Programming with Enterprise Single Sign-On

How to Create and Describe an Application to Single Sign-On

A common administrative task that you might need to perform is adding an affiliate application into the Enterprise Single Sign-On (SSO) database. Adding an affiliate application to the Enterprise SSO database enables you to associate users and credentials with the affiliated application.

Note
Creating an affiliated application requires membership in the "SSO Affiliate Administrator" account or above.

To create and describe an application in the SSO database

1. Create a new **ISSOAdmin** object.
2. Create a new application with a call to **ISSOAdmin.CreateApplication**.
3. Add the relevant fields describing the application with a call to **ISSOAdmin.CreateFieldInfo**.

   During this step, you tell the database that an application has users and associated passwords.
4. Push the newly created description out to the server with a call to **ISSOAdmin.UpdateApplication** or **ISSOAdmin2.UpdateApplication2**.

   The difference between the two methods is that **UpdateApplication2** uses an **IPropertyBag** as the way to describe the application updates, while **UpdateApplication** has multiple parameters.
5. Purge the local cache for the changes you made by calling **ISSOAdmin.PurgeCacheForApplication**.

   Purging the local cache is a security measure that prevents having the names and passwords that you describe in step 3 to exist in an unsecured location.

The following example shows how to create an application and add field information.

```
   public static bool AddApplication(string name, string admins, string users)
       {
          try
          {
             ISSOAdmin admin=new ISSOAdmin();
             // Create application.
             admin.CreateApplication(name, "SSO Sample Application", "administrator@ssoaffil
iateapplication.com", users, admins, SSOFlag.SSO_WINDOWS_TO_EXTERNAL | SSOFlag.SSO_FLAG_ALL
OW_TICKETS | SSOFlag.SSO_FLAG_VALIDATE_TICKETS, 2);
             // Add fields.
             admin.CreateFieldInfo(name, "User Id", SSOFlag.SSO_FLAG_NONE);
             admin.CreateFieldInfo(name, "Password", SSOFlag.SSO_FLAG_FIELD_INFO_MASK);
             // Enable application.
             admin.UpdateApplication(name, null, null, null, null, SSOFlag.SSO_FLAG_ENABLED,
SSOFlag.SSO_FLAG_ENABLED);
             // Purge changes.
             admin.PurgeCacheForApplication(name);
          }
          catch
          {
             return false;
          }
          return true;
       }
```

Programming with Enterprise Single Sign-On

How to Map Single Sign-On Credentials

When you know that you have affiliated applications in your Enterprise Single Sign-On database, you can map the credentials for a user to that application. Mapping the credentials of the current user to an affiliated application requires that you use a combination of the **ISSOMapper** and **ISSOMapping** interfaces.

To map between an affiliated application and user credentials

1. Create new instances of **ISSOMapper** and **ISSOMapping**.
2. Set the **ISSOMapping** properties to the relevant values.

   The relevant properties for **ISSOMapping** are the Microsoft Windows domain name of the user, the Windows user name, the name of the affiliated application, and the external user name.
3. Create the mapping with a call to ISSOMapping.Create.

   Calling **ISSOMapping.Create** propagates the local copy of the mapping out to the Enterprise Single Sign-On server.
4. Set the credentials on the mapping with a call to **ISSOMapper.SetExternalCredentials**.
5. Enable the mapping with a call to **ISSOMapping.Enable**.

The following example shows how to add mapping between a specified Enterprise Single Sign-On application and a user.

```
public static bool AddMapping(string application, string user, string XU, string XP)
{
   try
   {
      // Set mapping.
      ISSOMapper mapper=new ISSOMapper();
      ISSOMapping mapping=new ISSOMapping();
     string username=user.Substring(user.IndexOf('\\')+1);
      string userdomain=user.Substring(0, user.IndexOf('\\'));
      mapping.WindowsDomainName=userdomain;
      mapping.WindowsUserName=username;
      mapping.ApplicationName=application;
      mapping.ExternalUserName=XU;
      mapping.Create(0);
      // Set credentials.
      string[] credentials=new string[]{XP};
      mapper.SetExternalCredentials(application, XU, ref credentials);
      mapping.Enable(0);
   }
   catch
   {
      return false;
   }
   return true;
      }
```

Programming with Enterprise Single Sign-On

Logging on to a Remote or Local Application

After you finish setting affiliate credentials for your user, you can use Enterprise Single Sign-On service (ENTSSO) to provide access to applications. If the user is local, you can use ENTSSO to retrieve credentials for a non-Windows application. In contrast, if the user is remote, you can use ENTSSO to retrieve credentials for a local application.

In This Section

How to Log a Local User on to a Non-Windows Application

After you set up your user with an affiliate application, you can use Single Sign-On (SSO) to access the external user name and credentials of the current user. Using these credentials, you can then log your user on to the affiliate application that is running on a host server.

Note
In addition to setting the appropriate security protocols for SSO, you might also need to set additional security to allow your application to call SSO in the correct security context. If your application cannot call SSO in the correct security context, SSO will deny access to your application.

To set the security context for an SSO application

1. Identify what credentials your application needs to run successfully.

   For example, an application that uses Web services or.NET Framework remoting hosted in IIS needs to impersonate the client in order to pass the appropriate credentials on to SSO.

2. Confirm that the relevant security settings, such as those on virtual directories, application pools, and web.config files, are set to provide your application with those credentials.

   For more information about how to set security credentials, see Building Secure ASP.NET Applications: Authentication, Authorization, and Secure Communication.

   For more information about passing credentials for an ASP.NET Web service, see HOW TO: Pass Current Credentials to an ASP.NET Web Service.

To log a local user on to a host application

1. Receive the request to log the current user on to an application running on the host server.

   It is your responsibility to determine how the current user requests to be logged on to a host application.

2. Retrieve the credentials for the current user who is using **ISSOLookup1.GetCredentials** or **ISSOLookup2.GetCredentials**.

   You must supply the name of the host application together with any relevant flags. **GetCredentials** returns the associated user name and credentials for the host application.

   Note that you can use either **ISSOLookup1** or **ISSOLookup2**. The only difference is that **ISSOLookup2** also has a method for logging a remote user on to a local windows application.

3. Use the external user name and credentials to log on to the host application.

   It is your responsibility to determine how to use the credentials to log on to the host application.

Tasks

How to Log a Remote User on to a Local Application

How to Log a Remote User on to a Local Application

The other main feature of Enterprise Single Sign-On service (ENTSSO) is supporting a host-initiated process (HIP). ENTSSO interacts with HIP when a remote user tries to access a local Windows resource. Using ENTSSO, you can receive the request from the host user and request access to the local Windows application.

To log a remote user on to a local Windows application

1. Receive the request from the remote user.

   It is your responsibility to determine how to retrieve a request from the remote user.

2. Request that the remote user be given access to the specified affiliate application, using **ISSOLookup2.LogonExternalUser**.

   LogonExternalUser passes in the name of the application the external user wishes to access, the name of the external user, the associated credentials for the external user, and any relevant flags. If successful, **LogonExternalUser** returns a handle to a Windows access token.

   The remote user must already be identified in the Single Sign-On database, have their credentials in the database, and be associated with an affiliate application. Otherwise, **LogonExternalUser** returns an error. You can keep the user names and credentials up to date using Password Sync.

   In addition, you must have protocol transition enabled.

3. Use the Windows handle returned from **LogonExternalUser** to impersonate the user that the token represents.

How to Change the Behavior of a Single Sign-On Interface

Many of the objects in the Enterprise Single Sign-On (SSO) object model expose the IPropertyBag interface, which allows you to modify the behavior of the specified object. If you call QueryInterface on an SSO object, you can retrieve the IPropertyBag interface and use it to change the behavior of your current object.

To change the behavior for a specified SSO interface

1. Use QueryInterface on the specified interface to retrieve an IPropertyBag instance.
2. Use IPropertyBag.Write to set the property, type, and value for the interface.

   The following table describes the valid values for the IPropertyBag propName and ptrVar parameters.

propName	Type	ptrValue	Usable On
CurrentSSOServer	VT_BSTR	Name of the server to send the information to	All
Transaction	VT_UNKNOWN VT_EMPTY	A DTC ITransaction pointer, or NULL to clear the scope.	ISSOConfigStore::SetConfigInfo ISSOConfigStore::GetConfigInfo ISSOConfigStore::DeleteConfigInfo ISSOAdmin::CreateApplication ISSOAdmin::DeleteApplication ISSOAdmin::UpdateApplication ISSOAdmin::CreateFieldInfo ISSOMapper::GetFieldInfo
AppFilterFlags	VT_I4 VT_UI4	Flags to control what application to filter.	ISSOMapper::GetApplications ISSOMapper2::GetApplications2
AppFilterFlagsMask	VT_I4 VT_UI4	Flag mask to control what application to filter.	ISSOMapper::GetApplications ISSOMapper2::GetApplications2
AsyncCall	VT_BOOL	True to call using an async RPC; false to use a synchronous RPC.	ISSOConfigOM::GetServerStatus ISSOAdmin::GetGlobalInfo

- **CurrentSSOServer**: the standard behavior for determining which server to send SSO information to is as follows:

  1. Look in the registry for the current user. The server name can be set for the current user using the command line tools or GUI.
  2. Look in the registry for all users. The server name can be set for all users using the command line tools or GUI.
  3. If no SSO server name is found in the registry then use the current computer.

  Setting CurrentSSOServer to a specified server overrides the previous process for the specified interface. Once you set CurrentSSOServer, all subsequent method calls on the interface will be sent to the specified server.

- **Transaction**: specifies a DTC transaction that to scope the operations performed by the SSO object model. You must pass a DTC ITransaction pointer in *ptrValue*, or "null" to clear the current transaction scope.

- **AppFilterFlags/AppFilterMask**: controls what types of applications will be returned from ISSOMapper.GetApplications and ISSOMapper2.GetApplications. If the application flags match the flags specified by the filter flags and the filter flag

mask they will be returned. One way to perform application filtering is to set AppFilterFlagsMask to SSO_FLAG_APP_FILTER_BY_TYPE and to then set AppFilterFlags to one or more of the following:

SSO_APP_TYPE_INDIVIDUAL

SSO_APP_TYPE_GROUP

SSO_APP_TYPE_CONFIG_STORE

SSO_APP_TYPE_HOST_GROUP

SSO_APP_TYPE_PS_ADAPTER

SSO_APP_TYPE_PS_GROUP_ADAPTER

- **AsyncCall**: if true, then SSO will perform the method using an asynchronous remote procedure call (RPC). The method will return E_PENDING while in progress. Any other return value indicates that the method is completed. AsyncCall also allows you to poll the method for completion.

Issuing and Redeeming a Single Sign-On Ticket

After you link a user and an affiliate application, you can issue tickets to help ensure security while maintaining communications. Single Sign-On ticketing works just like other ticketing technologies: before sending the message off, you append the Single Sign-On ticket to the message as a string. The server receives your message, decodes the ticket, and uses the information as appropriate.

To issue a Single Sign-On ticket

1. Create a new ticket object with a call to I**SSOTicket**.
2. Issue the ticket with a call to I**SSOTicket.IssueTicket**.

To redeem a Single Sign-On ticket

1. Create a new ticket object with a call to I**SSOTicket**.
2. Redeem the ticket with a call to I**SSOTicket.RedeemTicket**.

Synchronizing Passwords

You synchronize a password by using a password sync adapter. This adapter should be able to communicate with a specific, remote, non-Windows system, and should also be able to instruct that system to update password information.

In This Section

How to Create a Password Sync Adapter

A password sync (PS) adapter is an application that uses the Password Sync Helper component to pass notifications to and from Enterprise Single Sign-On (SSO). Note that although the PS Helper component exposes a COM and a .NET Framework interface, your adapter does not necessarily have to be a COM component. You can design your adapter as a stand-alone process, a COM+ application, or a Windows service.

To create a password sync adapter

1. Inform Enterprise Single Sign-On service (ENTSSO) that your provider is active using **ISSOPSWrapper.InitializeAdapter**.

   InitializeAdapter informs ENTSSO that a provider, usually the same provider that is making the call, is currently turned on, and therefore will be communicating password updates to and from the system. You can also use **InitializeAdapter** to activate other resources such as group adapters.

2. Send password updates to ENTSSO by using **ISSOPSWrapper.SendNotification**.

   You must determine how you receive password updates from your non-Windows system. After you receive the update, you can pass the information on to ENTSSO using **SendNotification**. Note that **SendNotification** is not limited to sending password updates: the architecture of **SendNotification** also enables you to send other types of notifications.

3. Request password updates from ENTSSO by using **ISSOPSWrapper.ReceiveNotification**.

   Because the password sync adapter is a pull technology, ENTSSO never calls your adapter. Instead, your adapter periodically calls **ReceiveNotification** to see whether any password updates are available. You can choose to set the WAIT flag on **ReceiveNotification**. Setting WAIT blocks the thread until a notification is available.

   Note that ENTSSO delivers a password change to your adapter in plain text. It is the responsibility of the adapter to protect that password information against incorrect disclosure. It is also the responsibility of the adapter to protect itself against spoofing or attacks from other invalid sources, including spoofing of the Password Sync Helper component.

   After you receive a password update from ENTSSO through the *pReceiveNotification* parameter, you must pass this information on to your non-Windows system. As with **SendNotification**, you must determine the best way to communicate with the remote server.

4. Turn off your adapter using **ISSOPSWrapper.ShutdownAdapter**.

   ShutdownApplication should be the last method called by an adapter, and indicates that the adapter will no longer send or receive password updates to ENTSSO.

   Note that ENTSSO buffers any password changes a user makes while the adapter is shut down, up to a buffer size limit.

Synchronizing Passwords

How to Configure a Password Sync Adapter

After you have finished creating your password sync adapter, you must load your adapter on to a system. Additionally, you must inform Enterprise Single Sign-On (ENTSSO) and the configuration store that your application is a password sync adapter. You must register with the configuration store for security purposes: your adapter will request updates to passwords and other credentials. Therefore, ENTSSO must know that a given adapter is allowed to ask for such permissions.

To configure a password sync adapter

1. Create your adapter with the configuration store using the ssops tool.

   Using ssops, you load an XML configuration file into the configuration database that describes your application to Enterprise Single Sign-On.

2. After you create the adapter with the config database, you can modify the adapter information with **ISSOPSAdmin.SetAdapterProperties**.

   While the two methods are similar, **SetAdapterProperties** sends a message to the adapter when the configuration information changes.

3. To delete an adapter, use ISSOAdmin.DeleteApplication.

See Also
Other Resources
Synchronizing Passwords

How to Assign an Application to an Adapter

To process information between a local application and a remote server, an adapter must have one or more applications assigned to it.

To assign an application to an adapter

1. Add the application to the adapter by using **ISSOPSAdmin.AssignApplicationToAdapter**.
2. You can retrieve the current list of applications assigned to an adapter by using **ISSOAdmin.GetApplicationsForAdapter**.
3. Once you are finished, you can remove an application from an adapter by using **ISSOPSAdmin.RemoveApplicationFromAdapter**.

How to Create and Modify an Adapter Group

One of the new features of Single Sign-On (SSO) is the ability to create and modify adapter groups. As the name implies, an adapter group is a collection of adapters. You can use adapter groups to organize security settings and other properties for your adapters.

To create and modify an adapter group

1. Create the adapter group by using a call to the ssops tool.

   In the associated XML file, you must set the group flag as an adapter group.

2. Add one or more adapters to the adapter group by using **ISSOPSAdmin.AddAdapterToAdapterGroup**.

   At this point, your adapter group is ready to work as intended. If necessary, you can view the full list of associated adapters by using **ISSOPSAdmin.GetAdaptersForAdapterGroup**.

3. You can modify the settings of your adapter group using **ISSOPSAdmin.SetAdapterProperties**.

4. When you are finished, you can remove the adapter from the adapter group using **ISSOPSAdmin.RemoveAdapterFromAdapterGroup**.

5. Finally, you can delete the adapter group by using **ISSOAdmin.DeleteApplication**.

   You may choose instead to delete the adapter group by using the **-delete** command of the ssops tool.

Introduction to COM and COM+

The Component Object Model (COM) is a binary standard that enables software components to interoperate in a networked environment regardless of the language in which they were developed.

Transaction Integrator (TI) is based on COM, which defines a standard way of handling and reporting errors. (COM is the foundation for COM+.) To understand TI behavior and errors, you must understand how it uses COM.

Objects and clients are the basic building blocks of COM applications. An object is a piece of software that can do a specific task. A client is software that uses and controls objects.

COM can be compared to business relationships. There are many different businesses that provide their customers (clients) with products and services (objects) that the clients can use and control. COM applications are clients that use objects that can do specific tasks. For example, in computer technology, Powerpnt.exe depends on several Microsoft Office and Microsoft Windows utility objects to do most of the work involved with editing and presenting a presentation. The Powerpnt.exe is just a client to those utility objects and directs them to their tasks. When you want to open a .ppt file, a dialog box appears, from which you choose the file to open. This dialog box is displayed by a Windows utility object that can display a **File Open** dialog box, instead of by Powerpnt.exe.

Dividing software into clients and objects enables you to use those clients and objects as building blocks that can be combined and reused in many different ways by many different clients, just as standard building materials can be used to construct many different structures.

COM and COM+ are the key technologies that provide the infrastructure that enables clients and objects to work together. Other key COM concepts include methods, interfaces, classes, references, and components, which build on the foundation of clients and objects.

Introduction to COM and COM+

COM+ Defined

Component Services (COM+) consists of the latest version of COM, distributed COM (DCOM), and Microsoft Distributed Transaction Coordinator (DTC), plus additional functionality. With COM+, administrators can deploy and administer COM+ applications through a graphical user interface, or automate administrative tasks using a scripting or programming language. Software developers can use COM+ to visually configure routine component and application behavior, such as security and participation in transactions, and to integrate components into COM+ applications.

To open COM+, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Component Services**. It is also available in Transaction Integrator (TI) Manager: start TI Manager and double-click the **Component Services** folder.

Component Services provides standard application functionality for administration, deployment, security, reliability, and scalability. Component Services simplifies the administrator's work by providing a tool for administering all applications visually through a single user interface.

Concepts

COM Defined

Other Resources

Introduction to COM and COM+

Component Services Features

Component Services (COM+) builds on COM concepts and adds three major new elements: COM+ applications, increased administrator involvement, and interception. You can gain access to Component Services from within TI Manager.

A COM+ application is a COM component that includes one or more components developed and configured to work together by Component Services to simplify administration of application servers. Each COM+ application unites TI components (type libraries) and COM components with configuration information about how they should be deployed, thus making a single unit for deployment and administration. A wizard helps to deploy COM+ applications. You can easily administer COM+ applications by using Component Services in TI Manager. This feature gives administrators complete control over application server deployment and configuration. COM+ applications also aid in the configuration of an application's presentation tier. Administrators can use Component Services to quickly create application proxies that can be used to configure thousands of client computers.

Component Services expands the role of administrators by empowering administrators to do many tasks that were previously done exclusively by developers. In the application development phase, developers write their own custom type libraries or use TI Designer to create TI component libraries from COBOL transaction programs (TPs). Then developers deploy the TI components in a COM+ application and configure the application settings as needed. The COM+ application is a deployable unit that the developer can pass to the administrator to deploy.

The administrator receives a COM+ application file from a developer, and then uses Component Services to deploy that application on the server computer. Next, the administrator configures permissions to use the application, as well as other settings. Then, the administrator creates an application proxy, which is a file used to configure each client computer in the presentation tier. After using Microsoft Active Directory directory service and IntelliMirror to complete the client configuration, the administrator continues to use Component Services to monitor the application's behavior.

Component Services intercepts all calls from clients to objects, and you can use it to manage objects and their interaction with clients. Because of this interception capability, Component Services governs the interaction between objects and their clients, and does a lot of the work that would be done by objects themselves. You can design objects to do business logic only; Component Services handles everything else by tracking object behaviors and needs and by managing everything the objects do.

The following are the major features of Component Services that are supported by Transaction Integrator (TI):

- **Administration.** You can use the powerful Component Services user interface to administer the application server tier. You can use Component Services to ease deployment, configuration, monitoring, and upgrades. Component Services also gives administrators the ability to use scripts to control all administration.

- **Scalability.** Component Services achieves high scalability by pooling server resources so that when one person is not using them, another person can. When a resource is needed, it is taken from a shared pool. When the resource is no longer needed, it is returned to the pool. Component Services pools many resources, including threads, ODBC connections, OLE DB connections, and COM objects.

Note
TI supports the Microsoft Windows Server 2003 and Windows 2000 COM+ feature known as *object pooling*. To enable object pooling for a TI component, right-click the component, and click **Properties**. Then select the **Enable Object Pooling** check box on the **Activation** tab. There are overall system manageability benefits from enabling this feature for TI components because you can then specify the number of instances to be pre-initialized when the application starts by using the **Minimum Pool Size** field. You can also set an upper limit on the number of active instances by using the **Maximum Pool Size** field to prevent the server running Windows Server 2003 or Windows 2000 from flooding the host system.

- **Transaction Support for Reliability and Data Integrity.** Enterprise applications must have high levels of reliability and data integrity. Component Services provides reliability by offering transaction support. That is, either all the actions in a transaction occur, or none of them occurs. If all of the actions cannot take place, Component Services rolls back all of your object's work so that the databases are left in their original state.

- **Security.** Because Component Services acts as an intermediary between clients and objects, it is able to regulate access to application server functionality. By using the Component Services console, the administrator can give different users different access rights to the application.

- **Queued Components.** Component Services is integrated with another feature of Windows called Message Queuing (also known as MSMQ). Message Queuing gives enterprise applications the ability to continue running even when a server is unavailable. Clients can call COM objects when the COM object is currently unavailable, and the call is stored as a message in Message Queuing. After the server is available again, it retrieves the message from the message queue and processes the call to the COM object.

Distributed Applications

Applications that run partly on the Windows operating system and partly on the mainframe are known as distributed applications. Transaction Integrator (TI) components support all local and distributed applications that adhere to the Automation specifications and the distributed COM (DCOM) specifications. DCOM supports communication between objects on different computers on a network by handling the low-level details of network protocols. This enables use of distributed programs that consist of multiple processes working together to accomplish a single task. The Distributed Transaction Coordinator (DTC) is the part of Component Services that coordinates external or two-phase transactions.

Introduction to COM and COM+

Automation

Automation is COM-based technology that enables dynamic binding to COM objects at run time. An Automation server is an application that allows its objects, methods, and properties to be controlled by other applications through Automation. An Automation client (also called an Automation controller) is an application that manipulates the objects, methods, and properties of another application (the Automation server) through Automation. An Automation object is an object that is exposed to other applications or programming tools through Automation interfaces.

A Transaction Integrator (TI) component is a type library that exposes an Automation interface. When you deploy a TI component in a COM+ application, you create an Automation server that can be used by any other COM-based application (Automation client). The Automation client application can call the methods on the Automation interface of a TI Automation server (for example, a TI component deployed in a COM+ application) to invoke a CICS or IMS transaction program (TP) on a mainframe host computer.

An Automation client application connects to a TI Automation server application in one of two ways, declarative binding or late binding:

- Declarative binding is similar to programming the speed dialer on your phone. You look up the number once, and program it into the phone. After you verify that it is valid, a single button dials the number.

- Late binding is similar to looking up the phone number in a phone book before each call, and then dialing the phone.

Both declarative binding and late binding produce the intended result. However, the speed dialer (declarative binding) is more efficient when you make a call, but looking up the number each time (late binding) ensures that the number you are calling is still correct.

In declarative binding, you declare a variable as an application-defined object type. A type library, object library, or dynamic-link library is then referenced in the Automation client Tools Reference. Declarative binding is another name for virtual function table binding or vtable binding. A vtable is a data structure that holds the addresses for the methods and properties of each object in an Automation server. The vtable is contained within the referenced library.

Late binding allows you to create an Automation object as an Object or Variant data type. Late binding uses the **IDispatch** interface. **IDispatch** has no preexisting information about the server that it is calling. It assumes during its compile phase that the code is correct. It then attempts at run time to execute the code and trap for run-time errors.

Introduction to COM and COM+

COM Objects

COM objects are entities in memory that can do specific tasks. Each COM object is an instance of a COM class. COM objects are not files, but can manage or represent files. (A COM object does not usually represent any particular file.) Their lifetimes are short. COM objects are deleted when program execution is terminated.

See Also

Concepts

COM Defined

Viewing COM Classes, Interfaces, and Methods

Other Resources

Introduction to COM and COM+

COM Methods

A COM method is a specific task that a COM object can perform. When a client requests that an object complete a specific task, that client calls a method of the object. For example, Winword.exe (a client) can call the **Spellchecker** method of a **Word.Document** (object) to run a spell-checking session. A Transaction Integrator (TI) Automation client application can call a method of an Automation server to run a mainframe transaction program (TP) and return the results.

Introduction to COM and COM+

COM Interfaces

A COM interface is a specific, immutable set of COM methods. COM clients cannot detect the internal workings of the objects they are using. Therefore, it is important for clients and objects to communicate about and agree on the functionality that an object supplies to a client. This agreement, frequently called a contract, is implemented in software by a COM interface.

To facilitate communication, the COM interface supplies a way for clients to query objects whether they implement specific sets of methods. For example, by way of the interface, COM allows a client to query an object whether it implements a set of file management methods, **FileSave** and **FileOpen**. An interface is named by an Interface ID (IID), which is a globally unique identifier (GUID), a 16-byte number. It is a COM rule that an object must either implement an interface or not implement it. There is no in-between state.

COM rules require that all COM objects must implement the **IUnknown** interface. **IUnknown** is used for the following:

- **Lifetime management.** To determine when objects are no longer in use and thus can be destroyed.
- **Versioning.** To determine which specific interfaces an object supports.

Objects that implement the **IDispatch** interface are scriptable, or Automation compatible; scripting clients such as Windows Script Host (WSH) can use them. Objects that do not implement **IDispatch** cannot be scripted; that is, scripts cannot call them. Objects that do not implement **IDispatch** cannot be Automation servers; client applications cannot use their services. In both cases, this inability is due to the clients need to know certain details about objects before they can call them.

Automation is COM-based technology that enables dynamic binding to COM objects at run time. When a client COM application is compiled, it does not have all the information about the services offered by the Automation servers that it will be using. Later, during run time, the client application uses an Automation server's **IDispatch** interface to find detailed information about the services that the Automation server offers.

After a TI component is associated with a specific remote environment (RE), and then dropped into a COM+ application, that application (or package) becomes an Automation server with an **IDispatch** interface. Then a client COM application can call upon the TI Automation server to operate (automate) a mainframe-based transaction program (TP) and return the results to the calling client COM application.

COM Classes

A COM class is a definition in source code that can be used as a template for creating objects that implement the **IUnknown** interface and expose only their interfaces to clients.

Different objects implement different methods. COM classes ensure that a given client connects to exactly the right kind of object. Because each COM object is an instance of a specific COM class, COM classes actually classify objects. For example, one class of object is the **Word.Document** class. Any object in this class can manage Microsoft Word .doc files.

Each COM class has two identifiers, the programmatic identifier (ProgID) and the class ID (CLSID). When a client tells COM that it needs use an object, the client always specifies a ProgID or CLSID so that COM knows which class of object to create.

A ProgID is a human-readable registry entry that can be associated with a CLSID. You can use the ProgID within programs to create an instance of a COM class. For example, to create an instance of a COM class that has a ProgID of **Component.MyComponent**, use the following Visual Basic statement:

```
Set Component = CreateObject("Component.MyComponent")
```

A ProgID must not contain more than 39 characters, start with a digit, nor contain any punctuation (including underscores) other than periods. The pieces are separated by periods; no spaces occur within the ProgID. For example, Word.Document.6 is a valid ProgID. The typical format of a ProgID is:

```
<Library>.<ComponentName>.<VersionNumber>
```

Although the ProgID is human-readable, it should be used only in programs, and not displayed in the user interface. If you need a short displayable string for an object, call **IOleObject::GetUserType**.

A ProgID identifies a class, but with less precision than does a CLSID. The registry entry appears as follows:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Classes\<ProgID> = <CLSID>
```

You can use a ProgID in programming situations where it is not possible to use a CLSID. The ProgID is not guaranteed to be unique, so use them only where name collisions are manageable.

The CLSID is a globally unique identifier (GUID), such as the following that uniquely identifies the COM class:

```
{71AFDE33-F81B-11d2-B12B-00C04F8C2F72}
```

You can generate a GUID with a program such as Uuidgen.exe.

Introduction to COM and COM+

COM Components and TI Components

A COM component is a binary file (.dll or .exe) containing code for creating a COM object and servicing method calls to it. The COM component can contain code for one or more Transaction Integrator (TI) components, class factories, COM classes, registry-entry mechanisms, type libraries, and so on.

COM-based programs and applications are distributed and deployed as COM components. Each COM component uses interfaces to interoperate with each other in much the same way that a person uses an application user interface to interoperate with an application. Each COM interface contains one or more methods.

A TI component is a type library that acts as a proxy for a mainframe transaction program (TP). You can easily change a TI component into a true COM component by deploying it in a COM+ application. TI components all share the same implementation DLLs but are distinguished by their type libraries. Therefore, when you deploy a TI component in a COM+ application, it is the specific type library (.tlb file) that is registered.

The basic unit of distribution for COM is a component. You can deploy COM components on a computer other than your own. This is what distinguishes COM components from COM objects, which reside in memory and thus cannot be copied from computer to computer.

Deploying a COM component is a two-step process. First, copy the component onto the target computer. This is a file copy operation. Then register the component, that is, configure COM to recognize the component. This configuration information is stored in the registry (and in certain cases in a database called regdb.) In TI, registration is automatic. As soon as you drop a TI component into a COM+ application, the resulting TI Automation server is automatically registered on that computer.

Because TI Manager includes Component Services to deploy or remove TI components, TI component deployment is a matter of dragging your TI component into a COM+ application.

Viewing COM Classes, Interfaces, and Methods

Several tools are available for viewing the COM classes, interfaces, and methods that are deployed on your computer:

- **Component Services (COM+) in Windows 2000**

  Component Services (COM+) is a core part of Windows 2000. A class that has not been configured to use Component Services does not show up in Component Services.

- **OLE/COM Object Viewer (OLE View)**

  This tool shows all the deployed classes and gives comprehensive information about each class, with the exception of Component Services configuration information. It is available free at http://go.microsoft.com/fwlink/?LinkId=12793.

- **DCOMCNFG**

  This tool is present on any computer that has distributed COM (DCOM) installed, including all installations of Windows Server 2003, Windows XP Professional, and Windows 2000 Server. DCOMCNFG displays only a subset of the deployed classes, and shows much less information about each class than does OLEVIEW. Its main advantages are that it is automatically installed with DCOM and its graphical user interface (GUI) is less cluttered than the OLEVIEW GUI.

Windows Script Host COM Client

Microsoft Windows contains utility COM objects that you can use to manage system configuration, users, printers, Active Directory directory service, and so on. Windows Script Host is a client that controls those Windows objects through scripts. Scripts give administrators much more administrative power than batch (.bat) files afford. The administrator writes a script, a file ending with .vbs or .jvs, with content much like a .bat file. The administrator then double-clicks the script to load Windows Script Host and run the script.

The following is an example of a short Microsoft Visual Basic Scripting Edition (VBScript) client script. This script has only three lines. The first line establishes a connection to the COM object. The second line calls a method, and the third line displays the result.

