in the RBSP. That is, it represents a bit offset after the removal of any emulation\_prevention\_three\_byte syntax elements that preceded the start of the slice\_data() in the NAL unit. (For a definition of RBSP, refer to the H.264/AVC specification.)

When wBadSliceChopping is 2 or 3, the value of BitOffsetToSliceData shall be 0xFFFF.

When the byte that contains the referenced bit resides in the current bitstream data buffer, this byte shall be at the following location relative to the start of the bitstream data buffer:  $BSNALunitDataLocation + (BitOffsetToSliceData \gg 3) + 4 + K$ , where K is the number of emulation\_prevention\_three\_byte syntax elements that precede the start of the slice\_data() in the NAL unit. The value

$BitOffsetToSliceData \% 8$  specifies the number of most-significant bits (MSBs) of that byte that precede the referenced bit.

#### Reserved8Bits

This structure member has no meaning. The value shall be 0, and accelerators shall ignore the value.

#### RefPicList

Specifies reference picture list 0 and reference picture list 1, as follows:

- When slice\_type does not equal 2, 4, 7, or 9 (I or SI slices), RefPicList[0] specifies reference picture list 0, as follows:
  - For  $j = 0$  through  $num\_ref\_idx\_i0\_active\_minus1$ , entries RefPicList[0][j] shall contain Index7Bits values that refer to valid entries in the RefFrameList member of the associated picture parameters structure, except when Index7Bits equals 127. Valid entries are specified by setting Index7Bits equal to an index into the RefFrameList array.
  - For  $j = num\_ref\_idx\_i0\_active\_minus1 + 1$  through 31, the bPicEntry member of RefPicList[0][j] has no meaning and shall be 0xFF, and the accelerator shall ignore the values of these entries.
- When slice\_type does not equal 0, 2, 3, 4, 5, 7, 8, or 9 (I, P, SP, or SI slices), RefPicList[1] specifies reference picture list 1, as follows:
  - For  $j = 0$  through  $num\_ref\_idx\_i1\_active\_minus1$ , entries RefPicList[1][j] shall contain Index7Bits values that refer to valid entries in the RefFrameList member of the associated picture parameters structure, except when Index7Bits equals 127. Valid entries are specified by setting Index7Bits equal to an index into the RefFrameList array.
  - For  $j = num\_ref\_idx\_i1\_active\_minus1 + 1$  through 31, the bPicEntry member of RefPicList[1][j] has no meaning and shall be 0xFF, and the accelerator shall ignore the values of these entries.
- When slice\_type equals 2, 4, 7, or 9 (I or SI slices), all bPicEntry values in RefPicList[0] shall be 0xFF. The accelerator can rely on this constraint being fulfilled.
- When slice\_type equals 0, 2, 3, 4, 5, 7, 8, or 9 (I, P, SP, or SI slices), all bPicEntry values in RefPicList[1] shall be 0xFF. The accelerator can rely on this constraint being fulfilled.

For each entry RefPicList[i][j], the index variable i is interpreted as follows:

- If i is 0, i refers to reference picture list 0.
- If i is 1, i refers to reference picture list 1.

The index variable  $j$  is a reference to entry  $j$  in the reference picture list, unless the value of `Index7Bits` in the `DXVA_PicEntry_H264` structure for `RefPicList[i][j]` equals 127.

For index variables  $i$  and  $j$ , the value of `RefPicList[i][j]` is an index into the `RefFrameList` array of the DXVA picture parameters structure, unless the value of `Index7Bits` in the `DXVA_PicEntry_H264` structure for `RefPicList[i][j]` equals 127.

For each entry, if `Index7Bits` does not equal 127, `AssociatedFlag` is interpreted as follows:

- If the `field_pic` flag in the picture parameters data structure is 1 and `AssociatedFlag` is 0, the entry in the reference picture list is a top field.
- If the `field_pic` flag in the picture parameters data structure is 1 and `AssociatedFlag` is 1, the entry in the reference picture list is a bottom field.
- If `field_pic` is 0, then `AssociatedFlag` shall be 0. The accelerator can rely on this constraint being fulfilled.

The following table shows the interpretation of `AssociatedFlag` when `Index7Bits` does not equal 127.

<code>field_pic</code>	<code>AssociatedFlag</code>	Description
0	0	Frame.
1	0	Top field.
1	1	Bottom field.

If `Index7Bits` is 127, `AssociatedFlag` is interpreted as follows:

- If `AssociatedFlag` is 1, the entry in the reference picture list refers to a picture that is "non-existing," as defined by the H.264/AVC specification.
- If `AssociatedFlag` is 0, the entry in the reference picture list refers to a picture that is "not available," in the sense defined by subclause D.2.7 of the H.264/AVC specification for random access recovery points.

Reference indexes that refer to "non-existing" pictures are prohibited during the inter prediction process and should be detected as an error by the accelerator. It is recommended, but not required, that the accelerator resolve any such references in the same way as references to pictures that are "not available."

Reference indexes that refer to "not available" pictures shall be interpreted as references to pictures containing the following sample values, in accordance with subclause D.2.7 of the H.264/AVC specification:

- Luma values equal to  $(1 \ll (\text{bit\_depth\_luma\_minus8} + 7))$
- Chroma values equal to  $(1 \ll (\text{bit\_depth\_chroma\_minus8} + 7))$

### Weights

Specifies the weights and offsets used in the decoding process. This array is used for explicit mode weighted prediction.

For each entry `Weights[i][j][k][m]`, the index variable  $i$  has range  $[0..1]$  and is interpreted as follows:

- If  $i$  is 0,  $i$  refers to reference picture list 0.
- If  $i$  is 1,  $i$  refers to reference picture list 1.

The index variable  $j$  has range  $[0..31]$  and is a reference to entry  $j$  in the reference picture list.

The index variable  $k$  has range  $[0...2]$ , and is interpreted as follows:

Index	Description
0	$k$ refers to data for the luma (Y) component.
1	$k$ refers to data for the Cb chroma component.
2	$k$ refers to data for the Cr chroma component.

The index variable  $m$  has range  $[0...1]$  and is interpreted as follows:

- If  $m$  is 0,  $m$  refers to a weight used in the weighted prediction process.
- If  $m$  is 1,  $m$  refers to an offset used in the weighted prediction process.

If the value of `bPicEntry` for `RefPicList[i][j]` does not equal `0xFF`, `Weights[i][j][k][0]` contains a weight and `Weights[i][j][k][1]` contains an offset, both of which are used in the explicit weighted prediction process for list  $i$ , entry  $j$ , and component  $k$ .

If the value of `bPicEntry` for `RefPicList[i][j]` equals `0xFF`, or if explicit mode weighted prediction is not used for the current slice, `Weights[i][j][k][m]` has no meaning and shall be 0. Accelerators can rely on this constraint being fulfilled.

When performing implicit mode weighted prediction, the accelerator must compute the correct weights to apply, based on `CurrFieldOrderCnt` and `FieldOrderCntList` in the picture parameters data structure.

The following members correspond to the H.264/AVC syntax elements of the same name and affect the decoding process accordingly. If the syntax element is not present in the bitstream and has no inferred value according to the H.264/AVC specification, the host decoder shall set the value to 0. Accelerators can rely on this constraint being fulfilled.

- `first_mb_in_slice`
- `slice_type`
- `luma_log2_weight_denom`
- `chroma_log2_weight_denom`
- `num_ref_idx_l0_active_minus1`
- `num_ref_idx_l1_active_minus1`
- `slice_alpha_c0_offset_div2`
- `slice_beta_offset_div2`
- `slice_qs_delta`
- `slice_qp_delta`
- `redundant_pic_cnt`
- `direct_spatial_mv_pred_flag`
- `cabac_init_idc`
- `disable_deblocking_filter_idc`
- `slice_id`

#### Requirements

Header: Include `dxva.h`.

## 7.0 Macroblock Control Data Structure

The `DXVA_MBctrl_H264` structure contains macroblock control command data.

This structure is used when `bDXVA_Func` is 1 and the buffer type is `DXVA_MACROBLOCK_CONTROL_BUFFER` (DXVA 1.0) or `DXVA2_MacroBlockControlBufferType` (DXVA 2.0).

## 7.1 Syntax

```
typedef struct _DXVA_MBctrl_H264 {
union { struct {
    UINT bSliceID          : 8;
    UINT MbType5Bits      : 5;
    UINT IntraMbFlag      : 1;
    UINT mb_field_decoding_flag : 1;
    UINT transform_size_8x8_flag : 1;
    UINT HostResidDiff    : 1;
    UINT DcBlockCodedCrFlag : 1;
    UINT DcBlockCodedCbFlag : 1;
    UINT DcBlockCodedYFlag : 1;
    UINT FilterInternalEdgesFlag : 1;
    UINT FilterLeftMbEdgeFlag : 1;
    UINT FilterTopMbEdgeFlag : 1;
    UINT ReservedBit      : 1;
    UINT bMvQuantity      : 8;
};
    UINT dwMBtype;
};
    USHORT CurrMbAddr;
    USHORT wPatternCode[3];
    UCHAR bQpPrime[3];
    UCHAR bMBresidDataQuantity;
    ULONG dwMBdataLocation;
union {
    // Use the following struct when IntraMbFlag is 1.
    struct {
        USHORT LumaIntraPredModes[4];
        union { struct {
            UCHAR intra_chroma_pred_mode : 2;
            UCHAR IntraPredAvailFlags : 5;
            UCHAR ReservedIntraBit : 1;
        };
            UCHAR bMbIntraStruct;
        };
        UCHAR ReservedIntra24Bits[3];
    };
    // Use the following struct when IntraMbFlag is 0.
    struct {
        UCHAR bSubMbShapes;
        UCHAR bSubMbPredModes;
        USHORT wMvBuffOffset;
        UCHAR bRefPicSelect[2][4];
    };
};
};
} DXVA_MBctrl_H264, *LPDXVA_MBctrl_H264;
```

## 7.2 Semantics

### bSliceID

Index into the active array of slice control data structures for decoding the current macroblock. If the macroblock control command is not the first control command in the data buffer, the value of bSliceID shall equal the value of bSliceID for the preceding macroblock control command in the buffer plus p, where p is 0 or 1.

