## Scale-Out File Server for Application Data

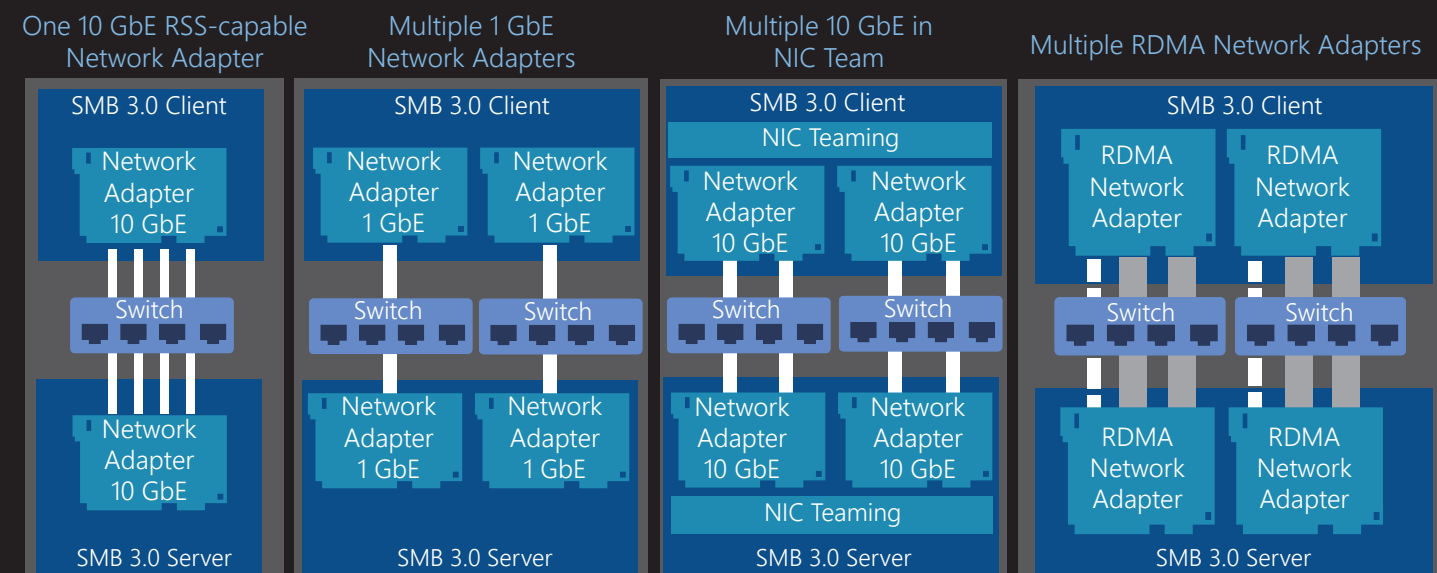

A Scale-Out File Server lets you store server application data (such as Hyper-V virtual machine files) on file shares and obtain a similar level of reliability, availability, manageability, and high performance as you would expect from a storage area network. All file shares are online on all nodes simultaneously. File shares associated with this type of clustered file server are called scale-out file shares.

## Server Message Block (SMB 3.0)

SMB Direct delivers scalable, fast, and efficient storage access. You can also benefit from fast data transfers and network fault tolerance using SMB Multichannel. SMB Multichannel and SMB Direct improves network communications between your Hyper-V server cluster and your File Server cluster. It also improves internode communications within your File Server cluster. Windows Server 2012 R2 uses version 3.0 of the SMB protocol.

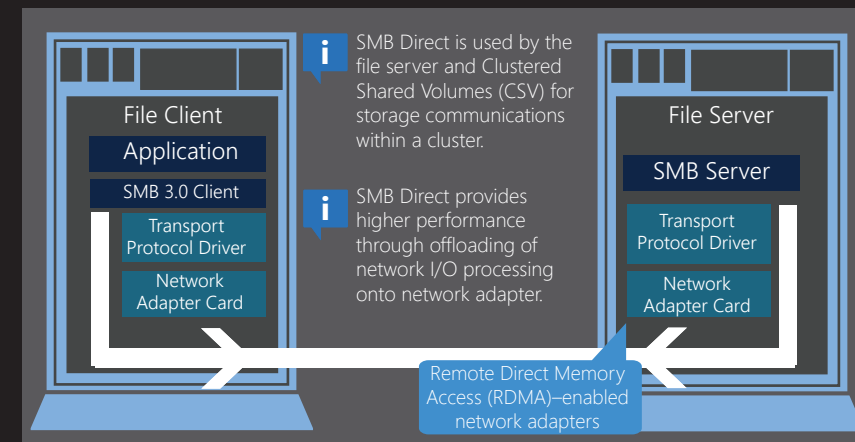

## SMB Multichannel

SMB Multichannel capability enables bandwidth aggregation and failover across multiple network adapters to provide aggregated throughput and resiliency to network failures.

## SMB Direct

SMB Direct delivers improved and enhanced network performance. SMB Direct supports the use of network adapters that have remote direct memory access (RDMA) capability. Network adapters that have RDMA can function at full speed with very low latency, while using less CPU.

## SMB Transparent Failover

SMB Transparent Failover supports server application workloads that require the connection to the storage infrastructure to be continuously available. The SMB file server and client work together to make failover of file server cluster nodes transparent to applications—for all file operations, and for both planned cluster resource moves and unplanned node failures.

### Hyper-V in a Failover Cluster

### Scale-Out File Server

SMB file shares are continuously available to store VHDs. File shares are accessible on all cluster nodes (active/active).