```
Set SaySvrObject = CreateObject("Saysvr.Sayclass")
Speech = SaySvrObject.SaySomething
MsgBox Speech
```

In this script:

- **Saysvr.Sayclass** specifies the COM class.
- **CreateObject** is the script's way of requesting that COM give it a reference to the object.
- **SaySvrObject** represents the reference to the object. After this line is completed, the script will have a live reference to the COM object.
- On the right side of the second line, the script uses its **SaySvrObject** reference to call the **SaySomething** method, which returns a string to the script.
- Speech represents the string returned by the script.
- The third line displays the Speech string in a Message Box.

Data Types

The Transaction Integrator (TI) run-time environment manages the process of converting host data types used by a host-based transaction program (TP) to and from the Automation data and data types used by a Microsoft Visual Basic or other Windows-based programming language.

The topics in this section give you tips for handling different types of data, and they explain how data types are converted and used in both IBM host and Automation programming languages.

TI supports Automation, COM aggregate, and mainframe data types. For a complete listing of the supported data types, see Supported TI Data Types

In This Section

Supported TI Data Types

Transaction Integrator (TI) supports the data types used by COM, .NET, COBOL, and Report Program Generator (RPG).

In This Section

Supported Automation Data Types

Automation data types are simple types that you can put into a Variant data type.

1-byte unsigned Integer (BYTE)
An Integer data type that has a positive value ranging from 0 through 255.

2-byte signed Integer
An Integer data type that can be either positive or negative. The most significant bit is the sign bit: 1 for negative values and 0 for positive values. The storage size of the integer is 2 bytes. A 2-byte signed Integer can have a range from –32,768 through 32,767.

4-byte signed Integer
An Integer data type that can be either positive or negative. The most significant bit is the sign bit: 1 for negative values and 0 for positive values. The storage size of a 4-byte signed Integer is 4 bytes. A 4-byte signed Integer can have a range from –2,147,483,648 through 2,147,483,647.

4-byte Real (Single)
A single-precision 32-bit (4-byte) floating-point Real data type (often called a Single). It ranges in value from –3.402823E38 through –1.401298E-45 for negative values, from 1.401298E-45 through 3.402823E38 for positive values, including 0.

8-byte Real (Double)
A double-precision 64-bit (8-byte) floating-point Real data type (often called a Double). It ranges in value from –1.79769313486232E308 through –4.94065645841247E-324 for negative values, from 4.94065645841247E-324 through 1.797693134862325E308 for positive values, including 0.

Boolean
An expression that can be evaluated either true (nonzero) or false (0). (You can use the keywords True and False to supply the values of –1 and 0, respectively.) The field data type Yes/No is Boolean and has the value of –1 for Yes and 0 for No. Several property page settings are Boolean, including Yes/No, True/False, and On/Off.

Variable-length String (BSTR)
A fundamental data type that holds character information. A String value can contain approximately 65,535 bytes (64 KB). It can be fixed-length or variable-length, and it contains one character per byte. Fixed-length Strings are declared to be a specific length. Variable-length Strings can be any length up to 64 KB, less a small amount of storage overhead. A variable length string can range from 0 to approximately 2 billion bytes (characters).

Currency
An 8-byte fixed-point data type that is useful for calculations involving money or for fixed-point calculations in which accuracy is extremely important. This data type is used to store numbers with up to 15 digits to the left of the decimal point and 4 digits to the right. Currency values can range from –922,337,203,685,477.5808 to 922,337,203,685,477.5807.

Date
A data type that is used to store a date, a time, or a date and time as a 64-bit Real number. The value to the left of the decimal point represents a date, and the value to the right of the decimal point represents a time. The Date data type values can range from January 1, 1000 to December 31, 9999.

Decimal
A data type that stores a signed, exact numeric value described as the number of digits appearing before and after a decimal point, with a maximum total of 18 digits.

Supported COM Aggregate Data Types

Array

A set of sequentially indexed elements having the same intrinsic data type. Transaction Integrator (TI) supports an array of any of the Automation data types. Each element of an array has a unique identifying index number. Changes made to one element of an array do not affect the other elements. TI supports multidimensional arrays. However, only the outermost array of a multidimensional array can vary in size; all the other arrays must be fixed in size. For more information, see Arrays.

User-Defined Type (UDT)

A data type that is defined in a program. A UDT can contain any of the Automation data types as well as arrays of those data types, recordsets, and nested UDTs. A UDT generally contains many different data types that are defined by the programming language used. In COBOL, UDTs are called RECORDS as are any declarations that contain lower-level numbers. For more information, see User-Defined Types.

Recordset

An Automation object, also known as an ActiveX Data Object (ADO) recordset, is the equivalent of a fixed or unbounded table that contains simple types in COBOL or report program generator (RPG) data declarations. After you have a recordset object, you can call methods on that object to gain access to its rows. Recordsets supported by TI have disconnected client-side cursors. For more information, see Recordsets and Datatables.

Other Resources
Supported TI Data Types

Supported .NET Aggregate Data Types

Datatable

A .NET Framework object that is the equivalent of a fixed or unbounded table that contains simple types in COBOL or Report Program Generator (RPG) data declarations. After you have a **DataTable** object, you can call methods on that object to gain access to its rows. Datatables supported by TI have disconnected, client-side cursors. For more information, see Recordsets and Datatables.

Structures

A user-defined value type. Like a class, structures can contain constructors, constants, fields, methods, properties, indexers, operators, and nested types. Unlike classes, however, structures do not support inheritance.

The distributed program call (DPC) programming model for the AS/400 supports:

- Only single-level .NET structures.
- Arrays of .NET structures.

The DPC programming model for the AS/400 does not support:

- Nesting of structures.
- Arrays within structures.
- Variable sized structures in which the last parameter is a string.

Array

A set of sequentially indexed elements that have the same intrinsic data type. Transaction Integrator (TI) supports an array of any of the .NET data types in this topic. Each element of an array has a unique identifying index number. Changes made to one element of an array do not affect the other elements. TI supports multidimensional arrays. However, only the outermost array of a multidimensional array can vary in size; all the other arrays must be fixed in size. For more information, see Arrays.

See Also

Other Resources

Supported TI Data Types

Supported COBOL Data Types

COMP-1

A 4-byte, single precision, floating-point Real data type that specifies internal floating-point items. The sign is contained in the first bit of the leftmost byte, and the exponent is contained in the remaining seven bits of that byte. The remaining three bytes hold the mantissa.

COMP-2

An 8-byte, double precision, floating-point Real data type that specifies internal floating-point items. The sign is contained in the first bit of the leftmost byte, and the exponent is contained in the remaining seven bits of the first byte. The remaining seven bytes hold the mantissa.

COMP-3 Packed Decimal

A packed decimal data type that specifies internal decimal items stored in packed decimal format. In the packed decimal format, each byte in a field represents two numeric digits except for the rightmost byte. The rightmost byte holds one digit and the sign. In other words, there are two digits in each character position except for the trailing character position that is occupied by the low-order digit and sign. The item can contain any of the digits from 0 through 9, plus a sign, to represent a value not exceeding 18 decimal digits. For example, the decimal value +123 is represented in two bytes as 0001 0010 0011 1100 in packed decimal format. For more information see, Zoned Decimal or Packed Decimal Data Types.

DISPLAY Zoned Decimal

An unpacked decimal data type that specifies internal decimal items stored in zoned decimal format. Zoned decimal format is synonymous with unpacked decimal format, which is a format for representing numbers where each digit is contained in bits 4 through 7 and the sign is contained in bits 0 through 3 of the least significant byte. Bits 0 through 3 of all bytes other than the least significant byte contain 1s (hex F). For example, the decimal value +123 is represented in three bytes as 1111 0001 1111 0010 1100 0011 in zoned decimal format. For more information see, Zoned Decimal or Packed Decimal Data Types.

DATE and TIME

Specifies a date and time by using group item of two PIC 9(7) COMP-3 Packed Decimal value.

TIME only

Specifies a time by using a PIC 9(7) COMP-3 Packed Decimal value.

DATE only

Specifies a date by using a PIC 9(7) COMP-3 Packed Decimal value.

PIC X

Specifies a single character in an Extended Binary Coded Decimal Interchange Code (EBCDIC) character string. EBCDIC is the native representation for character data on mainframes and AS/400s. Unicode is the native representation for character data on Windows-based platforms.

PIC X No Translation

Specifies a single COBOL character in an EBCDIC character string that is handled as if it were binary data. In other words, there is no translation from EBCDIC to Unicode or from Unicode to EBCDIC.

PIC G

Specifies a double-byte EBCDIC string.

PIC S9(4) COMP (Integer 16-bit)

Specifies an integer that is 16 bits, or 2 bytes, in length.

PIC S9(9) COMP (Integer 32-bit)

Specifies an integer that is 32 bits, or 4 bytes, in length.

Data Type Conversion

The Transaction Integrator (TI) run-time environment automatically converts data types between host-based COBOL or Report Program Generator (RPG) data types and the COM-based Automation data types that a Windows-based programming language like Visual Basic uses. The automatic conversion is based on information that you define in TI Project when you design and create a TI component (type library). This information is stored with the TI component and used by the TI runtime to convert the parameters of a method from the representation understandable by a COM-based or .NET-based programming language into the representation understandable by a host transaction program (TP).

Use TI Project to associate each Automation data type with each COBOL or RPG data type used in the host TP. TI provides default mappings between standard Automation data types and COBOL or RPG data types. You can either accept the default mappings or override the default with other mappings supported by TI. TI Project stores the conversion map in the TI component type library (.tlb) file. This conversion map is used to:

- Handle data moving between the TP and the TI component.
- Convert a TI component into a TP (export the host definition).
- Convert a TP into a TI component (import the host definition).

If a parameter used in a method call is not strictly typed, the TI run-time environment attempts to coerce the data type it receives into the data type it expects. If that coercion is successful, the call proceeds. If it is unsuccessful, an error is returned.

At run time, when a client application uses the TI Automation interface to call a method of the TI Automation server, the TI run-time environment uses the conversion map to handle the actual data conversion of the in and in/out parameters being sent to the mainframe TP. After TI converts the Microsoft® Windows® data, TI reformats the method call as a host system APPC/LU 6.2 or TCP/IP message. Then TI uses Microsoft Host Integration Server 2009 SNA or TCP/IP connectivity to forward the message to the mainframe. When the mainframe TP returns the in/out and out parameters, TI reformats the message for the return to Windows, converts the host data into Windows data, and returns the return value and parameters to the client application.

The choice of language or code page you made in TI Manager when you defined the remote environment (RE) determines which code page is used to convert from UNICODE (on the Automation side) to Extended Binary Coded Decimal Interchange Code (EBCDIC) (on the mainframe side). When you create an RE in TI Manager, you can either select a language to accept the default code page for that language, or select a specific code page.

If you need to convert to different target code pages (if you have, for example, target mainframes in different countries or regions), you need to set up an RE for each target because TI does not support conversions requiring the use of locale.

You can use TI Project to import COBOL or RPG, or to manually enter method descriptions to create Automation methods. When you import COBOL or RPG, each supported COBOL data type has a default Automation type. When you manually create a method, each Automation data type has a default host data type associated with it.

If you do not want to use a default Automation data type, you can use TI Project to change the Automation data type manually. If the new Automation type is compatible with the existing host data type, the existing COBOL or RPG data type is left unchanged. If it is not compatible, the host data type is changed, thus affecting your mainframe program.

In This Section

- Zoned Decimal or Packed Decimal Data Types
- Converting Data Types from RPG to OS/400 COBOL

Converting Data Types from Automation to OS/390 COBOL

Use the tables in this topic as a guide to specify how you want TI to handle conversions from Automation data types to COBOL data types. For more information about the specific data types, see Supported TI Data Types.

Use the following code key to interpret the codes in the **Possible Conversion Errors** and **Required Property Settings** columns in each table.

Code	Description
r	Range errors possible.
b	Possible loss of precision due to base 2 to base 16 conversion.
p	Possible loss of precision due to picture format scale specification.
m	Mapping errors possible.
f	yyyyddd and hhmmss.
A	You must specify **Truncate**, **Round**, or **Error** under **Error handling** on the **COBOL Definition** tab of the property page.
C	You must specify the precision and scale by filling in the **Digits left** and **Digits right** boxes on the **COBOL Definition** tab of the property page.
D	You must specify the string width by filling in the **Size** box on the **COBOL Definition** tab of the property page.
E	Unicode or EBCDIC mapping information is required, such as a code page.
F	For arrays whose length is less than the maximum specified, you must specify **Size of Filler** under **Trailing filler** on the **COBOL Definition** tab of the property page.
G	You must specify how to deal with strings. Click **Space Padded** or **Null terminated** under **String Delimiting** on the **COBOL Definition** tab of the property page. Then click **Truncate** or **Error** under **Error handling** on the **COBOL Definition** tab of the property page to specify what TI should do if the string is too long.
H	Maximum size is required.
I	Localization is required.
J	Optional SO and SI insertion and deletion is supported.

The following table shows the defaults that TI uses for converting Automation data types to COBOL data types.

Default

From Automation data type	To OS/390 COBOL data type	Possible conversion errors	Required property settings
1-byte unsigned Integer	PIC X No Translation	None	None
2-byte signed Integer	PIC S9(4) COMP (Integer 16-bit)	None	None
4-byte signed Integer	PIC S9(9) COMP (Integer 32-bit)	None	None
4-byte Real (Single)	COMP-1	br	None
8-byte Real (Double)	COMP-2	br	None
Boolean	PIC S9(4) COMP (Integer 16-bit)	None	None
Variable-length String	PIC X	m	DEG
Currency	COMP-3 Packed Decimal	pr	C

Date (date and time)	COMP-3 Packed Decimal	pf	CI
Date (date only)	COMP-3 Packed Decimal	pf	CI
Date (time only)	COMP-3 Packed Decimal	pf	CI
Decimal	COMP-3 Packed Decimal	pr	C
Array (any data type)	OCCURS fixed TIMES	None	FH

Note

When you convert whole or fractional numbers from Visual Basic Single or Visual Basic Double data types to Packed Decimal or distributed program call (DPC) Zoned Decimal data types, TI is limited to a precision from 1 through 18 digits left of the de cimal point (for example, 1.2345678901234567E+17). When you convert fractional numbers Packed Decimal or DPC Zoned Decimal data types, you should convert to Visual Basic Decimal data type.

The following table shows the other supported data type mappings that you can set in TI Project to override the defaults presented in the previous table.

Supported in Transaction Integrator

From Automation data type	To OS/390 COBOL data type	Possible conversion errors	Required property settings
1-byte unsigned Integer	PIC S9(4) COMP (Integer 16-bit)	None	None
1-byte unsigned Integer	COMP-3 Packed Decimal	None	C
2-byte signed Integer	COMP-3 Packed Decimal	None	C
2-byte signed Integer	DISPLAY Zoned Decimal	None	C
4-byte signed Integer	COMP-3 Packed Decimal	None	C
4-byte signed Integer	DISPLAY Zoned Decimal	None	C
4-byte Real (Single)	PIC S9(4) COMP (Integer 16-bit)	p,r	None
4-byte Real (Single)	PIC S9(9) COMP (Integer 32-bit)	p,r	None
4-byte Real (Single)	COMP-3 Packed Decimal	p,r	C
4-byte Real (Single)	DISPLAY Zoned Decimal	p,r	C
8-byte Real (Double)	PIC S9(4) COMP (Integer 16-bit)	p,r	None
8-byte Real (Double)	PIC S9(9) COMP (Integer 32-bit)	p,r	
8-byte Real (Double)	COMP-3 Packed Decimal	p,r	C
8-byte Real (Double)	DISPLAY Zoned Decimal	p,r	C
Boolean	PIC S9(9) COMP (Integer 32-bit)	None	None
Boolean	COMP-3 Packed Decimal	None	C
Variable-length String	PIC G	m	DEGJ
Currency	PIC S9(?)V9(?) COMP (16-bit)	pr	None
Currency	PIC S9(?)V9(?) COMP (32-bit)	pr	None
Currency	DISPLAY Zoned Decimal	pr	C
Decimal	PIC S9(?)V9(?) COMP (16-bit)	pr	None

Decimal	PIC S9(?)V9(?) COMP (32-bit)	pr	None
Decimal	DISPLAY Zoned Decimal	pr	C
Array (any data type)	OCCURS DEPENDING ON	None	FH

Note

When you convert whole or fractional numbers from Visual Basic Single or Visual Basic Double data types to Packed Decimal or DPC Zoned Decimal data types, TI is limited to a precision of 1 to 18 digits left of the decimal point (for example, 1.2345678901234567E+17).

The following table shows additional supported data type mappings that the TI run-time environment supports.

Supported only by the TI run-time environment

From Automation data type	To OS/390 COBOL data type	Possible conversion errors	Required property settings
1-byte unsigned Integer	PIC S9(9) COMP (Integer 32-bit)	None	None
1-byte unsigned Integer	DISPLAY Zoned Decimal	None	C
Boolean	DISPLAY Zoned Decimal	None	C

No other data type conversions from Automation to COBOL are supported by TI at this time.

Note

When the COBOL usage is DISPLAY without a sign and you change the Automation type to String, the COBOL picture is changed to PIC X, which has the same internal data representation. The length remains the same and therefore does not affect your mainframe program.

Data Type Conversion

Converting Data Types from OS/390 COBOL to Automation

Use the tables in this topic as a guide when you set up the way you want Transaction Integrator (TI) to handle conversions from COBOL data types to Automation data types. For more information about the specific data types, see Supported TI Data Types.

Use the following code key to interpret the codes in the **Possible Conversion Errors** and **Required Property Settings** columns in each table.

Code	Description
r	Range errors possible.
b	Possible loss of precision due to base 2 to base 16 conversion.
p	Possible loss of precision due to picture format scale specification.
m	Mapping errors possible.
f	yyyyddd and hhmmss.
A	You must specify **Truncate**, **Round**, or **Error** under **Error handling** on the **COBOL Definition** tab of the property page.
C	You must specify the precision and scale by filling in the **Digits left** and **Digits right** boxes on the **COBOL Definition** tab of the property page.
D	You must specify the string width by filling in the **Size** box on the **COBOL Definition** tab of the property page.
E	Unicode or EBCDIC mapping information is required, such as a code page.
F	For arrays whose length is less than the maximum specified, you must specify **Size of Filler** under **Trailing filler** on the **COBOL Definition** tab of the property page.
G	You must specify how strings should be dealt with. Click **Space Padded** or **Null terminated** under **String Delimiting** on the **COBOL Definition** tab of the property page. Then click **Truncate** or **Error** under **Error handling** on the **COBOL Definition** tab of the property page to specify what TI should do if the string is too long.
H	Maximum size is required.
I	Localization is required.
J	Optional SO and SI insertion and deletion is supported.

The following table shows the defaults that TI uses when you import COBOL source code.

Default

From OS/390 COBOL data type	To Automation data type	Possible conversion errors	Required property settings
COMP-1	4-byte Real (Single)	b,r	None
COMP-2	8-byte Real (Double)	b,r	None
COMP-3 Packed Decimal	Currency	p	AC
COMP-3 Packed Decimal	Decimal	p	AC
DATE and TIME	Date	None	I
TIME only	Date	None	I
DATE only	Date	None	I
PIC X	Variable-length String	m	DEG

PIC X No Translation	1-byte unsigned Integer	None	None
PIC S9(4) COMP (Integer 16-bit)	2-byte signed Integer	None	None
PIC S9(4) COMP (Integer 16-bit)	Boolean	None	None
PIC S9(9) COMP (Integer 32-bit)	4-byte signed Integer	None	None
OCCURS fixed TIMES	Array	None	None

Note

When you convert fractional numbers from Packed Decimal or distributed program call (DPC) Zoned Decimal data types, yo u should convert to Visual Basic Decimal data type.

For COMP, COMP-3, and DISPLAY numeric COBOL data types, the default is based on the precision and scale shown in the following table. When COBOL uses DISPLAY without a sign and you change the Automation type to String, the COBOL picture is changed to PIC X, which has the same internal data representation. The length remains the same and therefore does not affect your mainframe program.

Precision and scale for OS/390 COBOL	To Automation data type
Precision 1-4, scale 0	2-byte signed Integer
Precision 5-9, scale 0	4-byte signed Integer
Precision 5-7, scale 3-7	4-byte Real
Precision 8-18, scale 3-18	8-byte Real
Precision 1-18, scale 1-2	Currency
Precision 10-18, scale 0	Decimal

The following table shows the other supported data type mappings that you can set in TI Project to override the defaults presented previously in this topic.

Supported in Transaction Integrator

From OS/390 COBOL data type	To Automation data type	Possible conversion errors	Required property settings
COMP-1	Array	None	None
COMP-2	Array	None	None
COMP-3 Packed Decimal	2-byte signed Integer	p,r	AC
COMP-3 Packed Decimal	4-byte signed Integer	p,r	AC
COMP-3 Packed Decimal	4-byte Real (Single)	p,r	AC
COMP-3 Packed Decimal	8-byte Real (Double)	p	C
COMP-3 Packed Decimal	Boolean	None	None
COMP-3 Packed Decimal	1-byte unsigned Integer	r	None
COMP-3 Packed Decimal	Array	None	None
DISPLAY Zoned Decimal	2-byte signed Integer	p,r	AC
DISPLAY Zoned Decimal	4-byte Real (Single)	p,r	AC
DISPLAY Zoned Decimal	8-byte Real (Double)	p,r	AC
DISPLAY Zoned Decimal	Currency	p,r	AC

DISPLAY Zoned Decimal	Decimal	p,r	AC
DATE and TIME	Array	None	None
TIME only	Array	None	None
DATE only	Array	None	None
PIC X	Array	None	None
PIC X No Translation	Array	None	None
PIC G	Variable-length String	m	DEGJ
PIC G	Array	None	None
PIC S9(4) COMP (Integer 16-bit)	1-byte unsigned Integer	r	None
PIC S9(4) COMP (Integer 16-bit)	Array	None	None
PIC S9(9) COMP (Integer 32-bit)	Boolean	None	None
PIC S9(9) COMP (Integer 32-bit)	1-byte unsigned Integer	r	None
PIC S9(9) COMP (Integer 32-bit)	Array	None	None
PIC S9(?)V9(?) COMP (16-bit)	4-byte Real (Single)	p,r	None
PIC S9(?)V9(?) COMP (16-bit)	8-byte Real (Double)	p,r	None
PIC S9(?)V9(?) COMP (16-bit)	Currency	p,r	None
PIC S9(?)V9(?) COMP (16-bit)	Decimal	p,r	None
PIC S9(?)V9(?) COMP (32-bit)	4-byte Real (Single)	p,r	None
PIC S9(?)V9(?) COMP (32-bit)	8-byte Real (Double)	p,r	None
PIC S9(?)V9(?) COMP (32-bit)	Currency	p,r	None
PIC S9(?)V9(?) COMP (32-bit)	Decimal	p,r	None
OCCURS DEPENDING ON	Array	None	None

Note

When you convert fractional numbers from Packed Decimal or DPC Zoned Decimal data types, you should convert to Visual Basic Decimal data type.

The following table shows additional supported data type mappings that the TI run-time environment supports.

Supported only by the TI run-time environment

From OS/390 COBOL data type	To Automation data type	Possible conversion errors	Required property settings
DISPLAY Zoned Decimal	1-byte unsigned Integer	None	AC
DISPLAY Zoned Decimal	4-byte signed Integer	None	AC
DISPLAY Zoned Decimal	Boolean	None	AC

No other data type conversions from COBOL to Automation are supported by TI at this time.

Converting Data Types from Automation to RPG

Use the following table as a guide when you specify the way you want Transaction Integrator (TI) to handle conversions from Automation data types to Report Program Generator (RPG) data types.

TI Project default	RPG data type	Spec-ification	Field length	Field length meaning	Decimal places
Boolean (default)	Integer	I	5	digits	Blank
Boolean	Integer	I	10	digits	Blank
Boolean	Packed	P	3	digits	Blank,0
Byte (default)	Character	A	1	bytes	Blank
Byte	Unsigned	U	3-9	digits	Blank
Byte	Packed	P	3	digits	Blank,0
Byte	Integer	I	3-9	digits	Blank
Currency (default)	Packed	P	1-30	digits	Blank,0-4
Currency	Zoned	S	1-30	bytes	Blank,0-4
Currency	Binary	B	1-4	digits	Blank,0-4
Currency	Binary	B	5-9	digits	Blank,0-4
Date (Date)	*MDY	None	8	bytes	Blank
Date (Date)	*DMY	None	8	bytes	Blank
Date (Date)	*YMD	None	8	bytes	Blank
Date (Date)	*JUL	None	6	bytes	Blank
Date (Date)	*ISO	None	10	bytes	Blank
Date (Date)	*USA	None	10	bytes	Blank
Date (Date)	*EUR	None	10	bytes	Blank
Date (Date)	*JIS	None	10	bytes	Blank
Date (Time)	*HMS	None	8	bytes	Blank
Date (Time)	*ISO	None	8	bytes	Blank
Date (Time)	*USA	None	8	bytes	Blank
Date (Time)	*EUR	None	8	bytes	Blank
Date (Time)	*JIS	None	8	bytes	Blank
Date	Timestamp	Z	Number?	bytes	Blank
Decimal	Float	F	4	Bytes	Blank
Decimal	Float	F	8	Bytes	Blank
Decimal (default)	Packed	P	1-30	digits	Blank,0-30
Decimal	Zoned	S	1-30	bytes	Blank,0-30

Decimal	Binary	B	1-4	digits	Blank,0-4
Decimal	Binary	B	5-9	digits	Blank,0-9
Double (default)	Float	F	8	bytes	Blank
Double [1]	Packed	P	1-30	digits	Blank,0-30
Double [1]	Zoned	S	1-30	bytes	Blank,0-30
Double	Binary	B	1-4	digits	Blank,0-4
Double	Binary	B	5-9	digits	Blank,0-9
Integer (default)	Integer	I	1-5	digits	Blank
Integer	Packed	P	1-30	digits	Blank,0
Integer	Zoned	S	1-30	bytes	Blank,0
Integer	Binary	B	1-5	digits	Blank,0
Long (default)	Integer	I	1-9	digits	Blank
Long	Packed	P	1-30	digits	Blank,0
Long	Zoned	S	1-30	bytes	Blank,0
Long	Binary	B	1-9	digits	Blank,0
Single (default)	Float	F	4	bytes	Blank
Single [1]	Packed	P	1-30	digits	Blank,0-30
Single [1]	Zoned	S	1-30	bytes	Blank,0-30
Single	Binary	B	1-9	digits	Blank,0-9
String (default)	Character	A	1-32755	Bytes==Char	Blank
String	Graphic	G	1-16371	Char	Blank

Note

Note [1] in the preceding table indicates that when you convert whole or fractional numbers from Visual Basic Single or Visual Basic Double data types to Packed Decimal or distributed program call (DPC) Zoned Decimal data types, TI is limited to a precision from 1 through 18 digits to the left of the decimal point (for example, 1.2345678901234567E+17).

Note

While TI left-justifies all strings, the RPG MOVE command right-justifies all strings. If you are programming an RPG application, use the MOVEL or EVAL commands to perform the equivalent operation in RPG while manipulating a string. **See Also**

Supported TI Data Types

Converting Data Types from RPG to Automation

Data Type Conversion

Converting Data Types from RPG to Automation

Use the following tables as a guide when you set up the way you want Transaction Integrator (TI) to handle conversions from report program generator (RPG) data types to Automation data types. For more information about the specific data types, see Supported TI Data Types.

The following table describes the TI Project property abbreviations used in the data type tables that follow.

Abbreviation	Description
t	Truncate
e	Error
r	Round
sp	Space pad
nt	Null terminate
SO	Add leading shift in
SI	Add trailing shift out
PE	Pack even
TIP	TI Project

Pack even (PE) indicates that the definition specification uses the pack even option for RPG. PE indicates that the precision is an even number of digits when the From and To specification positions are used, which implies a byte count instead of a digit count and which might mean that the high-order digit position is ignored. For example, the following table shows how the number 256 in an RPG packed field is represented in internal memory.

Note
For purposes of this example, the number 256 fits in 2 bytes of memory in both the PE and No PE option.

Packed data type option	Byte 1	Byte 2		
	High-order byte high-order nibble	High-order byte low-order nibble	Low-order byte high-order nibble	Low-order byte Sign
No PE	2	5	6	0xf
PE	ignored	5	6	0xf

RPG data type	Spec-ification	RPG field length	TIP data type	TIP default error handling	TIP default field length	TIP default decimals	TIP default string handling
Character	A	1	Byte	None	None	None	None
Character	A	1-32755	String	t,e	80	None	sp,nt
Graphic	G	1-16371	String	t,e	80	None	sp
Binary	B	1-4	Currency	t,r,e	4	2	None
Binary	B	5-9	Currency	t,r,e	9	2	None

Data Type Conversion

Zoned Decimal or Packed Decimal Data Types

When it imports a host data declaration, Transaction Integrator (TI) converts Zoned Decimal (COBOL numeric PIC with DISPLAY or no USAGE, or RPG S data type) or Packed Decimal data types to Decimal or Currency Automation data types, respectively. Depending on the development application you are using, there might not be an equivalent for Decimal or Currency data types. If this is the case, use one of the following techniques to ensure that the data type works correctly with TI:

- Use language-supplied functions to manipulate the Automation types for Decimal or Currency.
- Within TI Project, if the data type has a fractional component, modify the method's parameter from the Decimal or Currency data type to the Floating Point Binary data type (double or single precision as appropriate). You can substitute a 16-bit or 32-bit binary Integer data type if the data declaration has no fractional component and the number of data declaration digits fits within the expected range.

Note
When you use the Floating Point Binary data type, the likelihood of a data conversion precision problem increases if fractions are involved. TI offers three options to handle data precision errors: Round (default), Truncate, or Error. The double-precision Floating Point Binary data type can handle host data declarations of up to fifteen digits.

Converting Data Types from RPG to OS/400 COBOL

The Transaction Integrator (TI) run-time environment supports the use of OS/400 COBOL running on an AS/400 computer. The following table lists the Report Program Generator (to data type conversions supported by the TI run-time environment.

RPG data type	OS/400 COBOL data type
Type A	PIC X
Type G	PIC G
Type S	PIC S99v99 Display
Type L Note Type L is not supported by the TI run-time environment.	PIC S99v99 Display Sign Leading Separate
Type R Note Type R is not supported by the TI run-time environment.	PIC S99v99 Display Sign Trailing Separate
Type P	PIC S99v99 Comp
Type B Note Type B is not supported by the TI run-time environment.	PIC S99V99 Comp
Type I 5 digits	PIC S9(1) to S9(4) Comp-3
Type U 5 digits Note Type U 5 is not supported by the TI run-time environment. Use Type I 5 instead.	PIC 9(1) to 9(4) Comp-3
Type I 10	PIC S9(5) to S9(9) Comp-3
Type U 10 Note Type U 10 is not supported by the TI run-time environment. Use Type I 10 instea d.	PIC 9(5) to 9(9) Comp-3
Type F 4	COMP-1
Type F 8	COMP-2
Type D	None
Type T	None
Type Z	None

Supported TI Data Types

Data Type Conversion

Integer Data Type

Binary Integer data types apply to COBOL COMP and Report Program Generator (RPG) Integer data types. Automation data types support only a 16-bit or 32-bit Integer. Therefore, you should ensure that your client application is passing binary integer equivalents to the Transaction Integrator (TI) Automation server.

Other Resources

Data Types

Decimal Data Type in Visual Basic

If the client application uses Visual Basic 6.0 and includes the DECIMAL data type, the decimal value in Visual Basic must be defined as a Variant, and then assigned a decimal value by the Visual Basic function **CDec**. This must be done for the component to execute properly within the TI component.

The following is an example:

```
Dim xxx as Variant
xxx = CDec(27)
```

If the client application uses Visual Basic .NET, the DECIMAL data type is defined directly.

See Also
Other Resources
Data Types

Variant Data Type

The type of each element in a message is fixed and defined by the information in the component library. Because mainframe programs do not support the Variant data type, you must fix the type of each parameter at design time in Transaction Integrator (TI) Project. Microsoft Visual Basic Scripting Edition (VBScript), which is often used to create Active Server Pages (ASP) in Web-based applications, supports only the Variant data type. It does not accept declared variables. As a result, if your COM+ client application calls a TI Automation server and passes parameters with Variant data types, the TI run-time environment forces each Variant data type into the type for each parameter as defined in the TI component library.

The Variant data type is not supported in Visual Basic .NET. Visual Basic .NET supports defining data types as objects, and then casting the objects as data types. TI does not support variables defined as objects cast to data types. All method parameters must be defined initially as data types, not objects.

Data Types

Recordsets and Datatables

A recordset is an Automation object that is a fixed-size, bounded, or unbounded table that contains simple rows of host data declarations (data types). A datatable is a .NET object that is identical to a recordset in every regard, except that you cannot use the **NewRecordset** function with datatables. After you have a recordset or datatable object, you can call methods on that object to gain access to its rows.

A recordset or datatable is implemented on top of row sets by Remote Data Service (RDS), which is a part of Microsoft Data Access Components (MDAC) version 2.5. You can use the **RDSServer.DataFactory** object to create a recordset or datatable and use ActiveX® Data Objects (ADO) to update or read the recordset.

A recordset or datatable provides a means of presenting and manipulating tabular data. Currently, recordsets cannot be nested, cannot contain arrays, and cannot contain user-defined types (UDTs).

Support for recordsets and databales enables TI to support what is effectively an array of a structure (or a record, in COBOL terminology) as well as a structure. A structure is represented as a fixed-size recordset or datatable where each column in the row contains a single data element. To deal with mainframe programming issues, TI classifies recordsets and datatables as fixed-size, bounded, or unbounded, in reference to the number of rows contained in the recordset or datatable.

Important
The OS/400 distributed program calls (DPC) programming model supports only fixed size recordsets and datatables. The pro gramming model does not support unbounded recordsets and datatables, nor does it support the use of the OCCURS DEPE NDING ON clause, or variably-sized recordsets and datatables.

For fixed-size, bounded, and unbounded TI recordsets and datatables, the layout of all rows in a particular recordset is the same and is defined at design time by using TI Project. If a recordset or datatable is an output or return value from the mainframe, TI run-time environment uses the **RDSServer.DataFactory** object to create a recordset or datatable and ADO to fill the recordset or datatable with the rows of data returned from the mainframe program.

Such a recordset is a disconnected recordset with a cursor type of adOpenForwardOnly. To scan the recordset requires calling **MoveFirst** and **MoveNext** to move through the rows. The recordset can be updated in place, but because it is disconnected from the true data source (the data source manipulated by the mainframe program that returned the data), the updates are not propagated to the original data source.

NewRecordset is a function that is supplied automatically for all TI components. This function is called to create a disconnected recordset object that can be passed into a TI method call. **NewRecordset** is provided as a convenience for TI client applications; it is not required to pass a recordset to a TI component's methods. The function can be called only for input or input/output recordset objects. The TI run-time environment creates a recordset object when the parameter is an output recordset object.

In This Section

Example Using the New Recordset Call

The following example code uses the **NewRecordset** property to create a new disconnected recordset object, and it passes the object as an input parameter to a Transaction Integrator (TI) method by way of the **IDispatch** interface. The *bstrName* parameter in the **IDispatch** call is the name of the recordset object (for example, **Recordset1**) as specified in TI Project. The call returns the dispatch pointer to an ActiveX® Data Objects (ADO) database recordset object if the call is successful. If the call is not successful, a NULL pointer is returned.

```
IDispatch * NewRecordset(
  BSTR bstrName);

Dim pMyRecord as Object
Dim pMyComponent as Object
Dim varFields(2) as Variant
Dim varValues(2) as Variant
On Error Goto SomeErrorHandler

' Create an instance of the TI object
set pMyComponent = CreateObject("MyComponent.Interface1")

' Create an instance of a recordset object
set pMyRecord = pMyComponent.NewRecordset("Recordset1")

' Fill in some recordset fields
varFields(0) = CStr("member1")
varFields(1) = CStr("member2")
varValues(0) = CInt(99)
varValues(1) = CLng(999)

' Add the recordset fields and values to the recordset object
pMyRecord.AddNew varFields, varValues

' Call the method with the recordset object as a parameter
pMyComponent.Method1(pMyRecord)
```

The TI run-time environment performs some compatibility checks between the structure definition for the recordset in the component library and the recordset object seen at run time. Any incompatibility will result in an Automation exception.

Note

Because a recordset cannot be nested, cannot contain arrays, and cannot contain user-defined types (UDTs), a COBOL data st ructure that is imported into TI Project might be flattened, resulting in an increase in the number of parameters that must be handled on the Automation side.

Bounded Recordsets
Unbounded Recordsets
RDS Recordset Requirements for Web Clients

Fixed-Size Recordsets

A fixed-size recordset holds a fixed number of rows that is exactly equal to the maximum number of rows that you specified at design time in Transaction Integrator (TI) Project. A parameter or return value can be defined as a fixed-size recordset for any of the TI programming models.

Among the three possible types of recordsets or datatables (fixed-size, bounded, or unbounded), the TI default is fixed-size.

If the COBOL data declaration contains an OCCURS DEPENDING ON clause, each OCCURS DEPENDING ON clause requires two parameters:

- The size of the OCCURS DEPENDING ON clause.
- The data representation (a single element or a COBOL record) within the OCCURS DEPENDING ON clause.

If the COBOL contains an OCCURS DEPENDING ON clause, when the recordset or datatable is returned to TI and processed at run time, the TI run-time environment looks for the value of the size parameter corresponding to the named parameter (from the OCCURS DEPENDING ON clause). When it sends a fixed-size recordset as an input parameter to the mainframe, the TI run-time environment sets the COBOL size parameter with the actual number of rows in the recordset.

The DPC programming model on the AS/400 platform supports a modified version of OCCURS DEPENDING. By using the OCCURS DEPENDING property to select a parameter to specify size for the array, DPC-invoked programs can receive and send arrays that are partially populated. For example, you might have a structure that is defined to occur 10 times and that you want to return to the client. However, there might be fewer than 10 occurrences that actually contain valid data (for example, if the array was filled from a database table that contained fewer than 10 rows). If you define the array using the OCCURS DEPENDING property, you do not have to fill the remaining occurrences with dummy data. The TI run-time environment will pass only the filled occurrences back to the client.

Data Transfer Options

Bounded Recordsets

A recordset that is the last input parameter or the last output parameter in a method can be bounded. This means its actual size (number of rows) can vary from zero up to the maximum number of rows specified at design time. A parameter or return value can be defined as a bounded recordset for all of the Transaction Integrator (TI) programming models except OS/400 distributed program calls (DPCs). The DPC programming model does not support bounded recordsets, datatables, or arrays.

A bounded recordset, datatable, or array must be the last parameter in a particular direction. The last input parameter can be bounded if it is a recordset or an array and there are no following input/output parameters. The last output parameter can be bounded if it is a recordset or an array and there are no following input/output parameters. An input/output parameter can be bounded if it is a recordset or an array and is the final parameter. The mainframe transaction program (TP) is responsible for sending a table of the correct size, depending on the number of elements or rows in use.

Whereas a fixed-size recordset must send the exact number of rows defined as the maximum within the recordset, the number of rows in a bounded recordset can vary from zero to the maximum.

Among the three possible types of recordsets (fixed-size, bounded, or unbounded), the TI default is fixed-size. To change a fixed-size recordset into a bounded recordset within Designer, set the property "variable sized final field" on the method that contains the parameter defined as a recordset to be bounded, to true.

Concepts

Fixed-Size Recordsets

Unbounded Recordsets

RDS Recordset Requirements for Web Clients

Unbounded Recordsets

The number of rows in an unbounded recordset or datatable is not specified (defined) before run time. A parameter or return value can be defined as an unbounded recordset or datatable for any of the following Transaction Integrator (TI) programming models:

- CICS User Data LU 6.2
- TCP Transaction Request Message User Data
- IMS User Data LU 6.2
- IMS Implicit
- IMS Explicit
- IMS Connect

Note
In the IMS Connect programming model, TI supports only output parameters as unbounded recordsets or datatable. In other words, you cannot send unbounded recordsets or datatables to the host from TI if you are using the IMS Connect model.

An unbounded recordset or datatable is always transmitted to or from the mainframe after all other data. TI supports at most one unbounded input parameter and one unbounded output parameter, and each must be the last parameter in a direction.

To make a fixed size recordset or database unbounded, use the designer to set the **Unbounded** property of the recordset to true. The property **Variable Sized Final Field** on the method associated with the unbounded recordset must be false.

After defining a recordset or datatable as unbounded, the designer **recordset** property class will contain a property called **variably sized rows**. Use this property to determine how the length of the row will be represented.

Unbounded recordsets or datatable that contain variably sized rows must receive the size of the recordset or datatable first, and then receive the data. Therefore, the size of the recordset or datatable must be sent first followed by a second send that contains the data. If TI expects to receive an unbounded recordset or datatable with variably sized rows, CICS must first send the length of the row, and then send the data for that row. These two steps are repeated for each row of the recordset or datatable. TI detects that there is no more data because CICS stops sending and an unbounded recordset or datatable must always be the last parameter sent to TI.

Fixed-Size Recordsets

Bounded Recordsets

RDS Recordset Requirements for Web Clients

RDS Recordset Requirements for Web Clients

If you have a Web-based Automation client application that uses a Remote Data Service (RDS) recordset control (most likely bound to a grid control) to display a table returned from a mainframe transaction program (TP), RDS requires that:

- The returned table be described as a recordset when you import your host data declaration into Transaction Integrator (TI) Project.

- The recordset be the return value from the method. The RDS control uses the HTTP protocol to marshal the recordset from the TI component on the server to the Web browser.

When you import a host data declaration, you must describe the table as a recordset. For more information, see Recordset Creation When Importing COBOL.

When you create the Automation method for your TI component in TI Project, be sure to have the method return the recordset as a return type instead of defining the recordset as a parameter. If you are importing the host code, when TI Project requests that you select the return value item, select the group item level for your table in the host declaration. To manually create a method, first manually describe or import the recordset in TI Project. Then use the **Insert** menu item to add the method that the Web client will call. Select the recordset you just described from the data type submenu list.

There are other properties that you can set on the recordset that is being returned. For details, see the shortcut Help for the **Recordsets** property page.

Fixed-Size Recordsets

Bounded Recordsets

Unbounded Recordsets

Recordset Creation When Importing COBOL

When you import COBOL in Transaction Integrator (TI) Project, you can choose between two ways to create recordsets and datatables: automatically and explicitly.

When you import COBOL to create or update an Automation method, TI Project automatically creates recordsets and datatables when it encounters a fixed or variable-length table (OCCURS clause). The value for the OCCURS clause's length specifier can be any value greater than or equal to 1. The table must conform to recordset rules, which means that it cannot contain arrays, and it cannot contain nested tables that cannot be flattened.

When you import COBOL to explicitly create or update a recordset or datatable, you can select any group item that conforms to recordset rules. For importing recordsets and datatables, the group item does not need to have an OCCURS clause. If an OCCURS clause is present, it is ignored.

The following COBOL source code was imported using the Import COBOLWizard. The INVOICES table was selected as the return value for the method.