---

Note Because bSliceID is 8 bits, a single macroblock control buffer can reference at most 256 slices. In the uncommon case that a single picture contains more than 256 slices, the host decoder must split the picture into multiple macroblock control buffers.

---

### MbType5Bits, IntraMbFlag

These two members specify the type of macroblock:

IntraMbFlag	MbType5Bits	Macroblock type
0	1	B_L0_16x16
0	2	B_L1_16x16
0	3	B_Bi_16x16
0	4	B_L0_L0_16x8
0	5	B_L0_L0_8x16
0	6	B_L1_L1_16x8
0	7	B_L1_L1_8x16
0	8	B_L0_L1_16x8
0	9	B_L0_L1_8x16
0	10	B_L1_L0_16x8
0	11	B_L1_L0_8x16
0	12	B_L0_Bi_16x8
0	13	B_L0_Bi_8x16
0	14	B_L1_Bi_16x8
0	15	B_L1_Bi_8x16
0	16	B_Bi_L0_16x8
0	17	B_Bi_L0_8x16
0	18	B_Bi_L1_16x8
0	19	B_Bi_L1_8x16
0	20	B_Bi_Bi_16x8

0	21	B_Bi_Bi_8x16
0	22	B_8x8
1	0	I_NxN
1	1–24	Intra_16x16
1	25	I_PCM
1	26	SI

---

Note These macroblock types are defined in subclause 7.4.5 of the H.264/AVC specification.

---

When IntraPicFlag in the picture parameters buffer is 1, IntraMbFlag shall be 1.

Combinations of values that do not appear in this table shall not occur, and accelerators should indicate a data format error if they encounter invalid combinations.

#### mb\_field\_decoding\_flag

Corresponds to the H.264/AVC syntax element of the same name and affects the decoding process accordingly. When MbaffFrameFlag in the picture parameters buffer is 0, this field shall equal the value of field\_pic\_flag.

#### transform\_size\_8x8\_flag

Corresponds to the H.264/AVC syntax element of the same name and affects the decoding process accordingly.

#### HostResidDiff

Specifies whether the accelerator performs the inverse transform.

Value	Description
0	The inverse transform is not bypassed for the macroblock. The host decoder sends any associated residual data in the transform (that is, coefficient) domain.
1	The inverse transform is bypassed for the macroblock, and any associated residual data is sent in the spatial domain.

If bConfigResidDiffHost in the configuration parameters buffer is 0, the value of HostResidDiff shall be 0. If ConfigResidDiffAccelerator is 0, the value of HostResidDiff shall be 1. If bConfigResidDiffHost and ConfigResidDiffAccelerator are both 1, the value of HostResidDiff may be 0 or 1.

#### DcBlockCodedCrFlag

If 1, the data for the Cr DC residual block is present. If 0, the data for the Cr DC residual block is not present. If HostResidDiff is 1, DcBlockCodedCrFlag has no meaning and shall be 0, and accelerators shall ignore the value.

---

Note DcBlockCodedCrFlag is not needed when the host decoder performs residual decoding.

---

**DcBlockCodedCbFlag**

If 1, the data for the Cb DC residual block is present. If 0, the data for the Cb DC residual block is not present. If HostResidDiff is 1, DcBlockCodedCbFlag has no meaning and shall be 0, and accelerators shall ignore the value.

---

Note DcBlockCodedCbFlag is not needed when the host decoder performs residual decoding.

---

**DcBlockCodedYFlag**

If 1, data for the luma DC residual block is present for an Intra\_16x16 macroblock. If 0, the luma DC residual block is not present for an Intra\_16x16 macroblock.

If any of the following conditions is true, DcBlockCodedCbFlag has no meaning and shall be 0, and accelerators shall ignore the value: HostResidDiff is 1; IntraMbFlag is 0; or MbType5Bits falls outside the range 1–24, inclusive.

---

Note DcBlockCodedYFlag is not needed when the host decoder performs residual decoding, or when the macroblock type is not Intra\_16x16.

---

**FilterInternalEdgesFlag**

If 1, the deblocking filter is applied across the internal edges of the luma residual blocks in the macroblock. If 0, the filter is not applied to the internal edges.

**FilterLeftMbEdgeFlag**

If 1, the deblocking filter is applied to the left edge of the macroblock. If 0, the filter is not applied to the left edge.

**FilterTopMbEdgeFlag**

If 1, the deblocking filter is applied to the top edge of the macroblock. If 0, the filter is not applied to the top edge.

**ReservedBit**

This structure member has no meaning. The value shall be 0, and accelerators shall ignore the value.

**bMvQuantity**

Size, in units of 4 bytes, of the motion vector data in the motion vector data buffer for the macroblock. If IntraMbFlag is 1, bMvQuantity has no meaning and shall be 0. Accelerators can rely on this constraint being fulfilled.

**dwMBtype**

Provides an alternate way to access the previous bit fields.

**CurrMbAddr**

Macroblock address of the current macroblock. This member corresponds to the variable of the same name in the H.264/AVC specification.

---

Note This member is located in a different place in the structure relative to prior DXVA decoding designs. The intent of this change was to improve data alignment characteristics.

---

**wPatternCode**

Contains bit flags that indicate whether a given residual data block is present. Residual data is in the transform domain if `HostResidDiff` is 0, or the spatial domain if `HostResidDiff` is 1. The bits of each array element use the numbering convention that the LSB is bit number 0. `wPatternCode[0]` contains bit flags for the luma component, specified as follows:

- If `transform_size_8x8_flag` is 0, bit number  $(15 - j)$  corresponds to the 4x4 block numbered  $j$  in the luma macroblock shown in Figure 1. When `HostResidDiff` is 0 and the macroblock type is `Intra_16x16`, the bits refer only to data for non-DC coefficients, because the DC coefficients are sent separately, and their presence is indicated by the `DcBlockCodedYFlag` flag.
- If `transform_size_8x8_flag` is 1, bit number  $(3 - j)$  corresponds to the 8x8 block numbered  $j$  in the luma macroblock shown in Figure 2.

`wPatternCode[1]` contains bit flags for the Cb component and `wPatternCode[2]` contains bit flags for the Cr component. These flags are specified as follows, where  $i$  equals 1 or 2 and "chroma component" refers to the Cb component for  $i = 1$ , or the Cr component for  $i = 2$ .

- If `chroma_format_idc` is 0 (monochrome), `wPatternCode[i]` has no meaning and shall be 0, and accelerators shall ignore the value.
- If `chroma_format_idc` is 1 (4:2:0), bit number  $(3 - j)$  of `wPatternCode[i]` corresponds to the 4x4 block numbered  $j$  in the chroma component of the macroblock shown in Figure 2. The remaining bits shall have no meaning and shall be 0, and the accelerator shall ignore their value.
- If `chroma_format_idc` is 2 (4:2:2), bit number  $(7 - j)$  of `wPatternCode[i]` corresponds to the 4x4 block numbered  $j$  in the chroma component of the macroblock shown in Figure 3. The remaining bits shall have no meaning and shall be 0, and the accelerator shall ignore their value.
- If `chroma_format_idc` is 3 (4:4:4), bit number  $(15 - j)$  of `wPatternCode[i]` corresponds to the 4x4 block numbered  $j$  in the chroma component of the macroblock shown in Figure 1.

Figure 3. Numbering of blocks for 4x4 blocks in an 8x16 region bQpPrime

Contains the values of  $QP'$  for the macroblock:

- bQpPrime[0] contains the value of  $QP'_Y$  for the luma component.
- bQpPrime[1] contains the value of  $QP'_C$  for the Cb component.
- bQpPrime[2] contains the value of  $QP'_C$  for the Cr component.

#### bMBresidDataQuantity

Total amount of residual difference data in the residual difference data buffer for the macroblock, in units of 16 bytes, rounded up if the value is not an exact integer.

---

Note The 16-byte unit was chosen to allow 768 (3 x 256) coefficients per macroblock, at 4 bytes per coefficient. An accelerator must be designed with caution to ensure that it does not read past the actual end of the residual difference data buffer (for example due to rounding in bMBresidDataQuantity or bugs in the host decoder).

---

#### dwMBdataLocation

Offset of the residual difference data for the macroblock within the residual difference data buffer, in units of 4 bytes.

The remainder of this structure is a union that contains two anonymous structures. The first structure is used when IntraMbFlag is 1. It contains the following members:

#### LumaIntraPredModes

Specifies the intra prediction modes of the luma prediction blocks, for macroblocks having IntraMbFlag of 1 and MbType5Bits in the range [0...24] (that is, macroblock types I\_NxN or Intra\_16x16).

- If MbType5Bits is 0 (I\_NxN) and transform\_size\_8x8\_flag is 0, then bits (j \* 4) through (j \* 4 + 3) of LumaIntraPredModes[i] contain the prediction mode of block number (i \* 4 + j), where i and j have range [0...3]. Luma blocks are numbered as shown in Figure 1, and the prediction mode is an Intra4x4PredMode value. (See subclause 8.3.1.1 of the H.264/AVC specification for more information.)
- If MbType5Bits is 0 (I\_NxN) and transform\_size\_8x8\_flag is 1, bits (j \* 4) through (j \* 4 + 3) of LumaIntraPredModes[0] contain the prediction mode of block j, where j has range [0...3]. Luma blocks are numbered as shown in Figure 2, and the prediction mode is an Intra8x8PredMode value. (See subclause 8.3.2.1 of the H.264/AVC specification.) The remaining array entries in LumaIntraPredModes (indexes 1 through 3) are not relevant and shall be 0, and the values shall be ignored by the accelerator.

- If MbType5Bits is in the range [1...24] (Intra\_16x16), bits 0–3 of LumaIntraPredModes[0] contain the prediction mode as an Intra16x16PredMode value. (See subclause 8.3.3 of the H.264/AVC specification.) The remaining bits in LumaIntraPredModes[0], as well as the remaining array entries (indexes 1–3), are not relevant and shall be 0, and the values shall be ingored by the accelerator.

In all cases, the bits of each array element use the numbering convention that the LSB is bit number 0.