```
01 CUSTOMER-DATA.
    05 CUSTOMER-NUMBER                PIC 9(9).
    05 INVOICES OCCURS 50 TIMES.
       10 INVOICE-NUMBER              PIC 9(9).
       10 INVOICE-DATE                PIC 9(7) COMP-3.
       10 INVOICE-AMOUNT              PIC S9(13)V9(2) COMP-3.
       10 INVOICE-DESCIPTION          PIC X(40).
    05 LAST-NAME                      PIC X(20).
    05 FIRST-NAME                     PIC X(20).
```

The resulting method was imported as:

```
GetInvoices(lCustomerNumber As Long, strLastName As String, strFirstName As String) As Obje
ct
```

The following Visual Basic code demonstrates how to call this method:

```
Dim objCustomer As Object   'Uses late binding
Dim objInvoices As ADODB.Recordset
Dim lCustomerNumber As Long
Dim iRow As Integer
Dim iCol As Integer
Dim strLastName As String
Dim strFirstName As String

'create an instance of the invoicing object
On Error GoTo ErrorHandler1
Set objCustomer = CreateObject("Customer.Invoicing.1")

lCustomerNumber = CLng(txtCustomerNumber)

'invoke the GetInvoices method
On Error GoTo ErrorHandler2
Set objInvoices = objCustomer.GetInvoices(lCustomerNumber _
    , strLastName, strFirstName)
'
' Transfer the Recordset data to a variant array in a single operation.
' This is efficient, but may not be suitable for larger Recordsets.
'
Dim Data As Variant

Data = objInvoices.GetRows
grdInvoices.Rows = UBound(Data, 2) + 1
grdInvoices.Cols = UBound(Data, 1) + 1
For iRow = 0 To UBound(Data, 2)
```

```
    grdInvoices.Row = iRow
    For iCol = 0 To UBound(Data, 1)
        grdInvoices.Col = iCol
        grdInvoices.Text = Data(iCol, iRow)
    Next iCol
Next iRow
```

Arrays

Transaction Integrator (TI) supports multidimensional arrays for all programming models except the OS/400 distributed program calls (DPCs). Only the outermost array of a multidimensional array can vary in size. All other arrays must be fixed-sized. For the OS/400 DPC programming model, TI supports only single-dimension arrays.

Arrays in Automation are actually SAFEARRAYs that contain information about their bounds as well as the data for the array elements. SAFEARRAYs are mapped to fixed-size arrays on the mainframe. SAFEARRAYs have a variable size and require custom information to be marshaled to and from fixed-size arrays on the mainframe.

Arrays are created on the mainframe during the import process when a simple data type has one or more OCCURS clauses or DIM keywords. The OCCURS clause can represent a fixed or variable-length table. Although it is possible in COBOL to have nested OCCURS DEPENDING clauses, only the OCCURS DEPENDING length specifier for the outermost table dimension is supported by TI. TI Project ignores nested length specifiers.

The mainframe developer might want to reflect the fixed nature of the array through to the COM object. The error-handling features of the TI run-time environment allow the developer to specify that an exception be raised if an array is not of the expected size. However, the mainframe developer might also want to take advantage of the flexible nature of SAFEARRAYs. TI supports an additional parameter that specifies the actual run-time size of the array. This parameter is supported with the same behavior as the OCCURS DEPENDING ON clause in COBOL. The maximum size of the array remains fixed, but the developer can determine the actual number of elements in the array received from the client.

The following custom information can be associated with either single or multidimensional arrays:

- Maximum size (on each dimension) (Integer: default 10). This value is automatically set to "x" if the COBOL imported into TI Project contains an OCCURS DEPENDING x TIMES clause.

- If the COBOL imported into TI Project contains an OCCURS DEPENDING ON clause, the actual size of the array is associated with the parameter specified by "name".

Visual Basic and Arrays

Visual Basic and Arrays

When you develop client applications with Microsoft Visual Basic Scripting Edition (VBScript), you cannot define methods that return arrays. If it is necessary to pass back array information, define an output parameter.

Transaction Integrator (TI) deals with multidimensional arrays in row major order. The outermost dimension of an array in COBOL equates to the leftmost dimension in an array on the Automation side. In Visual Basic, the convention is to use column major order for multidimensional arrays. Therefore, when you access multidimensional arrays in Visual Basic, remember that the array will be row major for TI purposes. This can be a problem if you use Visual Basic functions that deal with multidimensional arrays and expect those arrays to be in column major order. When you access individual array elements, however, this should not be a problem.

Note

Manually re-dimensioning a multidimension array that was generated by TI yields might cause the component to function in correctly.

Note

The Visual Basic command Option Base has no effect on COM SAFEARRAYs, such as those returned as Out or In/Out arrays f rom TI methods. These SAFEARRAYs always have a base value of 0, regardless of the option base setting.

The following COBOL sample shows a variable-length table:

```
01 UPDATEARRAY-INPUT-AREA.
   05 CUSTOMER-NUMBER                PIC 9(9) DISPLAY.
   05 LAST-NAME                      PIC X(20).
   05 FIRST-NAME                     PIC X(20).
   05 TABLE-LENGTH                   PIC 9(7) COMP-3.
   05 TABLE OCCURS 10 TIMES
         DEPENDING ON TABLE-LENGTH
         OF UPDATEARRAY-INPUT-AREA
                                    PIC S9(4) COMP.
```

TI Project creates the following method when you import the COBOL sample:

```
UpdateArray(lCustomerNo As Long, strLastName As String, strFirstName As String _
     , lcElements As Long, rgTable() As Integer)
```

The following Visual Basic code shows how to send and receive the table:

```
    Dim objCustomer As Object
    Dim i
    Dim rgTable() As Integer
    Dim lCustomerNo As Long
    Dim strLastName As String
    Dim strFirstName As String
    Dim lcElements As Long

    'create an instance of the invoicing object
    On Error GoTo ErrorHandler1
    Set objCustomer = CreateObject("Customer.Invoicing.1")

    lCustomerNo = 100231001
    strLastName = "Doe"
    strFirstName = "John"

    'Send over 5 elements
    lcElements = 5
    ReDim rgTable(lcElements)
```

```
For i = 0 To lcElements - 1
    rgTable(0) = i
Next i

'invoke the UpdateArray method
On Error GoTo ErrorHandler2
objCustomer.UpdateArray lCustomerNo, strLastName, strFirstName _
    , lcElements, rgTable

'lcElements now contains the number of elements returned in rgTable
```

Arrays

User-Defined Types

In general, a user-defined type (UDT) is equivalent to a structure in C, C++, or Report Program Generator (RPG) records or group item levels in COBOL, and UDTs in Visual Basic. UDTs can contain primitive elements, arrays of elements, recordsets, and nested UDTs.

You can use UDTs to define parameters. A parameter can be defined as a single UDT or as an array of UDTs. Likewise, UDTs can describe a method's return value. A method's return value can be defined as a single UDT or as an array of UDTs. However, you cannot use a UDT to describe a column within a recordset.

TI requires that if you use Visual Basic to build your UDTs, you must use Visual Basic version 6.0 or later.

Before you compile a Visual Basic application that calls a TI component that defines a UDT and that references that UDT within the Visual Basic application, you need to deploy the TI component to register it. If you compile the application before you deploy the TI component or if you fail to deploy the component at all, the Visual Basic client application will not start.

The distributed program call (DPC) programming model for the AS/400 supports:

- Only single-level UDTs and .NET structures.
- Arrays of UDTs and structures.

The DPC programming model for the AS/400 does not support:

- Nesting of UDTs and structures.
- Arrays within UDTs and structures.
- Variable sized UDTs in which the last parameter is a string.

In This Section

Requirements for UDT Support in Windows 2000

When Windows 2000 is installed, Transaction Integrator (TI) offers full functionality. Otherwise, TI restricts the use of user-defined types (UDTs). The functionality offered in this restricted mode is as follows:

- The TI Component Registrar recognizes that it is executing on a computer that does not have Service Pack 4 (SP4) installed. If the registrar is instructed to deploy a component when UDT support is not available, the registrar will search the type library to ensure that there are no UDTs. If UDTs are detected, the component deployment will fail and an error describing this failure will be written to the event log.

- TI Project recognizes that it is executing on a computer that does not have Windows 2000 installed. Although TI Project does not prevent UDTs within component descriptions, it warns users when UDTs are being used on a computer that does not have Windows 2000. Specifically, in TI Project, when the user attempts to save the type library, a UDT warning appears if UDTs are used in the component's description. This warning appears only after the first attempt to save a component description.

Creating UDTs by Importing Host Definitions

Using TI Project to Create UDTs

In Microsoft® Visual Studio® Transaction Integrator (TI) Project, you can create a user-defined type (UDT) manually by right-clicking the **User-Defined Type** folder, and then click **Add User-defined Type**. This automatically adds one member field of the type Integer. If only one member field exists in a UDT, you cannot delete that member field; you can only delete the entire UDT. You cannot delete a UDT if it is being used as a type by some other variable in the interface. The name of a UDT cannot be the same as a method name, recordset name, or any reserved names.

To add a member field to a UDT, right-click a previously defined UDT, and then click **Add User-defined Type Member**. A default member is created and can be modified by updating its properties in the **Properties** pane.

In addition to the **Automation** and **COBOL Definition** property pages for UDT member fields, an **Arrays** property page supports defining arrays of member fields, and a **Recordsets** property page supports definition of a maximum row count and options for recordset columns. The rules for arrays of recordsets are the same as for parameters. An OCCURS DEPENDING index must be one of the member fields above the array itself.

In TI Project, you can copy and paste UDT members from and to recordset members.

Arrays Defined in UDTs with Visual Basic

Concepts

Requirements for UDT Support in Windows 2000

Creating UDTs by Importing Host Definitions

Creating UDTs by Importing Host Definitions

The parser phase of the host import function identifies any group-level clause as a possible user-defined type (UDT). UDTs are created when you specify creating or updating a UDT or as the result of creating a method that contains a UDT. When you create or update a method, there is an additional wizard page following the **Select Return Value** page for specifying that groups of data items are UDTs or recordsets. This page also enables you to cancel the selection of groups of data items as UDTs or recordsets. For backward compatibility, the default data type of a group-level clause is a recordset if the group level has an OCCURS keyword. Also for backward compatibility (that is, updating a method), if there is no OCCURS keyword, the group level is flattened by default.

Arrays Defined in UDTs with Visual Basic

Concepts

Requirements for UDT Support in Windows 2000

Using TI Project to Create UDTs

Arrays Defined in UDTs with Visual Basic

In Visual Basic, if an array is defined within a user-defined type (UDT), you must re-dimension the array within the UDT before you populate the array. A UDT is a group of data types assigned to a single parameter, which is defined with an alias. In the following example, the UDT is defined within a Transaction Integrator (TI) type library, and not within the Visual Basic client.

The following example presents Visual Basic code that defines an array within a UDT:

```
*** Assign the udt defined within the comti typelib to a variable within the Visual Basic a
pplication.
Dim ClientUDT as UDT1
*** assign values to string data type within UDT1
ClientUDT.string = "ABCDEFG"
*** assign size before populating
ReDim ClientUDT.array1(10).
** start assigning values to array within UDT.
ClientUDT.array1(1) = 100
```

Note

In an array within a UDT, do not define the array within the Visual Basic client before you perform a re-dimension against the UDT. For all other data types within the UDT, you can immediately populate the values without having to define them within t he Visual Basic client data declarations.

Note

If you have an output or an in/out array inside a UDT, use a lower bound of zero for all array dimensions. Use zero because t ype libraries contain information only about array dimensions, not upper and lower bounds. Therefore, Convert has to choos e them arbitrarily when it creates the arrays.

Note

Report Program Generator (RPG) has additional limitations on the use of UDTs. RPG does not support:

- Nesting more than one level of arrays of UDTs.
- UDTs that contain recordsets within UDTs.

Transaction Request Messages

When you use TCP/IP to communicate with CICS, the client sends the host a transaction request message (TRM) request containing the Transaction Program ID, User ID, Password, and other administrative data to be used by the host. CICS sends the client a TRM reply containing additional administrative data. The data in the TRM is independent from the actual program data to be exchanged with the Transaction Program (TP) on the host.

You can find templates for various TRMs at \installation directory\Microsoft Host Integration Server\system\TIM\MicrosoftTRMDefs.tim. Use Microsoft Visual Studio to open the file, and then expand the **User-Defined Types** node. The following TRMs are defined as UDTs:

- TRMIN_MSLink
- TRMOUT_MSLink
- TRMIN_MSCCS
- TRMIN_IBMCCS
- TRMOUT_CCS

You can also find templates for various enhanced listener messages (ELMs) at \installation directory\Microsoft Host Integration Server\system\TIM\MicrosoftELMDefs.tim. Use Visual Studio to open the file, and then expand the **User-Defined Types** node. The following ELMs are defined as UDTs:

- ELMIN_MSLink
- ELMOUT_MSLink
- ELMIN_MSCCS
- ELMIN_IBMCCS
- ELMOUT_CCS

You can create a TRM or ELM template in COBOL to assist with your programming by exporting the TRM or ELM definition.

To create a TRM template in COBOL

1. Open Visual Studio.
2. On the **File** menu, point to **Open**, and then click **File**.
3. In the **Open File** dialog box, navigate to <drive>:\Program Files\Microsoft Host Integration Server\System\TIM\, and then click either **MicrosoftTRMDefs.tim** or **MicrosoftELMDefs.tim**.
4. On the **File** menu, click **Export Host Definition**.
5. In the **Export Host Definition** dialog box, type or select the file name, and then click **Save**.

You can substitute a custom TRM (or ELM) for the default TRM (or ELM) created by the TI runtime. Use the COMTIContext parameter to pass custom context data.

See Also

Tasks

How to Pass a Custom TRM

Concepts

Using Custom TRMs and ELMs with COMTIContext

Using Custom TRMs and ELMs with COMTIContext

Transaction Integrator (TI) developers can pass custom formatted transaction request messages (TRMs) or enhanced listener messages (ELMs) from a client program to the CICS system and receive custom formatted TRMs or ELMs.

Custom TRMs or ELMs are passed through context data. The context data is contained in the optional *COMTIContext* parameter defined in the client application code and must be the final parameter in the method call. A TRM destined for the host must be defined as a user-defined type (UDT) for the COM model, or a structure for the .NET Framework model. The name of the UDT must begin with the characters TRMIN. A TRM reply from the host must also be defined as a UDT. The name of the UDT must begin with the characters TRMOUT. Examples of valid TRM names are: TRMINMyVeryOwn, TRMINStandard, TRMOUTMyVeryOwn, and TRMOUTStandard.

The type library or structure can contain multiple TRM definitions, but you should include only one TRM for each direction (that is, one TRMIN and one TRMOUT) in the COMTIContext parameter in a single method call. For example, in Visual Basic each COMTIContext array is declared as a single dimension dynamic array of variants (that is, the number of occurrences is not specified).

If you define multiple TRMs for the same direction, the TI run time uses only the first TRM it encounters in the context array. (In some circumstances, the first TRM encountered might not always be the first one that you added to the context array). The TI run time ignores the remaining TRMs in the array until the TRM in use is destroyed. To ensure that the TI run time uses the correct TRM, do not add multiple TRMs intended for the same direction to a context array.

Note

The client application that manipulates the Context array must be able to access the appropriate file at run time. If you are using Visual Basic6.0, the application must be able to access COMTIContext.dll. If you are using Visual Basic .NET, the application must able to access Microsoft.HostIntegration.TI.ClientContext.dll.

Note

When you use Visual Basic .NET, the data structure used as a custom TRM must be associated to a parameter within the assembly. Therefore, you must create a dummy method within the assembly, a parameter assigned to the method, and the data structure to be used as the TRM. Failure to do so prevents you from referencing the structure within the Visual Basic .NET application. Associating a UDT to a method was not required in Visual Basic 6.0 because Visual Basic 6.0 allowed referencing of UDTs not associated with methods.

Host and Automation Data

The topics in this section cover issues around working with Windows-based Automation data and COBOL-based mainframe data.

In This Section

Variably Sized Data

A string or array parameter that is the last parameter in its direction (last of the inputs and in/outs or last of the outputs and in/outs) can be smaller than the maximum size specified, even without an associated actual size. The variable string or array must be a parameter or return value and cannot be contained in a recordset.

If the final field is an array, it can be an array of any type, including a recordset. If there is an unbounded output recordset, it is the only variably-sized data allowed because Transaction Integrator (TI) cannot handle two pieces of the data stream that are variable in size. If COBOL FILLER exists after the last parameter, that parameter cannot be variable in size.

Identify the possibility of variably sized data at design time in TI Project. In the Designer select the method whose parameter list contains the final field of string to be of variable size, and set the method property "Variable Sized Final Field" to true.

Host and Automation Data

Date and Time Parameters

Transaction Integrator (TI) converts and formats the **Date** and **Time** parameters exchanged with the host differently, depending on the programming language and the host platform.

You can use TI Project to set or change the properties of the **Date** parameter. The following table shows the formatting and valid separators for each **Host Data Type** in situations where the **Data Type** property of the parameter is set to **Date**.

Data Type Formats and Separators

Host Data Type	Format (default separator)	Valid separators	Length	Notes
DATE and TIME	yyyydddhhmmsss (two packed decimal fields)	None	8	None
DATE only (COBOL only)	yyyyddd (packed decimal)	None	4	(1) (2)
DATE only (RPG only *MDY)	mm/dd/yy	/-.,&	8	(5)
DATE only (RPG only *DMY)	dd/mm/yy	/-.,&	8	(5)
DATE only (RPG only *YMD)	yy/mm/dd	/-.,&	8	(5)
DATE only (RPG only *JUL)	yy/ddd	/-.,&	6	(5)
DATE only (RPG only *LONGJUL)	yyyy/ddd	None	8	None
TIME only (COBOL only)	hhmmsss (packed decimal)	None	4	(3) (4)
TIME only (RPG only *HMS)	hh:mm:ss	:.,&	8	None
ISO DATE and TIME	yyyy-mm-dd hh.mm.ss	space	19	None
ISO DATE only	yyyy-mm-dd	-	10	None
ISO TIME only	hh.mm.ss	.	8	None
USA DATE and TIME	mm/dd/yyyy hh:mm AM (or PM)	space	19	None
USA DATE only	mm/dd/yyyy	/	10	None
USA TIME only	hh:mm AM or hh:mm PM	:	8	None
JIS DATE and TIME	yyyy-mm-dd hh:mm:ss	space	19	None
JIS DATE only	yyyy-mm-dd	-	10	None
JIS TIME only	hh:mm:ss	:	8	None
EUR DATE and TIME	dd.mm.yyyy hh.mm.ss	space	19	None
EUR DATE only	dd.mm.yyyy	.	10	None
EUR TIME only	hh.mm.ss	.	8	None
TIMESTAMP	yyyy-mm-dd-hh.mm.ss.mmmm (length 26).	0001-01-01-00.00.00.000000	0001-01-01-00.00.00.000000	None

Where:

ISO = International Standards Organization

USA = IBM USA Standard

EUR = IBM European Standard

JIS = Japanese Industrial Standard Christian Era

Note
When a date is sent to the host, the host populates a seven-digit COMP-3 data type only with the Julian Date YYYYDDD and no other format.

Note
When a date is received from the host, the **Date** parameter must be packed as a valid Julian Date within a seven-digit COMP-3 data type.

Note
When a time is sent to the host, the host populates a seven-digit COMP-3 data type as HHMMSSS up to 100th of a second. For example, sending 01:12:03 AM populates the COMP-3 data type on the host with 0112030; sending 01:12:003 AM populates the COMP-3 data type on the host with 0112003.

Note
When a time is received from the host, the **Time** parameter must be packed within a seven-digit COMP-3 data type packed as HHMMSSS; data passed under any other format might not return the expected results.

Note
A two-digit year (yy) returned from the host is mapped to a four-digit year (yyyy) as follows:

00 to 39 is mapped as 20xx.

40 to 99 is mapped as 19xx.

Rounding occurs when TI receives the parameter from the host:

- The hour value of time rounds up the day of date.
- The minutes of time rounds up the hour of time.
- The first two digits of seconds influences the value of minutes.
- The third digit of second, or the one 1\100 value of seconds, does not influence the value of minutes. It would just be passed forward to the workstation and displayed.

For example:

- Assigning 1997001 to the host date field and 3701000 to the time field causes the workstation to display 01/02/1997 11:01:00 PM.
- Assigning 1197001 to the host date field and 0101610 to the time field causes the workstation to display 01/01/1997 01:02:01.
- Assigning 1197001 to the host date field and 0101619 to the time field, causes the workstation to display 01/01/1997 01:02:019.

Parameter Requirements

Requirements for the In, In/Out, and Out parameters might affect how you define a Transaction Integrator (TI) component or mainframe transaction program (TP). The In and In/Out parameters are sent to the mainframe-based TP from the TI Automation server. The Out and In/Out parameters are sent from the mainframe-based TP to the TI Automation server.

Best Parameter Order

The way parameters are ordered with regard to inputs and outputs determines the amount of data that must be transmitted, as well as the structure of the mainframe program. If you are creating a Transaction Integrator (TI) component in TI Project without importing COBOL code from a mainframe transaction program, place the parameters in the following order to minimize the amount of data transmitted:

- Input parameters
- Input/output parameters
- Output parameters

However, if you are using a CICS LINK LU 6.2, TCP TRM Link, or TCP ELM Link remote environment (RE) and importing COBOL data declarations into TI Project from an existing mainframe program, place the parameters in the order they appear in the COBOL data structure. In such a case, although the parameters are contained within the COMMAREA data structure, only the part of the COMMAREA containing the last input or input/output parameter is sent to the mainframe. The mainframe program is not affected by this ordering, but less data will be transmitted, especially in the case of small amounts of input data.

Maximum Amount of Parameter Data

The remote environment (RE) you use can affect the maximum possible message size. Programs associated with the CICS LINK LU 6.2, TCP TRM Link, or TCP ELM Link REs are limited by the maximum size of the COMMAREA (32,767 bytes). Therefore, the total byte size of all parameters cannot exceed 32 KB. Programs associated with distributed program call (DPC) are limited to a maximum of 65,500 bytes of user data. This maximum decreases as additional parameters are defined. DPC is limited to a maximum of 35 parameters.

The IMS Using LU 6.2 and CICS Using LU 6.2 REs have message size restrictions that, if exceeded, affect the programming logic in the mainframe program. Therefore, be careful not to exceed the limit if you use either of these REs.

Optional Metadata

As a developer, you can choose to have the Transaction Integrator (TI) run-time environment send and receive metadata to and from the mainframe transaction program (TP), and you can choose the content of that metadata.

Note
Metadata is not supported for distributed program call (DPC).

You can send or receive:

- No metadata.
- Only the method name as metadata.
- All metadata including the method name.

The TI run-time environment sends or receives metadata to or from the TP as instructed. Metadata assists the TP in:

- Identifying the format of the metadata (version information).
- Identifying the name of the method used to invoke the TP.
- Reporting detailed error information back to the client.

The metadata is not visible to the Automation client. The metadata is delivered to (or received from) the host TP as part of the request message sent to (or response message received from) the TP.

The metadata set includes the following data:

- TI run-time version.

  A string of characters, such as "Microsoft TI version 1.0.0," that uniquely identifies the TI run-time environment version that generated the request.

- Method name (32-character string) invoked by the client application code.
- Metadata block ID.

  A GUID, in character format, that uniquely identifies this block of exception data. The GUID supports the ability to have additional exception formats in the future and helps to ensure that any data received is valid.

- Variables with no assigned uses to date (reserved):
  - Boolean flag indicating whether the TP is ready to commit.
  - Boolean flag indicating whether the TP is ready to perform additional work.
  - Two Short Integers to hold pieces of the TI run-time environment version number, one Short Integer to hold the major version number and the other to hold the minor version number.
- Exception Block (used only in replies).

  A GUID, in binary format, that uniquely identifies this block of exception data. The GUID allows support of additional exception formats in the future and helps ensure the data received is valid:

- Boolean flag that indicates whether the TP is ready to commit.
- Boolean flag that indicates whether the TP is ready to perform additional work.
- Boolean flag that indicates whether an exception should be returned to the client application. If set, this flag also causes the transaction to quit.
- 16-bit integer that identifies the error (see the note later in this topic). You can assign this value, along with the 256-character message that describes the error, from the server so that the assigned value is returned when a TI run-time error occurs.
- 32-bit integer that identifies the context ID in the TP Help file (if any).
- 256-character message that describes the error. You can assign this value, along with the 16-bit integer that identifies the error from the server, so that the assigned value is returned when a TI run-time error occurs.

Metadata is always located at the beginning of the message.

Note

TI error messages have numbers in the range from 0 through 9999. Metadata error message numbers returned from the ma inframe can fall within the same range. To distinguish TI error messages from metadata messages returned from the mainfra me, TI adds 10000 to the number of any metadata error message returned from the mainframe.

Return Value Positioning

When an Automation method returns control to the calling application, it can return data as the method's value (as distinct from returning data as an output parameter). However, there is no analogous concept when you are dealing with a COBOL or Report Program Generator (RPG) data declaration.

Transaction Integrator (TI) allows you to select one of the data description entries in a data declaration that will be returned to the calling application. When you select an entry as the return value and that entry is not the first entry in the data declaration, the return value is said to be positioned after the parameters.

You can use this feature, for example, when your data declaration describes a table and you need to return a recordset on the Automation side. For example, if you are using Remote Data Service (RDS) to bind to a grid control for a Web application, your Automation method must return the recordset rather than define a parameter that represents an output recordset.

When you import host definitions, the Import COBOLor Import RPG Wizard provides a step that allows you to select data description entries as return values. If you are manually creating a method and you want the method's return value to be placed in a location other than at the front of the data declaration, you can specify the location on the **Advanced** tab of the method properties. Use the **Position return value after the parameter** drop-down list.

Data Transfer Options

You can use various options to transfer data to and from the mainframe transaction program (TP). These options apply to arrays, recordsets, and strings (or variable-length tables and display data in COBOL terms). The topics in this section describe each of the possible data transfer options. Choose the option that optimizes the amount of data to be transferred.

In This Section

- Using the OCCURS DEPENDING Clause to Define Variable-length Table
- Using Variably Sized Strings
- Using Variably Sized Rows
- Using Bounded Final Fields

Using the OCCURS DEPENDING Clause to Define Variable-length Table

In COBOL, you can use the OCCURS DEPENDING ON syntax to define a variable-length table in a data declaration. The storage for a variable-length table is dynamic, depending on the value in the length specifier variable. The amount of data passed is also dependent on the value in the length specifier variable: Only the number of elements specified are sent or received. The length specifier variable for a variable-length table must be a numeric type, and its direction must match the direction of the variable-length table it controls.

When you import COBOL into Transaction Integrator (TI) Project, and you specify variable-length tables as recordsets, the variable-length tables automatically become arrays or recordset objects whose size is limited by another parameter. The length specifier is exposed on the Automation side as a parameter and must be correctly set when the parameter is being sent to the host application.

To manually indicate that a parameter in a method is the length specifier for an array, first define the length specifier parameter, and then define the array or recordset parameter:

In the parameter property class to be defined as an ODO array, use the Designer to select the **Is Array** property. After **IsArray** is selected, the **Array Dimensions** and **Occurs depending on** property becomes available. Define the array's dimensions using the **Array Dimensions** property. Assign the ODO index to the parameter defined as the ODO array. Select the index by expanding the property **Occurs depending on**.

You can also manually indicate that a parameter in a method is the length specifier for a recordset parameter.

Follow the same steps as defined earlier; however, change the data type of the parameter from a simple data type to a recordset.

The following COBOL code shows a variable-length table:

```
01 CUSTOMER-DATA.
   05 CUSTOMER-NUMBER                PIC 9(9).
   05 LAST-NAME                      PIC X(20).
   05 FIRST-NAME                     PIC X(20).
   05 INVOICE-COUNT                  PIC 9(7) COMP-3.
   05 INVOICES OCCURS 50 TIMES DEPENDING ON INVOICE-COUNT.
      10 INVOICE-NUMBER              PIC 9(10).
      10 INVOICE-DATE                PIC 9(7) COMP-3.
      10 INVOICE-AMOUNT              PIC S9(13)V9(2) COMP-3.
      10 INVOICE-DESCRIPTION         PIC X(40).
```

The following is the method that is created when the previous COBOL is imported:

```
SendInvoices(lCustomerNo As Long, strLastName As String, strFirstName As String _
    , lcInvoices As Long) As Object
```

The following is an example of Microsoft® Visual Basic® code that calls an imported method:

```
Dim objCustomer As Object   'Uses late binding
Dim objInvoices As ADODB.Recordset
Dim lCustomerNumber As Long
Dim iRow As Integer
Dim iCol As Integer
Dim strLastName As String
Dim strFirstName As String

'create an instance of the invoicing object
On Error GoTo ErrorHandler1
Set objCustomer = CreateObject("Customer.Invoicing.1")

lCustomerNumber = CLng(txtCustomerNumber)
```

```
'invoke the GetInvoices method
On Error GoTo ErrorHandler2
Set objInvoices = objCustomer.GetInvoices(lCustomerNumber _
    , strLastName, strFirstName)
'
' Transfer the Recordset data to a variant array in a single operation.
' This is efficient, but may not be suitable for larger Recordsets.
'
Dim Data As Variant

Data = objInvoices.GetRows
grdInvoices.Rows = UBound(Data, 2) + 1
grdInvoices.Cols = UBound(Data, 1) + 1
```

Using Variably Sized Strings

When the last input parameter or the last output parameter in a method is a string, that string can be variably sized. Its size can vary from 0 to the maximum number of bytes specified for its length. When the return value is a string and it is positioned after all other output parameters, it can be the variably sized final output field.

The string must be sent or received last if it is to be variably sized. Otherwise, there is no reliable way to determine the end of a variably sized string and the next data item in the buffer. The logic of the host application sends only the data for the part of the string that is needed.

COBOL never sets the variably sized option for strings. To set this property manually, set the **Variable Sized Final Field** property to be variable. The property **Variable Sized Final Field** is subdivided into two parts by direction. Set the direction you want to true.

The following COBOL example has as its last data item a large string that could be optimized by sending only the size of the string:

```
01 CUSTOMER-DATA.
   05 CUST-HEADER.
      10 CUSTOMER-NUMBER             PIC 9(9).
      10 LAST-NAME                   PIC X(20).
      10 FIRST-NAME                  PIC X(20).
   05 COMMENTS                       PIC X(4096).
```

When imported, this COBOL code creates the following method:

```
CustomerInformation(lCustomerNo As Long,_
                    strLastName As String,_
                    strFirstName As String,-
                    strComments As String)
```

The following Visual Basic code calls the method:

```
Dim objCustomer As Object
    Dim lCustomerNo As Long
    Dim strLastName As String
    Dim strFirstName As String
    Dim strComments As String

    lCustomerNo = 100231

    'create an instance of the invoicing object
    On Error GoTo ErrorHandler1
    Set objCustomer = CreateObject("Customer.Invoicing.1")

    'invoke the SetInvoices method
    On Error GoTo ErrorHandler2
    objCustomer.CustomerInformation lCustomerNo, strLastName _
        , strFirstName, strComments
```

Using Variably Sized Rows

When the last column in a record is a string, the row can be variably sized. Its size can vary between zero and the maximum size specified in the picture clause. When you have variably sized rows, your application must explicitly specify the size of each row before the row is sent.

The actual size field is not visible on the Automation side. The Transaction Integrator (TI) run-time environment uses Automation services to determine the size of input data. When the TI run-time environment sends data to the host, it automatically sets the actual size field.

The Import COBOL Wizard never creates a recordset that has variably sized rows. Bring up properties for the recordset that contains the variably sized rows. The **Variable sized rows** property allows user to manually configure this option for a specific recordset. The **Variable sized rows** property offers advanced options. You can specify that the actual row size variable is a half-word or full-word binary. The actual size variable will include itself or will only include the size of the row.

The following COBOL example shows how the host application sends variably sized rows. The length field is included in the row size:

```
01  CUSTOMER-DATA.
    05  CUSTOMER-NUMBER                PIC 9(9).
    05  LAST-NAME                      PIC X(20).
    05  FIRST-NAME                     PIC X(20).
    05  INVOICE-COUNT                  PIC 9(7) COMP-3.
    05  INVOICES OCCURS 50 TIMES DEPENDING ON INVOICE-COUNT.
        10  INVOICE-DATA.
            15  INVOICE-ROW-SIZE       PIC S9(4) COMP.
             15  INVOICE-NUMBER         PIC 9(10).
             15  INVOICE-DATE           PIC 9(7) COMP-3.
             15  INVOICE-AMOUNT         PIC S9(13)V9(2) COMP-3.
         10  INVOICE-DESCRIPTION        PIC X(4096).
.
.
.
           MOVE LENGTH OF CUSTOMER-DATA TO SEND-LENGTH.
           SUBTRACT LENGTH OF INVOICES FROM SEND-LENGTH.
           EXEC-CICS SEND FROM(CUSTOMER-DATA)
                          LENGTH(SEND-LENGTH)
                          END-EXEC.

           PERFORM VARYING ROW FROM 1 BY 1 UNTIL ROW > INVOICE-COUNT
               INSPECT INVOICE-DESCRIPTION TALLYING INVOICE-ROW-SIZE
                   FOR CHARACTERS BEFORE INITIAL '   '
               ADD LENGTH OF INVOICE-DATA TO INVOICE-ROW-SIZE
               EXEC-CICS SEND FROM(INVOICE-ROW-SIZE)
                              LENGTH(2)
                              END-EXEC
               EXEC-CICS SEND FROM(INVOICES(ROW))
                              LENGTH(INVOICE-ROW-SIZE)
                              END-EXEC
           END-PERFORM.
```

The following COBOL example shows how the host application sends variably-sized rows. The length field is not included in the row size:

```
       01  CUSTOMER-DATA.
          05  CUSTOMER-NUMBER                PIC 9(9).
          05  LAST-NAME                      PIC X(20).
          05  FIRST-NAME                     PIC X(20).
          05  INVOICE-COUNT                  PIC 9(7) COMP-3.
          05  INVOICE-ROW-SIZE               PIC S9(4) COMP.
         05  INVOICES OCCURS 50 TIMES DEPENDING ON INVOICE-COUNT.
             10  INVOICE-DATA.
                  15  INVOICE-NUMBER         PIC 9(10).
                  15  INVOICE-DATE           PIC 9(7) COMP-3.
```

```
                15  INVOICE-AMOUNT           PIC S9(13)V9(2) COMP-3.
              10  INVOICE-DESCRIPTION         PIC X(4096).
.
.
.
           MOVE SIZE OF CUSTOMER-DATA TO SEND-LENGTH.
           SUBTRACT LENGTH OF INVOICES FROM SEND-LENGTH.
           SUBTRACT LENGTH OF INVOICE-ROW-SIZE FROM SEND-LENGTH.
           EXEC-CICS SEND FROM(CUSTOMER-DATA)
                          LENGTH(SEND-LENGTH)
                          END-EXEC.

           PERFORM VARYING ROW FROM 1 BY 1 UNTIL ROW > INVOICE-COUNT
               INSPECT COMMENTS TALLYING INVOICE-ROW-SIZE
                   FOR CHARACTERS BEFORE INITIAL '   '
               ADD LENGTH OF INVOICE-DATA TO INVOICE-ROW-SIZE
               EXEC-CICS SEND FROM(INVOICE-ROW-SIZE)
                              LENGTH(LENGTH OF INVOIVE-ROW-SIZE)
                              END-EXEC

               EXEC-CICS SEND FROM(INVOICES(ROW))
                              LENGTH(INVOICE-ROW-SIZE)
                              END-EXEC
           END-PERFORM.
```

Tasks

Using the OCCURS DEPENDING Clause to Define Variable-length Table

Using Variably Sized Strings

Using Bounded Final Fields

Using Bounded Final Fields

When the last input or the last output parameter in a method is an array or recordset, that parameter can be bounded. Its size can vary from 0 to the maximum number of elements or rows specified. The array or recordset must be last to be bounded. Otherwise, there is no reliable way to determine the end of a bounded array or recordset and the beginning of the next field in the buffer. The host application must take care of sending the truncated table.

The Automation client handles this option automatically. The Transaction Integrator (TI) run-time environment sends a truncated amount of data based on the Automation bounds and detects the truncated data and creates the appropriate Automation type when data is received.

The Import COBOL Wizard never sets the bounded option for arrays or recordsets. To set this manually for the final parameter in a method, use the Designer to assign a value to the property **Maximum Occurrence**. This field defines the maximum number of rows the recordset may contain. On the method containing the recordset, set the property **Variable Sized Final Field** to true by direction to make the recordset bounded.

If the method contains a recordset that is unbounded, you cannot also specify a bounded or variably-sized final field for that direction. For example, if Parameter1 is an output parameter, and it is an unbounded recordset, the final output parameter cannot be a bounded array or recordset or variably-sized string. When the return value is positioned after all other output parameters, the return value can be the bounded final output field.

The following COBOL example sends only some of the rows in a recordset:

```
01  INVOICE-COUNT                        PIC S9(4) COMP.
01  CUSTOMER-DATA.
    05  CUSTOMER-NUMBER                  PIC 9(9).
    05  LAST-NAME                        PIC X(20).
    05 INVOICES OCCURS 50 TIMES.
               10  INVOICE-NUMBER              PIC 9(10).
               10  INVOICE-DATE                PIC 9(7) COMP-3.
               10  INVOICE-AMOUNT              PIC S9(13)V9(2) COMP-3.
.
.
.
            MOVE SIZE OF CUSTOMER-DATA TO SEND-LENGTH.
            SUBTRACT LENGTH OF INVOICES FROM SEND-LENGTH.
            EXEC-CICS SEND FROM(CUSTOMER-DATA)
                           LENGTH(SEND-LENGTH)
                           END-EXEC.
            PERFORM VARYING I FROM 1 BY 1 UNTIL I = INVOICE-COUNT
                COMPUTE SEND-LENGTH = LENGTH OF INVOICE-NUMBER +
                                      LENGTH OF INVOICE-DATE +
                                      LENGTH OF INVOICE-AMOUNT
                EXEC-CICS SEND FROM(INVOICES(I))
                               LENGTH(SEND-LENGTH)
                               END-EXEC.
            END-PERFORM.
```

Mainframe Character Strings and Code Pages

When Transaction Integrator (TI) sends data to a mainframe-based transaction program (TP), the TI run-time environment transforms Unicode strings received as parameters, fields, or columns into mainframe character strings. Likewise, when it receives data from a mainframe TP, the TI run-time environment converts the mainframe character strings into Unicode strings to be returned as output values to the calling client application.

TI categorizes these strings of characters sent to and received from the mainframe as follows:

- Extended Binary Coded Decimal Interchange Code (EBCDIC) strings.
- IBM double-byte character set (DBCS) strings.
- Intermixed strings containing both EBCDIC and IBM DBCS strings with the necessary shift-out (SO) and shift-in (SI) characters.

The TI run-time environment determines the type of mainframe character string based on the following information:

- How the parameter, field, or column is defined in the TI component that was built by using TI Project.
- The code page defined for the specific remote environment (RE) that was associated with the active TI Automation server when it was deployed. When you create an RE in TI Manager, you specify a code page for that RE.

In This Section

How to Assign a Different Code Page to a Remote Environment

Use a remote environment (RE) to describe each CICS or IMS mainframe environment. Use Transaction Integrator (TI) Manager to create, modify, and delete REs.

Every RE description includes a property value for the code page that is to be used by the TI run-time environment to convert characters to and from mainframe data representations.

When you create a new RE, TI Manager automatically selects a code page based on the current system locale. However, you can replace this default value with a code page that you select.

As needed, you can use TI Manager to assign a different code page to any RE.

To select a different code page for an RE

1. On the **Start** menu, point to **Programs**, then **Microsoft Host Integration Server 2009**, and then click **TI Manager**.
2. Expand the **Remote Environments** node.
3. Right-click the remote environment to be modified, and then click **Properties**.
4. On the **Locale** tab, clear the check box **Use default code page for the selected locale**.
5. On the **Locale** tab, select the new code page from the **Code page** dropdown list.

Only the code page value is significant to the TI run-time environment when it converts character data. Although you can use the locale displayed on the **Locale** property page to select the code page, the TI run-time environment ignores it and uses only the code page value that is associated with that locale.

Mainframe Character Strings and Code Pages

IBM DBCS Code Pages

Transaction Integrator (TI) recognizes the following code pages as IBM double-byte character set (DBCS) code pages:

Code page	Description
930	IBM Extend Katakana and IBM Japanese (for Japan)
931	IBM English lower case and IBM Japanese (for Japan)
933	IBM Hungle Extend single-byte and IBM Hungle (for Korea)
935	IBM English single-byte and IBM simplified Chinese (for PRC)
937	IBM English single-byte and IBM traditional Chinese
939	IBM English Extend lower case and IBM Japanese (for Japan)

All other code pages delivered with Host Integration Server 2009 are handled as Extended Binary Coded Decimal Interchange Code (EBCDIC) code pages, which use a single byte to represent a character.

When the TI run-time environment converts UNICODE characters to DBCS characters, it uses standard Microsoft Windows NLS code pages.

The following table lists the DBCS code pages and their corresponding NLS code pages.

DBCS code page	NLS code page required by TI
930	932 ANSI Japan
931	932 ANSI Japan
933	949 ANSI Korean
935	936 ANSI Chinese (China, Singapore)
937	950 ANSI Chinese
939	932 ANSI Japan

The list of code pages on the **Locale** property page for a remote environment includes a DBCS code page only if the corresponding NLS code page is loaded on the computer. The following code pages have been added for European support.

Code page	IBM or open systems name	Display name
923	ISO 8859-15 Latin 9 (Euro)	Latin-9 (Euro)
924	IBM Latin - 1/Open System	Latin-1 Open System (Euro)
858	OEM - Multilingual Latin 1 (Euro)	OEM - Multilingual Latin 1 (Euro)
1140	IBM EBCDIC - U.S./Canada (Euro)	U.S./Canada (Euro)
1141	IBM EBCDIC - Germany (Euro)	Germany (Euro)
1142	IBM EBCDIC - Denmark/Norway (Euro)	Denmark/Norway (Euro)

Mainframe Character Formats

In Transaction Integrator (TI) Project, you can specify the mainframe character format that the TI run-time environment will create when sending data to the mainframe. There are two mainframe character formats supported by TI:

- PIC X(n) COBOL, or RPG A
- PIC G(n) COBOL, or RPG G

When you create string parameters, fields, or columns in TI Project, the PIC X(*n*) or RPG A data type format is selected automatically.

If necessary, you can use the **Properties** command to change the mainframe character format.

If you select the PIC X or RPG A format for a string, the TI run-time environment converts this string to either an Extended Binary Coded Decimal Interchange Code (EBCDIC) character string or an intermixed character string. Specifically, if the TI component you define in TI Project is assigned to a remote environment (RE) with an EBCDIC code page, the TI run-time environment converts a string that has a PIC X or RPG A format into an EBCDIC string. If the TI component's RE identifies a double-byte character set (DBCS) code page, the TI run-time environment converts a string that has a PIC X format as an intermixed string (not supported for RPG).

If you select the PIC G or RPG G format for a string, the TI run-time environment always converts the string into a DBCS string. Therefore, any TI component that uses a string with a PIC G or RPG G format must be assigned to an RE that has a DBCS code page.

If a TI component using a string with a PIC G or RPG G format is assigned to an RE that has an EBCDIC code page, the TI run-time environment reports a conversion error when it attempts to convert the string to or from the PIC G or RPG G format. The TI run-time environment places an error message describing this conversion problem in the Windows Event Log, and it returns an error to the invoking client application.

The following table summarizes how the selection of string format and code page controls the type of character conversion performed by the TI run-time environment.

String format	EBCDIC code page	DBCS code page
PIC X or RPG A	EBCDIC string	Intermixed string
PIC G or RPG G	TI run-time environment reports conversion errors.	DBCS string

String Dimension Values

The meaning of a string's dimension (the *n* part of the PIC X(n) or RPG A(n) and the *n* part of the PIC G(n) or RPG G(n) formats) is based on the character format in use. You specify a string's dimension on the **COBOL Definition** property page in Transaction Integrator (TI) Project.

- The dimension value for a string with a PIC G or RPG G format gives the number of double-byte characters that are used in the mainframe representation of the string. No SO and SI character pair is added when a string with a PIC G or RPG G format is converted.
- The dimension value for a string with a PIC X or RPG A format gives the number of bytes that are used in its mainframe representation. The number of characters that can be placed into or taken from a PIC X or RPG A formatted string varies depending on the number of :
    - Double-byte character set (DBCS) characters, each of which requires two bytes of storage.
    - SO and SI character pairs needed. Each two-byte pair must encapsulate each contiguous stream of DBCS characters.

Developers using TI must take into account this variability in the size of an intermixed string when they specify dimension values in TI Project.

The number of bytes for a string converted using an EBCDIC code page with a PIC X or RPG A format is identical to the number

of characters because there are no DBCS characters in the string.

However, for a string converted using a DBCS code page with a PIC X or RPG A format, the actual number of characters that can be placed in a given number of bytes varies. For example, if the conversion to or from UNICODE does not require the use of DBCS characters (that is, no SO and SI character is used in the mainframe string), each character occupies a single byte. However, if DBCS characters do appear within the mainframe string, the SO and SI character pairs are needed.

How the Import Wizard Defines Strings

When you use Transaction Integrator (TI) Project's Import wizard to import a host definition to create new methods and recordsets, the wizard selects the mainframe character format based on the imported host definition. The following table shows how the wizard maps different COBOL declarations to a string.

COBOL type	**Type of string created**
PIC X(*n*) or RPG A	String of size *n* bytes
PIC G(*n*) or RPG G	String of size *n* characters

How to Pad Mainframe Character Strings with Spaces

You can define the properties for a string such that the Transaction Integrator (TI) run-time environment adds space characters to pad the mainframe representation of the string instead of depending on a null termination character.

To use either a space character or null termination character

1. In Microsoft Visual Studio, right-click the object, and then click **Properties**.
2. Under **Host Data Type Information** in the **Properties** pane, click **String Delimiting**.
3. Select either **Space Padded** or **Null Terminated**.

The following table describes what happens with each delimiting option (**Space Padded** or **Null terminated**) when converting to the type of string indicated.

Type of string operation	**What happens for each type of string delimiting operation**
Conversion to EBCDIC string	**Space Padded.** The TI run-time environment adds single-byte space characters to the end of the string until all bytes in the PIC X formatted string are filled.
	Null terminated. The TI run-time environment adds a single null character to the end of the string if there is room in the PIC X count for the byte.
Conversion from EBCDIC string	**Space Padded.** The TI run-time environment strips single-byte space characters from the end of the string.
	Null terminated. The TI run-time environment scans from the beginning of the string and stops the conversion at the first null character it encounters in the string.
Conversion to DBCS string	**Space Padded.** The TI run-time environment adds double-byte space characters to the end of the string until all characters in the PIC G formatted string are filled.
	Null terminated. The TI run-time environment adds a double-byte character set (DBCS) null character to the end of the string if there is room in the PIC G count for the bytes.
Conversion from DBCS string	**Space Padded.** The TI run-time environment strips double-byte space characters from the end of the string.
	Null terminated. The TI run-time environment scans from the beginning of the string and stops the conversion at the first DBCS null character it encounters in the string.
Conversion to Intermixed string	**Space Padded.** The TI run-time environment adds single-byte space characters to the end of the string until all bytes in the PIC X formatted string are filled. If the terminating character in the UNICODE string maps to a DBCS character, the TI run-time environment adds an SI character before it adds the space characters.
	Null terminated. The TI run-time environment adds a single byte null character to the end of the string if there is room in the PIC X count. If the terminating character in the UNICODE string maps to a DBCS character, the TI run-time environment adds an SI character before it adds the null character.

Conversion from Intermixed string	**Space Padded.** The TI run-time environment strips the terminating single-byte and double-byte space characters from the end of the string. When it strips the space characters, the TI run-time environment treats any terminating SI character as if it were a space.
	Null terminated. The TI run-time environment scans from the beginning of the string and stops the conversion at the first null character (of either width) it encounters.

Special handling occurs for a string that is last in the host buffer and that is flagged as *last is variable*. For example:

- **Space Padded.** Upon conversion to an Extended Binary Coded Decimal Interchange Code (EBCDIC) string, the string is terminated by the length count of the containing buffer, so it contains no additional space characters. Upon conversion from an EBCDIC string, the buffer is considered terminated by the length count of the containing buffer; then the string is examined for blank padding. The host can send this string blank padded beyond the significant data or not blank padded but with the last significant character of the string in the last position in the containing buffer. The space character is determined by the type of string (single, double, or intermixed).

- **Null terminated.** Upon conversion to an EBCDIC string, the string is sent as is. The TI run-time environment checks the length of the string, and then checks that the exact number of characters is sent. In other words, the number of characters sent is equal to the length of the string. No null terminator or spaces are appended to the end of the string.

The following tables show how string delimiting works when the **String delimiting** property is set to **Space Padded** versus **Null terminated** in combination with the variable size setting. All examples assume the mainframe data declaration as PIC X(5). "b" represents a space,"?" represents unassigned data, and "\0" represents a null.

String delimiting set to Space Padded and variable size not active

Workstation	Direction	Mainframe
ABC\0	To Host	'ABCbb'
ABCb	To Host	'ABCbb'
CBA	From Host	'CBAbb'
CBA\0?	From Host	'CBA\0?'
CBA\0	From Host	'CBA\0b'

String delimiting set to Space Padded and variable size active

Workstation	Direction	Mainframe
ABC\0	To Host	'ABC'
Abb	To Host	'Abb'
CBA	From Host	'CBAbb'
CBA\0?	From Host	'CBA\0?'
CBA\0	From Host	'CBA\0b'

String delimiting set to Null terminated and variable size not active

Workstation	Direction	Mainframe
ABC\0	To Host	'ABC\0?'
ABC	From Host	'ABC\0?'
ABCbb	From Host	'ABCbb'

ABC	From Host	ABC\0\0'

String delimiting set to Null terminated and variable size active

Workstation	Direction	Mainframe
ABC\0	To Host	'ABC\0'
ABC	From Host	'ABC\0?'
ABCbb	From Host	'ABCbb'
ABC	From Host	ABC\0\0'

Truncating Undefined Portions of Strings

You can define the properties for a string such that the Transaction Integrator (TI) run-time environment truncates undefined characters when it converts UNICODE strings to mainframe data representations instead of generating an error message. To do so, click **Truncate** under **Error handling** on the string's **Host Definition** tab (property page) in TI Project.

When truncation is turned on, the TI run-time environment limits the number of characters to the string's previously specified dimension value when it converts a character string to an Extended Binary Coded Decimal Interchange Code (EBCDIC) or double-byte character set (DBCS) character string.

When it converts to intermixed strings, the TI run-time environment ensures that all shift-out (SO) characters have matching shift-in (SI) characters. It adds a terminating SI character when truncation occurs in the middle of a contiguous stream of DBCS characters. Also, the TI run-time environment ensures that it does not leave a partial DBCS character when it adds the SI character.

If blank padding and truncation are specified for a string, the TI run-time environment might need to add an EBCDIC space character after a terminating SI character is added.

Converting Data Types from OS/390 COBOL to Automation

Adding Leading SO and Trailing SI Characters

For PIC G formatted strings, you can instruct the Transaction Integrator (TI) run-time environment to add a leading shift-out (SO) character and a trailing shift-in (SI) character by selecting the **Add Leading SO and Trailing SI** check box on the string's **COBOL Definition** tab (property page) in TI Project.

If the **Add Leading SO and Trailing SI** check box is selected, the TI run-time environment handles two additional bytes in the mainframe data structure used for describing the double-byte character set (DBCS) string. When it formats a message sent to the mainframe, the TI run-time environment adds the leading SO and trailing SI bytes. When it interprets a message received from the mainframe, the TI run-time environment discards the leading SO and the trailing SI bytes.

The dimension value of the PIC G string always specifies the number of double-byte DBCS characters in the strings, regardless of the presence or absence of the surrounding SO and SI characters.

The use of this automatic SO and SI handling is hidden from the client application. However, the mainframe application must ensure that the appropriate PIC X declarations surround the declaration of the PIC G string.

TI Project generates the appropriate declarations for the surrounding SO and SI bytes, as shown in the following sample code:

```
01     A-SOSI-WRAPPED-DBCS.
       05  LEADING-SO-1                          PIC X.
       05  MY-DBCS-STRING                        PIC G(80).
       05  LEADING-SI-1                          PIC X.
```

The Import COBOL Wizard in TI Project does not set the option to add leading SO and trailing SI bytes. In other words, the Import COBOL Wizard places no significance on the presence of PIC X declarations surrounding a PIC G string. If an existing mainframe transaction program (TP) uses COBOL declarations that contain explicit declarations for SO and SI characters that wrap PIC G strings, you must manually modify the interface created by the Import COBOL Wizard.

Maximum Buffer Sizes for Remote Environments

Both Transaction Integrator (TI) and mainframe applications must be designed not to exceed the following buffer size or transfer limitations:

TCP Transaction Request Message (TRM) Link

The maximum buffer size for input/output is 32767 bytes. This limit is defined by the maximum allowable size of the COMMAREA.

TCP Enhanced Listener Message (ELM) Link

The maximum buffer size for input/output is 32767 bytes. This limit is defined by the maximum allowable size of the COMMAREA.

TCP Transaction Request Message (TRM) User Data

The buffer size for input/output is unlimited.

TCP Enhanced Listener Message (ELM) User Data

The buffer size for input/output is unlimited.

IMS Connect (TCP/IP)

The maximum segment size that TI can send to IMS is 32754 bytes. This limit is defined by the total number of bytes (32767) in an IMS message segment minus the following number of bytes:

- 2 bytes for the LL (Length field).
- 2 bytes for the ZZ (Control Information field).
- 9 bytes for the maximum TRANCODE.

The total amount of data that can be sent to, or received from, an IMS server program using the TCP/IP IMS Connect programming model is unlimited.

IMS Implicit (TCP/IP)

The buffer size for input is from 1 through 32755 bytes. In other words, the IMS Assist Module rejects a request with zero bytes of user data, and the IMS Listener rejects a request with more than 32755 bytes of user data.

The buffer size for output is from 0 through 32755 bytes. The IBM IMS default Listener enforces the limit of 32755 bytes of input/output data. The IBM IMS Assist Module enforces the required minimum of 1 byte of input.

IMS Explicit (TCP/IP)

The buffer size for input/output is unlimited.

OS/400 Distributed Program Calls (DPC)

The total buffer size is 65535 bytes and is reduced by the required headers. The send requires 23 bytes of header.

Each parameter, of either direction, requires 12 bytes of overhead on the send. Each in\out or out parameter requires 12 bytes of overhead within memory on the return trip.

CICS LINK LU 6.2

The maximum buffer size for input/output is 32767 bytes. This limit is defined by the maximum allowable size of the COMMAREA.

CICS User Data LU 6.2

The buffer size for input/output is unlimited. However, if the size of the input buffer is greater than 32 KB, TI sends the data in multiple chunks of 32 KB. In such a case, the mainframe application must do multiple receives to gather all the input data.

IMS Using LU 6.2

The maximum segment size that TI will send to IMS is 32754 bytes. This limit is defined by the total number of bytes (32767) in

an IMS message segment minus the following number of bytes:

- 2 bytes for the LL (Length field).
- 2 bytes for the ZZ (Control Information field).
- 9 bytes for the maximum TRANCODE.

The total amount of data that can be sent to, or received from, an IMS server program that uses LU 6.2 is unlimited.

Alignment Problems with Generated COBOL

COBOL aligns data elements at the 01 level on double-word boundaries. This practice causes a potential problem in CICS non-DPL applications that use TI-generated data declarations along with error metadata. If you code your COBOL application to receive the error metadata and the input parameters in one RECEIVE, the parameters are placed immediately adjacent to the metadata in memory. However, because the error metadata does not end on a double-word boundary, this action puts the parameters 4 bytes ahead of where the COBOL code expects them.

You can prevent this problem. When you click either the **Include method name** or the **Include all information** option under **Meta data** on the **Advanced** tab of a method's property page, verify that the mainframe program issues two RECEIVE commands to handle incoming data for the method. The first RECEIVE pulls in the metadata block, and the second RECEIVE pulls in the data for the method. When COBOL is generated for the method, an additional 01 block is generated for the metadata. When the **Include all information** option is selected, you are also expected to create an additional SEND for the metadata before sending the method data back to the Automation client application.

FILLER for Discontiguous Output Area and Return Value

COBOL FILLER

If COBOL data declarations that are imported into Transaction Integrator (TI) Project contain a COBOL FILLER clause or clauses, space is allocated in the message so that the filler is represented correctly for the mainframe program's data alignment. The filler is hidden from the Automation interface.

Concepts

FILLER Optimization

Other Resources

Filler

TI Application Cannot Reference FILLER

There are at least three possible causes for why the application cannot reference FILLER data:

- Mainframe or COBOL specifics.
- Automation specifics.
- Procedure using TI Project.

The following provides details of these three causes.

Mainframe or COBOL Specifics

When a FILLER keyword is encountered in the import process, the Transaction Integrator (TI) run-time environment adjusts the offset for the position of the data that follows the filler in a send or receive buffer by the length of the filler. This leaves untranslated gaps in the buffers that are sent to (or received from) the host and allows your data to overlay correctly onto the data declaration that describes it.

Automation Specifics

The Automation method does not reference the filler data description entries.

Procedure Using TI Project

The filler that is at the start of a data declaration is associated with a method, recordset, datatable, user-defined type (UDT), or .NET structure. You can view or change filler that is associated with a method from the **Advanced** tab of the method's properties page. To view or change a filler that is associated with a method, recordset, or UDT, right-click the method, recordset, or UDT, and then click **Properties**.

Filler that follows a data description entry is associated with the data description entry (or parameter for methods, column for recordsets, or member for UDTs). You can view or change filler that is associated with a parameter, column, or member from the **COBOL Definitions** tab of the parameter, column, or member properties. When filler follows the data description entry that you have specified as the return value, you can view or change that filler from the **COBOL Definitions** tab of the method's properties.

The following example shows a COBOL data declaration that uses FILLER:

```
01 CUSTOMER-DATA.
   05 CUSTOMER-INFO.
      10 LAST-NAME               PIC X(20).
      10 FIRST-NAME              PIC X(20).
      10 FILLER                  PIC X(12).
   05 DEMOGRAPHICS.
      10 DEMO-AGE                PIC 999.
      10 DEMO-INCOME             PIC S9(9)V99 COMP-3.
      10 DEMO-SEX                PIC X.
      10 DEMO-MSTATUS            PIC X.
      10 FILLER                  PIC X(40).
```

The resulting method is:

```
CustomerDemographics(strLastName As String, strFirstName As String, iAge As Integer _
    , curIncome As Currency, strSex As String, strMStatus As String)
```

The following is an example of the Visual Basic code that calls the method:

```
Dim objCustomer As Object
    Dim strLastName As String
    Dim strFirstName As String
    Dim iAge As Integer
```

```
    Dim curIncome As Currency
    Dim strSex As String
    Dim strMStatus As String

    strLastName = "Doe"
    strFirstName = "John"

    'create an instance of the invoicing object
    On Error GoTo ErrorHandler1
    Set objCustomer = CreateObject("Customer.Invoicing.1")

    'invoke the SetInvoices method
    On Error GoTo ErrorHandler2
    objCustomer.CustomerDemographics strLastName, strFirstName _
        , iAge, curIncome, strSex, strMStatus
```

Filler

How to Use REDEFINES in COBOL

The COBOL import process in Transaction Integrator (TI) Project recognizes the REDEFINES clause in a data description entry and correctly associates the redefining entries with the redefined entry. You must select one of the redefined or redefining clauses as the entry that represents the data that will be transmitted.

The redefining entries can use less space than the redefined entry. If you select a redefining entry that is smaller than the redefined entry, TI Project automatically adds filler so that the data will correctly overlay the data description when it is sent to the host. If the redefining entry represents a table with multiple fields, the last field contains the filler.

The following COBOL example shows a REDEFINES clause. The redefining clause was selected during import:

```
01 CUSTOMER-DATA.
   05 CUSTOMER-ID                          PIC X(10).
   05 CUSTOMER-ID-PARTS REDEFINES CUSTOMER-ID.
      10 LOCATION                          PIC X(3).
      10 NAME-ABREV                        PIC X(5).
```

The resulting method that is imported is:

```
CreateCustomerID(strLocation As String, strNameAbrev As String)
```

The COBOL generated for this method is:

```
01 CREATECUSTOMERID-INPUT-AREA.
   05 LOCATION              PIC X(3).              INPUT
   05 NAME-ABREV            PIC X(5).              INPUT
   05 FILLER                PIC X(2).              INPUT
```

The FILLER is added to the CUSTOMER-ID redefined area. When this FILLER occurs at the end of send or receive buffers, for performance reasons it is not sent.

The following is an example of Visual Basic code that calls this method:

```
    Dim objCustomer As Object
    Dim strLocation As String
    Dim strNameAbrev As String

    strLocation = "101"
    strNameAbrev = "SPORT"

    'create an instance of the invoicing object
    On Error GoTo ErrorHandler1
    Set objCustomer = CreateObject("Customer.Invoicing.1")

    'invoke the CreateCustomerID method
    On Error GoTo ErrorHandler2
    objCustomer.CreateCustomerID strLocation, strNameAbrev
```

Other Resources

Filler

FILLER Optimization

The Transaction Integrator (TI) run-time environment optimizes buffers sent to the host by not sending the bytes corresponding to FILLER that appear at the end of the input data declaration.

In a CICS LU 6.2 environment, use both the MAXLENGTH and NOTRUNCATE options on the RECEIVE statement when the TI run-time environment receives an input area that contains FILLER as the last data item description. However, this requirement does not apply to CICS LINK and IMS transaction programs.

Other Resources

Filler

FILLER for Discontiguous Output Area and Return Value

If the return value is discontiguous from the output area, you must calculate and manually specify the filler between the return value and the output area.

The following example shows the calculation for the filler from the original COBOL that goes into the Import Wizard (the byte counts on the right are added as an illustration):

```
01  OUTPUT-AREA.
           05  SELECTED-OUTPUT-AREA.
               10  FIELD1                      PIC S9(4)       COMP.     [2 Bytes]
               10  FIELD2                      PIC S9(9)       COMP.     [4 Bytes]
           05  DISCONTIG-UNSELECTED-AREA.
               10  NOTSELECTED                 PIC X(10).                 [10 Bytes]
               10  ALSO-NOTSELECTED            PIC S9(9)       COMP.     [4 Bytes]
           05  RETVAL                          PIC S9(9)       COMP.     [4 Bytes]
```

In this case, because the return value follows the output area, filler must be added to the last output parameter. To do this, perform the following steps.

1. Unlock the method.
2. In the details pane, click **FIELD2**.
3. On the **File** menu, click **Properties**, and then click the **COBOL Definition** tab.
4. In the **From Host** box, type 14 as the trailing filler.
5. Click **OK**.

To verify your modified code, in **TI Project**, use the **Export** command on the **File** menu. You can then see your code in Notepad.

The following is the output with the added filler:

```
       01  DISCONTIGCBL-OUTPUT-AREA.
           05  LL                           PIC S9(4) COMP.         OUTPUT     [2 Bytes
]
           05  ZZ                           PIC S9(4) COMP.         OUTPUT     [2 Bytes
]
           05  FIELD1                       PIC S9(4) COMP.         OUTPUT     [2 Bytes
]
           05  FIELD2                       PIC S9(9) COMP.         OUTPUT     [4 Bytes
]

           05  RETVAL                       PIC S9(9) COMP.         OUTPUT     [4 Bytes
]
```

Variable-length Tables and CICS LINK

When an OCCURS clause describes a variable-length table in the CICS LINK environment, the storage that the table uses on the host varies depending on the value of the length specifier. COBOL handles this storage automatically on the host, but for Transaction Integrator (TI) to determine where in the buffer to place data sent to the host and where to unpack data from the host, you must give it the value of the length specifier variable on which the table size depends.

Any data that follows a variable-length table must be correctly offset in the buffer immediately following the table, regardless of the maximum length of the table. TI must have the length specifier value for a variable-length table both when it packs the buffer to be sent and when it unpacks the buffer that is received.

If an OCCURS clause describes a variable-length table, you must specify the table and the length specifier that controls the table length as input/output in TI Project. The TI run-time environment must be able to detect the length both when the buffer is sent to the host and when it is received from the host. When you import COBOL or manually create a method that describes a variable-length table in TI Project, this restriction is enforced.

Note
Information in this topic also applies to arrays.

Arrays

Sending Binary Data to the Host

The Transaction Integrator (TI) run-time environment does not translate binary data (Byte in Visual Basic, VT_UI1 in Automation, or unsigned char in C++) when it sends it to the mainframe. Instead, TI copies the binary data unchanged into a PIC X data representation on the mainframe. To define a string of binary data, define it as an array.

Host and Automation Data

COMTIContext Interface

Use the **ICOMTIContext** interface to add, remove, and query information in the Transaction Integrator (TI Context). The following methods implement the **ICOMTIContext** interface.

In This Section

ClearAllContext

ClosePersistentConnection

CountContext

DeleteContext

GetConnectionInfo

QueryContextInfo

ReadContext

UpdateContextInfo

WriteContext

ClearAllContext

Use the **ClearAllContext** method to remove all the entries in a TI Context array.

Syntax

```
HRESULT ClearAllContext (
```

Parameters

prgContextArray

This SAFEARRAY parameter contains the TI Context that is to be cleared.

Return Codes

S_OK

The method call completed successfully.

E_INVALIDARG

One or more of the parameters passed are invalid.

E_FAIL

An internal processing error occurred.

See Also

Reference

Other Resources

Using a Persistent Connection

ClosePersistentConnection

Use the **ClosePersistentConnection** method to close the persistent connection by contacting the COM+ or .NET Framework application object without the need for a call to the server object.

Syntax

```
HRESULT ClosePersistentConnection (
```

Parameters

COMTIContextArray

This SAFEARRAY contains the state of the connection.

Return Codes

S_OK

The method call completed successfully.

E_INVALIDARG

One or more of the parameters passed are invalid.

E_FAIL

An internal processing error occurred.

QueryContextInfo
ReadContext
UpdateContextInfo
WriteContext

Other Resources

Using a Persistent Connection

CountContext

Use the **CountContext** method to acquire a count of the entries in a TI Context array.

Syntax

```
HRESULT CountContext (
```

Parameters

prgContextArray

This SAFEARRAY parameter contains TI Context entries that are passed to and returned from COM+ objects.

pulContextEntriesCount

Upon successful completion of the call, this integer parameter contains a count of the number of entries in the specified TI Context array.

Return Codes

S_OK

The method call completed successfully.

E_INVALIDARG

One or more of the parameters passed are invalid.

E_FAIL

An internal processing error occurred.

Using a Persistent Connection

DeleteContext

Use the **DeleteContext** method to remove an entry in a TI Context array.

Syntax

```
HRESULT DeleteContext (
```

Parameters

bstrContextEntryName

This string parameter contains the name of the TI Context entry to be removed.

prgContextArray

This SAFEARRAY parameter contains the TI Context entries that are passed to and returned from COM+ objects.

Return Codes

S_OK

The method call completed successfully.

E_INVALIDARG

One or more of the parameters passed are invalid.

E_FAIL

An internal processing error occurred.

Using a Persistent Connection

GetConnectionInfo

Use the **GetConnectionInfo** method to query the state of the persistent connection.

Syntax

```
HRESULT GetConnectionInfo (
```

Parameters

COMTIContextArray

This SAFEARRAY contains the state of the connection.

pfConnectionIsPersistent

This BOOL parameter is set to TRUE if the connection is persistent and active.

pfConnectionIsViable

This BOOL parameter is set to TRUE if the connection is active.

Return Codes

S_OK

The method call completed successfully.

E_INVALIDARG

One or more of the parameters passed are invalid.

E_FAIL

An internal processing error occurred.

Using a Persistent Connection

QueryContextInfo

Use the **QueryContextInfo** method to acquire a count of the entries in a TI Context array, the names of the context entries, and the data types of the context entries.

Syntax

```
HRESULT QueryContextInfo (
```

Parameters

prgContextArray

This SAFEARRAY parameter contains the TI Context entries that are passed to and returned from COM+ objects.

pulContextEntriesCount

Upon successful completion of the call, this integer parameter contains a count of the entries in the specified TI Context array.

prgContextNameArray

This SAFEARRAY of strings parameter contains the TI Context entry names.

prgContextTypeArray

This SAFEARRAY of integers parameter contains the TI Context entry data types.

Return Codes

S_OK

The method call completed successfully.

E_INVALIDARG

One or more of the parameters passed are invalid.

E_FAIL

An internal processing error occurred.

Other Resources

Using a Persistent Connection

ReadContext

Use the **ReadContext** method to acquire the value of an entry in a TI Context array.

Syntax

```
HRESULT ReadContext (
```

Parameters

bstrContextEntryName

This string parameter contains the name of the TI Context entry to be retrieved.

pvarContextEntryValue

This VARIANT parameter contains the value of the context entry identified by bstrContextEntryName.

prgContextArray

This SAFEARRAY parameter contains the TI Context entries that are passed to and returned from COM+ objects.

Return Codes

S_OK

The method call completed successfully.

E_INVALIDARG

One or more of the parameters passed are invalid.

E_FAIL

An internal processing error occurred.

Other Resources

Using a Persistent Connection

UpdateContextInfo

Use the **UpdateContextInfo** method to update the client **COMTIContext** array with the current state of the connection.

Syntax

```
HRESULT UpdateContextInfo (
```

Parameters

COMTIContextArray

This SAFEARRAY contains the state of the connection.

Return Codes

S_OK

The method call completed successfully.

E_INVALIDARG

One or more of the parameters passed are invalid.

E_FAIL

An internal processing error occurred.

Other Resources

Using a Persistent Connection

WriteContext

Use the **WriteContext** function to add or replace an entry in a TI Context array.

Syntax

```
HRESULT WriteContext (
```

Parameters

bstrContextEntryName

This string parameter contains the name under which the TI Context entry will be stored and accessed. Some context entry names are predefined by Microsoft. You are free to define your own (although there is no way to deal with such in the COM+ application).

varContextEntryValue

This VARIANT parameter contains the value to be stored for the context entry identified by bstrContextEntryName.

prgContextArray

This SAFEARRAY parameter contains the TI Context entries that are passed to and returned from COM+ objects.

Return Codes

S_OK

The method call completed successfully.

E_INVALIDARG

One or more of the parameters passed are invalid.

E_FAIL

An internal processing error occurred.

COMTIContext Keywords

Use the COMTIContext keywords as commands to override the contents of a transaction request message (TRM).

In This Section

CONNTIMEOUT

Use the CONNTIMEOUT keyword to reclaim orphaned persistent connections. **CONNTIMEOUT** takes an integer value specifying, in seconds, how long to wait before a persistent connection is considered abandoned and then automatically closed. The timing starts as the client call processing is completed by the COM+ or .NET generic object.

ProgNameOverride

PASSWORD

CONNTYPE

Use the CONNTYPE keyword to establish a persistent connection by setting **CONNTYPE** to **OPEN**. If a call with **CONNTYPE** set to **OPEN** completes successfully, the returned **COMTIContext** array **CONNTYPE** keyword has a value of **USE**. To make a call and terminate the persistent connection, set the **CONNTYPE** keyword to **CLOSE**. If a call with **CONNTYPE** set to **CLOSE** completes successfully, the returned **COMTIContext** array **CONNTYPE** keyword has a value of **NONPERSISTENT**.

ProgNameOverride
PASSWORD

IMS_LTERM

Use the **IMS_LTERM** to override the default LTERM that an Information Management Systems (IMS) connect call uses while processing the host transaction within IMS. The COMTIContext context name is **IMS_LTERM**, and its value must be from one through eight alphanumeric characters.

Note
If the **IMS_LTERM** is assigned more than eight characters, the **IMS_LTERM** value is not passed to the host transaction and th e host transaction continues to use the system provided default LTERM.

TI Component Properties

In the Microsoft® Visual Studio® .NET 2003 environment, Transaction Integrator (TI) component properties appear and are edited in the **Properties** pane. When you select an entity in the Visual Studio tree view or list view, its properties appear in categories in the **Properties** pane. When you select multiple items, the intersection of their properties appear to allow for bulk edit.

Note
The properties of the TI components are not intended to be set or changed programmatically. Setting or changing the properties programmatically may cause the component to function incorrectly.

Standard Transaction Request and Reply Messages

To support the TCP transaction request message (TRM) Link programming model and the TCP TRM User Data programming model, Transaction Integrator (TI) supports two variations of the CICS Standard Listener TRM.

In This Section

TRM Format for the TCP TRM Link Programming Model

This topic describes the format and content of the transaction request message (TRM) used by the TCP TRM Link programming model.

TRM Request Message

The following table shows the contents of the request message.

TranID	Comma	Client in data
4	1	35

TranID

Transaction ID of the Concurrent Server to be started by the Listener.

Comma

A comma (,) separates the transaction ID from the Client in data.

Client in data

35 bytes of data used by the CICS TCP/IP security exit and passed to the Concurrent Server in the transaction initiation message (TIM).

Client in data for Microsoft Security Exit format

The following code block describes the format of the client in data for the Microsoft security exit.

Syntax

```
struct CLIENT_IN_DATA {
   BYTE    bUserID[8];
   BYTE    bPassword[8];
   BYTE    bLinkToName[8];
   USHORT  usCommareaLen;
   BYTE    bReserved[9];
} UNALIGNED;
```

Client in data for IBM Security Exit format

The following code block describes the format of the client in data for the IBM security exit.

Syntax