---

**Note** For the case where IntraMbFlag is 1 and MbType5Bits is in the range [1...24], only 2 bits are actually required to express the value of Intra16x16PredMode. However, 4 bits are used to make the representation consistent for all three types of intra spatial prediction.

---

If IntraMbFlag is 0, LumaIntraPredModes has no meaning.

#### intra\_chroma\_pred\_mode

Corresponds to the H.264/AVC syntax element of the same name and affects the decoding process accordingly for macroblocks in which IntraMbFlag is 1. If IntraMbFlag is 0, intra\_chroma\_pred\_mode has no meaning.

#### IntraPredAvailFlags

Contains five 1-bit flags that specify whether the values of samples from neighboring macroblocks can be used in intra prediction, for macroblocks having IntraMbFlag equal to 1. The bits are interpreted as follows, where sample position  $p[x,y]$  is defined relative to the position of the upper-left sample of the current macroblock, in the sense given in subclauses 6.4.8 and 6.4.9 of the H.264/AVC specification. The LSB of these five bits is bit number 0.

- Bit 4: If 1, the values of all samples  $p[-1, y]$  for vertical positions  $y$  corresponding to the top half of the current macroblock can be used. If 0, some or all of them cannot be used.
- Bit 3: If 1, the values of all samples  $p[-1, y]$  for vertical positions  $y$  corresponding to the bottom half of the current macroblock can be used. If 0, some or all of them cannot be used.
- Bit 2: If 1, the values of all samples  $p[x, -1]$  for horizontal positions  $x$  in the above-neighboring macroblock can be used. If 0, some or all of them cannot be used.
- Bit 1: If 1, the values of all samples  $p[x, -1]$  for horizontal positions  $x$  in the above-right neighboring macroblock can be used. If 0, some or all of them cannot be used.
- Bit 0: If 1, the value of the sample  $p[-1, -1]$  in the above-left neighboring macroblock can be used. If 0, it cannot be used.

If IntraMbFlag is 0 or MbType5Bits is 25 (I\_PCM), IntraPredAvailFlags has no meaning.

---

**Note** When decoding video that is encoded using the H.264/AVC specification, bits 3 and 4 must have the same value unless all of the following are true: constrained\_intra\_pred\_flag is 1; mb\_field\_decoding\_flag is 1; and mb\_field\_decoding\_flag for the macroblock pair to the left of the current macroblock is 0 (which can occur only when MbaffFrameFlag is 1).

---

#### ReservedIntraBit

This member is used if IntraMbFlag is 1 and all of the following conditions are true:

- MbaffFrameFlag is 1.
- mb\_field\_decoding\_flag is 0.
- transform\_size\_8x8\_flag is 1.

If all of these conditions are true, ReservedIntraBit indicates whether the value of the sample at position  $p[-1, 7]$  in a left-neighboring macroblock can be used. If ReservedIntraBit is 1, this sample value can be used. Otherwise, this sample value cannot be used when all of these conditions are true. The sample position  $[-1, 7]$  uses the indexing convention such that  $[0, 0]$  is the upper-left sample position in a macroblock.

If IntraMbFlag is 1 but any of the conditions listed previously is not true, ReservedIntraBit shall be 0 and accelerators shall ignore the value. The value 1 is reserved in this case. If IntraMbFlag is 0, ReservedIntraBit has no meaning.

---

**Note** The value of ReservedIntraBit is needed to determine the filtered value  $p'$  of the luma sample at relative position  $[0, 7]$  for some intra prediction modes. For example, when all of the conditions listed previously are true, if the left neighboring region is in a field macroblock pair and  $((\text{LumaIntraPredModes}[0] \gg 8) \& 0x000F)$  equals 0 (indicating the use of Intra\_8x8\_vertical prediction mode for the lower-left 8x8 luma block of the macroblock), this flag is needed to determine the prediction value of the left-most column of the lower half of the macroblock, according to subclauses 8.3.2.2.1 and 8.3.2.2.2 of the H.264/AVC specification. Specifically, if the value of sample  $p[-1, 7]$  can be used, the samples in the left-most column of the lower half of the macroblock have a predicted value equal to  $(p[-1, 7] + p[0, 7] * 2 + p[1, 7] + 2) \gg 2$ . Otherwise, if  $p[-1, 7]$  cannot be used, the predicted value is  $(p[0, 7] * 3 + p[1, 7] + 2) \gg 2$ . Again, this equation follows the indexing convention such that

$[0, 0]$  is the upper-left sample position in a macroblock. This is not the indexing convention used in the referenced sections of the H.264/AVC specification, where indexes are relative to the prediction block rather than the entire macroblock.

In prior versions of this specification, ReservedIntraBit was always 0, and there was no indicator for the availability of the sample value at  $p[-1, 7]$ . The value of the four least significant bits of ReservedBits16 in the picture parameters structure was defined to be 0 or 1 in the earlier versions of this specification; in the current version, the four least significant bits of ReservedBits16 shall be 2.

---

#### bMbIntraStruct

Accesses the entire 8 bits of the previous three members.

#### ReservedIntra24Bits

This structure member has no meaning. When IntraMbFlag is 1, the value shall be 0, and accelerators shall ignore the value.

The second structure in the union is used when IntraMbFlag is 0. It contains the following members: bSubMbShapes

If IntraMbFlag is 0 and MbType5Bits is 22 (B\_8x8), this member specifies the shape of the sub-macroblock partitions in each sub-macroblock. Bits  $(i * 2)$  and  $(i * 2 + 1)$  specify the values of SubMbPartWidth() and SubMbPartHeight() for submacroblock  $i$ , as follows:

Bit $(i * 2 + 1)$	Bit $(i * 2)$	SubMbPartWidth	SubMbPartHeight
0	0	8	8

0	1	8	4
1	0	4	8
1	1	4	4

Sub-macroblocks are numbered as shown in Figure 2. The LSB is bit number 0.

If IntraMbFlag is 1 or MbType5Bits is not 22, bSubMbShapes has no meaning. When MbType5Bits is not 22 and IntraMbFlag is 0, bSubMbShapes shall be 0 and accelerators shall ignore the value.

#### bSubMbPredModes

If IntraMbFlag is 0 and MbType5Bits is 22 (B\_8x8), this member specifies the submacroblock prediction mode for each sub-macroblock. Bits  $(i * 2)$  and  $(i * 2 + 1)$  specify the sub-macroblock prediction mode of the sub-macroblock partitions in submacroblock  $i$ , as follows:

Bit $(i * 2 + 1)$	Bit $(i * 2)$	Sub-macroblock prediction mode
0	0	Pred_L0
0	1	Pred_L1
1	0	BiPred

Sub-macroblocks are numbered as shown in Figure 2. The LSB is bit number 0.

If IntraMbFlag is 1 or MbType5Bits is not 22, bSubMbPredModes has no meaning. When MbType5Bits is not 22 and IntraMbFlag is 0, bSubMbPredModes shall be 0, and accelerators shall ignore the value.

#### wMvBuffOffset

If IntraMbFlag is 0, specifies the offset within the motion vector data buffer of the motion vectors for the macroblock, in units of motion vectors (4 bytes per motion vector).

---

**Note** The 16-bit size of wMvBuffOffset means that for very large picture sizes (8192 or more macroblocks—that is, pictures larger than 1920x1080 HDTV), it is theoretically possible the decoder would need more than one data buffer per picture, because the H.264/AVC specification allows a worst-case average of 8 motion vectors per macroblock ( $8192 \times 8 = 65,536$ ).

---

#### bRefPicSelect

Specifies the reference indexes into the reference picture list for the inter prediction process of the macroblock. For  $i$  in the range  $[0..1]$ , and  $j$  in the range  $[0..3]$ , bRefPicSelect $[i][j]$  specifies the reference index for list  $i$  and macroblock partition  $j$  or sub-macroblock  $j$ , where the numbering of macroblock partitions and submacroblocks follows the convention shown in the upper half of Figure 6-9 in the H.264/AVC specification (labeled "Macroblock partitions" in the figure).

If IntraMbFlag is 0, the value bRefPicSelect $[i][j]$  is valid for all values of  $i$  and  $j$  that are used in the inter prediction process of the macroblock. The value determines the referenced frame

or field, as specified by subclause 8.4.2.1 of the H.264/AVC specification, and is interpreted as follows:

- If MbaffFrameFlag is 0 or mb\_field\_decoding\_flag is 0, bRefPicSelect[i][j] is used directly as an index into RefPicList[i].
- If MbaffFrameFlag is 1 and mb\_field\_decoding\_flag is 1, the value of  $\text{bRefPicSelect}[i][j] \gg 1$  is used as an index into RefPicList[i], and the LSB of bRefPicSelect[i][j] specifies whether the field has the same parity as the current macroblock. If the LSB is 0, the referenced field has the same parity as the current macroblock; otherwise, it has the opposite parity. The following table shows how to interpret this bit, given the value of CurrMbAddr.

CurrMbAddr % 2	bRefPicSelect[i][j] % 2	Description
0	0	Top field of the referenced frame.
0	1	Bottom field of the referenced frame.
1	0	Bottom field of the referenced frame.
1	1	Top field of the referenced frame.

---

Note If CurrMbAddr % 2 is 0, the current macroblock is the top macroblock of a macroblock pair. If CurrMbAddr % 2 is 1, the current macroblock is the bottom macroblock of a macroblock pair.

---

If IntraMbFlag is 0, values of bRefPicSelect[i][j] for values of i and j that are not used in the inter prediction process of the macroblock shall be 0, and accelerators shall ignore these values.

If IntraMbFlag is 1, bRefPicSelect has no meaning.

#### Requirements

Header: Include dxva.h.

## 8.0 Residual Difference Data Buffers

This section describes the format of the residual difference data buffers.

Residual difference data buffers are used when bDXVA\_Func is 1 and the buffer type is DXVA\_RESIDUAL\_DIFFERENCE\_BUFFER (DXVA 1.0) or DXVA2\_MacroBlockControlBufferType (DXVA 2.0).

### 8.1 Ordering of Residual Blocks within Macroblocks

Blocks of residual data within a macroblock, including the DC blocks that appear separately in the bitstream, will appear in the same order in which they appear in the H.264/AVC bitstream. Within the data for a single macroblock, all luma residual blocks precede all chroma residual blocks.