```
struct CLIENT_IN_DATA2 {
   BYTE    bSecFlag;
   BYTE    bPassword[8];
   BYTE    bUserID[8];
   BYTE    bLinkToName[8];
   USHORT  usCommareaLen;
   BYTE    bReserved[8];
} UNALIGNED;
```

TRM Reply Message

The following table shows the contents of the reply message.

TRM reply msg length	Formatted field length	Formatted field code	*Data*
4	4	1	*0-n*

Note
The formatted field length, formatted field code, and data can be repeated multiple times in a single message.

TRM reply msg length

The total length of the TRM reply message. This length is the sum of all the lengths of the formatted fields that follow in the message and does not include the length of the TRM reply msg length field itself.

Formatted field length

The length of the formatted field.

The formatted field length is the sum of the combination of the Formatted field code length and the Data length.

Formatted field code

A 1-byte code that describes the information passed from the Concurrent Server back to the client.

You cannot change the Formatted field code.

The field codes are specific to the communication handling between the WIP and HIP TCP Transports and the MSCMTICS, MSHIPLNK and TCP Concurrent Server programs.

Data

0 or more bytes of information that is associated with a specific formatted field.

You may change the information stored in Data. If you change Data, be sure that you also change the TRM Reply and the Formatted Field Length to the new values.

The length of Data is equal to the formatted field length minus the size of the formatted field code.

Normal codes

The following table shows the meaning of the normal codes.

Code	Type	Meaning
0x01	Info	Version ID for Microsoft® Transaction Integrator Concurrent Server
0x02	Info	User Data
0x07	Info	Execution OK

Error codes

The following table shows the meaning of the error codes.

Code	Type	Meaning
0x03	Error	Invalid ProgID
0x04	Error	Invalid TranID
0x05	Error	Inquiry Failed
0x06	Error	Inquiry Status
0x08	Error	Program ABEND
0x09	Error	Execution Failed
0x0A	Error	Invalid TRM

For more information about the format of the TRM, see the TRM definition file at <drive>:\Program Files\Microsoft Host Integration Server\System\TIM\MicrosoftTRMDefs.tim. Use Microsoft Visual Studio® .NET 2003 to view the file.

Note
The formatted field length, formatted field code, and data can be repeated multiple times in a single message.

ELM reply msg length

The total length of the ELM reply message. This length is the sum of all the lengths of the formatted fields that follow in the message and does not include the length of the ELM reply msg length field itself.

Formatted field length

The length of the formatted field.

The formatted field length is the sum of the combination of the Formatted field code length and the Data length.

Formatted field code

A 1-byte code that describes the information passed from the Concurrent Server back to the client.

You cannot change the Formatted field code.

The field codes are specific to the communication handling between the WIP and HIP TCP Transports and the MSCMTICS, MSHIPLNK and TCP Concurrent Server programs.

Data

0 or more bytes of information that is associated with a specific formatted field.

You may change the information stored in Data. If you change Data, be sure that you also change the TRM Reply and the Formatted Field Length to the new values.

The length of Data is equal to the formatted field length minus the size of the formatted field code.

Normal codes

The following table shows the meaning of the normal codes.

Code	Type	Meaning
0x01	Info	Version ID for Microsoft® Transaction Integrator Concurrent Server
0x02	Info	User Data

0x07	Info	Execution OK

Error codes

The following table shows the meaning of the error codes.

Code	Type	Meaning
0x03	Error	Invalid ProgID
0x04	Error	Invalid TranID
0x05	Error	Inquiry Failed
0x06	Error	Inquiry Status
0x08	Error	Program ABEND
0x09	Error	Execution Failed
0x0A	Error	Invalid ELM

For more information about the format of the TRM, see the TRM definition file at <drive>:\Program Files\ Microsoft Host Integration Server\System\TIM\MicrosoftTRMDefs.tim. Use Microsoft Visual Studio® .NET 2003 to view the file.

Enhanced Listener CICS Administration

ELM Format for the TCP ELM User Data Programming Model

This section describes the format and content of the enhanced listener message (ELM) used by the TCP ELM User Data programming model.

ELM Request Message

The following table shows the contents of the request message.

Client in data
35

Client in data

35 bytes of data used by the CICS TCP/IP security exit and passed to the Concurrent Server in the transaction initiation message (TIM).

Client in data for Microsoft Security Exit format

The following code block describes the format of the client in data for the Microsoft security exit.

Syntax

```
struct CLIENT_IN_DATA {
   BYTE    bUserID[8];
   BYTE    bPassword[8];
   BYTE    bReserved[19];
} UNALIGNED;
```

Client in data for IBM Security Exit format

The following code block describes the format of the client in data for the IBM security exit.

Syntax

```
struct CLIENT_IN_DATA2 {
   BYTE    bSecFlag;
   BYTE    bPassword[8];
   BYTE    bUserID[8];
   BYTE    bReserved[18];
} UNALIGNED;
```

ELM Reply Message

The following table shows the contents of the reply message.

ELM reply msg length	Formatted field length	Formatted field code	*Data*
4	4	1	*0-n*

Note
The formatted field length, formatted field code, and data can be repeated multiple times in a single message.

ELM reply msg length

The total length of the ELM reply message. This length is the sum of all the lengths of the formatted fields that follow in the message and does not include the length of the ELM reply msg length field itself.

Formatted field length

The length of the formatted field.

The formatted field length is the sum of the combination of the Formatted field code length and the Data length.

Formatted field code

A 1-byte code that describes the information passed from the Concurrent Server back to the client.

You cannot change the Formatted field code.

The field codes are specific to the communication handling between the WIP and HIP TCP Transports and the MSCMTICS, MSHIPLNK and TCP Concurrent Server programs.

Data

0 or more bytes of information that is associated with a specific formatted field.

You may change the information stored in Data. If you change Data, be sure that you also change the TRM Reply and the Formatted Field Length to the new values.

The length of Data is equal to the formatted field length minus the size of the formatted field code.

Normal codes

The following table shows the meaning of the normal codes.

Code	Type	Meaning
0x01	Info	Version ID for Microsoft Transaction Integrator Concurrent Server
0x02	Info	User Data
0x07	Info	Execution OK

Error codes

The following table shows the meaning of the error codes.

Code	Type	Meaning
0x03	Error	Invalid ProgID
0x04	Error	Invalid TranID
0x05	Error	Inquiry Failed
0x06	Error	Inquiry Status
0x08	Error	Program ABEND
0x09	Error	Execution Failed
0x0A	Error	Invalid ELM

For more information about the format of the TRM, see the TRM definition file at <drive>:\Program Files\ Microsoft Host Integration Server\System\TIM\MicrosoftTRMDefs.tim. Use Microsoft Visual Studio® .NET 2003 to view the file.

Enhanced Listener CICS Administration

Enhanced Listener CICS Administration

The following code defines a CICS Enhanced Listener. There are several new keywords available for use with the Enhanced Listener. The parameter definitions describe how these new Listener configuration values are used for support the TI Enhanced Listener feature.

```
      EZACICD TYPE=LISTENER,  Listener record definition              X
             FORMAT=ENHANCED,  Enhanced Listener                      X
             APPLID=XYZ12345,  Application ID of CICS region          X
             TRANID=CSKM,      Transaction name for Listener          X
             PORT=1234,        Port number for Listener               X
             IMMED=YES,        Listener starts up at initialization?  X
             NUMSOCK=50,       Number of sockets supported by Listener X
             ACCTIME=30,       Timeout value for Accept               X
             GIVTIME=30,       Timeout value for Givesocket           X
             REATIME=30,       Timeout value for Read                 X
             CSTRAN=MSCS,      Name of child server transaction       X
             CSSTTYPE=KC,       Child server startup type             X
             CSDELAY=000000,   Child server delay interval            X
             MSGLEN=35,        Length of input message                X
             PEEKDATA=NO,       Peek option                           X
             MSGFORM=EBCDIC,   Output message format                  X
```

CSTRANID

This parameter is specific to the enhanced version of the Listener and specifies the default child server transaction that the Listener starts.

For enhanced listener message (ELM) Link support, this value should be set to MSCS to conform to the samples that Microsoft delivers with the product. The MSCS transaction code should be associated with the mscmtics.cbl program that supports the Standard and Enhanced Listener protocols. Otherwise, this parameter is the transaction ID that will be executed for each request made to the designated port.

CSSTTYPE

This parameter is specific to the enhanced version of the Listener and specifies the default start method for the child server task. This parameter can be overridden by the security/transaction exit. Possible values are IC, KC, and TD.

IC

Indicates that the child server task is started using EXEC CICS START with the value specified by CSDLYINT (or an overriding value from the security/transaction exit) as the delay interval.

KC

Indicates that the child server task is started using EXEC CICS START with no delay interval.

TD

Indicates that the child server task is started using the EXEC CICS WRITEQ TD command, which uses transient data to trigger the child server task.

CSDLYINT

This parameter is specific to the enhanced version of the Listener and is applicable only if CSSTTYPE is IC. It specifies the delay interval to be used on the EXEC CICS START command, in the form hhmmss (hours/minutes/seconds).

MSGFORM

This parameter is specific to the enhanced version of the Listener and indicates whether an error message returned to the client should be in ASCII or Extended Binary Coded Decimal Interchange Code (EBCDIC) format. ASCII is the default. MSGFORM is displayed as MSGFORMat on the IBM-supplied CICS Transaction screens.

For TI Enhanced Listener support, this value must be set to EBCDIC.

MSGLEN

This parameter is specific to the enhanced version of the Listener and specifies the length of the data to be received from the client by the Listener. The valid range is from 0 through 999. If the value is 0, the Listener does not read in any data from the client.

For TI Enhanced Listener support, this value must be the size of the ELM that is delivered. The size of the ELM is 35.

PEEKDATA

This parameter is specific to the enhanced version of the Listener and applies only if MSGLEN is not 0.

A value of NO indicates that the Listener performs a normal read of the client data. The child server application accesses this data in the data area-2 portion of the transaction initiation message (TIM).

A value of YES indicates that the Listener reads the data using the Peek option. The data remains queued in TCP/IP and the child server applications read it in rather than accessing it through the TIM.

For TI Enhanced Listener support, this value must be set to NO. Setting this value to NO instructs the Enhanced Listener to read the ELM (35 bytes) and place it in the TIM in the data area-2 field.

The mscmtics.cbl Concurrent Server uses the information in this area to determine what server program to link to.

For more information about the format of the ELM, see the ELM definition file at <drive>:\Program Files\Microsoft Host Integration Server\System\TIM\MicrosoftELMDefs.tim. Use Microsoft Visual Studio® .NET 2003 to view the file.

Microsoft Concurrent Server

The MSCS transaction (program mscmtics.cbl) samples support both the Standard and the Enhanced Listener. The transaction program can be started by either the Enhanced or Standard Listener.

Each listener passes a unique transaction initiation message (TIM) to the transaction program when the Concurrent Server is started. The Standard Listener formats and passes the TIM shown in the following code sample. The length of this TIM is 72 bytes.

```
01  TRANSACTION-INITIATION-MESSAGE.
    05  GIVE-TAKE-SOCKET    PIC 9(8) COMP.
    05  LSTN-NAME           PIC X(8).
    05  LSTN-SUBNAME        PIC X(8).
    05  CLIENT-IN-DATA      PIC X(35).
    05  FILLER              PIC X(1).
    05  SOCKADDR-IN-PARM.
        15 SIN-FAMILY       PIC 9(4) COMP.
        15 SIN-PORT         PIC 9(4) COMP.
        15 SIN-ADDRESS      PIC 9(8) COMP.
        15 SIN-ZERO         PIC X(8).
```

The Enhanced Listener formats and passes the TIM shown in the following code sample. The length of this TIM is 189 bytes.

```
01  TRANSACTION-INITIATION-MESSAGE.
    05  GIVE-TAKE-SOCKET    PIC 9(8) COMP.
    05  LSTN-NAME           PIC X(8).
    05  LSTN-SUBNAME        PIC X(8).
    05  CLIENT-IN-DATA      PIC X(35).
    05  FILLER              PIC X(1).
    05  SOCKADDR-IN-PARM.
        15 SIN-FAMILY       PIC 9(4) COMP.
        15 SIN-PORT         PIC 9(4) COMP.
        15 SIN-ADDRESS      PIC 9(8) COMP.
        15 SIN-ZERO         PIC X(8).
    05  FILLER              PIC X(80).
    05  DATA-AREA-2-LEN     PIC 9(4) COMP.
    05  DATA-AREA-2         PIC X(35).
```

The mscmtics.cbl sample Concurrent Server can determine whether the Standard or the Enhanced Listener was used by evaluating the length of the TIM received.

In a scenario where the Enhanced Listener started the Microsoft Concurrent Server, the mscmtics.cbl program looks at the Client-in-data that is contained in the ELM found in the TIM data area-2 field. The Client-in-data contains the name of the CICS Server program to be executed and the length of the request data to be received from the client. The following code sample shows the contents of this data area.

```
       01 CLIENT-IN-DATA                   PIC X(35).
       01 FILLER REDEFINES CLIENT-IN-DATA.
          05 CID-USERID                    PIC X(8).
          05 CID-PASSWORD                  PIC X(8).
          05 CID-LINK-TO-PROG              PIC X(8).
          05 CID-COMMAREA-LEN              PIC S9(4) COMP.
          05 CID-DATA-LEN                  PIC S9(8) COMP.
          05 CID-VERSION                   PIC X.
             88 CID-VERSION-1              VALUE X'00'.
             88 CID-VERSION-2              VALUE X'01'.
          05 CID-FLAGS                     PIC X(2).
             88 CID-FLAGS-PERSISTENT-NONE  VALUE X'0001'.
             88 CID-FLAGS-PERSISTENT-OPEN  VALUE X'0002'.
             88 CID-FLAGS-PERSISTENT-USE   VALUE X'0004'.
             88 CID-FLAGS-PERSISTENT-CLOSE VALUE X'0008'.
          05 CID-RESERVED                  PIC X.
          05 CID-FORMAT                    PIC X.
```

```
           88 CID-FORMAT-NOTSET           VALUE X'00'.
           88 CID-FORMAT-MS                VALUE X'01'.
           88 CID-FORMAT-IBM               VALUE X'02'.
```

OLE DB Providers Programmer's Reference

The OLE DB specification version 2.0 defines a number of objects and interfaces.

Microsoft OLE DB Provider for AS/400 and VSAM supports the OLE DB objects and interfaces appropriate for an OLE DB data provider accessing a non-SQL host file system.

Microsoft OLE DB Provider for DB2 supports the OLE DB objects and interfaces appropriate for an OLE DB data provider accessing an SQL database.

This section also provides a comparison of the objects and interfaces supported by OLE DB Provider for AS/400 and VSAM and OLE DB Provider for DB2.

Note
Do not use double or real columns when specifying **UPDATE** or **DELETE** statements on the MsDb2DataAdapter. These rows will not be found and will throw the concurrency violation exception.

	IViewFilter	Yes
	IViewRowset	Yes
	IViewSort	Yes

Command Object (OLE DB Provider for AS/400 and VSAM)

The **Command** object is created by an OLE DB consumer, or by a service provider on behalf of a consumer. A **Command** object is used to execute a distributed data management (DDM)-specific command on a remote DDM server. The **Command** object currently supports executing Command Language commands on AS/400 DDM servers.

It is important not to confuse a command, which is an OLE COM object, and its command text, which is a string. Commands are generally used for data definition, such as creating a table or granting privileges, and data manipulation, such as updating or deleting rows. A special case of data manipulation using the **Command** object is opening a rowset (a table).

Before a consumer can use a command, it must determine if commands are supported. To do this, the consumer calls **QueryInterface** for **IDBCreateCommand** on a session. If this interface is exposed, the provider supports commands. To create a command, the consumer then calls **IDBCreateCommand::CreateCommand** on the session. A single session can be used to create multiple commands.

When the command is first created, it does not contain a command text. The consumer sets the command text with **ICommandText::SetCommandText**. Because the text command syntax is provider-specific, the consumer passes the globally unique identifier (GUID) of the syntax to use. For use with Microsoft OLE DB Provider for AS/400 and VSAM, the GUID is DBGUID_DBSQL. Note that under OLE DB Provider for AS/400 and VSAM, this GUID does not signify that the text command is a superset of ANSI SQL. The level at which the provider supports ANSI SQL is specified by the DBPROP_SQLSUPPORT property. This property is a bitmask specifying the level of support for SQL. OLE DB Provider for AS/400 and VSAM sets this property to DBPROPVAL_SQL_NONE, indicating that SQL is not supported.

The syntax supported by OLE DB Provider for AS/400 and VSAM for command text is as follows:

```
EXEC COMMAND DDMCmd
```

where *DDMCmd* represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands enable you to request functions from the OS/400 operating system. Some examples are the Delete File (DLTF) or Display File Description DSPFFD) commands. These are the same commands that could be issued at the command prompt if you were connected to an AS/400 through a 5250 terminal session. For a detailed list of possible commands, see the OS/400 CL reference for your platform.

The syntax supported by OLE DB Provider for AS/400 and VSAM to open a rowset (table) using command text is as follows:

```
EXEC OPEN FileName
```

where *FileName* represents one of the following host file naming conventions listed in the following table.

Host file type	File naming convention
VSAM Data Sets	DATASETNAME.FILENAME
Partitioned Data Sets	DATASETNAME.FILENAME(MEMBER)
OS/400 Files	LIBRARY/FILE
OS/400 Files	LIBRARY/FILENAME
OS/400 File Members	LIBRARY/FILE(MEMBER)
OS/400 File Members	LIBRARY.FILENAME(MEMBER)

Note that if a member of a library contains a dot in the member name, the member name must be surrounded by double quotes. For example, if the member name is NAMES.DAT, the proper syntax used to open a rowset using command text is as follows:

```
EXEC OPEN LIBRARY/FILE("NAMES.DAT")
```

To execute the command, the consumer calls **ICommand::Execute**. If the command text specifies the command to open a

rowset, (an **EXEC OPEN** command), **Execute** instantiates the rowset and returns an interface pointer to it.

The following interfaces of the **Command** object are supported by the current version of OLE DB Provider for AS/400 and VSAM:

- **IAccessor**
- **IColumnsInfo**
- **ICommand**
- **ICommandProperties**
- **ICommandText**
- **IConvertType**
- **ISupportErrorInfo**

DataSource Object (OLE DB Provider for AS/400 and VSAM)

The **DataSource** object is created by an OLE DB consumer. The **DataSource** object contains the knowledge and ability to connect to an IBM mainframe or AS/400 computer over Advanced Program-to-Program Communications (APPC) and LU 6.2 (through Microsoft Host Integration Server 2009) or over TCP/IP. The **DataSource** object is used to create one or more **Session** objects.

The following interfaces of the **DataSource** object are supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM:

- **IDBCreateSession**
- **IDBInitialize**
- **IDBProperties**
- **IPersist**
- **IPersistFile**
- **ISupportErrorInfo**

ErrorObject Object (OLE DB Provider for AS/400 and VSAM)

The **ErrorObject** object is created by any interface on any SNA OLE DB object. The **ErrorObject** object is used to retrieve additional information when an error occurs.

The following interface of the **ErrorObject** object is supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM:

- **IErrorRecords**

The **IErrorRecords** interface returns **ErrorRecord** objects with detailed information about the error that occurred.

ErrorRecord Object (OLE DB Provider for AS/400 and VSAM)

The **ErrorRecord** object is created by calling the **IErrorRecord** interface on the **ErrorObject** object. An **ErrorObject** is created on any interface on any SNA OLE DB object when an error occurs. The **ErrorRecord** object is used to retrieve additional information when an error occurs.

The following interface of the **ErrorRecord** object is supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM:

- **IErrorInfo**

OLE DB interface methods return error information in two ways. The error code returned by an interface method, known as the **return code**, indicates the overall success or failure of a method. Error records provide detailed information about the error, such as a text description of the error, the globally unique identifier (GUID) of the interface that defined the error, and provider-specific error information. Error objects in OLE DB are an extension of the error objects in Automation. They use many of the same mechanisms, and can be used as Automation error objects.

OLE DB error return codes are of type HRESULT. There are two general classes of return codes: success and warning codes, and error codes.

Success and warning codes begin with S_ or DB_S_ and indicate that the method successfully completed. The standard OLE DB error codes are defined in the OLEDBERR.H include file.

If the return code is other than S_OK or S_FALSE, it is likely that an error occurred from which the method was able to recover. For example, **IRowset::GetNextRows** returns DB_S_ENDOFROWSET when it is unable to return the requested number of rows due to reaching the end of the rowset. If a single warning condition occurs, the method returns the code for that condition. If multiple warning conditions occur, the method describes the hierarchy of warning return codes indicating which warning code should be returned when given a choice between multiple warning return codes.

Error codes begin with E_ or DB_E_ and indicate that the method failed completely and was unable to do any useful work. For example, **GetNextRows** returns E_INVALIDARG when the pointer in which it is to return a pointer to an array of row handles (*prghRows*) is null. An exception to this is that some of the methods that return DB_E_ERRORSOCCURRED allocate memory in which to return additional information about these errors. Consumers must free this memory. For information about which methods allocate memory in this case, see the methods that return DB_E_ERRORSOCCURRED. Although error codes can indicate run-time errors, such as running out of memory, they generally indicate programming errors. If multiple errors occur, the code that is returned is provider-specific. If both errors and warnings occur, the method fails and returns an error code.

All methods can return S_OK, E_FAIL, and E_OUTOFMEMORY. The E_OUTOFMEMORY code applies only to those methods which allocate memory that is returned to the consumer. In some cases, the E_OUTOFMEMORY code might be eliminated by calling the method requesting fewer returned values, such as fewer rows from **GetNextRows**.

Index Object (OLE DB Provider for AS/400 and VSAM)

An OLE DB index, also known as an **index rowset**, is a rowset built over an index in a data source. It is generally used in conjunction with a rowset built over a base table in the same data source. Each row of the index rowset contains a bookmark that points to a row in the base-table rowset. Thus, an OLE DB consumer can traverse the index rowset and use it to access rows in the base-table rowset.

Indexes are created using the index interfaces of the **Rowset** object. Index rowsets allow an application to read records efficiently by means of a key.

The following index interfaces of the **Rowset** object are supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM when applied to AS/400 keyed physical files, AS/400 logical files, VSAM KSDS files with unique keys, and VSAM RRDS files with unique keys:

- **IAccessor**
- **IColumnsInfo**
- **IConvertType**
- **IRowset**
- **IRowsetChange**
- **IRowsetFind**
- **IRowsetIdentity**
- **IRowsetIndex**
- **IRowsetInfo**
- **IRowsetLocate**
- **IRowsetRefresh**
- **IRowsetScroll**
- **IRowsetUpdate**
- **IRowsetView**
- **ISupportErrorInfo**

OLE DB Provider for AS/400 and VSAM supports integrated indexes using the **IRowsetIndex** interface based on the underlying rowset.

Rowset Object (OLE DB Provider for AS/400 and VSAM)

Rowset objects are created by **Session** objects. The **Rowset** object exposes data in tabular format.

The following interfaces of the **Rowset** object are supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM:

- **IAccessor**
- **IChapteredRowset**
- **IColumnsInfo**
- **IConvertType**
- **IRowset**
- **IRowsetChange**
- **IRowsetFind**
- **IRowsetIdentity**
- **IRowsetIndex**
- **IRowsetInfo**
- **IRowsetLocate**
- **IRowsetRefresh**
- **IRowsetUpdate**
- **IRowsetView**
- **ISupportErrorInfo**

Note
The **IRowsetFind** interface is only supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM when applied to AS/400 keyed physical files, AS/400 logical files, VSAM KSDS files with unique keys, and VSAM RRDS files with unique keys.

Session Object (OLE DB Provider for AS/400 and VSAM)

The **Session** object is created by a **DataSource** object. The **Session** object is used to create one or more **Rowset** objects.

The following interfaces of the **Session** object are supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM:

- **IDBCreateCommand**
- **IDBSchemaRowset**
- **IGetDataSource**
- **IOpenRowset**
- **ISessionProperties**
- **ISupportErrorInfo**

Consumers can get information about a data store without knowing its structure by using the **IDBSchemaRowset** methods. The methods on this interface can be used to retrieve advanced schema information. OLE DB Provider for AS/400 and VSAM organizes this information into a set of schemas that contain tables for each schema. These schema rowsets are identified by globally unique identifiers (GUIDs).

The following schema rowset GUIDs are supported by OLE DB Provider for AS/400 and VSAM:

- DBSCHEMA_COLUMNS
- DBSCHEMA_INDEXES
- DBSCHEMA_PROVIDER_TYPES
- DBSCHEMA_TABLES

The following table lists these GUIDs and the columns for which restrictions can be specified on the schema rowset when using OLE DB Provider for AS/400 and VSAM. The number of restriction columns for each schema rowset are defined as constants prefixed with CRESTRICTIONS_ in the OLE DB header files. Restriction values are treated as literals rather than as search patterns. For example, the restriction value "A_C" matches "A_C" but not "ABC".

GUID	Number of restrictions	Restriction columns
DBSCHEMA_COLUMNS	4	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME COLUMN_NAME
DBSCHEMA_INDEXES	5	TABLE_CATALOG TABLE_SCHEMA INDEX_NAME TYPE TABLE_NAME
DBSCHEMA_PROVIDER_TYPES	2	DATA_TYPE BEST_MATCH
DBSCHEMA_TABLES	4	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME TABLE_TYPE

The **IDBSchemaRowset** interface allows an application to pass at run time the target library of a partitioned data set (PDS), a dataset, or a member name when using the **IDBSchemaRowset:GetSchemas** function to retrieve the schema.

This following example illustrates using a target library to retrieve a table schema:

```
hr = pIDBSchemaRowset->GetRowset(
        NULL,                          // punkOuter
        DBSCHEMA_TABLES,               // schema IID
         2L,                           // # of restrictions
```

```
        rgRestrictions,             // array of restrictions
        IID_IRowset,                // rowset interface
        0L,                         // # of properties
        NULL,                       // properties
        (IUnknown**)&pIRowset);     // rowset pointer
```

The variable *rgRestrictions* is an array containing two restriction values. The first array entry is VT_EMPTY and the second array entry is the target library name.

View Object (OLE DB Provider for AS/400 and VSAM)

The **View** object is created on a **Rowset** object. The **View** object is used to expose simple operations, such as sorting and filtering a rowset by applying a view. Views can be applied when opening a **Rowset** object or applied to an existing **Rowset** object.

The following interfaces of the **View** object are supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM when applied to AS/400 keyed physical files, AS/400 logical files, VSAM KSDS files with unique keys, and VSAM RRDS files with unique keys:

- **IAccessor**
- **IColumnsInfo**
- **ISupportErrorInfo**
- **IViewChapter**
- **IViewFilter**
- **IViewRowset**
- **IViewSort**

OLE DB Property Support in the OLE DB Provider for AS/400 and VSAM

The following table summarizes the provider-specific OLE DB version 2.0 properties in the SNAOLEDB_DBPROPSET_DBINIT property set that are supported by the current version of Microsoft OLE DB Provider for AS/400 and VSAM.

OLE DB Property ID	Description
DBPROP_SNAOLEDB_APPCMODE	When logical unit (LU) 6.2 (SNA) is selected for the Network Transport Library (DBPROP_SNAOLEDB_NETTYPE), this property is the Advanced Program-to-Program Communications (APPC) mode and must be set to a value that matches the host configuration and SNA server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This VT_BSTR type property normally defaults to QPCSUPP.
DBPROP_SNAOLEDB_BINASCHAR	This property indicates whether to process binary fields (Character Code Set Identifier or CCSID of 65535) as character data type fields on a per data source basis. The host CCSID and PC Code Page values are required input parameters when this parameter is true. This VT_BOOL type property defaults to VARIANT_FALSE, do not process binary fields as character fields.
DBPROP_SNAOLEDB_HCDPATH	The fully qualified file name of the distributed data management (DDM) host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the SNA system directory. This VT_BSTR type property is required when connecting to mainframe systems and is optional when connecting to OS/400.
DBPROP_SNAOLEDB_HOSTCCSID	The CCSID matching the data as represented on the host. This property is required when processing binary data as character data. Unless the DBPROP_SNAOLEDB_BINASCHAR property is set to **true**, character data is converted based on the host column CCSID and default ANSI code page. This VT_I4 property defaults to U.S./Canada (37).
DBPROP_SNAOLEDB_LIBRARY	The default AS/400 library to be accessed. This VT_BSTR property is not required for mainframe access and is optional when connecting to AS/400 files.
DBPROP_SNAOLEDB_LOCALLU	When LU 6.2 (SNA) is selected for the Network Transport Library, this property is the name of the local LU alias configured in the SNA server.

DBPROP_SNAOLEDB_NETADDRESS	When TCP/IP has been selected for the Network Transport Library, this property is used to locate the target host computer. This parameter indicates the IP address or TCP/IP host name alias associated with the DDM server on the host. The network address is required when connecting through TCP/IP.
DBPROP_SNAOLEDB_NETPORT	When TCP/IP has been selected for the Network Transport Library, this property is used to locate the target DDM service access port when connecting by using TCP/IP. This parameter represents the TCP/IP port used for communication with the DDM service on the host. The default value for the VT_BSTR type property is 446.
DBPROP_SNAOLEDB_NETTYPE	This property which represents the dynamic link library used for transport designates whether the provider connects by using SNA LU 6.2 or TCP/IP for network communication. The possible values for this parameter are TCP/IP or SNA. If TCP/IP is selected, values for Network Address (DBPROP_SNAOLEDB_NETADDRESS) and Network Port (DBPROP_SNAOLEDB_NETPORT) are required. TCP/IP connectivity to the mainframe is not supported by OLE DB Provider for AS/400 and VSAM. If SNA is selected, values for APPC Local LU Alias (DBPROP_SNAOLEDB_LOCALLU), APPC Mode Name (DBPROP_SNAOLEDB_APPCMODE), and APPC Remote LU Alias (DBPROP_SNAOLEDB_REMOTELU) are required. This value for this VT_BSTR property defaults to SNA.
DBPROP_SNAOLEDB_PCCODEPAGE	The PC Code Page property ID indicates the code page to be used on the computer for character code conversion. This property is required when processing binary data as character data. Unless DBPROP_SNAOLEDB_BINASCHAR is set to true, character data is converted based on the default ANSI code page configured in Windows. If this parameter is set to Binary or 65535, no character code conversions will take place. The default value for this VT_I4 type property is 1252 (Latin-1).
DBPROP_SNAOLEDB_REMOTELU	When LU 6.2 (SNA) is selected for the Network Transport Library (DBPROP_SNAOLEDB_NETTYPE), this property ID is the name of the remote LU alias configured in the SNA server.
DBPROP_SNAOLEDB_REPAIRKEY	This property ID provides for repair of invalid key offsets received from OS/400 when keys have been defined using the Digital Data System (DDS) "RENAME" clause. This parameter indicates whether the OLE DB provider should repair any host key values set in the registry. This VT_BOOL type property defaults to VARIANT_FALSE.
DBPROP_SNAOLEDB_STRICTVAL	This property indicates whether strict validation should be used. This VT_BOOL type property defaults to VARIANT_FALSE.

OLE DB Object Support in the OLE DB Provider for DB2

The following table summarizes the OLE DB version 2.0 objects that are supported by the current version of Microsoft® OLE DB Provider for DB2.

OLE DB object	Support
Command Object	Yes, most interfaces
CustomErrorObject	Yes, all interfaces
DataSource Object	Yes, some interfaces
Enumerator	No
ErrorObject Object	Yes, all interfaces
ErrorRecord Object	Yes, all interfaces
Index	No
MultipleResults	No
Rowset Object	Yes, some interfaces
Session Object	Yes, some interfaces
Transaction Object	Yes, some interfaces
TransactionOptions	Yes, all interfaces
View	No

OLE DB Interface Support in the OLE DB Provider for DB2

The following table summarizes the OLE DB version 2.0 interfaces that are supported by the current version of Microsoft OLE DB Provider for DB2.

Object	Interface	Support
Command Object	**IAccessor**	Yes
	IColumnsInfo	Yes
	IColumnsRowset	No
	ICommand	Yes
	ICommandPersist	No
	ICommandPrepare	Yes
	ICommandProperties	Yes
	ICommandText	Yes
	ICommandWithParameters	Yes
	IConvertType	Yes
	ISupportErrorInfo	Yes
CustomErrorObject Object	**IErrorLookup**	Yes
	ISQLErrorInfo	Yes
DataSource Object	**IDBAsynchStatus**	No
	IConnectionPointContainer	No
	IDBCreateSession	Yes
	IDBDataSourceAdmin	No
	IDBInfo	Yes
	IDBInitialize	Yes
	IDBProperties	Yes
	IPersist	Yes
	IPersistFile	Yes
	ISupportErrorInfo	Yes
Enumerator	**IDBInitialize**	No

	IDBProperties	No
	IParseDisplayName	No
	ISourcesRowset	No
	ISupportErrorInfo	No
ErrorObject Object	**IErrorRecords**	Yes
ErrorRecord Object	**IErrorInfo**	Yes
Index	**IAccessor**	No
	IColumnsInfo	No
	IConvertType	No
	IRowset	No
	IRowsetChange	No
	IRowsetFind	No
	IRowsetIdentity	No
	IRowsetIndex	No
	IRowsetInfo	No
	IRowsetLocate	No
	IRowsetRefresh	No
	IRowsetScroll	No
	IRowsetUpdate	No
	IRowsetView	No
	ISupportErrorInfo	No
MultipleResults	**IMultipleResults**	No
	ISupportErrorInfo	No
Rowset Object	**IAccessor**	Yes
	IChapteredRowset	No
	IColumnsInfo	Yes
	IColumnsRowset	No

	IConnectionPointContainer	No
	IConvertType	Yes
	IDBAsynchStatus	No
	IRowset	Yes
	IRowsetChange	Yes
	IRowsetChapterMember	No
	IRowsetFind	No
	IRowsetIdentity	No
	IRowsetIndex	No
	IRowsetInfo	Yes
	IRowsetLocate	No
	IRowsetRefresh	No
	IRowsetScroll	No
	IRowsetUpdate	Yes
	IRowsetView	No
	ISupportErrorInfo	Yes
Session Object	**IAlterIndex**	No
	IAlterTable	No
	IDBCreateCommand	Yes
	IDBSchemaRowset	Yes
	IGetDataSource	Yes
	IIndexDefinition	No
	IOpenRowset	Yes
	ISessionProperties	Yes
	ISupportErrorInfo	Yes
	ITableDefinition	No

	ITransaction	Yes
	ITransactionJoin	No
	ITransactionLocal	Yes
	ITransactionObject	Yes
Transaction Object	**IConnectionPointContainer**	No
	ISupportErrorInfo	Yes
	ITransaction	Yes
TransactionOptions	**ISupportErrorInfo**	Yes
	ITransactionOptions	Yes
View	**IAccessor**	No
	IColumnsInfo	No
	ISupportErrorInfo	No
	IViewChapter	No
	IViewFilter	No
	IViewRowset	No
	IViewSort	No

Command Object (OLE DB Provider for DB2)

The **Command** object is created by an OLE DB consumer, or by a service provider on behalf of a consumer. A **Command** object is used to execute a distributed data management (DDM)-specific command on a remote DDM server. The **Command** object currently supports executing Command Language commands on AS/400 DDM servers.

It is important not to confuse a command, which is an OLE COM object, and its command text, which is a string. Commands are generally used for data definition, such as creating a table or granting privileges, and data manipulation, such as updating or deleting rows. A special case of data manipulation using the **Command** object is the creation of rowsets based on DB2 tables. When using the command text with DB2/400 on the AS/400 computer, table names specified in a command are by default passed as uppercase. If a table name uses mixed case, the table name must be passed in a quoted string.

Before a consumer can use a command, it must determine if commands are supported. To do this, the consumer calls **QueryInterface** for **IDBCreateCommand** on a session. If this interface is exposed, the provider supports commands. To create a command, the consumer then calls **IDBCreateCommand::CreateCommand** on the session. A single session can be used to create multiple commands.

When the command is first created, it does not contain a command text. The consumer sets the command text with **ICommandText::SetCommandText**. Because the text command syntax is provider-specific, the consumer passes the globally unique identifier (GUID) of the syntax to use. For use with Microsoft OLE DB Provider for DB2, the GUID is DBGUID_DBSQL. Note that under OLE DB Provider for DB2, this GUID signifies that the text command is a superset of ANSI SQL. The level at which the provider supports ANSI SQL is specified by the DBPROP_SQLSUPPORT property. This property is a bitmask specifying the level of support for SQL.

The syntax supported by OLE DB Provider for DB2 for command text is as Entry-Level ANSI SQL 92 (with some exceptions based on the DB2 server host platform).

Legal SQL commands are documented in the following publications published by IBM:

- *AS/400 Advanced Series: DB2 for AS/400 SQL Reference Version 4* (Document Number SC41-5612-00)
- *DB2 for OS/390 Version 5: SQL Reference* (Document Number SC26-8966)

To execute the command, the consumer calls **ICommand::Execute**. If the command text specifies the command to open a rowset, **Execute** instantiates the rowset and returns an interface pointer to it.

The following interfaces of the **Command** object are supported by the current version of OLE DB Provider for DB2:

- **IAccessor**
- **IColumnsInfo**
- **ICommand**
- **ICommandPrepare**
- **ICommandProperties**
- **ICommandText**
- **ICommandWithParameters**
- **IConvertType**
- **ISupportErrorInfo**

When using the **ICommand** object, Microsoft OLE DB Provider for DB2 cannot derive parameter type information from the data store. The OLE DB client application must supply the native parameter type information through **ICommandWithParameters::SetParameterInfo** function. The OLE DB provider uses the type information specified by **SetParameterInfo** to determine how to convert parameter data from the type supplied by the consumer (as indicated by the

wType value in the binding structure) to the native type used by the data store. When the consumer specifies a data type with known precision, scale, and size values, any information supplied by the consumer for precision, scale, or size is ignored by OLE DB Provider for DB2.

The information that the consumer supplies must be correct and must be supplied for all parameters. OLE DB Provider for DB2 cannot verify the supplied information against the parameter metadata, although the OLE DB provider can determine that the specified values are legal values for the provider. The result of executing a command using incorrect parameter information or passing parameter information for the wrong number of parameters is undefined. For example, if the parameter type is **LONG** and the consumer specifies a type indicator of DBTYPE_STR in **ICommandWithParameters::SetParameterInfo**, OLE DB Provider for DB2 converts the data to a string before sending it to the data store. Because the data store is not expecting a **LONG**, this will likely result in an error.

CustomErrorObject Object (OLE DB Provider for DB2)

The **CustomErrorObject** object is created by a **Command** object when a command error occurs. The **CustomErrorObject** object is used to retrieve additional information when an error occurs.

The following interfaces of the **CustomErrorObject** object are supported by the current version of Microsoft OLE DB Provider for DB2:

- **IErrorLookup**
- **ISQLErrorInfo**

DataSource Object (OLE DB Provider for DB2)

The **DataSource** object is created by an OLE DB consumer. The **DataSource** object contains the knowledge and ability to connect to DB2 over Advanced Program-to-Program Communications (APPC) and LU 6.2 (through Host Integration Server 2009) or over TCP/IP. The **DataSource** object is used to create one or more **Session** objects.

The following interfaces of the **DataSource** object are supported by the current version of Microsoft OLE DB Provider for DB2:

- **IDBCreateSession**
- **IDBInfo**
- **IDBInitialize**
- **IDBProperties**
- **IPersist**
- **IPersistFile**
- **ISupportErrorInfo**

ErrorObject Object (OLE DB Provider for DB2)

The **ErrorObject** object is created by any interface on any DB2 OLE DB object. The **ErrorObject** object is used to retrieve additional information when an error occurs.

The following interface of the **ErrorObject** object is supported by the current version of Microsoft OLE DB Provider for DB2:

- **IErrorRecords**

The **IErrorRecords** interface returns **ErrorRecord** objects with detailed information on the error that occurred.

ErrorRecord Object (OLE DB Provider for DB2)

The **ErrorRecord** object is created by calling the **IErrorRecord** interface on the **ErrorObject** object. An **ErrorObject** is created on any interface on any SNA OLE DB object when an error occurs. The **ErrorRecord** object is used to retrieve additional information when an error occurs.

The following interface of the **ErrorRecord** object is supported by the current version of Microsoft OLE DB Provider for DB2:

- **IErrorInfo**

OLE DB interface methods return error information in two ways. The error code returned by an interface method, known as the **return code**, indicates the overall success or failure of a method. Error records provide detailed information about the error, such as a text description of the error, the globally unique identifier (GUID) of the interface that defined the error, and provider-specific error information. Error objects in OLE DB are an extension of the error objects in Automation. They use many of the same mechanisms, and can be used as Automation error objects.

OLE DB error return codes are of type HRESULT. There are two general classes of return codes: success and warning codes, and error codes.

Success and warning codes begin with S_ or DB_S_ and indicate that the method successfully completed. The standard OLE DB error codes are defined in the OLEDBERR.H include file.

If the return code is other than S_OK or S_FALSE, it is likely that an error occurred from which the method was able to recover. For example, **IRowset::GetNextRows** returns DB_S_ENDOFROWSET when it is unable to return the requested number of rows due to reaching the end of the rowset. If a single warning condition occurs, the method returns the code for that condition. If multiple warning conditions occur, the method describes the hierarchy of warning return codes, indicating which warning code should be returned when given a choice between multiple warning return codes.

Error codes begin with E_ or DB_E_ and indicate that the method failed completely and was unable to do any useful work. For example, **GetNextRows** returns E_INVALIDARG when a null pointer in which the OLE DB provider returns a pointer to an array of row handles (*prghRows*). An exception to this is that some of the methods that return DB_E_ERRORSOCCURRED allocate memory to return additional information about these errors. Consumers must free this memory. For information about which methods allocate memory in this case, see the methods that return DB_E_ERRORSOCCURRED.

Although error codes can indicate run-time errors, such as running out of memory, they generally indicate programming errors. If multiple errors occur, the code that is returned is provider-specific. If both errors and warnings occur, the method fails and returns an error code.

All methods can return S_OK, E_FAIL, and E_OUTOFMEMORY. The E_OUTOFMEMORY code applies only to those methods which allocate memory that is returned to the consumer. In some cases, the E_OUTOFMEMORY code might be eliminated by calling the method requesting fewer returned values, such as fewer rows from **GetNextRows**.

Rowset Object (OLE DB Provider for DB2)

Rowset objects are created by **Session** objects. The **Rowset** object exposes data in tabular format.

The following interfaces of the **Rowset** object are supported by the current version of Microsoft OLE DB Provider for DB2.

- **IAccessor**
- **IColumnsInfo**
- **IConvertType**
- **IRowset**
- **IRowsetChange**
- **IRowsetInfo**
- **IRowsetUpdate**
- **ISupportErrorInfo**

Session Object (OLE DB Provider for DB2)

The **Session** object is created by a **DataSource** object. The **Session** object is used to create one or more **Rowset** objects.

The following interfaces of the **Session** object are supported by the current version of Microsoft OLE DB Provider for DB2:

- **IDBCreateCommand**
- **IDBSchemaRowset**
- **IGetDataSource**
- **IOpenRowset**
- **ISessionProperties**
- **ISupportErrorInfo**
- **ITransaction**
- **ITransactionLocal**
- **ITransactionObject**

Consumers can get information about a data store without knowing its structure by using the **IDBSchemaRowset** methods. The methods on this interface can be used to retrieve advanced schema information. OLE DB Provider for DB2 organizes each DB2 database server in a set of schemas that contain tables for each schema. These schema rowsets are identified by globally unique identifiers (GUIDs).

The following schema rowset GUIDs are supported by OLE DB Provider for DB2:

- DBSCHEMA_COLUMNS
- DBSCHEMA_INDEXES
- DBSCHEMA_PRIMARY_KEYS
- DBSCHEMA_PROCEDURES
- DBSCHEMA_PROCEDURE_PARAMETERS
- DBSCHEMA_PROVIDER_TYPES
- DBSCHEMA_TABLES

The following table lists these GUIDs and the columns for which restrictions can be specified on the schema rowset when using OLE DB Provider for DB2. The number of restriction columns for each schema rowset are defined as constants prefixed with CRESTRICTIONS_ in the OLE DB header files. Restriction values are treated as literals rather than as search patterns. For example, the restriction value "A_C" matches "A_C" but not "ABC".

GUID	Number of restrictions	Restriction columns
DBSCHEMA_COLUMNS	4	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME COLUMN_NAME
DBSCHEMA_INDEXES	4	TABLE_CATALOG TABLE_SCHEMA INDEX_NAME TABLE_NAME

DBSCHEMA_PRIMARY_KEYS	3	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME
DBSCHEMA_PROCEDURES	4	PROCEDURE_CATALOG PROCEDURE_SCHEMA PROCEDURE_NAME PROCEDURE_TYPE
DBSCHEMA_PROCEDURE_PARAMETERS	4	PROCEDURE_CATALOG PROCEDURE_SCHEMA PROCEDURE_NAME PARAMETER_NAME
DBSCHEMA_PROVIDER_TYPES	2	DATA_TYPE BEST_MATCH
DBSCHEMA_TABLES	4	TABLE_CATALOG TABLE_SCHEMA TABLE_NAME TABLE_TYPE

Note that the TYPE restriction on the DBSCHEMA_INDEXES GUID is not supported by OLE DB Provider for DB2.

The PROCEDURE_SCHEMA restriction on the DBSCHEMA_PROCEDURE GUID and the DBSCHEMA_PROCEDURE_PARAMETERS GUID is not supported when connecting to DB/2 on OS/390 platforms.

Transaction Object (OLE DB Provider for DB2)

The **Transaction** object is created by a **Session** object. The **Transaction** object is used to manage transactions on one or more **Rowset** objects.

The following interfaces of the **Transaction** object are supported by the current version of Microsoft OLE DB Provider for DB2:

- **ISupportErrorInfo**
- **ITransaction**

The current implementation of OLE DB Provider for DB2 services all OLE DB **Session**, **Command**, and **Rowset** objects present in a given instance of the **DataSource** object through a single Advanced Program-to-Program Communications (APPC) conversation or TCP/IP connection. One implication of this design is that if two **Rowset** objects, each created from a different OLE DB **Session** object, use explicit commitment control through the **ITransaction** interface, they will interfere with each other. When a **Commit** or **Abort** for one instance is invoked, all work for the **DataSource** object will be either committed or aborted. This may yield undesirable results. The work around to this problem is to instantiate two instances of the **DataSource** object.

OLE DB Property Support in the OLE DB Provider for DB2

OLE DB Provider for DB2 included with Host Integration Server 2009 supports a different set of provider-specific properties than the earlier OLE DB Provider for DB2 supplied with SNA Server 4.0. The sections below provide information about provider-specific and standard OLE DB properties supported by the current and the previous version of OLE DB provider.

In This Section

OLE DB Provider-Specific Property Support in the OLE DB Provider for DB2

The following table summarizes the provider-specific OLE DB version 2.0 properties in the DB2OLEDB_DBPROPSET_DBINIT property set that are supported by the version of Microsoft OLE DB Provider for DB2 included with Host Integration Server 2009.

OLE DB Property ID	Description
DBPROP_DB2OLEDB_APPCMODE	When logical unit (LU) 6.2 (SNA) is selected for the Network Transport Library (DBPROP_DB2OLEDB_NETTYPE), this property is the Advanced Program-to-Program Communications (APPC) mode and must be set to a value that matches the host configuration and SNA server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This VT_BSTR type property normally defaults to QPCSUPP.
DBPROP_DB2OLEDB_BINASCHAR	This property indicates whether to process binary fields (Character Code Set Identifier or CCSID of 65535) as character data type fields on a per data source basis. The host CCSID and PC Code Page values are required input parameters when this parameter is true. This VT_BOOL type property defaults to VARIANT_FALSE, do not process binary fields as character fields.
DBPROP_DB2OLEDB_CATALOGCOL	The name of the collection where OLE DB Provider for DB2 looks for catalog information. This is the default schema, the "SCHEMA" name for the target collection of tables and views. This property is the Data Schema value when configuring data sources. OLE DB Provider for DB2 uses this default schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection. For DB2, the default schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the default schema is the target COLLECTION name. For DB2 Universal Database (UDB), the default schema is the SCHEMA name. If the user does not provide a VT_BSTR value for DBPROP_DB2OLEDB_CATALOGCOL, the OLE DB provider uses the USER_ID provided at logon. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Because these values for the default schema are inappropriate in many cases, it is essential that the Default Schema value in the data source be defined.
DBPROP_DB2OLEDB_HOSTCCSID	The CCSID matching the data as represented on the host. This property is required when processing binary data as character data. Unless the DBPROP_DB2OLEDB_BINASCHAR property ID is set to **true**, character data is converted based on the host column CCSID and default ANSI code page. This VT_I4 type property defaults to 37 (U.S./Canada).
DBPROP_DB2OLEDB_LOCALLU	When LU 6.2 (SNA) is selected for the Network Transport Library, this property is the name of the local LU alias configured in the SNA server. This VT_BSTR type property has no default value.

DBPROP_DB2OLEDB_NETADDRESS	When TCP/IP has been selected for the Network Transport Library, this property is used to locate the target host computer. This parameter indicates the IP address or TCP/IP host name alias associated with the DDM server on the host. The network address is required when connecting by using TCP/IP. This VT_BSTR type property defaults to SNA.
DBPROP_DB2OLEDB_NETPORT	When TCP/IP has been selected for the Network Transport Library, this property is used to locate the target DDM service access port when connecting by using TCP/IP. This parameter represents the TCP/IP port used for communication with the DDM service on the host. This VT_BSTR type property defaults to 446.
DBPROP_DB2OLEDB_NETTYPE	This property, which represents the dynamic-link library used for transport, designates whether the provider connects through SNA LU 6.2 or TCP/IP for network communication. The possible values for this parameter are TCPIP or SNA. If TCPIP is selected, values for Network Address (DBPROP_DB2OLEDB_NETADDRESS) and Network Port (DBPROP_DB2OLEDB_NETPORT) are required. If SNA is selected, values for APPC Local LU Alias (DBPROP_DB2OLEDB_LOCALLU, APPC), Mode Name (DBPROP_DB2OLEDB_APPCMODE), and APPC Remote LU Alias (DBPROP_DB2OLEDB_REMOTELU) are required. This VT_BSTR type property defaults to SNA.
DBPROP_DB2OLEDB_PACKAGECOL	The name of the Distributed Relational Database Architecture (DRDA) target collection (AS/400 library) where Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be the same as the Default Schema (DBPROP_DB2OLEDB_DEFAULTSCH). Microsoft OLE DB Provider for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. OLE DB Provider for DB2 will create packages dynamically in the location to which the user points using this property ID. This VT_BSTR type property has no default value.
DBPROP_DB2OLEDB_PCCODEPAGE	The PC Code Page property ID indicates the code page to be used on the computer for character code conversion. This property is required when processing binary data as character data. Unless DBPROP_DB2OLEDB_BINASCHAR is set to true, character data is converted based on the default ANSI code page configured in Windows. If this parameter is set to Binary or 65535, no character code conversions will take place. This VT_I4 type property defaults to 1252 (Latin 1).
DBPROP_DB2OLEDB_PLATFORM	The target DB2 platform property value is used to optimize performance of the OLE DB provider when executing operations such as data conversion. The following values for this property are supported by OLE DB Provider for DB2: ● DB2/MVS ● DB2/NT ● DB2/6000 ● DB2/400 This VT_BSTR property has a default value of DB2/MVS.

DBPROP_DB2OLEDB_QUALIFIERCOL	The name of the schema (collection/owner) used to fully qualify unqualified object names. Note that this attribute allows the user to access database objects without fully qualifying the object using a collection (schema) qualifier. The OLE DB provider sends this value to DB2 using a **SET CURRENT SQLID** statement, instructing th e DBMS to use this value when locating unqualified objects (for example, tables and views) referenced in SQL statemen ts. If you do not set a value for default qualifier, no **SET** statement is issued by the ODBC driver. This OLE DB property is only valid when connecting to DB2 for MVS (OS/390, z/OS). This VT_BSTR type property has a default value of .
DBPROP_DB2OLEDB_REMOTELU	When LU 6.2 (SNA) is selected for the Network Transport Library (DBPROP_DB2OLEDB_NETTYPE), this property is the name of the remote LU alias configured in the SNA server. This VT_BSTR type property has no default value.
DBPROP_DB2OLEDB_TPNAME	This property represents the default transaction program (TP) name for the DB2 DRDA application server (AS), which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, t his property is set to 0X07F9F9F9. This VT_BSTR type property has no default value.
DBPROP_DB2OLEDB_UNITSOFWORK	This property indicates whether two-phase commit (distributed unit of work) used for transactions is supported for thi s data source. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transacti on Coordinator, and SNA LU 6.2 Resync Service. The following values for this property are supported by OLE DB Provider for DB2: ● Remote unit of work (RUW) ● Distributed unit of work (DUW) This VT_BSTR type property has a default value of RUW. Distributed unit of work (two-phase commit) works only with DB2 for OS/390 v5R1 or later. This option also requires t hat the SNA LU 6.2 service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

OLE DB Data Source Property Support in the OLE DB Provider for DB2

The following table summarizes the standard OLE DB version 2.0 data source properties from the DBPROP_DATASOURCE property set that are supported by the version of Microsoft OLE DB Provider for DB2 included with Host Integration Server 2009.

OLE DB Property ID	Comments
DBPROP_CURRENTCATALOG	The name of the current catalog. This property is derived from the *Initial Catalog* parameter when configuring data sources. An application can use the CATALOGS schema rowset to enumerate catalogs. This VT_BSTR type property defaults to the value configured in the data source for *Initial Catalog*.

ODBC Driver for DB2 Programmer's Reference

The Microsoft ODBC Driver for DB2 enables users to access IBM DB2 from within an ODBC-aware application. ODBC defines a standard set of interfaces that provide access to disparate databases. This section provides reference material needed to program for the ODBC Driver for DB2.

For general information about programming for the ODBC Driver for DB2, see the ODBC Driver for DB2 Programmer's Guide section of the SDK.

In This Section

Programming Considerations When Using the ODBC Driver for DB2

ODBC Conformance

ADO Object, Method, Property, and Collection Support for AS/400, VSAM and DB2

Programming Considerations When Using the ODBC Driver for DB2

The Microsoft ODBC Driver for DB2 provides passthrough support for SQL statements. No SQL parsing is provided. The user must know what SQL syntax is supported for the target DB2-implementation. For information on what SQL syntax is supported, see the specific DB2 SQL Reference and DB2 Application Programming and SQL Guide for the specific platform.

The ODBC Driver for DB2 does not parse the SQL statements to qualify table names. Consequently, users of the ODBC Driver for DB2 must use either two-part or three-part (fully qualified) object names when naming tables, views, and stored procedures in DB2. A two-part table name would consist of the user ID and table, <UserID>.<Table>. One-part names (just the table name) will not succeed unless the combination of the DB2 collection and schema name correspond directly to the ODBC User ID

The Microsoft ODBC Driver for DB2 does not insert the correct value for the fraction when using a parameterized insert with the TIMESTAMP data type.

Microsoft Data Access Components (MDAC) supports the option of using a client cursor engine. This service component is implemented as part of OLE DB, ADO, and Remote Data Services (RDS). When using ADO, a client cursor is enabled by setting the **CursorLocation** property on the recordset to **adUseClient**. When using the ADO Client Cursor Engine with DB2 for OS/390, the developer must configure the ODBC Driver for DB2 Auto Commit Mode property in the DSN or connection string to **FALSE**. This is not required when connecting to DB2 for OS/400.

The ODBC Driver for DB2 included with Host Integration Server 2009 supports updating capabilities when used with a client cursor engine and the following requirements are met:

- To support updates (UPDATE, INSERT, and DELETE), the values in at least one column in the target table must be unique.
- The Auto Commit parameter must be set to **FALSE** when configuring the data source or when this parameter is passed as part of a connection string.

Previous versions of the ODBC Driver for DB2 do not support any updating capabilities when used with a client cursor engine. In other words, if a client cursor engine is enabled using RDS or ADO, the ODBC Driver for DB2 cannot be used to update data on the host. The ADO recordset is treated as if it were read-only. When using the ADO Client Cursor Engine with DB2 for OS/390, the developer must configure the ODBC Driver for DB2 Auto Commit parameter in the data source or connection string to FALSE. This is not required when connecting to DB2 for OS/400.

When the intent is to update records with a server-side cursor, DB2 requires that the SQL **SELECT** statement also include the FOR UPDATE option. For example, to select all records from the AUTHORS table in the DB2 collection called PUBS with intent to update requires the following SQL syntax:

```
SELECT * FROM PUBS.AUTHORS FOR UPDATE
```

When using DB2 for MVS V4R1 and DB2 for OS/400 V3R2, there are further requirements to indicate the columns that you intend to update. For example, to update the AU_LNAME and AU_FNAME columns in the PUBS.AUTHORS table, the following SQL syntax must be used:

```
SELECT * FROM PUBS.AUTHORS FOR UPDATE OF AU_LNAME, AU_FNAME
```

The Microsoft ODBC Driver for DB2 provides support for distributed transactions and DRDA Distributed Unit of Work, and can participate in a distributed transaction coordinated by Microsoft Distributed Transaction Coordinator. This feature is only available when connecting to one of the following across an LU 6.2 network connection:

- DB2 for OS/390 V5R1 or later.
- DB2 for DB2/400 V4R3 or later.

This option also requires that the SNA LU 6.2 service is selected as the network transport and Microsoft Transaction Server (MTS) is installed. The Microsoft ODBC Driver for DB2 does not support automatic transaction enlistment under Microsoft Transaction Server.

Applications should not commit or roll back transactions by executing **COMMIT** or **ROLLBACK** statements using the **SQLExecute** or **SQLExecDirect** ODBC functions. The effects of doing this are undefined, and the ODBC Driver for DB2 no longer knows when a transaction is active. Applications should call the **SQLEndTran** ODBC function instead.

Microsoft Visual Studio offers a number of ADO data-bound controls, including a data grid and the ADO Data control. When using these ADO data controls, the developer must set the **CursorLocation** property on the recordset to **adUseClient**. Additionally, when using these ADO data controls with DB2 for OS/390, you must set the ODBC Driver for DB2 Auto Commit parameter in the data source or connection string to **FALSE**.

You can use Microsoft Query (MSQUERY) supplied with Microsoft Office Excel and Microsoft Office to access ODBC data sources using the ODBC Driver for DB2. When a data of a column defined with TIMESTAMP data type is updated using Microsoft Query, the microseconds portion of the TIMESTAMP is not updated properly. The result is that updating any TIMESTAMP value using Microsoft Query will cause the loss of fractional seconds.

The Microsoft ODBC Driver for DB2 is not supported for use with the Microsoft ODBC .NET Framework Data Provider. When accessing DB2 from ADO.NET, use the Microsoft OLE DB Provider for DB2 in conjunction with the Microsoft OLE DB .NET Framework Data Provider.

In This Section

Stored Procedure Support Using the ODBC Driver for DB2

The Microsoft ODBC Driver for DB2 supports calling DB2 stored procedures, returning output parameters and single and multiple result sets.

Support for Isolation Levels Using the ODBC Driver for DB2

The Microsoft ODBC Driver for DB2 provides flexibility in dealing with issues of isolation levels and transaction state. The ODBC **SQLSetConnectAttr** function is used to set the isolation level that is to be used for a connection. This function would be called with the attribute parameter set to SQL_ATTR_TXN_ISOLATION and the *ValuePtr* parameter pointing to an integer value indicating the isolation level requested. This integer value is a 32-bit bitmask that sets the transaction isolation level for the current connection.

The allowable values for isolation level (the *ValuePtr* parameter when calling **SQLSetConnectAttr**) can be determined by calling **SQLGetInfo** with InfoType equal to SQL_TXN_ISOLATION_OPTION. The following table list the allowable values for isolation level using the ODBC Driver for DB2 supplied with Host Integration Server.

ODBC Isolation Level Attribute	**Description**
SQL_TXN_READ_COMMITTED	When this attribute value is set, it isolates any data read from changes by others and changes made by others by others cannot be seen. The re-execution of the read statement is affected by others. This does not support a repeatable read. This is the default value for isolation level This isolation level is also called Cursor Stability (CS) in IBM DB2 documentation.
SQL_TXN_READ_UNCOMMITTED	When this attribute value is set, it does not isolate data read from changes by others and changes made by others by others can be seen. The re-execution of the read statement is affected by others. This does not support a repeatable read. This isolation level is called Uncommitted Read (UR) in IBM DB2 documentation.
SQL_TXN_REPEATABLE_READ	When this attribute value is set, it isolates any data read from changes by others and changes made by others cannot be seen. The re-execution of the read statement is affected by others. This supports a repeatable read. This isolation level is called Read Stability (RS) in IBM DB2 documentation.
SQL_TXN_SERIALIZABLE	When this attribute value is set, it isolates any data read from changes by others and changes made by others by others cannot be seen. The re-execution of the read statement is not affected by others. This supports a repeatable read. This isolation level is called Repeatable Read (RR) in IBM DB2 documentation.

The SQL_ATTR_TXN_ISOLATION attribute can be set only if there are no open transactions on the connection. An application must call **SQLEndTran** to commit or roll back all open transactions on a connection, before calling **SQLSetConnectAttr** with this option.

Some connection attributes support substitution of a similar value if the data source does not support the value specified in *ValuePtr*. In such cases, the driver returns SQL_SUCCESS_WITH_INFO and SQLSTATE 01S02 (Option value changed). To determine the substituted value, an application calls **SQLGetConnectAttr**.

Code Page Support Using the ODBC Driver for DB2

When creating data sources or file DSNs for use with the ODBC Driver for DB2, the Host character code set identifier (CCSID) should be configured in the data source to match the DB2 data as represented on the remote host computer. The Host CCSID parameter defaults to EBCDIC U.S./Canada (37).

On Windows 2000, the appropriate ANSI NLS file for your locale is installed automatically when you install a localized version of Windows 2000.

The following sections discuss the character code set identifiers (CCSIDs) supported by ODBC Driver for DB2 in Host Integration Server 2009.

In This Section

ANSI Code Page Support Using the ODBC Driver for DB2

IBM DB2 Universal Database for Windows NT and IBM DB2 Universal Database for AIX are frequently configured to use ANSI code pages, for example ANSI 1253 (Greek). Host Integration Server 2009 includes support for some ANSI code pages for purposes of ANSI-to-UNICODE-to-ANSI conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2. These ANSI code pages can be used when accessing IBM DB2 Universal Database on Windows NT and IBM DB2 ON AIX (not all of these ANSI code pages are supported on IBM DB2 Universal Database for AIX).

The following table shows the ANSI character code set identifiers (CCSIDs) supported by ODBC Driver for DB2 in Host Integration Server 2009.

Microsoft Display Name	Microsoft NLS Code Page	IBM CCSID	Comments
ANSI - Arabic	1256	1256	
ANSI - Baltic	1257	1257	
ANSI - Cyrillic	1251	1251	
ANSI - Central Europe	1250	1250	
ANSI - Greek	1253	1253	
ANSI - Hebrew	1255	1255	
ANSI - Latin I	1252	1252	Support for this codepage is normally installed as part of the operating system on Windows 2000.
ANSI - Turkish	1254	1254	
ANSI/OEM - Japanese Shift JIS	932	932	
ANSI/OEM - Korean	949	949	
ANSI/OEM - Simplified Chinese GBK	936	936	
ANSI/OEM - Thai	874	874	
ANSI/OEM - Traditional Chinese Big5	950	950	
ANSI/OEM - Viet Nam	1258	1258	

The Microsoft Display Name is the name found in the Windows 2000 definitions for these NLS files. The Microsoft NLS Code Page column represents the code page number that is registered and associated with an ANSI-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the ODBC Driver for DB2. When setting the Host CCSID or PC Code Page parameter using a connection string, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the ANSI code page in IBM publications, which for these supported ANSI CCSIDs are the same as the Microsoft CCSID values. IBM lists their ANSI support in publications by referencing the display name which for these ANSI code pages is the same as the Microsoft display name. The ODBC Driver for DB2 does not recognize or display the IBM CCSID values when configuring data sources. The ODBC Driver for DB2 maps the Microsoft NLS numbers to ANSI NLS files which correspond with the appropriate IBM CCSID numbers. The Microsoft ODBC Driver for DB2 passes the corresponding IBM CCSID to the DB2 system at run time even though you configure the driver to use the Microsoft

NLS number.

These are the only ANSI pages currently supported by the ODBC Driver for DB2 in Host Integration Server 2009 and in SNA Server 4.0 with Service Pack 3 or later. IBM supports additional ANSI pages, however, the ANSI code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM ANSI code pages (CCSIDs) match.

EBCDIC Code Page Support Using the ODBC Driver for DB2

IBM DB2 for MVS, IBM DB2 for OS/390, and IBM DB2 for OS/400 are frequently configured to use EBCDIC code pages, for example EBCDIC 875 (Greek Modern). Host Integration Server 2009 includes support for most EBCDIC code pages for purposes of EBCDIC-to-UNICODE-to-ANSI, ANSI-to-UNICODE-to-EBCDIC, and EBCDIC-to-UNICODE-to-EBCDIC conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2. These EBCDIC code pages can be used when accessing IBM DB2 on a variety of platforms (not all of these EBCDIC code pages are supported on all versions of IBM DB2).

The following table shows the EBCDIC character code set identifiers (CCSIDs) supported by ODBC Driver for DB2 in Host Integration Server 2009.

Microsoft Display Name	Microsoft NLS Code Page	IBM CCS ID	Comments
IBM EBCDIC - Arabic	20420	420	
IBM EBCDIC - Cyrillic (Russian)	20880	880	
IBM EBCDIC - Cyrillic (Serbian, Bulgarian)	21025	1025	
IBM EBCDIC - Denmark/Norway	20277	277	
IBM EBCDIC - Denmark/Norway (Euro)	1142	1142	
IBM EBCDIC - Finland/Sweden	20278	278	
IBM EBCDIC - Finland/Sweden (Euro)	1143	1143	
IBM EBCDIC - France	20297	297	
IBM EBCDIC - France (Euro)	1147	1147	
IBM EBCDIC - Germany	20273	273	
IBM EBCDIC - Germany (Euro)	1141	1141	
IBM EBCDIC - Greek	20423	423	
IBM EBCDIC - Greek (Modern)	875	875	
IBM EBCDIC - Hebrew	20424	424	
IBM EBCDIC - Icelandic	20871	871	
IBM EBCDIC - Icelandic (Euro)	1149	1149	
IBM EBCDIC - International	500	500	
IBM EBCDIC - International (Euro)	1148	1148	
IBM EBCDIC - Italy	20280	280	
IBM EBCDIC - Italy (Euro)	1144	1144	

IBM EBCDIC - Japan English/Kanji (Extended)	939	939	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japan English/Kanji (Extended)	5035	5035	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japan Katakana/Kanji (Extended)	930	930	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japan Katakana/Kanji (Extended)	5026	5026	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Japanese	931	931	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Korea (Extended)	933	933	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Latin America/Spain	20284	284	
IBM EBCDIC - Latin America/Spain (Euro)	1145	1145	
IBM EBCDIC - Multilingual/ROECE (Latin-2)	870	870	
IBM EBCDIC - Simplified Chinese (Extended)	935	935	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Thai	20838	838	
IBM EBCDIC - Traditional Chinese (Extended)	937	937	Support for this double-byte character set is supplied using TRNSDT.
IBM EBCDIC - Turkish (Latin-3)	20905	905	
IBM EBCDIC - Turkish (Latin-5)	1026	1026	
IBM EBCDIC - U.S./Canada	037	37	
IBM EBCDIC - U.S./Canada (Euro)	1140	1140	
IBM EBCDIC - United Kingdom	20285	285	
IBM EBCDIC - United Kingdom (Euro)	1146	1146	

The Microsoft Display Name is the name found in the Windows 2000 definitions for these NLS files. The Microsoft NLS Code Page column represents the code page number that is registered and associated with an EBCDIC-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the ODBC Driver for DB2. When setting the Host CCSID or PC Code Page parameter using a connection string, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the EBCDIC code page in IBM publications. IBM lists their EBCDIC support in publications by referencing the display name which for these EBCDIC code pages is the same as the Microsoft display name. The ODBC Driver for DB2 does not recognize or display the IBM CCSID values when configuring data sources using data links. The ODBC Driver for DB2 maps the Microsoft NLS numbers to EBCDIC NLS files which correspond with the

appropriate IBM CCSID numbers. The Microsoft ODBC Driver for DB2 passes the corresponding IBM CCSID to the DB2 system at run time even though you configure the driver to use the Microsoft NLS number.

These are the only EBCDIC pages currently supported by the ODBC Driver for DB2 in Host Integration Server 2009 and in SNA Server 4.0 with Service Pack 3 or later. IBM supports additional EBCDIC pages; however, the EBCDIC code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM EBCDIC code pages (CCSIDs) match.

ISO Code Page Support Using the ODBC Driver for DB2

IBM DB2 Universal Database for Windows NT and IBM DB2 Universal Database for AIX are frequently configured for an ISO code page, for example ISO 819 (Latin I). Host Integration Server 2009 includes support for some ISO code pages for purposes of ISO-to-UNICODE-to-ANSI, ANSI-to-UNICODE-to-ISO, and ISO-to-UNICODE-to-ISO conversions when using the OLE DB Provider for DB2 or the ODBC Driver for DB2. These ISO code pages can be used when accessing IBM DB2 Universal Database for Windows NT and IBM DB2 Universal Database for AIX.

The following table shows the ISO character code set identifiers (CCSIDs) supported by ODBC Driver for DB2 in Host Integration Server.

Microsoft Display Name	Microsoft NLS Code Page	IBM CCSID	Comments
ISO 8859-1 Latin 1	28591	819	
ISO 8859-2 Central Europe	28592	912	
ISO 8859-5 Cyrillic	28595	915	
ISO 8859-6 Arabic	28596	1089	
ISO 8859-7 Greek	28597	813	
ISO 8859-8 Hebrew	28598	916	
ISO 8859-9 Turkish	28599	920	
ISO 6937 Non-Spacing Accent	20269	819	Note that ISO 6937 (CCSID 20269) is not supported by the ODBC Driver for DB2, but is displayed in the list of configuration options when creating or modifying data sources.
ISO 8859-15 Latin 9 (Euro)	20865	923	NLS Code Page 819 with support for the euro.

The ///Microsoft Display Name is the name found in the Windows 2000 definitions for these NLS files.

The Microsoft NLS Code Page column represents the code page number that is registered and associated with an ISO-to-UNICODE NLS resource file. The Microsoft NLS number should be set as the Host CCSID when configuring data sources when using the ODBC Driver for DB2. When setting the Host CCSID or PC Code Page attribute/property using a connection string, the Microsoft NLS number should be used for this parameter.

The IBM CCSID column represents the CCSID given to the ISO code page in IBM publications. IBM lists their ISO support in publications by referencing the locale name (Bulgaria for ISO 8859-5 and 915, for example) rather than simply using ISO 8859-5 Cyrillic as used by Microsoft. The ODBC Driver for DB2 does not recognize or display the IBM CCSID values when configuring data sources. The ODBC Driver for DB2 maps the Microsoft NLS numbers to ISO NLS files which correspond with the appropriate IBM CCSID numbers. The Microsoft ODBC Driver for DB2 passes the corresponding IBM CCSID to the DB2 system at run time even though you configure the driver to use the Microsoft NLS number.

Note that IBM CCSID 819 is associated with both ISO 8859-1 Latin 1 and ISO 6937 Non-Spacing Accent. It is up to the user to choose the standard ISO 8859-1 Latin 1 code page by selecting NLS code page 28591 or the modified code page ISO 6937 Non-Spacing Accent by selecting NLS code page 20269. Note that ISO 6937 Non-Spacing Accent (CCSID 20269) is not currently supported by the ODBC Driver for DB2, but is displayed in the configuration options when creating or modifying data

sources.

IBM CCSID 916 (ISO 8859-8) supports Hebrew "visual sort order". IBM CCSID 920 (ISO 8859-8 derivation) supports Hebrew "logical sort order". Although Microsoft supports the logical sort order with NLS 38598, this NLS file is only distributed with Internet Explorer 5 or Windows 2000. The ODBC Driver for DB2 has not been tested using the ISO 8859-8 derivation matching IBM CCSID 920 and does not support this configuration.

These are the only ISO pages currently supported in Host Integration Server and in SNA Server 4.0 with Service Pack 3 or later. Microsoft supports a number of additional ISO pages. IBM also supports additional ISO pages. However, the code pages listed in the table above are the only cases where the Microsoft NLS pages and IBM CCSIDs match.

DBCS Code Page Support Using the ODBC Driver for DB2

The ODBC Provider for DB2 supports Double-Byte Character String (DBCS) data, including conversions between DBCS and ANSI code pages. Conversions between DBCS and ISO code pages are also supported, as are positioned updates against DBCS EBCDIC implementations of DB2.

The DB2 GRAPHIC data types (GRAPHIC, VARGRAPHIC, and LONG VARGRAPHIC) are now explicitly supported. These DB2 data types support DBCS (not mixed) data. Mixed data types are supported using CHAR FOR MIXED DATA, VARCHAR FOR MIXED DATA, and LONGVARCHAR FOR MIXED DATA.

Parameterized SQL statements and calling stored procedures when the parameter values contain Mixed or DBCS characters are supported.

When performing a SQL statement with inline data, character strings can be prefixed with a G or g to denote that the data is DBCS and is to be used with a graphic column. Only double-byte characters can be used with a graphic column. For example:

```
CREATE TABLE NAMES (COL1 GRAPHIC(64), COL2 CHAR(64))
INSERT INTO NAMES (COL1, COL2) VALUES (GDBCS data, MBCS or SBCS data)
```

The prefixes n (graphic) and gx (hexadecimal graphic) are also supported.

Data Conversion Using the ODBC Driver for DB2

The design of ODBC APIs is similar to other ISAM APIs. The APIs are handle-based. After opening a file, the application can determine the buffer size required to store a row, use the cursor APIs to move, and optionally retrieve one or more rows of data using the row-level binding.

Data is converted to default SQL data types, as defined in ODBC. The following table lists these conversions.

DB2 data type	Default SQL Data Type	Exposed as Native Type in SQLGetTypeInfo	Comments
BIGINT			An 8-byte integer. This data type is supported on DB2 UDB only.
BLOB			A Binary Large Object (BLOB) is a varying-length string that can be up to 2 gigabytes in length. A BLOB is primarily intended to hold binary data. This data type is not supported by the ODBC Driver for DB2.
CHAR (BIT)	SQL_BINARY	No	A fixed length (double-byte only) character string.
CHAR (SBCS)	SQL_CHAR	Yes	A fixed-length SBCS character string.
CHAR (MIXED)	SQL_CHAR	No	A fixed-length mixed (single and double-byte) character string.
CLOB			A Character Large Object(CLOB) is a varying-length string that can be up to 2 gigabytes in length. A CLOB is used to store large single-byte character set data. A CLOB is considered to be a character string. This data type is not supported by the ODBC Driver for DB2.
DATE	SQL_TYPE_DATE	Yes	A 10-byte date string. This data type is converted to an SQL_DATE for use by ODBC.
DBCLOB			A Double-Byte Character Large Object (DBCLOB) is a varying-length string of double-byte characters that can be up to 2 gigabytes in length (1,073,741,823 double-byte characters). A DBCLOB is used to store large double-byte character set data. A DBCLOB is considered to be a graphic string. It is not supported by the ODBC Driver for DB2.
DECIMAL	SQL_DECIMAL	Yes	A packed decimal number.
DOUBLE	SQL_DOUBLE	Yes	An 8-byte double-precision floating point number.
FLOAT	SQL_FLOAT	Yes	An 8-byte double-precision floating point number. This data type is the same as a DOUBLE.

GRAPHIC (DBCS)	SQL_CHAR	No	A fixed-length graphic string consisting of a sequence of double byte (DBCS only) character string data.
INTEGER	SQL_INTEGER	Yes	A 4-byte integer with a precision of 10 digits ranging in value from -2,147,463,648 to +2,147,483,647.
LONG VARCHAR (BIT)	SQL_BINARY	No	A varying-length (double-byte only) character string.
LONG VARCHAR (SBCS)	SQL_CHAR	No	A varying-length SBCS character string.
LONG VARCHAR (MIXED)	SQL_CHAR	No	A varying-length mixed-character (single and double-byte) string.
LONG VARGRAPHIC (DBCS)	SQL_LONGVARCHAR	No	A varying-length graphic string consisting of a sequence of double byte (DBCS only) character string data.
SMALLINT	SQL_SMALLINT	Yes	A SMALLINT (small integer) is a two-byte integer with a precision of 5 digits ranging from -32,768 to +32,767.
REAL	SQL_REAL	Yes	A 4-byte single-precision floating point number.
TIME	SQL_TYPE_TIME	Yes	An 8-byte time string. When using ActiveX Data Objects to return data from a DB2 TIME data type, ADO returns a DATETIME value.
TIMESTAMP	SQL_TYPE_TIMESTAMP	Yes	A 26-byte string representing the date, time, and microseconds.
VARCHAR (BIT)	SQL_BINARY	No	A varying-length (double-byte only) character string.
VARCHAR (SBCS)	SQL_CHAR	Yes	A varying-length character string.
VARCHAR (MIXED)	SQL_CHAR	No	A varying-length mixed (single and double-bye) character string.
VARGRAPHIC (DBCS)	SQL_VARCHAR	No	A varying-length graphic string consisting of a sequence of double byte (DBCS only) character string data.

Not all platforms and versions of DB2 support all of the above-referenced data types. Consult your IBM SQL Reference for the specific target and platform and version of DB2.

The ODBC Driver for DB2 exposes only selected DB2 data types as native types in the ODBC catalog function **GetTypeInfo**. For example, the driver does not expose LONG CHARACTER or VARYING LONG CHARACTER types. Rather these types are exposed as CHARACTER and VARYING CHARACTER respectively. Also, the driver exposes CHARACTER FOR SBCS DATA, CHARACTER FOR MIXED DATA, and CHARACTER FOR BIT DATA as CHARACTER. The driver exposes VARYING CHARACTER FOR SBCS DATA, VARYING CHARACTER FOR MIXED DATA, and VARYING CHARACTER FOR BIT DATA as VARYING CHARACTER. However, the ODBC Driver for DB2 returns these LONG and VARYING LONG data types if one reads a table with these data types. For example, when reading a table with a variable character string of length greater than 254 bytes, the ODBC Driver for DB2 returns a LONG VARCHAR.

The maximum length of the DB2 character and graphic string data types is dependent on the DB2 platform and version. For example, a CHAR type on DB2 for OS/390 V5R1 has a maximum length of 254 bytes, whereas a CHAR type on DB2/400 V4R4 has a maximum length of 32,766 bytes.

Data conversions from a large numeric type to a small numeric type are supported (from DOUBLE to SINGLE and from INT to SMALLINT, for example), however truncation and conversion errors can occur that will not be reported by the ODBC Driver for DB2.

For more information on support for the DB2 character data types of subtype MIXED using the ODBC Driver for DB2, see Code Page Support Using the ODBC Driver for DB2.

Using the ODBC Driver for DB2, certain conversions of strings from EBCDIC to ASCII and then back to EBCDIC are asymmetric, and can result in strings that are different from the original. The EBCDIC specification contains ordinals for which there is no defined character. The ODBC Driver for DB2 translates all such undefined characters to the question mark character ("?"). So when ASCII strings containing these characters are converted back to EBCDIC, these undefined characters are replaced with question marks. To protect EBCDIC strings containing undefined characters, these fields should be tagged as binary strings and mapped by the application.

The affected ANSI-to-EBCDIC character conversions include the following:

Character value (decimal)	Character value (hexadecimal)	ANSI code page 1252	EBCDIC character after conversion to CCSID 37
128	0x80	Not used	?
130	0x82	Single low quote	?
131	0x83	Latin F with hook	?
132	0x84	Double low quote	?
133	0x85	Ellipsis	?
134	0x86	Dagger	?
135	0x87	Double dagger	?
136	0x88	Per mile	?
137	0x89	S with caron	?
138	0x8A	Left angle	?
139	0x8B	Ligature OE	?
140	0x8C	Not used	?
142	0x8E	Not used	?

145-156	0x91-0x9C		?
158-159	0x9E-0x9F		?

Floating Point Considerations Using the ODBC Driver for DB2

When real or double (synonymous with float) data is inserted into a DB2 table as a floating point data type, it is stored in scientific notation. For example, FLOAT(1.1) would be stored as +1.10000E+000.

Care must be taken when executing SQL statements to make sure that the proper data type specified in the SQL statement matches the values stored in DB2. For example, the following select statement would match values in DB2 stored as decimal 1.1:

```
SELECT * FROM TEST WHERE C1 = 1.1
```

If the data in DB2 was stored as real numbers, there would not be a match since decimal 1.1 is stored as 1.1, not the representation of +1.10000E+000. When DB2 parses and executes the SQL **SELECT** statement, it interprets 1.1 as a decimal type. When doing the **SELECT** query, DB2 does not implicitly do the conversion to floating point. In this case, the SQL statement should explicitly typecast the 1.1 so that DB2 looks for the correct format (the scientific notation format). The **SELECT** query would look like the following:

```
SELECT * FROM TEST WHERE C1 = REAL(1.1)
```

This will give the expected results. The SQL **REAL** function converts the decimal 1.1 to the proper format before DB2 executes the actual select.

Usernames and Passwords Using the ODBC Driver for DB2

When connecting to remote DB2 systems, most users must be authenticated by the remote system by passing a valid user ID and password.

The AS/400 computer is case-sensitive with regard to user ID and password; it accepts them only in uppercase. The ODBC Driver for DB2 automatically converts the user ID and password into uppercase when connecting to a DB2 for OS/400 system.

The mainframe is not case-sensitive; the user ID and password is acceptable in lowercase or uppercase.

DB2 Universal Database (UDB) for Windows NT is case-sensitive; it supports mixed case passwords. Users must enter a password in the correct mixed case. When entering a user ID, use only the Windows NT user name and not the Windows NT domain name.

Errors Returned by the ODBC Driver for DB2

The ODBC Driver for DB2 generates errors in the following areas:

- ODBC Driver Manager
- Microsoft ODBC Driver for DB2
- DRDA Application Requester network client

The ODBC Driver Manager is a shared library that establishes connections with ODBC drivers, submits requests to ODBC drivers, and returns results to applications. An ODBC Driver Manager error has the following format:

```
[vendor] [ODBC DLL] message
```

For example:

```
[Microsoft] [ODBC DLL] Driver does not support this function.
```

If you encounter this type of error, check the last ODBC call the application made for possible problems. For further information on ODBC Driver Manager errors, contact your ODBC application vendor or refer to the ODBC documentation available from Microsoft Press.

An error reported by the Microsoft ODBC Driver for DB2 has the following format:

```
[Microsoft] [ODBC Driver for DB2] message
```

For example:

```
[Microsoft] [ODBC Driver for DB2] Invalid precision specified.
```

If you encounter this type of error is, check the last ODBC call the application made for possible problems. For further information on ODBC Driver errors, contact your ODBC application vendor or refer to the ODBC documentation available from Microsoft Press.

When using the Microsoft ODBC Driver for DB2, data source refers to the target database. An error that occurs in the data source is returned with the data source name and in the following format:

```
[Microsoft] [ODBC Driver for DB2] [data_source] message
```

For example, an ODBC application may receive the following message from a DB2 data source running on an IBM mainframe:

```
[Microsoft] [ODBC Driver for DB2] [DB2] DB2-0919: specified length too long for CHAR column
```

If you encounter this type of error, the application attempted to perform an operation not supported by the DB2 database system. Check the DB2 database system documentation for more information or consult your database administrator.

Two-Phase Commit over TCP/IP Support Using the ODBC Driver for DB2

Two-phase commit (2PC) is a host server-installed protocol that ensures that updates to multiple instances of a database on a network either succeed or fail in their entirety. Host Integration Server 2009 supports 2PC over TCP/IP, allowing you to gain the security of a 2PC connection over the Internet.

Host Integration Server supports 2PC works using three components: the DTC, the Resync Service, and the transaction log. The DTC governs the normal DTC transaction flow: enlist, prepare, commit, and abort. The Resync service coordinates transaction recovery in case of any failure or disconnection, while the transaction log maintains a log of information that is needed in case of recovery.

You can perform a 2PC transaction with the ODBC Driver for DB2 using **SQLSetConnAttr**. Using a 2PC transaction is automatic. However, you may need to configure your 2PC connection using tools such as ODBC Connection Manager.

Troubleshooting the ODBC Driver for DB2

The Windows 2000 Event Viewer can be a useful tool for troubleshooting data access in some cases. The ODBC Driver for DB2 does not issue events. However, when SNA (APPC/LU 6.2) is used for the network transport for the ODBC Driver for DB2, the low-level SNA APPC transport issues events on the SNA connection.

The ODBC Driver for DB2 supplied with Host Integration Server 2009 has the ability to trace DRDA data flows when used over TCP/IP. This capability is accessible from the SNADB2 Service tracing inside the Trace utility shipped with Host Integration Server 2009.

This facility shows the same data as an APPC trace but without the control indicators (for example, What_Received). Socket errors are traced and the error codes can be looked up in Winsock2.h supplied with the Win32 SDK.

When the ODBC Driver for DB2 passes an error code, the best source in which to look-up the meaning of the return code is often the SQL Reference or SQL Messages and Codes Reference for the target SQL database. In this case, the target database is one of the DB2 platforms supported by the ODBC Driver for DB2.

The ODBC Driver for DB2 maintains an internal integer variable named SQLCODE and an internal 5-byte character string variable named SQLSTATE used to check the execution of SQL statements on DB2. SQLCODE is set by DB2 after each SQL statement is executed. DB2 returns the following values for SQLCODE:

- If SQLCODE = 0, execution was successful.
- If SQLCODE > 0, execution was successful with a warning.
- If SQLCODE < 0, execution was not successful.
- SQLCODE = 100, "no data" was found. For example, a **FETCH** statement returned no data because the cursor was positioned after the last row of the result table.

SQLSTATE is also set by DB2 after the execution of each SQL statement. Application programs can check the execution of SQL statements by testing SQLSTATE instead of SQLCODE. SQLSTATE provides application programs with common codes for common error conditions (the values of SQLSTATE are product-specific only if the error or warning is product-specific). Furthermore, SQLSTATE is designed so that application programs can test for specific errors or classes of errors.

SQLSTATE values consist of a two-character class code value, followed by a three-character subclass code value. The first character of an SQLSTATE value indicates whether the SQL statement was executed successfully or unsuccessfully (equal to or not equal to zero, respectively). Class code values represent classes of successful and unsuccessful execution conditions. The following table describes SQLSTATE class codes used by DB2.

Class Code	Description of Error Class
00	Successful completion. Execution of the SQL statement was successful and did not result in any type of warning or exception condition.
01	Warning
02	No data
07	Dynamic SQL error
08	Connection exception
0A	Feature not supported
0F	Invalid token
21	Cardinality violation

22	Data exception
23	Constraint violation
24	Invalid cursor state
25	Invalid transaction state
26	Invalid SQL statement identifier
2D	Invalid transaction termination
34	Invalid cursor name
39	External function call exception
40	Transaction rollback
42	Syntax error or access rule violation
44	WITH CHECK OPTION violation
51	Invalid application state
53	Invalid operand or inconsistent specification
54	SQL or product limit exceeded
55	Object not in prerequisite state
56	Miscellaneous SQL or product error
57	Resource not available or operator intervention
58	System error

The SQLSTATE value of HY000 is defined as a driver-specific error. An SQLSTATE of 08S01 (connection exception with a subclass code of S01) also indicates a driver-specific error. This means the SQLCODE should be looked up in the driver-specific documentation included with the ODBC Driver for DB2.

If the SQLSTATE does not indicate a driver-specific error when the ODBC Driver for DB2 passes back an SQLSTATE of 08S01, it indicates a network error. For example, an SQLCODE of -603 is a driver-specific error that is mapped to DB2OLEDB_COMM_HOST_CONNECT_FAILED in the db2oledb.h include file supplied with the ODBC Driver for DB2. Errors with an SQLSTATE of 08S01 are documented in the db2oledb.h include file (the SQLCODE value) which is located on the Host Integration Server 2009 CD in the SDK\Include subdirectory.

The following steps are useful in researching an error. Start by reading the provided error text returned by the ODBC Driver for DB2. In some cases, the error text may provide limited information. For example, error text from an SQLCODE of -603 reads:

```
Test connection failed because of an error in initializing driver.
Could not connect to specified host.
```

The next step is to lookup the SQLSTATE to determine the source of the error. Is the error a DB2 error, a network client error, or an ODBC Driver error? An SQLSTATE of 08S01 is defined as follows:

```
Communication link failure.
```

This definition is intended to inform the user, administrator, or developer that the error is one related to the ODBC driver's underlying network client.

Unfortunately, many of the SQLSTATE codes returned by the ODBC Driver for DB2 are DB2 errors and are not documented in the ODBC Driver for DB2 Help.

The SQLSTATE of HY000 is defined as a driver-specific error. An SQLSTATE of 08S01 also indicates a driver-specific error. In this case, you should look up the SQLCODE in the driver-specific documentation included with the ODBC Driver for DB2.

If the SQLSTATE does not indicate a driver-specific error, you should look up the SQLCODE in the appropriate DB2 manual for the target platform. For example, an SQLCODE of -603 is documented in Appendix B, "SQLCODEs and SQLSTATEs," in the *AS/400 Advanced Series DB2 for AS/400 SQL Programming, Version 4*, document number SC41-5611-00 published by IBM. An SQLCODE of -603 corresponds to SQLSTATE 23515 in the DB2 for OS/400 error code list. For example, the explanation for this SQLCODE is:

```
Unique index cannot be created because of duplicate keys.
```

When the SQLSTATE and the SQLCODE definitions documented in these appendixes create a mismatch with the actual errors returned, it usually indicates a driver-specific error condition.

A final step in understanding an error is to check the db2oledb.h file. This file is not installed by Setup for the Host Integration Client 2000, but is located on the CD-ROM for in the SDK\Include folder. An SQLCODE (for example, -603) can be found by searching the rightmost column of the db2oledb.h file for a value near to 603. For instance, locate the comment "/* -600 */" and then count down three additional lines to line number 603. The internal error code -603 is defined as follows:

```
DB2OLEDB_COMM_HOST_CONNECT_FAILED.
```

This particular error usually indicates a problem with the configuration parameters or the connection string passed.

ODBC Conformance

The Microsoft ODBC Driver for DB2 supports ODBC 2.*x* and ODBC 3.*x* functions. SQL grammar conformance varies, depending on the version of the DB2 database that is accessed. The following sections list the ODBC functions and attributes supported by the Microsoft ODBC Driver for DB2.

In This Section

Support for ODBC 2 Core Functions

The following table lists the ODBC 2.*x* Core functions that are supported by the Microsoft ODBC Driver for DB2.

ODBC 2.*x* Core Functions	**Functions Supported by the Microsoft ODBC Driver for DB2**
SQLAllocConnect	Yes
SQLAllocEnv	Yes
SQLAllocStmt	Yes
SQLBindCol	Yes
SQLCancel	Yes
SQLColAttributes	Yes
SQLConnect	Yes
SQLDescribeCol	Yes
SQLDisconnect	Yes
SQLError	Yes
SQLExecDirect	Yes
SQLExecute	Yes
SQLFetch	Yes
SQLFreeConnect	Yes
SQLFreeEnv	Yes
SQLFreeStmt	Yes
SQLGetCursorName	Yes
SQLNumResultCols	Yes
SQLPrepare	Yes
SQLRowCount	Yes
SQLSetCursorName	Yes
SQLSetParam	In ODBC 2.0, the ODBC 1.0 **SQLSetparam** function was replaced by **SQLBindParameter**
SQLTransact	Yes

Support for ODBC 2 Level 1 Functions

The following table lists the ODBC 2.*x* level 1 functions that are supported by the Microsoft ODBC Driver for DB2.

ODBC 2.*x* level 1 functions	**Functions supported by the Microsoft ODBC Driver for DB2**
SQLBindParameter	Yes
SQLColumns	Yes
SQLDriverConnect	Yes
SQLGetConnectOption	Yes
SQLGetData	Yes
SQLGetFunctions	Yes
SQLGetInfo	Yes
SQLGetStmtOption	Yes
SQLGetTypeInfo	Yes
SQLParamData	Yes
SQLPutData	Yes
SQLSetConnectOption	Yes
SQLSetStmtOption	Yes
SQLSpecialColumns	Yes
SQLStatistics	Yes
SQLTables	Yes

Support for ODBC 2 Level 2 Functions

The following table lists the ODBC 2.*x* level 2 functions that are supported by the Microsoft ODBC Driver for DB2.

ODBC 2.*x* level 2 functions supported	**Functions supported by the Microsoft ODBC Driver for DB2**
SQLBrowseConnect	No
SQLColumnPrivileges	No
SQLDataSources	Yes. This function is actually supported by the ODBC Driver Manager
SQLDescribeParam	No
SQLDrivers	Yes. This function is actually supported by the ODBC Driver Manager
SQLExtendedFetch	Yes, but supports forward scrolling only
SQLForeignKeys	No
SQLMoreResults	Yes
SQLNativeSQL	Yes
SQLNumParams	Yes
SQLParamOptions	Yes
SQLPrimaryKeys	Yes, but SQL grammar conformance varies depending on the version of the DB2 database that is accessed
SQLProcedureColumns	Yes
SQLProcedures	Yes
SetPos	Yes
SQLSetScrollOptions	Yes
SQLTablePrivileges	No

Support for ODBC 3 Functions

The following table lists the ODBC 3.0 functions that are supported by the Microsoft ODBC Driver for DB2.

ODBC 3.0 functions	Functions supported by the Microsoft ODBC Driver for DB2
SQLAllocHandle	Yes
SQLBulkOperations	No
SQLCloseCursor	Yes
SQLColAttribute	Yes
SQLCopyDesc	Yes
SQLEndTran	Yes
SQLFetchScroll	Yes, but supports forward scrolling only
SQLFreeHandle	Yes
SQLGetConnectAttr	Yes
SQLGetDescField	Yes
SQLDescRec	Yes
SQLGetDiagField	Yes
SQLGetDiagRec	Yes
SQLGetEnvAttr	Yes
SQLGetStmtAttr	Yes
SQLRowCount	Yes
SQLSetConnectAttr	Yes
SQLSetDescField	Yes
SQLSetDescRec	Yes
SQLSetEnvAttr	Yes
SQLSetStmtAttr	Yes

Support for ODBC Connection Attributes

The following table lists the ODBC connection attributes support using the Microsoft ODBC Driver for DB2. Note that the connection attributes in this list use the ODBC Version 3.0 attribute names, rather than the older ODBC 1.0 names.

ODBC connection attribute	ODBC version	Attribute supported by the Microsoft ODBC Driver for DB2
SQL_ATTR_ACCESS_MODE	1.0	Yes
SQL_ATTR_ASYNC_ENABLE	3.0	No
SQL_ATTR_AUTO_IPD	3.0	No
SQL_ATTR_AUTOCOMMIT	1.0	Yes
SQL_ATTR_CONNECTION_DEAD	3.5	No
SQL_ATTR_CONNECTION_TIMEOUT	3.0	No
SQL_ATTR_CURRENT_CATALOG	2.0	Yes
SQL_ATTR_ENLIST_IN_DTC	3.0	Yes
SQL_ATTR_ENLIST_IN_XA	3.0	No
SQL_ATTR_LOGIN_TIMEOUT	1.0	No
SQL_ATTR_METADATA_ID	3.0	No
SQL_ATTR_ODBC_CURSORS	2.0	Yes, handled by ODBC Driver Manager
SQL_ATTR_PACKET_SIZE	2.0	No
SQL_ATTR_QUIET_MODE	2.0	Yes
SQL_ATTR_TRACE	1.0	Yes, handled by ODBC Driver Manager
SQL_ATTR_TRACEFILE	1.0	Yes, handled by ODBC Driver Manager
SQL_ATTR_TRANSLATE_LIB	1.0	No
SQL_ATTR_TRANSLATE_DLL	1.0	No
SQL_ATTR_TRANSLATE_OPTION	1.0	No
SQL_ATTR_TXN_ISOLATION	1.0	Yes

Support for ODBC Statement Attributes

The following table lists the ODBC statement attribute support using the Microsoft ODBC Driver for DB2. Note that the statement attributes in this list use the ODBC Version 3.0 attribute names, rather than the older ODBC 1.0 names.

ODBC statement attribute	ODBC version	Attribute supported by the Microsoft ODBC Driver for DB2
SQL_ATTR_APP_PARAM_DESC	3.0	Yes
SQL_ATTR_APP_ROW_DESC	3.0	Yes
SQL_ATTR_ASYNC_ENABLE	1.0	No
SQL_ATTR_CONCURRENCY		No
SQL_ATTR_CURSOR_SCROLLABLE	3.0	No
SQL_ATTR_CURSOR_SENSITIVITY	3.0	No
SQL_ATTR_CURSOR_TYPE	1.0	Yes, but the ODBC Driver for DB2 supports a forward scrolling only cursor type
SQL_ATTR_ENABLE_AUTO_IPD	3.0	No
SQL_ATTR_FETCH_BOOKMARK_PTR	3.0	No
SQL_ATTR_IMP_PARAM_DESC		Yes, handled by ODBC Driver Manager
SQL_ATTR_IMP_ROW_DESC		Yes, handled by ODBC Driver Manager
SQL_ATTR_KEYSET_SIZE	1.0	No
SQL_ATTR_MAX_LENGTH	1.0	No
SQL_ATTR_MAX_ROWS	1.0	No
SQL_ATTR_METADATA_ID	3.0	Yes
SQL_ATTR_NOSCAN	1.0	Yes
SQL_ATTR_PARAM_BIND_OFFSET_PTR	3.0	Yes
SQL_ATTR_PARAM_BIND_TYPE	3.0	Yes
SQL_ATTR_PARAM_OPERATION_PTR	3.0	Yes
SQL_ATTR_PARAM_STATUS_PTR	3.0	Yes
SQL_ATTR_PARAMS_PROCESSED_PTR	3.0	Yes

SQL_ATTR_PARAMSET_SIZE	3.0	Yes
SQL_ATTR_QUERY_TIMEOUT	1.0	No
SQL_ATTR_RETRIEVE_DATA	1.0	No
SQL_ATTR_ROW_ARRAY_SIZE	3.0	Yes
SQL_ATTR_ROW_BIND_OFFSET_PTR	3.0	Yes
SQL_ATTR_ROW_BIND_TYPE	1.0	Yes
SQL_ATTR_ROW_NUMBER	1.0	No
SQL_ATTR_ROW_OPERATION_PTR	3.0	No
SQL_ATTR_ROW_STATUS_PTR	3.0	Yes
SQL_ATTR_ROWS_FETCHED_PTR	3.0	Yes

ADO Object Support in the ODBC Driver for DB2

The following table summarizes the Microsoft ActiveX Data Objects (ADO) version 2.0 objects that are supported by the current version of the Microsoft Open Database Connectivity (ODBC) Driver for DB2.

ADO object	Support
Collection	Yes, most methods
Command Object	Yes, some methods, some properties, and all collections
Connection Object	Yes, some methods, some properties, and all collections
Error Object	Yes, some properties
Field Object	Yes, no methods, most properties, and all collections
Parameter Object	Yes, most methods, most properties, and all collections
Recordset Object	Yes, most methods, most properties, and all collections

The **Parameter** object will be supported by a later version of the ODBC Driver for DB2. For more information about ADO object support, see ADO Object Support in the OLE DB Provider for AS/400 and VSAM and ADO Object Support in the OLE DB Provider for DB2.

In This Section

ADO Method Support in the ODBC Driver for DB2

The following table summarizes the ActiveX Data Objects (ADO) version 2.0 object methods that are supported by the current version of the Microsoft ODBC Driver for DB2.

ADO object	Method	Support
Collection Object	**Append** Method	No
	Clear Method	Yes
	Delete Method	Yes
	Item Method	Yes
	Refresh Method	Yes
Command Object	**CreateParameter** Method	Yes
	Cancel Method	No
	Execute Method	Yes
Connection Object	**BeginTrans** Method	Yes
	Cancel Method	No
	Close Method	Yes
	CommitTrans Method	Yes
	Execute Method	Yes
	Open Method	Yes
	OpenSchema Method	Yes
	RollbackTrans Method	Yes
Field Object	**AppendChunk** Method	No
	GetChunk Method	No
	ReadFromFile Method	No
	WriteToFile Method	No
Parameter Object	**AppendChunk** Method	No
Recordset Object	AddNew Method	Yes
	Cancel Method	No
	CancelBatch Method	Yes

	CancelUpdate	Yes
	Clone Method	Yes
	Close Method	Yes
	Delete Method	Yes
	Find Method	No
	GetRows Method	Yes
	Move Method	Yes
	MoveFirst Method	Yes
	MoveLast Method	Yes, when using a client-side cursor only
	MoveNext Method	Yes
	MovePrevious Method	Yes, when using a client-side cursor only
	NextRecordset Method	No
	Open Method	Yes
	Requery Method	Yes
	Resync Method	No
	Save Method	Yes
	Seek Method	No
	Supports Method	Yes
	Update Method	Yes
	UpdateBatch Method	Yes

Note

The **Collection** object is actually a special case, representing a collection of other ADO objects. These collection objects support several methods:

- **Append** to add an object to a collection.
- **Clear** to empty all objects from a collection.
- **Delete** to remove a single object from a collection.
- **Item** to return a specific member object of a collection by name or ordinal number.
- **Refresh** to update the objects in a collection to reflect objects available from and specific to the ODBC Driver.

ADO Property Support in the ODBC Driver for DB2

The following table summarizes the ActiveX Data Objects (ADO) version 2.0 object properties that are supported by the current version of Microsoft ODBC Driver for DB2.

ADO object	Property	Support
Command Object	ActiveConnection Property	Yes
	CommandText Property	Yes
	CommandTimeout Property	No
	CommandType Property	Yes
	Prepared Property	Yes
	State Property	Yes
Connection Object	Attributes Property	Yes
	CommandTimeout Property	No
	ConnectionString Property	Yes
	ConnectionTimeout Property	No
	CursorLocation Property	Yes
	DefaultDatabase Property	No
	IsolationLevel Property	Yes
	Mode Property	Yes
	Provider Property	Yes
	State Property	Yes
	Version Property	Yes
Error Object	Description Property	Yes
	HelpContext Property	No
	HelpFile	No
	NativeError Property	Yes
	Number Property	Yes
	Source Property	Yes
	SQLState Property	Yes

Field Object	ActualSize Property	Yes
	Attributes Property	Yes
	DataFormat Property	No
	DefinedSizeProperty	Yes
	Name Property	Yes
	NumericScale Property	Yes
	OriginalValue Property	Yes
	Precision Property	Yes
	Type Property	Yes
	UnderlyingValue Property	Yes
	Value Property	Yes
Parameter Object	**Attributes** Property	Yes
	Direction Property	Yes
	Name Property	Yes
	NumericScale Property	Yes
	Precision Property	Yes
	Size Property	Yes
	Type Property	Yes
	Value Property	Yes
Recordset Object	**AbsolutePage** Property	No
	AbsolutePosition Property	No
	ActiveCommand Property	Yes
	ActiveConnection Property	Yes
	BOF Property	Yes
	Bookmark Property	Yes
	CacheSize Property	Yes
	CursorLocation Property	Yes

	CursorType Property	Yes
	DataMember Property	No
	DataSource Property	No
	EditMode Property	Yes
	EOF Property	Yes
	Filter Property	No
	Index Property	No
	LockType Property	Yes
	MarshalOptions Property	No
	MaxRecords Property	Yes
	PageCount Property	No
	PageSize Property	No
	RecordCount Property	No
	Sort Property	No
	Source Property	Yes
	State Property	Yes
	Status Property	Yes
	StayInSync Property	No

ADO Collection Support in the ODBC Driver for DB2

The following table summarizes the Microsoft® ActiveX® Data Objects (ADO) version 2.0 object collections that are supported by the current version of the Microsoft ODBC Driver for DB2.

ADO object	Collection	Support
Command Object	**Parameters** Property	Yes
	Properties Property	Yes
Connection Object	**Errors** Property	Yes
	Properties Property	Yes
Field Object	**Properties** Property	Yes
Parameter	**Properties** Property	Yes
Recordset Object	**Fields** Property	Yes
	Properties Property	Yes

Command Object in the ODBC Driver for DB2 (ADO)

The ActiveX Data Objects (ADO) **Command** object is a definition of a specific command that is to be executed against an Open Database Connectivity (ODBC) Driver data source.

Command objects can be used to create a **Recordset** object and obtain records, execute a bulk operation, or manipulate the structure of a database. When using the Microsoft ODBC Driver for DB2, some collections, methods, or properties of a **Command** object can generate an error when called.

The primary purpose of the **Command** object in the context of the ODBC Driver for DB2 is to issue SQL commands for execution by the remote DB2 target server. Legal SQL commands are documented for the target DB2 platforms in SQL Reference Guides published by IBM.

The following table lists the **Command** object methods, properties, and collections that are supported by the current version of the ODBC Driver for DB2.

Name	Comment
Execute Method	Evaluates command text (only supported *Options* parameter for this method is **adCmdText**, which indicates that this is an SQL text command).
ActiveConnection Property	Sets or returns the information used to establish a connection to a data source (see notes following).
CommandText Property	Sets or returns the command text to be executed.
CommandType Property	Sets or returns the type of command in a **CommandText** property.
State Property	Describes the current state of an object.
Properties collection	Collections of properties on the command.

The **Execute** method executes a command and returns a **Recordset** object, if appropriate. The **Command** object can be used to open tables or execute SQL commands on a remote DB2 server. If errors occur, you can examine them with the **Errors** collection on the **Connection** object.

You can create a **Command** object independently of a previously defined **Connection** object by setting the **ActiveConnection** property of the **Command** object to a valid connection string (for the proper syntax, see the **ConnectionString** property of the **Connection** object). ADO still creates a **Connection** object, but it does not assign that object to an object variable. However, if multiple **Command** objects are to be associated with the same connection, the **Connection** object should be explicitly created and opened. This assigns the **Connection** object to an object variable. If the **ActiveConnection** property of the **Command** object is not set to this object variable, ADO creates a new **Connection** object for each **Command** object, even if the same connection string is used.

The **ActiveConnection** property associates an open connection with a **Command** object. The **CommandText** property defines the text version of a command (**SELECT ALL FROM TABLE**, for example). The **CommandType** property specifies the type of command described in the **CommandText** property prior to execution to optimize performance. The **CommandType** property must be set to **adCmdText** for use with the ODBC Driver for DB2.

Connection Object in the ODBC Driver for DB2 (ADO)

The ActiveX Data Objects (ADO) **Connection** object represents an open connection to an Open Database Connectivity (ODBC) data source. The **Provider** property sets the ODBC Driver to use. Setting the **ConnectionString** properties configures the connection before opening the data source. The **Version** property determines the version of the ADO implementation in use.

The **Open** method establishes the physical connection to the data source and the **Close** method terminates the connection. If errors occur, these can be examined with the **Errors** collection.

The following table lists the **Connection** object methods, properties, and collections that are supported by the current version of the Microsoft ODBC Driver for DB2.

Name	Comment
Close Method	Closes a connection to a data source.
Execute Method	Evaluates command text.
Open Method	Opens a connection to a data source and can optionally pass **ConnectionString** parameters with thi s method.
OpenSchema Method	Obtains database schema information from the ODBC Driver.
Attributes Property	One or more characteristics supported for a given **Connection** object.
ConnectionString Prope rty	Contains the information used to establish a connection to a data source (see notes following this tab le).
CursorLocation proper ty	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
IsolationLevel Property	Sets or returns the level of isolation for a **Connection** object.
Mode Property	Indicates the available permissions for modifying data in a connection.
Provider Property	Sets or returns the name of the provider for a connection.
State Property	Describes the current state of an object.
Version Property	Returns the version number of the ADO implementation in use.
Errors collection	Collections of **Error** objects on the connection.
Properties collection	Collections of properties on the connection.

The information needed to establish a connection to a data source can be set in the **ConnectionString** property or passed as part of the **Open** method. In either case, this information must be in a specific format for use with the ODBC Driver for DB2. This information can be a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons. The following table list the supported ADO-defined arguments for the **ConnectionString** property.

Argument	Description

Data Source	A required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file that is stored in the Program Files\Common Files\ODBC\Data Sources directory.
File Name	Name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed.
Location	The remote database name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.
Password	Valid mainframe or AS/400 password for use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database.
Provider	Name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "DB2 OLEDB".
User ID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database.

The ODBC Driver for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the following tables. The arguments supported by ODBC Driver for DB2 supplied with Host Integration Server 2009 differ from the arguments supported by the earlier ODBC Driver for DB2 included with SNA Server 4.0.

The following table describes the arguments supported by the ODBC Driver for DB2 supplied with Host Integration Server 2009.

Argument	**Description**
BAC	When the *BinAsChar* parameter is set to **true** (1), the ODBC Driver for DB2 treats binary data type fields (with a Code Character Set Identifier (CCSID) of 65535) as character data type fields on a per-data source basis. The **CCSID** and **PCCodePage** values are required input parameters.
CCSID	The CCSID matching the DB2 data as represented on the remote computer. The **CCSID** property is required when processing binary data as character data. Unless the **BinAsChar** value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character *Code Page* to use on the computer. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Microsoft® Windows®. If this argument is omitted, the default value is set to Latin 1 (1252).
DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.

DS	The *Default Schema* parameter is the name of the collection where the ODBC Driver for DB2 looks for catalog information. The *Default Schema* parameter is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses *Default Schema* to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (for example, ODBC Catalog SQLTables). For DB2, the *Default Schema* is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the *Default Schema* is the target COLLECTION name. For DB2 Universal Database (UDB), the *Default Schema* is the SCHEMA name. If the user does not provide a value for *Default Schema*, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the **Default Schema** value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
LLU	When SNA is used for the network transport, this field is the name of the remote logical unit (LU) alias configured in Host Integration Server.
MN	When SNA is used for the Network Transport Library (NTL), the **Mode Name** field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to *QPCSUPP*.
NA	When TCP/IP is used for the NTL, the *Network Address* parameter indicates the IP address or the hostname alias of the host DB2 server.
NP	When TCP/IP is used for the NTL, the *Network Port* parameter indicates the TCP/IP port used for communication with the target DB2 Distributed Relational Database Architecture (DRDA) service. The default value is TCP/IP port 446.
NTL	The *Network Transport Library* parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for **NetAddr** and **NetPort** are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA Application Requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the *Package Collection* parameter.
PDS	The *Provider Data Source* is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "DB2OLEDB".

PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the *Parameter* parameter.
RDB	The *Remote Database Name* parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 Installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The **RDBNAM** value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no **RDBNAM** value, then a value can be created using the **Add** option. In DB2 Universal Database, this property is referred to as DATABASE.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
TPN	The *Transaction Program (TP) Name* parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, the alternative TP Name is set to 0X07F9F9F9.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the *User ID* parameter.
UOW	Determines whether two-phase commit is enabled. The possible values for this parameter are distributed unit of work (DUW) or remote unit of work (RUW). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note

Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using the ODBC Driver for DB2 is as follows:

```
Conn.Provider="DB2OLEDB"
Conn.ConnectionString = "UID=USERNAME;PWD=password",&_
  "LLU=LOCAL;RLU=DATABASE",&_
  "MN=QPCSUPP;CCSID=37;CP=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note

The &_ character combination is used for continuing long lines in Visual Basic.

When opening a connection object in ADO 2.0, you must specify the *Prompt* connection property. For example, the following

syntax is valid with ADO 1.5 and ADO 2.0 and prompts the user for **ConnectionString** properties, as shown in the following code:

```
Conn.ConnectionString = "Provider=DB2OLEDB
Conn.Properties("PROMPT")=adPromptAlways
Conn.Open
```

A sample **Open** method call with these parameters is as follows:

```
RS.Open "Accounting",Conn,0,1,1
```

The last three parameters to the **Open** method correspond with the *CursorType* (the **adOpenForwardOnly** enum is 0, for example), *LockType* (the **adLockReadOnly** enum is 1, for example), and *Options* (**adCmdText** is 1, which indicates that the source name should be evaluated as SQL text). The *Options* parameter must be set to **adCmdText** (1) when used with a data source name with ODBC Driver for DB2.

The following table describes the allowable values for CCSID when using SNA National Language Support (SNANLS) for character code conversions (the default).