If a block contains only zero coefficients, the host decoder does not need to convey that block to the accelerator, even if the block was present in the bitstream. Instead, the decoder can set the bit

in the indicated coded block pattern to 0. This rule has particular significance for the Intra\_16x16 macroblock modes in which the value of CodedBlockPatternLuma is 15, as derived from the value of mb\_type (see Table 7-11 in the H.264/AVC specification). In that case, zero-valued blocks may be present in the bitstream but are not required to be present in the DXVA data.

The same rule applies when host-based inverse transform processing is used—that is, when the host decoder sends residual difference data in the spatial domain. Only nonzero blocks in the spatial domain need to be sent to the accelerator.

The preceding information should be sufficient to specify the block order. The remainder of this section provides further detail for clarification.

### 8.1.1 Ordering of Luma Residual Blocks within Macroblocks

There are three cases to consider for luma residual blocks.

#### 8.1.1.1 Luma Blocks for Intra\_16x16 Macroblocks

In this mode, there are 17 luma blocks. If all of them are present in the bitstream, they are ordered as shown in Figure 4.

When using accelerator-based inverse transform processing—that is, when residual differences are sent in the coefficient domain—the host decoder sends the luma residual blocks to the accelerator in the order shown in Figure 4.

When using host-based inverse transform processing—that is, when residual differences are sent in the spatial domain—the luma DC block is not present. (This block belongs inherently to the coefficient domain.) Instead, the host decoder incorporates the effects of the luma DC block into the spatial-domain residual difference data. The resulting residual luma data contains blocks 1–16 in Figure 4, in the order shown.

Figure 4. Ordering of luma blocks when mb\_type is Intra\_16x16

#### 8.1.1.2 Luma Blocks for non-Intra\_16x16 Macroblocks with 4x4 Transform

In this mode, there are 16 luma blocks. If all of them are present in the bitstream, they are ordered as shown in Figure 1.

#### 8.1.1.3 Luma Blocks for non-Intra\_16x16 Macroblocks with 8x8 Transform

In this mode, there are 4 luma blocks. If all of them are present in the bitstream, they are ordered as shown in Figure 2.

## 8.1.2 Ordering of Chroma Residual Blocks within Macroblocks

There are four cases to consider for chroma residual blocks.

### 8.1.2.1 Chroma Blocks for Monochrome Macroblocks

In this mode, there are no chroma blocks.

### 8.1.2.2 Chroma Blocks for 4:2:0 Macroblocks

In this mode, there are 10 chroma blocks. If all of them are present in the bitstream, they are ordered as shown in Figure 5. (The DC coefficient blocks are shown as smaller than the AC coefficient blocks, because they are 2x2 rather than 4x4.)

When using accelerator-based inverse transform processing, the host decoder sends the chroma residual blocks to the accelerator in the order shown in Figure 5.

When using host-based inverse transform processing, blocks 0 and 1 in Figure 6 are not present. (These blocks belong inherently to the coefficient domain.) Instead, the host decoder incorporates the effects of the chroma DC blocks into the spatial-domain residual difference data. The resulting residual chroma data contains blocks 2–9, in the order shown in Figure 5.

Figure 5. Ordering of chroma blocks for 4:2:0 macroblocks

### 8.1.2.3 Chroma Blocks for 4:2:2 Macroblocks

In this mode, there are 18 chroma blocks. If all of them are present in the bitstream, they are ordered as shown in Figure 6. (The DC blocks are shown as narrower than the AC blocks, because they are 2x4 rather than 4x4.) The highest-priority profiles for DXVA support do not include 4:2:2 chroma macroblocks.

When using accelerator-based inverse transform processing, the host decoder sends the chroma residual blocks to the accelerator in the order shown in Figure 6.

When using host-based inverse transform processing, blocks 0 and 1 in Figure 6 are not present. (These blocks belong inherently to the coefficient domain.) Instead, the host decoder incorporates the effects of the chroma DC blocks into the spatial-domain residual difference data. The resulting residual chroma data contains blocks 2–17, in the order shown in Figure 6.

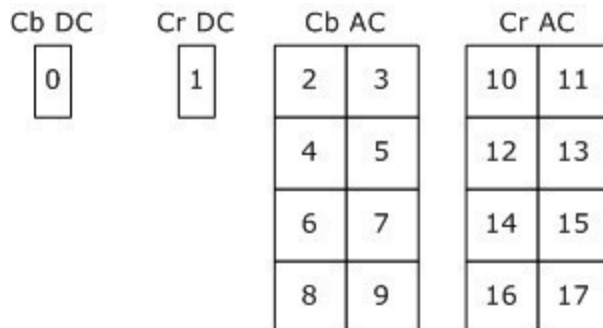

Figure 6. Ordering of chroma blocks for 4:2:2 macroblocks

### 8.1.2.4 Chroma Blocks for 4:4:4 Macroblocks

In this mode, there are 34 chroma blocks. If all of them are present in the bitstream, they are ordered as shown in Figure 7. The highest-priority profiles for DXVA support do not include 4:4:4 chroma macroblocks.

When using accelerator-based inverse transform processing, the host decoder sends the chroma residual blocks to the accelerator in the order shown in Figure 7.

When using host-based inverse transform processing, blocks 0 and 1 in Figure 7 are not present. (These blocks belong inherently to the coefficient domain.) Instead, the host decoder incorporates the effects of the chroma DC blocks into the spatial-domain residual difference data. The resulting residual chroma data contains blocks 2–33, in the order shown in Figure 7.

Figure 7. Ordering of chroma blocks for 4:4:4 macroblocks

## 8.2 Transform Coefficients

This section describes how transform coefficients are represented in the residual difference data buffer.

The DXVA\_TCoefSingle structure defined in the DXVA 1.0 specification is sufficient for decoding H.264/AVC video in which  $\text{BitDepth}_Y$  and  $\text{BitDepth}_C$  both equal 8 (that is, 8-bit luma and chroma). Therefore, all of the DXVA decoding profiles that are currently defined use this structure.

The end-of-block (EOB) flag in the structure is set to 1 for the last coefficient that the host decoder sends for each transform block. (The EOB flag is the LSB of the  $w\text{IndexWithEOB}$  member.) For any frequency indexes of a transform block that are not sent by the host decoder, the coefficients may be inferred:

- When performing an inverse 4x4 non-Hadamard transform for the luma samples of an Intra\_16x16 macroblock or the chroma samples of a macroblock, the host decoder will not send the DC coefficient and the value will be inferred as follows:
- If the host decoder has sent DC transform block coefficients, the DC coefficient will be inferred from the content of that transform block.
- Otherwise, the inferred DC coefficient is 0.
- Otherwise, any missing coefficients are inferred to be 0.

The index in the DXVA\_TCoefSingle structure is a frequency index in raster-scan order of the form  $u + W * v$ , where

- $u$  is the horizontal frequency index.
- $v$  is the vertical frequency index.
- $W$  is a constant:

- For the 2x2 or 2x4 chroma Hadamard DC transform,  $W = 2$ .
- For the 4x4 transforms (Hadamard 4x4 DC transform or 4x4 non-Hadamard transform),  $W = 4$ .
- For the 8x8 non-Hadamard transforms,  $W = 8$ .

For host-based parsing, the accelerator should not be designed with any dependency on receiving transform coefficients in either zig-zag or field scan order.

The accelerator performs the inverse quantization scaling process, although this requires including  $QP'_Y$  and  $QP'_C$  in the macroblock control commands.

Support for luma and chroma bit depths greater than 8 is lower priority. In the current DXVA\_TCoefSingle structure, the 16-bit TCoefValue value does not have enough precision for higher bit depths. Although hypothetically a new structure could have been defined for all H.264/AVC decoding profiles in DXVA, the current design does not define such a structure. If a new structure is defined in the future, it is expected to be specified as follows:

```
typedef union _DXVA_TCoefLong {
    struct {
        UINT EOB :
        1;
        UINT Index : 7;
        INT Value : 24;
    };
    INT iValue;
} DXVA_TCoefLong, *LPDXVA_TCoefLong;
```

This structure is essentially equivalent to the following:

```
typedef INT32 DXVA_TCoefLong;

#define readDXVA_TCoefLongIDX(tcoef) (((tcoef) >> 1) & 0x7F)
#define readDXVA_TCoefLongEOB(tcoef) ((tcoef) & 1)
#define readDXVA_TCoefLongValue(tcoef) ((tcoef) >> 8)

#define setDXVA_TCoefLongIDX(tcoef, idx) ((tcoef) |= ((idx) << 1))
#define setDXVA_TCoefLongEOB(tcoef, eob) ((tcoef) |= (eob))
#define setDXVA_TCoefLongValue(tcoef, val) ((tcoef) |= ((val) << 8))

#define writeDXVA_TCoefLongIDX(tcoef, idx, eob, val) \
    ((tcoef) = (((val) << 8) | ((idx) << 1) | eob))
```

Some alternatives to this structure are possible as well, and Microsoft solicits feedback on the following ideas:

- Placing the coefficient values in the 24 LSBs instead of the 24 MSBs.
- Moving the EOB flag to the MSB of the index byte instead of its LSB.
- Moving the EOB flag into the MSB or LSB of the 24-bit coefficient value. (This would enable support of a hypothetical future 16x16 transform size.)

### 8.3 I\_PCM Residuals

When the decoded video has 8 bits per decoded sample (that is, when the I\_PCM residuals are sent as a string of byte-aligned bytes in the compressed H.264/AVC bitstream), the host decoder sends I\_PCM residuals in the same format and order (8 bits per sample) in which they appear in the bitstream, which is raster scan order.

There are currently no defined DXVA decoding profiles that use I\_PCM samples with bit depth greater than 8. For future use, Microsoft is considering two alternatives:

- Placing the sample values as tightly-packed strings of bytes containing the raw data from the bitstream. This design would require the accelerator to unpack the alignment of the samples within the bytes.
- Having the host decoder unpack the bytes and send samples to the accelerator as 16-bit samples in raster scan order. This approach would require more processing on the host and increased bus data flow.

It is possible the design will use the first approach when HostResidDiff is 0 and the second when HostResidDiff is 1.

### 8.4 Transform-Bypass Residuals

For transform-bypass residuals (that is, residuals sent when the `qp_prime_y_zero_transform_bypass_flag` syntax element is 1 and  $QP'_Y$  is 0), the host decoder would send residuals to the accelerator as 16-bit signed values for each sample, in raster order within each residual block.

Currently, however, no defined DXVA decoding profiles support transform-bypass residuals, as these are found only in the 4:4:4 professional profiles of the H.264/AVC standard.

### 8.5 Other Spatial-Domain Residuals

When HostResidDiff is 0, for macroblocks that are not I\_PCM macroblocks and not transform-bypass macroblocks, the host decoder sends the residual difference data blocks as 16-bit signed values for each sample, in raster order within each spatialdomain residual block. These blocks are 4x4 or 8x8, depending on the value of `transform_size_8x8` in the macroblock command data structure.

## 9.0 Deblocking Filter Control Data Structure

The macroblock command data structure has all of the information needed to control the deblocking filter process for macroblocks, provided the accelerator has access to the relevant macroblock command buffers when it performs the deblocking filter. (The accelerator needs data from the macroblock command buffer for the current macroblock, as well as the macroblocks to the left of the current macroblock and above the current macroblock.) Therefore, it is possible for an accelerator to perform the deblocking filter using only these buffers (or data copied from these buffers) without receiving any additional data from the host decoder.

This section contains an alternative set of structures for H.264/AVC deblocking filter control. The intent is for accelerators to indicate whether they can perform the deblocking filter using only macroblock command buffers. An accelerator that lacks this capability is considered to have reduced acceleration capabilities and will use the data structures described in this section.

The value of `bDXVA_Func` is 5 for deblocking filter control buffers. The buffer type is `DXVA_DEBLOCKING_CONTROL_BUFFER` (DXVA 1.0) or `DXVA2_DeblockingControlBufferType` (DXVA 2.0).

## 9.1 IndexA and IndexB Data Structure

The `DXVA_DeblockIndexAB_H264` structure contains the `IndexA` and `IndexB` variables needed to filter a component (Y, Cb, or Cr) of a macroblock.

The structure contains the values of `IndexA` and `IndexB` that control the filtering process for a macroblock, including the filtering across the left and top edges of the macroblock, but not including the filtering across the right and bottom edges. The order of the deblocking filter operations is given in the H.264/AVC specification. Although each of the `IndexA` and `IndexB` values requires only 6 bits of dynamic range, 8 bits are used for each structure member.

### 9.1.1 Syntax

```
typedef struct _DXVA_DeblockIndexAB_H264 {
    UCHAR bIndexAinternal;
    UCHAR bIndexBinternal;
    UCHAR bIndexAleft0;
    UCHAR bIndexBleft0;
    UCHAR bIndexAleft1;
    UCHAR bIndexBleft1;
    UCHAR bIndexAtop0;
    UCHAR bIndexBtop0;
    UCHAR bIndexAtop1;
    UCHAR bIndexBtop1;
} DXVA_DeblockIndexAB_H264, *LPDXVA_DeblockIndexAB_H264;
```

### 9.1.2 Semantics

`bIndexAinternal`, `bIndexBinternal`

Specifies the values of `IndexA` and `IndexB` that apply when filtering across the internal edges of the current macroblock.

`bIndexAleft0`, `bIndexBleft0`

Specifies the values of `IndexA` and `IndexB` that apply to filtering across the left edge of the current macroblock when `bIndexAleft1` and `bIndexBleft1` do not apply.

`bIndexAleft1`, `bIndexBleft1`

Specifies the values of `IndexA` and `IndexB` that apply when filtering across the left edge of the current macroblock under either of the following conditions:

- The `FieldModeCurrentMbFlag` member of the deblocking control data structure (described in section 9.2) is 0; the `FieldModeLeftMbFlag` member of that structure is 1; and filtering across the left edge of the current macroblock is applied along the lines of the bottom field of the current macroblock. -OR-
- `FieldModeCurrentMbFlag` is 1; `FieldModeLeftMbFlag` is 0; and filtering across the left edge of the current macroblock is applied along the lines of the bottom half of the current macroblock.

`bIndexAtop0`, `bIndexBtop0`

Specifies the values of `IndexA` and `IndexB` that apply to filtering across the top edge of the current macroblock when `bIndexAtop1` and `bIndexBtop1` do not apply.

`bIndexAtop1`, `bIndexBtop1`

Specifies the values of `IndexA` and `IndexB` that apply when filtering across the top edge of the current macroblock under the following condition:

- The `FieldModeCurrentMbFlag` member of the deblocking control data structure is 0; the `FieldModeAboveMbFlag` member of that structure is 1; and filtering across the top edge of the current macroblock is applied along the lines of the bottom field of the current macroblock.

### Requirements

Header: Include `dxva.h`.

## 9.2 Deblocking Control Data Structure

The `DXVA_Deblock_H264` structure contains data to control the deblocking filter process for a macroblock.

### 9.2.1 Syntax

```
typedef struct _DXVA_Deblock_H264 { USHORT
CurrMbAddr; union {
struct {
    UCHAR ReservedBit          : 1;
    UCHAR FieldModeCurrentMbFlag : 1;
    UCHAR FieldModeLeftMbFlag   : 1;
    UCHAR FieldModeAboveMbFlag  : 1;
    UCHAR FilterInternal8x8EdgesFlag : 1;
    UCHAR FilterInternal4x4EdgesFlag : 1;
    UCHAR FilterLeftMbEdgeFlag   : 1;
    UCHAR FilterTopMbEdgeFlag    : 1;
};
    UCHAR FirstByte;
};
    UCHAR Reserved8Bits;
    UCHAR bbSinternalLeftVert;
    UCHAR bbSinternalMidVert;
    UCHAR bbSinternalRightVert;
    UCHAR bbSinternalTopHorz;
    UCHAR bbSinternalMidHorz;
    UCHAR bbSinternalBotHorz;
    USHORT wbSLeft0;
    USHORT wbSLeft1;
    USHORT wbSTop0;
    USHORT wbSTop1;
    DXVA_DeblockIndexAB_H264 IndexAB[3];
} DXVA_Deblock_H264, *LPDXVA_Deblock_H264;
```

### 9.2.2 Semantics

#### `CurrMbAddr`

Macroblock address of the current macroblock. The value corresponds to the variable of the same name in the H.264/AVC specification.

#### `ReservedBit`

This structure member has no meaning. The value shall be 0, and accelerators shall ignore the value.

**FieldModeCurrentMbFlag**

Specifies whether the current macroblock is considered a field macroblock for purposes of the deblocking filter.

Value	Description
0	The current macroblock is considered a frame macroblock.
1	The current macroblock is considered a field macroblock.

**FieldModeLeftMbFlag**

Specifies whether the left-neighboring macroblock is considered a field macroblock for purposes of the deblocking filter.

Value	Description
0	The left-neighboring macroblock is considered a frame macroblock.
1	The left-neighboring macroblock is considered a field macroblock.

**FieldModeAboveMbFlag**

Specifies whether the above-neighboring macroblock is considered a field macroblock for purposes of the deblocking filter.

Value	Description
0	The above-neighboring macroblock is considered a frame macroblock.
1	The above-neighboring macroblock is considered a field macroblock.

**FilterInternal8x8EdgesFlag**

If 1, the filter shall be applied across the internal luma edges of the macroblock that lie on 8x8 block boundaries. Otherwise, the filter shall not be applied across such edges.

**FilterInternal4x4EdgesFlag**

If 1, the filter shall be applied across the internal luma edges of the macroblock that lie on 4x4 block boundaries. Otherwise, the filter shall not be applied across such edges.

If **FilterInternal4x4EdgesFlag** is 1, **FilterInternal8x8EdgesFlag** shall be 1. If **FilterInternal8x8EdgesFlag** is 0, **FilterInternal4x4EdgesFlag** shall be 0. Accelerators can rely on this constraint being fulfilled.

**FilterLeftMbEdgeFlag**

If 1, the filter is applied to the left edge of the macroblock. Otherwise, it is not applied to the left edge.

**FilterTopMbEdgeFlag**

If 1, the filter is applied to the top edge of the macroblock. Otherwise, it is not applied to the top edge.

**FirstByte**

Accesses the entire 8 bits of the union.

**Reserved8Bits**

This structure member has no meaning. The value shall be 0, and accelerators shall ignore the value.

**bbSinternalLeftVert**

Contains boundary strength parameters for the filtering across the left-most internal 4x4 vertical edges in the luma component of the macroblock.

If `FilterInternal4x4EdgesFlag` is 0, `bbSinternalLeftVert` shall be 0. Accelerators can rely on this constraint being fulfilled.

For  $i$  in the range  $[0..3]$ , bits  $(i * 2)$  and  $(i * 2 + 1)$  contain the boundary strength of the left edge of block number  $i$  shown in Figure 8. The LSB is bit number 0.

	0		
	1		
	2		
	3		

Figure 8. Numbering of left-most internal 4x4 vertical edges in the luma component of a macroblock `bbSinternalMidVert`

Contains boundary strength parameters for the filtering across the middle internal 4x4 vertical edges in the luma component of the macroblock.

If `FilterInternal8x8EdgesFlag` is 0, `bbSinternalMidVert` shall be 0. Accelerators can rely on this constraint being fulfilled.

For  $i$  in the range  $[0..3]$ , bits  $(i * 2)$  and  $(i * 2 + 1)$  contain the boundary strength of the left edge of block number  $i$  shown in Figure 9. The LSB is bit number 0.

		0	
		1	
		2	
		3	

Figure 9. Numbering of middle internal 4x4 vertical edges in the luma component of a macroblock `bbSinternalRightVert`

Contains boundary strength parameters for the filtering across the right-most internal 4x4 vertical edges in the luma component of the macroblock.

If `FilterInternal4x4EdgesFlag` is 0, `bbSinternalRightVert` shall be 0. Accelerators can rely on this constraint being fulfilled.

For  $i$  in the range  $[0..3]$ , bits  $(i * 2)$  and  $(i * 2 + 1)$  contain the boundary strength of the left edge of block number  $i$  shown in Figure 10. The LSB is bit number 0.

			0
			1
			2
			3

Figure 10. Numbering of right-most internal 4x4 vertical edges in the luma component of a macroblock `bbSinternalTopHorz`

Contains boundary strength parameters for the filtering across the top-most internal 4x4 horizontal edges in the luma component of the macroblock.

If `FilterInternal4x4EdgesFlag` is 0, `bbSinternalTopHorz` shall be 0. Accelerators can rely on this constraint being fulfilled.

For  $i$  in the range  $[0..3]$ , bits  $(i * 2)$  and  $(i * 2 + 1)$  contain the boundary strength of the top edge of block number  $i$  shown in Figure 11. The LSB is bit number 0.

0	1	2	3

Figure 11. Numbering of top-most internal 4x4 horizontal edges in the luma component of a macroblock `bbSinternalMidHorz`

Contains boundary strength parameters for the filtering across the middle internal 4x4 horizontal edges in the luma component of the macroblock.

If `FilterInternal8x8EdgesFlag` is 0, `bbSinternalMidHorz` shall be 0. Accelerators can rely on this constraint being fulfilled.

For  $i$  in the range  $[0..3]$ , bits  $(i * 2)$  and  $(i * 2 + 1)$  contain the boundary strength of the top edge of block number  $i$  shown in Figure 12. The LSB is bit number 0.

0	1	2	3

Figure 12. Numbering of middle internal 4x4 horizontal edges in the luma component of a macroblock

`bbSinternalBotHorz`

Contains boundary strength parameters for the filtering across the bottom-most internal 4x4 horizontal edges in the luma component of the macroblock.

If FilterInternal4x4EdgesFlag is 0, bbSinternalBotHorz shall be 0. Accelerators can rely on this constraint being fulfilled.

For  $i$  in the range  $[0...3]$ , bits  $(i * 2)$  and  $(i * 2 + 1)$  contain the boundary strength of the top edge of block number  $i$  shown in Figure 13. The LSB is bit number 0.

Figure 13. Numbering of bottom-most internal 4x4 horizontal edges in the luma component of a macroblock `wbSLeft0`

Contains boundary strength parameters for the filtering across the left-most 4x4 vertical edges in the luma component of the macroblock. The value applies to the filtering across the left edge of the current macroblock for the edges that are not controlled by `wbSLeft1`.

If FilterLeftMbEdgeFlag is 0, `wbSLeft0` shall be 0. Accelerators can rely on this constraint being fulfilled.

When the boundary strengths in `wbSLeft0` are applicable, `wbSLeft0` shall be interpreted as follows. In all cases, the LSB of `wbSLeft0` is bit number 0. Let CurrMB be the current macroblock, and let macroblock A be the top macroblock of the macroblock pair located to the left of the CurrMB, as shown in Figure 17.

- If FieldModeCurrentMbFlag equals FieldModeLeftMbFlag, bits  $(i * 4)$  through  $(i * 4 + 3)$  of `wbSLeft0` contain the boundary strength for filtering the left edge of block number  $i$  in CurrMB, where blocks are numbered as shown in Figure 14.

- If `FieldModeCurrentMbFlag` is 0 and `FieldModeLeftMbFlag` is 1, bits  $(i * 4)$  through  $(i * 4 + 3)$  contain the boundary strength for filtering the left edge of block number  $i$  in `CurrMB` with the right edge of macroblock A. The blocks in `CurrMB` are numbered as shown in Figure 14.
- If `FieldModeCurrentMbFlag` is 1 and `FieldModeLeftMbFlag` is 0, bits  $(i * 4)$  through  $(i * 4 + 3)$  contain the boundary strength for filtering across the left edge of the top half of `CurrMB` with the right edge of block number  $i$  in macroblock A, where the 4x4 blocks in macroblock A are shown in Figure 15.

			0
			1
			2
			3

Figure 15. Numbering of right-most vertical edges in the luma component of a macroblock that neighbors the current macroblock on its left `wbSLeft1`

Contains boundary strength parameters for the filtering across the left-most 4x4 vertical edges in the luma component of the macroblock. This structure member applies under the following conditions:

- `FieldModeCurrentMbFlag` is 0, `FieldModeLeftMbFlag` is 1, and filtering across the left edge of the current macroblock is applied along the lines of the bottom field of the current macroblock.
- OR-
- `FieldModeCurrentMbFlag` is 1, `FieldModeLeftMbFlag` is 0, and filtering across the left edge of the macroblock is applied along the lines of the bottom half of the current macroblock.

If `FilterLeftMbEdgeFlag` is 0, `wbSLeft1` shall be 0. Accelerators can rely on this constraint being fulfilled.

If `FieldModeCurrentMbFlag` equals `FieldModeLeftMbFlag`, `wbSLeft1` shall be 0. Accelerators can rely on this constraint being fulfilled.

When the boundary strengths in `wbSLeft1` are applicable, `wbSLeft1` shall be interpreted as follows. In all cases, the LSB of `wbSLeft1` is bit number 0. Let `CurrMB` be the current macroblock, and let macroblock B be the bottom macroblock of the macroblock pair located to the left of the `CurrMB`, as shown in Figure 17.

- If `FieldModeCurrentMbFlag` is 0 and `FieldModeLeftMbFlag` is 1, bits  $(i * 4)$  through  $(i * 4 + 3)$  contain the boundary strength for filtering along the left edge of block number  $i$  in `CurrMB` with the right edge of macroblock `B`. The blocks in `CurrMB` are numbered as shown in Figure 14.
- If `FieldModeCurrentMbFlag` is 1 and `FieldModeLeftMbFlag` is 0, bits  $(i * 4)$  through  $(i * 4 + 3)$  contain the boundary strength for filtering across the left edge of the bottom half of `CurrMB` with the right edge of block number  $i$  in macroblock `B`. The blocks in `B` are numbered as shown in Figure 15.

#### `wbSTop0`

Contains boundary strength parameters for the filtering across the top-most 4x4 horizontal edges in the luma component of the current macroblock. The value applies to the filter across the top edge of the current macroblock when `wbSTop1` does not apply.

If `FilterTopMbEdgeFlag` is 0, `wbSTop0` shall be 0. Accelerators can rely on this constraint being fulfilled.

Bits  $(i * 4)$  through  $(i * 4 + 3)$  of `wbSTop0` contain the boundary strength for the top edge of block number  $i$  of the current macroblock, where blocks are numbered as shown in Figure 16. The LSB is bit number 0.

0	1	2	3

Figure 16. Numbering of top-most 4x4 vertical edges in the luma component of a macroblock

#### `wbSTop1`

Contains boundary strength parameters for the filter across the top-most 4x4 horizontal edges in the luma component of the current macroblock.

This structure member applies when `FieldModeCurrentMbFlag` is 0, `FieldModeAboveMbFlag` is 1, and the filtering across the top edge of the current macroblock is applied across the lines of the bottom field of the current macroblock.

The value of `wbSTop1` shall be 0 if any of the following is true:

`FilterTopMbEdgeFlag` is 0; `FieldModeCurrentMbFlag` is 1; or `FieldModeAboveMbFlag` is 0. Accelerators can rely on this constraint being fulfilled.

Bits  $(i * 4)$  through  $(i * 4 + 3)$  of `wbSTop1` contain the boundary strength for the top edge of block number  $i$  of the current macroblock, where blocks are numbered as shown in Figure 16. The LSB is bit number 0.

#### `IndexAB`

An array of `DXVA_DeblockIndexAB_H264` structures that contains `IndexA` and `IndexB` values for the sample components:

- `IndexAB[0]` contains values for the luma (Y) component.
- `IndexAB[1]` contains values for the Cb chroma component.
- `IndexAB[2]` contains values for the Cr chroma component.

Figure 17. Relative positioning of neighboring macroblocks

#### Requirements

Header: Include dxva.h.

## 10.0 Motion Vector Data Structure and Ordering

This section describes the data structure for motion vectors and the ordering of motion vectors within the data buffer.

### 10.1 Motion Vector Data Structure

Motion vectors are specified using the `DXVA_MVvalue` structure. Motion vectors are sent whenever the associated macroblock is not an intra macroblock (that is, when `IntraMbFlag` in the macroblock control command buffer is 0). Motion vectors are placed in a separate buffer.

---

**Note** This design differs from previous DXVA decoding designs, in which motion vectors were placed in the macroblock control buffer.

---

The `DXVA_MVvalue` structure is used when `bDXVA_Func` is 1 and the buffer type is `DXVA_MOTION_VECTOR_BUFFER` (DXVA 1.0) or `DXVA2_MotionVectorBuffer` (DXVA 2.0).

#### 10.1.1 Syntax

```
typedef struct _DXVA_MVvalue { SHORT horz, vert;
} DXVA_MVvalue, *LPDXVA_MVvalue;
```

#### 10.1.2 Semantics

**horz**

Contains the horizontal component of the motion vector, in units of one fourth of the horizontal luma-sample frame or field grid position. (In the horizontal direction, the units are the same for field macroblocks and frame macroblocks.)

**vert**

Contains the horizontal component of the motion vector.

- If `mb_field_decoding_flag` in the macroblock control buffer is 1, the units are one fourth of the vertical luma-sample field grid position.
- If `mb_field_decoding_flag` is 0, the units are one fourth of the vertical luma-sample frame grid position.

Requirements

Header: Include `dxva.h`.

## 10.2 Ordering of Motion Vectors

The ordering of the motion vectors is determined by the motion segmentation partitioning. The following fields in the macroblock command buffer define the number of motion partitions in the macroblock or sub-macroblock:

- `IntraMbFlag` and `MbType5bits`: Together, these fields define the macroblock type.
- `bSubMbShapes`: Specifies the shape of the sub-macroblock partitions in each submacroblock, for `B_8x8` macroblocks.

For each motion partition, the following applies:

- If the motion partition uses list 0 prediction (that is, inter prediction using only list 0), the host decoder sends the list 0 motion vector for the partition.
- If the motion partition uses list 1 prediction (inter prediction using only list 1), the host decoder sends the list 1 motion vector for the partition.
- If the motion partition uses bidirectional prediction, the host decoder sends the list 0 motion vector for the partition, followed immediately by the list 1 motion vector for the partition.

---

Note This section was modified in June 2007 to match implementations that had been deployed using this ordering.

---

### 10.2.1 Ordering of Motion Partitions for 16x16 Macroblock Motion or 8x8 Sub-macroblock Motion

If `IntraMbFlag` is 0 and `MbType5bits` is 1, 2, or 3, there is only one motion partition for the macroblock. If `IntraMbFlag` is 0 and `MbType5bits` is 22, then for sub-macroblocks with 8x8 motion, there is only one motion partition for the sub-macroblock.

### 10.2.2 Ordering of Motion Partitions for 16x8 Macroblock Motion or 8x4 Sub-macroblock Motion

If `IntraMbFlag` is 0 and `MbType5bits` is 4, 6, 8, 10, 12, 14, 16, 18, or 20, there are two motion partitions for the macroblock. If `IntraMbFlag` is 0 and `MbType5bits` is 22, then for sub-macroblocks with 8x4 motion, there are two motion partitions for the submacroblock. These motion partitions are sent in the order shown in Figure 18.

Figure 18. Ordering of motion partitions for 16x8 motion in a macroblock or 8x4 motion in an 8x8 sub-macroblock

### 10.2.3 Ordering of Motion Partitions for 8x16 Macroblock Motion or 4x8 Sub-macroblock Motion

If IntraMbFlag is 0 and MbType5bits is 5, 7, 9, 11, 13, 15, 17, 19, or 21, there are two motion partitions for the macroblock. If IntraMbFlag is 0 and MbType5bits is 22, then for sub-macroblocks with 4x8 motion, there are two motion partitions for the submacroblock. These motion partitions are sent in the order shown in Figure 19.

Figure 19. Ordering of motion partitions for 8x16 motion in a macroblock or 4x8 motion in an 8x8 sub-macroblock

### 10.2.4 Ordering of Motion Partitions for 8x8 Sub-macroblocks

If IntraMbFlag is 0 and MbType5bits is 22 (B\_8x8), the 8x8 sub-macroblocks are scanned in the order shown in Figure 2. The motion partitions within each submacroblock are sent in the order specified in 10.2.1, 10.2.2, or 10.2.3, depending on the partitioning of the associated sub-macroblock.

## 11.0 Film-Grain Synthesis Data Structure

The DXVA\_FilmGrainChar\_H264 structure contains information needed for film-grain synthesis. This data structure has been designed to support the full capabilities of the H.264/AVC film-grain synthesis SEI message, except for the limitation on the size of some arrays in the data structure.

This structure is used when bDXVA\_Func is 6 and the buffer type is DXVA\_FILM\_GRAIN\_BUFFER (DXVA 1.0) or DXVA2\_FilmGrainBuffer (DXVA 2.0).

The host decoder sends the command to perform film-grain synthesis in a separate function call from those used to decode the compressed picture. This design may allow the decoder to decode or post-process more pictures ahead of the display process.

Unless specified otherwise, the accelerator's action in response to this command is specified in the Society of Motion Picture and Television Engineers (SMPTE) registered disclosure document RDD 05-2006, Film Grain Technology - Specifications for H.264 | MPEG-4 AVC Bitstreams, which can be purchased from SMPTE. That document specifies some constraints on the content of the film-grain characteristics syntax. In such use, the value of AssociatedFlag shall be 0 for both InPic and OutPic. Accelerators should verify that these constraints are fulfilled.

At the present time, no alternative uses of this data structure are defined for DXVA.

## 11.1 Syntax

```
typedef struct _DXVA_FilmGrainCharacteristics {
    USHORT wFrameWidthInMbsMinus1;
    USHORT wFrameHeightInMbsMinus1;
    DXVA_PicEntry_H264 InPic;
    DXVA_PicEntry_H264 OutPic;
    USHORT PicOrderCnt_offset;
    INT CurrPicOrderCnt;
    UINT StatusReportFeedbackNumber;
    UCHAR model_id;
    UCHAR separate_colour_description_present_flag;
    UCHAR film_grain_bit_depth_luma_minus8;
    UCHAR film_grain_bit_depth_chroma_minus8;
    UCHAR film_grain_full_range_flag;
    UCHAR film_grain_colour primaries;
    UCHAR film_grain_transfer_characteristics;
    UCHAR film_grain_matrix_coefficients;
    UCHAR blending_mode_id;
    UCHAR log2_scale_factor;
    UCHAR comp_model_present_flag[4];
    UCHAR num_intensity_intervals_minus1[4];
    UCHAR num_model_values_minus1[4];
    UCHAR intensity_interval_lower_bound[3][16];
    UCHAR intensity_interval_upper_bound[3][16];
    SHORT comp_model_value[3][16][8];
} DXVA_FilmGrainChar_H264, *LPDXVA_FilmGrainChar_H264;
```

## 11.2 Semantics

### wFrameWidthInMbsMinus1

Width of the frame containing this picture, in units of macroblocks, minus 1. (The width in macroblocks is wFrameWidthInMbsMinus1 plus 1.)

### wFrameHeightInMbsMinus1

Height of the frame containing this picture, in units of macroblocks, minus 1. (The height in macroblocks is wFrameHeightInMbsMinus1 plus 1.) When the picture is a field, the height of the frame is twice the height of the picture and is an integer multiple of 2 in units of macroblocks.

### InPic

Specifies the uncompressed input frame surface for the picture to which film-grain synthesis is to be applied. The AssociatedFlag field in InPic is interpreted as follows:

Value	Description
1	The input and output pictures are the bottom fields of the uncompressed frame surfaces.
0	The input and output pictures are either complete frames, or the top fields of the uncompressed frame surfaces, depending on the value of AssociatedFlag in OutPic.

#### OutPic

Specifies the uncompressed output frame surface for the output of the film-grain synthesis process. The AssociatedFlag field in OutPic is interpreted as follows:

Value	Description
1	The input and output pictures are single fields of the uncompressed frame surfaces.
0	The input and output pictures are complete frames.

The value of Index7Bits in OutPic might or might not equal the value of Index7Bits in InPic. For example, when performing film-grain synthesis on a non-reference picture, the input and output surfaces may be the same.

#### PicOrderCnt\_offset

Corresponds to the variable of the same name in the SMPTE registered disclosure document.

#### CurrPicOrderCnt

Specifies the value of the PicOrderCnt() function for the current picture, as defined by the H.264/AVC specification.

#### StatusReportFeedbackNumber

Arbitrary number set by the host decoder to use as a tag in the status report feedback data. The value should not equal 0 and should be different in each call to Execute. For more information, see section 12.0, Status Report Data Structure.

The remaining members of this structure correspond to elements in the H.264/AVC filmgrain characteristics SEI message and have the same semantics, except for the following:

- All non-relevant members of the data structure shall be 0. For example, this rule applies to the values of the six structure members that follow `separate_colour_description_present_flag` when that flag is 0.
- Some structure members use more bits than are required to hold the value of the H.264/AVC syntax element.
- Some arrays that are specified as containing three elements in H.264/AVC are given four elements in this structure to provide more sensible memory alignment.
- Arrays that could have a dimension as high as 256 in H.264/AVC have been given 16 elements in this structure, which is expected to be sufficient for practical use.

The constraints that are specified in H.264/AVC on the values of syntax elements shall be obeyed for the values in this structure.

#### Requirements

Header: Include `dxva.h`.

## 12.0 Status Report Data Structure

The `DXVA_Status_H264` structure is used to report status information from the accelerator to the host decoder.

This structure is used when `bDXVA_Func` is 7. The status reporting command does not use a compressed buffer. Instead, the host decoder provides a buffer as private output data. For more information, see section 1.5.1, Status Reporting.

The status information command should be asynchronous to the decoding process. The host decoder should not wait to receive status information on a process before it proceeds to another process. After the host decoder has received a status report for a particular operation, the accelerator shall discard that information and not report it again. (That is, the results of each particular operation shall not be reported to the host decoder more than once.) Accelerators shall be capable of providing status information for every buffer for every operation performed.

Accelerators are required to store up to 512 `DXVA_Status_H264` structures internally, pending status requests from the host decoder. An accelerator may exceed this value. If the accelerator discards reporting information, it should discard the oldest data first.

The accelerator should provide status reports in approximately reverse temporal order of when the operations were completed. That is, status reports for the most recently completed operations should appear earlier in the list of status report data structures.

---

Note As noted previously, the word should describes guidelines that are encouraged but are not mandatory requirements.

---

### 12.1 Syntax

```
typedef struct _DXVA_Status_H264 {
    UINT
    StatusReportFeedbackNumber;
    DXVA_PicEntry_H264 CurrPic;
    UCHAR field_pic_flag;
    UCHAR bDXVA_Func;
    UCHAR bBufType;
    UCHAR bStatus;
    UCHAR bReserved8Bits;
    USHORT wNumMbsAffected;
} DXVA_Status_H264, *LPDXVA_Status_H264;
```

### 12.2 Semantics

#### StatusReportFeedbackNumber

Contains the value of `StatusReportFeedbackNumber` set by the host decoder in the picture parameters data structure or the film-grain synthesis buffer for the associated operation.

#### CurrPic

Specifies the uncompressed destination surface that was affected by the operation.

If `field_pic_flag` is 1, the `AssociatedFlag` field in `CurrPic` is interpreted as follows:

Value	Description

0	The current picture is the bottom field of the uncompressed destination frame surface.
1	The current picture is the top field of the uncompressed destination frame surface.

If `field_pic_flag` is 0, `AssociatedFlag` has no meaning and shall be 0.

#### `field_pic_flag`

If 0, the current picture is a frame. If 1, the current picture is a field. `BDXVA_Func`

Specifies the function associated with the status report information. The value must be one of the following:

Value	Description
1	Compressed picture decoding.
5	Deblocking filter.
6	Film-grain synthesis.

For more information about these function values, see section 1.5.

#### `bBufType`

Indicates the type of compressed buffer associated with this status report. If `bStatus` is 0, the value of `bBufType` may be 0xFF. This value indicates that the status report applies to all of the compressed buffers conveyed in the associated `Execute` call. Otherwise, if `bBufType` is not 0xFF, it must contain one of the following values, defined in `dxva.h`:

Value	Description
<code>DXVA_PICTURE_DECODE_BUFFER</code> (1)	Picture decoding parameter buffer.
<code>DXVA_MACROBLOCK_CONTROL_BUFFER</code> (2)	Macroblock control buffer.
<code>DXVA_RESIDUAL_DIFFERENCE_BUFFER</code> (3)	Residual difference data buffer.
<code>DXVA_DEBLOCKING_CONTROL_BUFFER</code> (4)	Deblocking filter control buffer.
<code>DXVA_INVERSE_QUANTIZATION_MATRIX_BUFFER</code> (5)	Inverse quantization matrix buffer.
<code>DXVA_SLICE_CONTROL_BUFFER</code> (6)	Slice control buffer.
<code>DXVA_BITSTREAM_DATA_BUFFER</code> (7)	Bitstream data buffer.
<code>DXVA_MOTION_VECTOR_BUFFER</code> (16)	Motion vector buffer.
<code>DXVA_FILM_GRAIN_BUFFER</code> (17)	Film-grain synthesis buffer.

Note These values are the constants used in DXVA 1.0. The equivalent constants in DXVA 2.0 have different numeric values. For status reporting, the DXVA 1.0 constants are used.

#### bStatus

Indicates the status of the operation.

Value	Description
0	The operation succeeded.
1	Minor problem in the data format. The host decoder should continue processing.
2	Significant problem in the data format. The host decoder may continue executing or skip the display of the output picture.
3	Severe problem in the data format. The host decoder should restart the entire decoding process, starting at a sequence or random-access entry point.
4	Other severe problem. The host decoder should restart the entire decoding process, starting at a sequence or random-access entry point.

If the value is 3 or 4, the host decoder should halt the decoding process unless it can take corrective action.

#### bReserved8Bits

This structure member has no meaning, and the value shall be 0.

#### wNumMbsAffected

If bStatus is not 0, this member contains the accelerator's estimate of the number of macroblocks in the decoded picture that were adversely affected by the reported problem. If the accelerator does not provide an estimate, the value is 0xFFFF.

If bStatus is 0, the accelerator may set wNumMbsAffected to the number of macroblocks that were successfully affected by the operation. If the accelerator does not provide an estimate, it shall set the value either to 0 or to 0xFFFF.

#### Requirements

Header: Include dxva.h.

## 13.0 Restricted-Mode Profiles

The following restricted-mode profiles for DXVA operation of H.264/ACV decoding are defined. The GUIDs that identify these profiles are defined in the header file dxva.h.

### 13.1 DXVA\_ModeH264\_MoComp\_NoFGT Profile

This profile supports the features necessary for a decoder that conforms to the H.264/AVC Main and High profiles. In this profile, the host decoder performs bitstream parsing, inverse quantization scaling, and inverse transform processing. The accelerator performs motion compensation and deblocking, without film-grain synthesis.

1. Configuration parameters:

- `bConfigBitstreamRaw = 0`
- `bConfigMBcontrolRasterOrder = 1` required, 0 encouraged
- `bConfigResidDiffHost = 1`
- `bConfigSpatialResid8 = 0`
- `bConfigResid8Subtraction = 0`
- `bConfigSpatialHost8or9Clipping = 0`

- - 
  - 
  - 
  - 
  - 
  - 
  - bConfigBitstreamRaw = 0
  - bConfigMBcontrolRasterOrder = 1 required, 0 encouraged
  - bConfigResidDiffHost = 0
  - bConfigSpatialResid8 = 0
  - bConfigResid8Subtraction = 0
  - bConfigSpatialHost8or9Clipping = 0
  - bConfigSpatialResidInterleaved = 0
  - bConfigIntraResidUnsigned = 0
  - bConfigResidDiffAccelerator = 1 bConfigHostInverseScan = 1 bConfigSpecificIDCT = 2
  - bConfig4GroupedCoefs = 0 or 1
2. All data buffers shall contain only data that is consistent with the constraints specified for the High profile of H.264/AVC.
  3. Film grain synthesis is not supported in this profile.

### 13.4 DXVA\_ModeH264\_IDCT\_FGT Profile

This profile supports the features necessary for a decoder that conforms to the H.264/AVC Main and High profiles. In this profile, the host decoder performs bitstream parsing. The accelerator performs inverse quantization scaling, inverse transform processing, motion compensation, deblocking, and film-grain synthesis.

1. Configuration parameters:
  - bConfigBitstreamRaw = 0
  - bConfigMBcontrolRasterOrder = 1 required, 0 encouraged
  - bConfigResidDiffHost = 0
  - bConfigSpatialResid8 = 0
  - bConfigResid8Subtraction = 0
  - bConfigSpatialHost8or9Clipping = 0
  - bConfigSpatialResidInterleaved = 0
  - bConfigIntraResidUnsigned = 0
  - bConfigResidDiffAccelerator = 1
  - bConfigHostInverseScan = 1
  - bConfigSpecificIDCT = 2
  - bConfig4GroupedCoefs = 0 or 1
2. All data buffers shall contain only data that is consistent with the constraints specified for the High profile of H.264/AVC.
3. Support for film-grain synthesis, as specified by the SMPTE registered disclosure document listed in section 11.0, is required in this profile.

- 
- 
- 
- 

### 13.5 DXVA\_ModeH264\_VLD\_NoFGT Profile

This profile supports the features necessary for a decoder that conforms to the H.264/AVC Main and High profiles. In this profile, the accelerator performs bitstream parsing, inverse quantization scaling, inverse transform processing, motion compensation, and deblocking, without film-grain synthesis.

1. Configuration parameters:
  - bConfigBitstreamRaw = 1 or 2
  - bConfigMBcontrolRasterOrder = 0
  - bConfigResidDiffHost = 0
  - bConfigSpatialResid8 = 0
    - bConfigResid8Subtraction = 0
    - bConfigSpatialHost8or9Clipping = 0
    - bConfigSpatialResidInterleaved = 0
    - bConfigIntraResidUnsigned = 0
    - bConfigResidDiffAccelerator = 1
    - bConfigHostInverseScan = 1
  - bConfigSpecificIDCT = 2
  - bConfig4GroupedCoefs = 0
2. All data buffers shall contain only data that is consistent with the constraints specified for the High profile of H.264/AVC.
3. Film-grain synthesis is not supported in this profile.

### 13.6 DXVA\_ModeH264\_VLD\_FGT Profile

This profile supports the features necessary for a decoder that conforms to the H.264/AVC Main and High profiles. In this profile, the accelerator performs bitstream parsing, inverse quantization scaling, inverse transform processing, motion compensation, deblocking, and film-grain synthesis.

1. Configuration parameters:
  - bConfigBitstreamRaw = 1 or 2
  - bConfigMBcontrolRasterOrder = 0
  - bConfigResidDiffHost = 0
  - bConfigSpatialResid8 = 0
  - bConfigResid8Subtraction = 0
  - bConfigSpatialHost8or9Clipping = 0
  - bConfigSpatialResidInterleaved = 0
  - bConfigIntraResidUnsigned = 0
  - bConfigResidDiffAccelerator = 1
  - bConfigHostInverseScan = 1
  - bConfigSpecificIDCT = 2
  - bConfig4GroupedCoefs = 0

- - 
  - 
  - 
  - 
  -
2. All data buffers shall contain only data that is consistent with the constraints specified for the High profile of H.264/AVC.
  3. Support for film grain synthesis, as specified by the SMPTE registered disclosure document listed in section 11.0, is required in this profile.

### 13.7 DXVA\_ModeH264\_VLD\_WithFMOASO\_NoFGT Profile

This profile supports the features necessary for a decoder that conforms to all of the following H.264/AVC profiles: Constrained Baseline, Baseline, Main, and High. In this profile, the accelerator performs bitstream parsing, inverse quantization scaling, inverse transform processing, motion compensation, and deblocking, without film-grain synthesis.

---

Note An accelerator that supports this profile shall support the flexible macroblock order (`num_slice_groups_minus1 > 0`) and arbitrary slice order features of the Baseline profile of H.264/AVC. It shall also allow redundant slices to be present in the H.264/AVC

bitstream data, although there is no requirement to process any redundant slices that might be present.

---

1. Configuration parameters:

- bConfigBitstreamRaw = 1 or 2
  - bConfigMBcontrolRasterOrder = 0 (has no meaning in VLD mode)
  - bConfigResidDiffHost = 0
  - bConfigSpatialResid8 = 0
  - bConfigResid8Subtraction = 0
  - bConfigSpatialHost8or9Clipping = 0
  - bConfigSpatialResidInterleaved = 0
  - bConfigIntraResidUnsigned = 0
  - bConfigResidDiffAccelerator = 1
  - bConfigHostInverseScan = 1
  - bConfigSpecificIDCT = 2
  - bConfig4GroupedCoefs = 0
2. All data buffers shall contain only data that is consistent with the constraints specified for the Constrained Baseline, Baseline, Main, or High profile of H.264/AVC.
3. Film-grain synthesis is not supported in this profile. This profile is identified by the following GUID value:

{D5F04FF9-3418-45D8-9561-32A76AAE2DDD}

This GUID is currently not defined in the Windows SDK. To use this GUID, add the following declaration to the dxva.h header file:

```
// {D5F04FF9-3418-45D8-9561-32A76AAE2DDD}
DEFINE_GUID(DXVA_ModeH264_VLD_WithFMOASO_NoFGT, 0xd5f04ff9, 0x3418,
0x45d8, 0x95, 0x61, 0x32, 0xa7, 0x6a, 0xae, 0x2d, 0xdd);
```

Hardware accelerators that support the DXVA\_ModeH264\_VLD\_WithFMOASO\_NoFGT profile should also advertise support for the DXVA\_ModeH264\_VLD\_NoFGT profile (section 13.5) because the capabilities required to support DXVA\_ModeH264\_VLD\_WithFMOASO\_NoFGT are a superset of the capabilities required for DXVA\_ModeH264\_VLD\_NoFGT.