EBCDIC character set	**CCSID value**
Arabic	20420
Binary (No Conversion)	65535
Chinese (Simplified)	935
Chinese (Traditional)	937
Cyrillic (Russian)	20880
Cyrillic (Serbian, Bulgarian)	21025
Denmark/Norway (euro)	1142
Denmark/Norway	20277
Finland/Sweden (euro)	1143
Finland/Sweden	20278
France (euro)	1147
France	20297
Germany (euro)	1141
Germany	20273
Greek (Modern)	875
Greek	20423
Hebrew	20424
Icelandic (euro)	1149

Icelandic	20871
International (euro)	1148
International	500
Italy (euro)	1144
Italy	20280
Japanese (English-lower)	931
Japanese (Extend English)	939
Japanese (Extend Katakana)	930
Japanese (Katakana)	290
Japanese (Katakana-Kanji)	5026
Japanese (Latin-Kanji)	5035
Korean	933
Latin America/Spain (euro)	1145
Latin America/Spain	20284
Latin-1 Open System (euro)	20924
Latin-1 Open System	1047
Multilingual/ROECE (Latin-2)	870
Thai	20838
Turkish (Latin-5)	1026
Turkish	20905
U.S./Canada (euro)	1140
U.S./Canada	37
United Kingdom (euro)	1146
United Kingdom	20285

Note that the SNANLS conversions use the locale configured for the data sources using data links. For more information, see SNA National Language Support Programmer's Guide.

The following table describes the allowable values for CCSID when using ANSI/OEM for character code conversions.

ANSI/OEM character set	**CCSID value**

ANSI - Arabic	1256
ANSI - Baltic	1257
ANSI - Cyrillic	1251
ANSI - Eastern Europe	1250
ANSI - Greek	1253
ANSI - Hebrew	1255
ANSI - Latin I	1252
ANSI - Turkish	1254
ANSI/OEM - Korean (Extended Wansung)	949
ANSI/OEM - Japanese Shift-JIS	932
ANSI/OEM - Simplified Chinese GBK	936
ANSI/OEM - Traditional Chinese Big5	950
ANSI/OEM - Thai	874
ANSI/OEM - Vietnam	1258

Error Object in the ODBC Driver for DB2 (ADO)

The ActiveX Data Objects (ADO) **Error** object contains details about data access errors pertaining to a single operation involving ADO. You can read the properties of an **Error** object to obtain specific details about each error.

The **Error** object does not support any methods or collections; however, the **Errors** collection supported by other objects provides the standard **Collection** methods (**Clear** and **Delete**). **Error** objects are automatically appended to the **Errors** collection by the Open Database Connectivity (ODBC) Driver when they occur. The following table lists the **Error** object properties that are supported by the current version of the Microsoft® ODBC Driver for DB2.

Property Name	**Comment**
Description Property	The text of the error alert that is returned based on the minor error code (specific to the ODBC Driver for DB2) contained in the **Error** object resulting from an error.
NativeError Property	A **Long** integer value of the error code returned by the ODBC Driver for DB2.
Number Property	The **Long** integer value of the ODBC error constant.
Source Property	A **string** that indicates the name of the object or application that originally generated an error.

Field Object in the ODBC Driver for DB2 (ADO)

The ActiveX Data Objects (ADO) **Field** object represents a column of data with a common data type. Each **Field** object corresponds to a column in a **Recordset** object.

The following table lists the **Field** object methods, properties, and collections that are supported by the current version of Microsoft ODBC Driver for DB2.

Name	Comment
ActualSize Property	Actual length of a field's value.
Attributes Property	One or more characteristics supported for a given **Field** object.
DefinedSize Property	Defined size of a **Field** object.
Name Property	Name of the **Field** object.
NumericScale Property	Scale of numeric values in a **Field** object for numeric data.
OriginalValue Property	Value of a **Field** object that existed in the record before changes were made.
Precision Property	Degree of precision for numeric values in a **Field** object for numeric data.
Type Property	Operational type or data type for a **Field** object.
UnderlyingValue Property	Current value of a **Field** object.
Value Property	Value assigned to a **Field** object in a **Recordset**.
Properties collection	Collections of properties on the field.

Recordset Object in the ODBC Driver for DB2 (ADO)

The ActiveX Data Objects (ADO) **Recordset** object represents the entire set of records from a base table. At any time, the **Recordset** object refers to only one record within the set as the current record.

The following table lists the **Recordset** object methods, properties, and collections that are supported by the current version of the Microsoft ODBC Driver for DB2.

Name	Comment
AddNew Method	Creates a new record for an updateable **Recordset** object.
CancelBatch Method	Cancels a pending batch update.
CancelUpdate Method	Cancels any changes made to a current record or to a new record prior to calling the **UpdateBatch** method.
Clone Method	Creates a duplicate **Recordset** object from an existing **Recordset** object.
Close Method	Closes an open object and any dependent objects.
Delete Method	Deletes the current record in an open **Recordset** object or an object from a collection.
GetRows Method	Retrieves multiple records of a **Recordset** into an array.
Move Method	Moves the position of the current record in a **Recordset** object.
MoveFirst Method	Moves to the first record in a specified **Recordset**.
MoveLast Method	Moves to the last record in a specified **Recordset**. This method is only supported when using a client-side cursor.
MoveNext Method	Moves to the next record in a specified **Recordset**.
MovePrevious Method	Moves to the previous record in a specified **Recordset**. This method is only supported when using a client-side cursor.
Open Method	Opens a cursor on a **Recordset**.
Requery Method	Updates the data in a **Recordset** object by re-executing the query on which the object is based (equivalent to calling the **Close** and **Open** methods in succession).
Save Method	Saves a **Recordset** in a file or **Stream** object.
Supports Method	Determines whether a specified **Recordset** object supports a particular type of function.
Update Method	Saves any changes you make to the current record of a **Recordset** object.
UpdateBatch Method	Writes all pending batch updates to disk.
ActiveCommand Property	Returns the **Command** object that created the specified **Recordset**.

ActiveConnection Property	Sets or returns the **Connection** object that the specified **Recordset** object currently belongs.
BOF Property	Indicates whether the current record position is before the first record in a **Recordset** object.
Bookmark Property	Returns a bookmark that uniquely identifies the current record in a **Recordset** object or sets the current record in a **Recordset** object identified by a valid bookmark.
CacheSize Property	Sets or returns the number of records from a **Recordset** object that are cached locally in memory.
CursorLocation Property	Sets or returns the location of the cursor (whether the cursor is on the client or the server side).
CursorType Property	Sets or returns the type of cursor used in a **Recordset** object. Only the **adOpenForwardOnly CursorType** is supported by the current version of the ODBC Driver for DB2.
EditMode Property	Indicates the editing status of the current record type.
EOF Property	Indicates whether the current record position is after the last record in a **Recordset** object.
LockType Property	Sets or returns the types of locks placed on records during editing. The ODBC Driver for DB2 supports locks of type **adLockReadOnly** and **adLockPessimistic**.
MaxRecords Property	Sets or returns the maximum number of records to return to a **Recordset** from a query.
Source Property	Sets or returns the source (table name or command object) for the data in a **Recordset**.
State Property	Describes the current state of an object.
Status Property	Indicates the status of the current record with respect to batch updates or other bulk operations.
Fields collection	Collections of fields on the **Recordset**.
Properties collection	Collections of properties on the **Recordset**.

Managed Provider for DB2 Programmer's Reference

The Managed Provider for DB2 enables users to access IBM DB2 from within a managed code application, and serves as a bridge between a DB2 data source and an ADO DataSet. This section provides the reference material needed to program the Managed Provider for DB2.

Managed Data Provider for Host Files Programmer's Reference

SELECT Statement

The following describes the **SELECT** statement parsing used in the Managed Provider for Host Files and provides sample **SELECT** statements.

Syntax

SELECT <Column Collection> FROM Filename WHERE <Where Clause>

SELECT <Column Collection> FROM Filename AS <AssemblyName.SchemaName> WHERE <Where Clause>

Examples

```
SELECT * FROM FILE_NAME
SELECT COL_NAME1, COL_NAME2… FROM FILE_NAME
```

See Also

Other Resources

SQL Parsing in the Managed Data Provider for Host Files

INSERT Statement

The following describes the syntax of the **INSERT** statement for the Managed Provider for Host Files, and provides sample **INSERT** statements.

Syntax

INSERT INTO Filename VALUES (<Values>)

INSERT INTO Filename AS <AssemblyName.SchemaName> VALUES (<Values>)

INSERT INTO Filename (<Column Collection>) VALUES (<Values>)

INSERT INTO Filename AS <AssemblyName.SchemaName> (<Column Collection>) VALUES (<Values>)

Example

The following are sample **INSERT** statements for the Managed Provider for Host Files.

```
INSERT INTO Filename (COL1, COL2…) VALUES(value1, Value2…)
INSERT INTO Filename AS Library_VSAM.NUMBERS  (OUT1_CHAR1, UNION1, UNION2, UNION3, UNION4,
UNION5, UNION6, OUT1_DECIMAL, OUT1_DOUBLE, OUT1_SINGLE) VALUES  ("RECORD", {1234}, {2765788
53}, {1234}, {271111111}, {-1234}, {-135363175}, 100, 100, 100)Comments
```

Managed Data Provider for Host Files Programmer's Reference

UPDATE Statement

The following describes the **UPDATE** statement for the Managed Provider for Host Files and provides a sample **UPDATE** statement.

Syntax

UPDATE Filename SET (<Values>)

UPDATE Filename SET (<Values>) WHERE <Where Clause>

UPDATE Filename AS <AssemblyName.SchemaName> SET (<Values>)

UPDATE Filename AS <AssemblyName.SchemaName> SET (<Values>) WHERE <Where Clause>

UPDATE Filename SET (<Column Collection>) (<Values>)

UPDATE Filename SET (<Column Collection>) (<Values>) WHERE <Where Clause>

Example

The following is a sample **UPDATE** statement for the Managed Provider for Host Files.

```
UPDATE Filename SET (OUT1_INTEGER) (7) WHERE <Applicable where clause >
```

Other Resources

SQL Parsing in the Managed Data Provider for Host Files

DELETE Statement

The following describes the **DELETE** statement for the Managed Provider for Host files.

Syntax

DELETE FROM Filename

DELETE FROM Filename WHERE <Where Clause>

DELETE FROM Filename AS <AssemblyName.SchemaName>

DELETE FROM Filename AS <AssemblyName.SchemaName> WHERE <Where Clause>

SQL Parsing in the Managed Data Provider for Host Files

Column Collection Parsing

The following describes the column collection parsing for the Managed Provider for Host Files and provides a sample parsed column collection.

1. Check for *** OR**

2. Check for column identifiers separated by commas.

3. After every column name, check whether the **AS** keyword is provided.

   If **AS** is provided, the next token should be the CLR data type, such as **Int32** or **String**).

Example

The following is a sample parsed column collection for the Managed Provider for Host Files.

```
*
Col1, Col2, …
Col1 AS String, Col2 as Int32, …
Col1 AS String, Col2, Col3, …Comments
Optional comments.
```

Other Resources

SQL Parsing in the Managed Data Provider for Host Files

WHERE Clause Parsing

The following describes the parsing rules for a **WHERE** clause for the Managed Provider for Host Files and provides sample parsing statements.

1. Check whether the token is **KEY** or **POSITION**.

2. If the token is **KEY**:

    a. The next token should be an open parenthesis (**(**), followed by the column collection, followed by a close parenthesis (**)**).

    b. The next token can be **=** or **EQUALS** or **BETWEEN**.

    c. If the token is **=** or **EQUALS**, then it should be followed by values. Refer to Value Parsing for details about the values.

    d. If the token is **BETWEEN**, then it should be followed by a value, optionally followed by the **INCLUSIVE** or **EXCLUSIVE** keyword. Then it should be followed by **AND**, followed by another value, optionally followed by **INCLUSIVE** or **EXCLUSIVE**.

3. If the token is **POSITION**:

    a. The next token can be **=** or **EQUALS** or **BETWEEN**.

    b. If the token is **=** or **EQUALS**, then it should be followed by values. Refer to Value Parsing for details about the values.

    c. If the token is **BETWEEN**, then it should be followed by a value, optionally followed by the **INCLUSIVE** or **EXCLUSIVE** keyword. Then it should be followed by **AND**, followed by another value, optionally followed by **INCLUSIVE** or **EXCLUSIVE**.

Example

The following is a sample set of parsing statements for the **WHERE** clause for the Managed Provider for Host Files.

```
WHERE KEY (KEY_COL) = ‘1290’
WHERE KEY (KEY_COL) EQUALS ‘1290’
WHERE KEY (KEY_COL) BETWEEN  1290 AND 1390
WHERE KEY (KEY_COL) BETWEEN  1290 INCLUSIVE AND 1390 EXCLUSIVE
WHERE POSITION = 101
WHERE POSITION EQUALS 101
WHERE POSITION BETWEEN 101 AND 201
WHERE POSITION BETWEEN 101 EXCLUSIVE AND 201 INCLUSIVE
```

SQL Parsing in the Managed Data Provider for Host Files

Value Parsing

The following describes the syntax for value parsing for the Managed Provider for Host Files and provides an example.

Syntax

The primitive values are separated by commas. If there are complex data types like Unions or Arrays, then they are enclosed in curly brackets, like {value}.

Example

The following is an example of value parsing for the Managed Provider for Host Files.

```
("RECORD”,{1234},{276578853},{1234},{271111111},{-1234},
{-135363175},100,100,100)
```

See Also

Other Resources

SQL Parsing in the Managed Data Provider for Host Files

Parameterized Queries

The host file provider supports parameterized queries. In this case, instead of using the values directly in the SQL statement, a placeholder can be used.

Syntax

WHERE KEY (KEY_COLUMN) BETWEEN (@p1) AND (@p2)

See Also

Other Resources

SQL Parsing in the Managed Data Provider for Host Files

Limitations

The following describes the limitations on SQL statements for the Managed Provider for Host Files.

SQL Limitations

- If the table contains a complex type (for example, Unions), then the **INSERT** and **UPDATE** commands should set the values for all the complex types.
- Data definition language (DDL) commands like **ALTER** and **CREATE** are not supported.
- Any form of data control language (DCL) is not supported.
- The expression: {COLUMN NAME} AS {EXPRESSION} is not supported.

ActiveX Controls Programmer's Reference

Host Integration Server 2009 provides ActiveX controls that enable many Host Integration Server features to be easily accessed from a large number of client development environments. The APIs of these controls are listed in this section.

For general information about programming for ActiveX controls, see the ActiveX Controls Programmer's Guide section of the SDK.

For sample code that uses ActiveX controls, see the Data Integration Samples section in the SDK.

In This Section

Data Queue ActiveX Control Programmer's Reference

This section provides reference information about specific ActiveX methods, properties, and event notifications supported by the Microsoft Data Queue ActiveX control. The function syntax and code examples are based on Microsoft Visual Basic.

In This Section

AddQueueItem Method

The **AddQueueItem** method on an **IEGDataQueue** object adds a record to a specified data queue using the Microsoft® Data Queue ActiveX® control.

Syntax

```
object.AddQueueItem QueueItem, fBlock
```

Parameters

QueueItem

This required parameter representing an **IEIGDataQueueItem** object instance specifying the queue item to add to the queue.

fBlock

This optional parameter specifies whether the operation should block until the completion status is known. This parameter can be set to one of the **eigAnswerYesNoEnum** constants shown in the table following the Parameters section.

Values for the eigAnswerYesNoEnum constants

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the operation should block until the completion status is known.
eigAnswerNo	1	This value indicates that the operation should not block. This is the default value for this parameter if it is omitted from the method call.

Remarks

The queue the item is sent to is represented by **QItemType** property on the **IEIGDataQueueItem**. The *QueueItem*is an object of type **IEIGDataQueueItem** that may have been initialized by the user or returned by a call to **GetQueueItem**.

Cancel Method

The **Cancel** method on an **IEGDataQueue** object terminates a transfer operation that is already in progress. This method cancels an item transfer using the Microsoft® Data Queue ActiveX® control.

Syntax

```
object.Cancel
```

Parameters

None.

Remarks

The **Cancel** method is used to cancel a transfer operation that is already in progress.

CancelQueue Method

The **CancelQueue** method on an **IEGDataQueue** object indicates that an application using the Microsoft® Data Queue ActiveX® control no longer wants to be notified of an incoming queue data item. This can be used to stop pending notifications that were queued as a result of calling **GetQueueItem**.

Syntax

```
object.CancelQueue CancelReqCount, CancelReqType, KeyValue
```

Parameters

CancelReqCount

This optional parameter is a count (a short value) of the number of outstanding queue receive requests to cancel. This parameter defaults to a value of 1.

CancelReqType

This optional parameter specifies the type of queue request to cancel. This parameter can be set to one of the **eigQItemTypeEnum** constants shown in the table following the Parameters section.

KeyValue

This optional parameter is a VARIANT representing the key value and has no default value. If the *CancelReqType* is eigKQItem, then this value specifies the key value to stop waiting for.

Values for the eigQItemTypeEnum constants

Enumeration	Value	Description
eigKQItem	0	A keyed item.
eigQItem	1	A non-keyed item. This is the default value for this parameter if it is not specified.

This parameter defaults to **eigQItem**.

Remarks

An application can call the **CancelQueue** method passing a *CancelReqCount* value of 0, in order to retrieve the number of queued receive requests.

It is possible that a notification event is in process during this method call. If this occurs, the application may receive a notification following the successful completion of this function. Entering a *CancelReqCount* value that is larger than the queued requests will result in all requests being cancelled. No error will be returned under this condition. Calling this method while no queued requests are outstanding will result in a noncritical error return code indicating this condition.

CCSID Property

The **CCSID** property on an **IEGDataQueueCtrl** object indicates the character code set identifier (CCSID) that must match the data in the queue as represented on the remote host computer. This property affects how data conversion is handled using the Microsoft® Data Queue ActiveX® control. This property sets or returns a short value representing a host CCSID for the data file. The default value for this property is 37 representing a CCSID for U.S./Canada.

Syntax

```
current CCSID = object.CCSID
object.CCSID = 37
```

Remarks

The **CCSID** property is used to set or return the character code set identifier (CCSID) matching the data in the data queue as represented on the remote host computer. This value is used for data conversion of any character data in the host data queue to the **PCCodePage** property specified representing ANSI or Unicode character data on the computer running Microsoft® Windows®.

ClearAll Method

The **ClearAll** method on the **EIGDataQueue** object removes all items from the queue.

Syntax

```
object.ClearAll OverWrite
```

Parameters

OverWrite

This optional parameter specifies whether to overwrite data in the queue. This parameter can be set to one of the **eigAnswerYesNoEnum** constants shown in the table following the Parameters section.

Values for the eigAnswerYesNoEnum constants

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the operation should overwrite data in the queue. This is the default value for this parameter if it is omitted from the method call.
eigAnswerNo	1	This value indicates that the operation should not overwrite data in the queue.

Connect Method

The **Connect** method on an **IEGDataQueueCtrl** object establishes a connection to the configured host using the Microsoft® Data Queue ActiveX® control and reports to the user an indication of the success or failure of the action.

Syntax

```
object.Connect
```

Parameters

None.

Remarks

The **Connect** method is used to establish a connection to the host.

If the Data Queue ActiveX control support DLL cannot be loaded, the Win32® **SetErrorMode** function is called with an error value of SEM_NOOPENFILEERRORBOX | SEM_FAILCRITICALERRORS. Other types of errors are returned using the **ISupportErrorInfo** object.

ConnectionState Property

The **ConnectionState** property on an **IEGDataQueueCtrl** object indicates the current state of the connection to the host using the Microsoft® Data Queue ActiveX® control. The state of a connection can be unspecified, idle, connecting, connected, or disconnecting. This property returns a Long value representing a **eigConnectionStateEnum**. The default value for this property is **eigConnStateIdle**.

Syntax

```
currentConnectionState = object.ConnectionState
```

Remarks

The **ConnectionState** property is used to return the current state of the connection to the host. This property is read-only and can be one of the following **eigConnectionStateEnum** constants:

Enumeration	**Value**	**Description**
eigConnStateUnspecified	-1	This value indicates that the connection state is unspecified.
eigConnStateIdle	0	This value indicates that the connection state is idle and no connection to the host exists.
eigConnStateConnecting	1	This value indicates that the connection state is in the process of connecting to the host.
eigConnStateConnected	2	This value indicates that the connection state is connected indicating a connection to the host.
eigConnStateDisconnecting	3	This value indicates that the connection state is in the process of disconnecting from the host.

ConnectionType Property

The **ConnectionType** property on an **IEGDataQueueCtrl** object indicates the network transport used for this connection. This property sets or returns a Long value representing an **eigConnectionTypeEnum**. The default value for this property is **eigConnTypeAPPC** indicating an APPC connection using SNA.

Syntax

```
currentConnectionType = object.ConnectionType
```

Remarks

The **ConnectionType** property is used to set or return the connection type used to connect to the host. This property can be one of the following **eigConnectionTypeEnum** constants:

Enumeration	Value	Description
eigConnTypeUnspecified	-1	This value indicates that the connection type is unspecified.
eigConnTypeAPPC	0	This value indicates an APPC connection to the host using SNA LU 6.2.

If APPC (SNA LU 6.2) is selected for **ConnectionType**, then values for the **LocalLU**, **ModeName**, and **RemoteLU** properties are required.

CreateQueue Method

The **CreateQueue** method on an **IEGDataQueue** object creates a data queue using the Microsoft® Data Queue ActiveX® control. Following the successful creation of the queue, the object has a virtual connection to the data queue, such that a single instance of this object represents a single queue connection. In order to break this connection, the application can modify the **QueueName** property thus altering the queue association to a new value.

Syntax

```
object.CreateQueueMaxMsgLength, QAuthority, QueueClass,
        AddSenderInfo, HostCCSID, InitialSize, queueLoc, recordLenCls,
        Title, AllowDupKeys, MakeKeyLen
```

Parameters

MaxMsgLength

This required parameter indicates the maximum length of a record in the queue represented as a short integer with possible values ranging from 1 to 31,744. This parameter defaults to a value of 256.

QAuthority

This required parameter specifies the authority to grant users of this queue. This parameter can be set to one of the **eigQAuthorityEnum** constants shown in the table following the Parameters section.

QueueClass

This required parameter indicates how the data will be received from the data queue. This parameter can be set to one of the **eigQClassEnum** constants shown in the table following the Parameters section.

AddSenderInfo

This required parameter indicates whether the queue sender's ID should be kept. This parameter can be set to one of the **eigAnswerYesNoEnum** constants shown in the table following the Parameters section.

HostCCSID

This optional parameter indicates the character code set identifier (CCSID) represented as a short to be used on the host and affects how data conversion is handled. This value must match the data in the queue as represented on the remote host computer. This parameter has no default value, but if this parameter is not specified the *HostCCSID* defaults to the value of the **CCSID** property set on the **IEGDataQueueCtl** object.

InitialSize

This optional parameter indicates the initial data queue size represented as a short integer.

queueLoc

This optional parameter indicates the queue location represented as VARIANT_BOOL.

recordLenCls

This optional parameter indicates the record length class. This parameter can be set to one of the **eigRecordLenClsEnum** constants shown in the table following the Parameters section.

Title

This optional parameter indicates a text description of the queue represented as a BSTR with a maximum length of 50 characters. The default value for this parameter is an empty string.

AllowDupKeys

This optional parameter indicates whether duplicate keys are allowed. This parameter can be set to one of the **eigAnswerYesNoEnum** constants shown in the table following the Parameters section.

Note that this parameter is only valid if the *QueueClass* is specified as **eigQClassKeyed**.

MakeKeyLen

This optional parameter indicates the maximum length of a key for this data queue represented as a short integer ranging

from 1 to 256. Note that this parameter is only valid if the *QueueClass* is specified as **eigQClassKeyed**. This parameter has no default value.

The eigQAuthorityEnum constants

Enumeration	Value	Description
eigQAuthUnspecified	-1	This value indicates that the authority is unspecified.
eigQAuthDefault	0	This value indicates directory default authorization. This is the default value for this parameter if it is not specified.
eigQAuthAll	1	This value indicates all authorization.
eigQAuthExclude	2	This value indicates exclude authorization.
eigQAuthChange	3	This value indicates change authorization.
eigQAuthUse	4	This value indicates use authorization.
eigQAuthLibCreate	5	This value indicates library create authorization.

The eigQClassEnum constants

Enumeration	Value	Description
eigQClassUnspecified	-1	No value
eigQClassFIFO	0	A first in, first out queue. This is the default value for this parameter if it is not specified.
eigQClassLIFO	1	A last in, first out queue.
eigQClassKeyed	2	A keyed ordered queue.

The eigAnswerYesNoEnum constants

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the sender ID should be kept.
eigAnswerNo	1	This value indicates that the sender ID should not be kept. This is the default value for this parameter if it is not specified in the method call.

The eigRecordLenClsEnum constants

Enumeration	Value	Description
eigRecordLenUnspecified	-1	This value indicates that the record length class is unspecified.
eigRecordLenFixed	0	This value indicates fixed length records. This is the default value for this parameter if it is not specified.
eigRecordLenInitVarLen	1	This value indicates initial variable record length.
eigRecordLenVarLen	2	This value indicates variable record length.

Remarks

The type of data queue created is dependent on the value of the *QueueClass* parameter. If a *QueueClass* of **eigQClassKeyed** is specified, then a keyed data queue is created. A *QueueClass* of **eigQClassFIFO** and **eigQClassLIFO** will result in a non-keyed data queue being created.

CreateQueueContainer Method

The **CreateQueue** method on an **IEGDataQueueCtl** object creates an instance of an **IEIGDataQueue** container object using the Microsoft® Data Queue ActiveX® control and optionally initializes the **QueueName** property. The default value for this property is VT_EMPTY.

Syntax

```
object.CreateQueueContainer QueueName
```

Parameters

QueueName

This optional parameter is a BSTR string representing the name of the data queue that this object instance is connected to. This parameter corresponds with the value for the QueueName property.

Remarks

The created queue object is assumed to be associated with the connection object that created it for the life of the connection or the life of the queue object.

DeleteQueue Method

The **DeleteQueue** method on an **IEGDataQueue** object clears all messages from the queue and then deletes the queue using the Data Queue ActiveX® control.

Syntax

```
object.DeleteQueue OverWriteData
```

Parameters

OverWriteData

This required parameter indicates whether data should be overwritten in the data queue. This parameter can be set to one of the **eigAnswerYesNoEnum** constants listed in the table following the Parameters section.

The eigAnswerYesNoEnum constants

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the operation should overwrite data in the queue. This is the default value for this parameter if it is omitted from the method call.
eigAnswerNo	1	This value indicates that the operation should not overwrite data in the queue.

This parameter had a default value of **eigAnswerYes.**

Disconnect Method

The **Disconnect** method on an **IEGDataQueueCtrl** object terminates an existing connection to a host computer using the Microsoft® Data Queue ActiveX® control.

Syntax

```
object.Disconnect
```

Parameters

None.

Remarks

The **Disconnect** method is used to terminate a connection to the host. Errors are returned using the **ISupportErrorInfo** object.

GetQueueItem Method

The **GetQueueItem** method on an **IEGDataQueue** object receives an item from a keyed queue using the Microsoft® Data Queue ActiveX® control.

Syntax

```
object.GetQueueItemQueueType, BlockComplete, PeekQItem,
        ProvideExtInfo, TimeOut, UserProfile, SenderInfo, SearchKey,
        SearchOrder, QueueItem
```

Parameters

QueueType

This required parameter specifies the type of the queue request. This parameter can be set to one of the **eigQItemTypeEnum** constants listed in the table following the Parameters section.

BlockComplete

This required parameter specifies whether the operation should block until the completion status is known. This parameter can be set to one of the **eigAnswerYesNoEnum** constants listed in the table following the Parameters section.

PeekQItem

This required parameter indicates whether to keep the record in the data queue. This parameter can be set to one of the **eigAnswerYesNoEnum** constants listed in the table following the Parameters section.

ProvideExtInfo

This required parameter indicates whether to provide information in the External Job, name, and user properties. This parameter can be set to one of the **eigAnswerYesNoEnum** constants listed in the table following the Parameters section.

TimeOut

This required parameter indicates the amount of time in seconds represented as a short value to block before indicating a failure. This parameter has a default value of 0.

UserProfile

This required parameter indicates whether to provide user profile feedback. This parameter can be set to one of the **eigAnswerYesNoEnum** constants listed in the table following the Parameters section.

SenderInfo

This required parameter indicates whether the sender's ID should be returned. This parameter can be set to one of the **eigAnswerYesNoEnum** constants listed in the table following the Parameters section.

SearchKey

This optional parameter indicates the key used in conjunction with the *SearchOrder* parameter used to identify the queue data item being requested. This must be the same length as specified in the **CreateDataQueue** method call. This parameter is represented as a VARIANT and has no default value.

Note that this parameter is only valid when the *QueueClass* for the data queue is **eigQClassKeyed**.

SearchOrder

This optional parameter indicates the relational order used in receiving keyed data queue items. This parameter can be set to one of the **eigSearchKeyEnum** constants listed in the table following the Parameters section.

Note that this parameter is only valid when the *QueueClass* for the data queue is **eigQClassKeyed**.

QueueItem

This returned parameter is the requested **IEGDataQueueItem**.

The eigQItemTypeEnum constants

Enumeration	Value	Description

eigKQItem	0	A keyed item.
eigQItem	1	A non-keyed item. This is the default value for this parameter if it is not specified.

The eigAnswerYesNoEnum constants

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the sender ID should be returned.
eigAnswerNo	1	This value indicates that the sender ID should not be returned. This is the default value for this parameter if it is not specified in the method call.

The eigSearchKeyEnum constants

Enumeration	Value	Description
eigSearchKeyUnspecified	-1	This value indicates that the *SearchOrder* parameter is unspecified.
eigSearchKeyEqual	0	This value indicates a search for items equal to the specified *SearchKey* parameter.
eigSearchKeyGreaterThan	1	This value indicates a search for items greater than the specified *SearchKey* parameter.
eigSearchKeyLessThan	2	This value indicates a search for items less than the specified *SearchKey* parameter.
eigSearchKeyGreaterEqual	3	This value indicates a search for items greater than or equal to the specified *SearchKey* parameter.
eigSearchKeyLessEqual	4	This value indicates a search for items less than or equal to the specified *SearchKey* parameter.

Remarks

If the *BlockComplete* parameter is **eigAnswerNo** and no queue item is available, the request will be queued. Following the receipt of a queue data item, an event will be fired to the client indicating the availability of data. The client application will be required to call this function again in order to receive the queue data.

If the *BlockComplete* parameter is **eigAnswerYes** and no data arrives on the queue within the specified amount of time, the operation is cancelled and no data is returned. An error indication is returned to the client indicating that a timeout has occurred.

Each call to this method may result in a queued process. Multiple calls may result in multiple notifications.

If the *SenderInfo* item is empty, then the information will not be returned. The client must allocate the storage as an indication that it wishes to receive this information. The type of data queue is dependent on the value of the *QueueClass* parameter when the data queue is created. For a *QueueClass* of **eigQClassKeyed**, a keyed data queue is created. A *QueueClass* of **eigQClassFIFO** or **eigQClassLIFO** will result in a non-keyed data queue being created.

LocalLU Property

The **LocalLU** property on an **IEGDataQueueCtrl** object indicates the local LU alias for an APPC (SNA LU 6.2) connection type to the remote host computer using the Microsoft® Data Queue ActiveX® control. This property sets or returns a BSTR string value representing the local LU name. The default value for this property is the "LOCAL" string.

Syntax

```
currentLocalLu = object.LocalLU
object.LocalLu = "Local2"
```

Remarks

The **LocalLU** property is used to set or return the local LU alias. When LU 6.2 (SNA) is selected for the ConnectionType property, this property must match the name of the local LU alias configured using SNA Manager.

ModeName Property

The **ModeName** property on an **IEGDataQueueCtrl** object indicates the APPC mode used for an APPC (SNA LU 6.2) connection type to the remote host computer using the Microsoft® Data Queue ActiveX® control. This property sets or returns a BSTR string value representing the APPC mode. The default value for this property is the "QPCSUPP" string.

Syntax

```
currentAppcMode = object.ModeName
object.ModeName = "QPCSUPP"
```

Remarks

The **ModeName** property is used to set or return the APPC mode. When APPC (LU 6.2 SNA) is selected for the ConnectionType property, this field must bet set to the APPC mode that matches the host configuration and Microsoft® Host Integration Server configuration.

Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security).

Password Property

The **Password** property on an **IEGDataQueueCtrl** object indicates the password used for authentication. This property affects connection and authentication to a host computer using the Microsoft® Data Queue ActiveX® control. This property sets or returns a BSTR and has no default value.

Syntax

```
currentUserPassword = object.Password
object.Password = Dialog.UserPassword
```

Remarks

The **Password** property is used to set or return the password used for authenticating the user on a host computer. A valid user name and password are normally required to access data on a host computer. The password is case-sensitive and is normally displayed as asterisks in a dialog box for security purposes.

PCCodePage Property

The **PCCodePage** property on an **IEGDataQueueCtrl** object indicates the code page to be used on the PC. This property affects how data conversion is handled using the Microsoft® Data Queue ActiveX® control. This property sets or returns a short value representing the PC code page for the data file. The default value for this property is 1252 representing a PC code page of Latin 1.

Syntax

```
currentPCCodePage = object.PCCodePage
object.PCCodePage = 1252
```

Remarks

The **PCCodePage** property is used to set or return the code page to be used on the PC. This value is used for data conversion of any character data in the host file to ANSI or Unicode character data in the local file on the computer running Microsoft® Windows®.

QueryAttribute Method

The **QueryAttribute** method on the **EIGDataQueue** object returns the value of an attribute associated with a data queue.

Syntax

```
object.QueryAttribute Attribute, Value
```

Parameters

Attribute

This required parameter indicates the attribute value to be retrieved. This parameter can be set to one of the **eigAttributeEnum** constants listed in the table following the Parameters section.

Value

This required parameter points to a variant that will receive the value for this attribute.

The eigAttributeEnum constants

Enumeration	Value	Description
eigAttributeUnspecified	-1	No value
eigAttributeCCSID	0	The code character set identifier used on the host.
eigAttributeDirName	1	Directory name
eigAttributeDataClass	2	Data class name
eigAttributeKeyDef	3	Key definition
eigAttributeDupKeys	4	Indicates whether the duplicate keys capability is enabled for this data queue.
eigAttributeMgmCls	5	Management class name
eigAttributeQueCls	6	The queue class corresponding with the *QueueClass* parameter on the **CreateQueue** method.
eigAttributeSize	7	The queue initial size
eigAttributeQLoc	8	Queue location
eigAttributeSenderInfo	9	Queue senders ID kept
eigAttributeMaxMsgLen	10	The maximum record length for a message.
eigAttributeRecLenClass	11	Record length class
eigAttributeStgClass	12	Storage class name
eigAttributeTitle	13	Description text

Remarks

Most of these attributes correspond with the parameters specified to the CreateQueue method when the data queue is created.

QueueName Property

The **QueueName** property on an **IEGDataQueue** object indicates the name of the data queue this object is associated with.

Syntax

```
currentQueueName = object.QueueName
object.QueueName = "OrderEntry"
```

Remarks

The value of the **QueueName** property is the name of the queue represented as a BSTR string.

Following the successful creation of a queue using the CreateQueue method, the object has a virtual connection to the data queue, such that a single instance of this object represents a single queue connection. In order to break this connection, a client application can modify the **QueueName** property thus altering the queue association to a new value.

RemoteLU Property

The **RemoteLU** property on an **IEGDataQueueCtrl** object indicates the remote LU alias for an APPC (SNA) connection type to the remote host computer using the Microsoft® Data Queue ActiveX® control. This property sets or returns a BSTR string value representing the remote LU name. This property has no default value.

Syntax

```
currentRemoteLu = object.RemoteLU
object.RemoteLu = "Remote10"
```

Remarks

The **RemoteLU** property is used to set or return the remote LU alias. When LU 6.2 (SNA) is selected for the ConnectionType property, this property must match the name of the remote LU alias configured using SNA Manager.

SetAttribute Method

The **SetAttribute** method on the **EIGDataQueue** object changes an attribute associated with a data queue.

Syntax

```
object.SetAttribute Attribute, Value
```

Parameters

Attribute

This required parameter indicates the attribute to be set. This parameter can be set to one of the **eigAttributeEnum** constants listed in the table following the Parameters section.

Value

This required parameter specifies a variant representing the value to set for this attribute.

The eigAttributeEnum constants

Enumeration	Value	Description
eigAttributeUnspecified	-1	No value
eigAttributeCCSID	0	Coded character set identifier
eigAttributeDirName	1	Directory name
eigAttributeDataClass	2	Data class name
eigAttributeKeyDef	3	Key definition
eigAttributeDupKeys	4	Duplicate keys capability
eigAttributeMgmCls	5	Management class name
eigAttributeQueCls	6	The queue class corresponding with the *QueueClass* parameter on the **CreateQueue** method.
eigAttributeSize	7	Queue initial size
eigAttributeQLoc	8	Queue location
eigAttributeSenderInfo	9	Queue senders ID kept
eigAttributeMaxMsgLen	10	Record length
eigAttributeRecLenClass	11	Record length class
eigAttributeStgClass	12	Storage class name
eigAttributeTitle	13	Description text

Remarks

Most of these attributes correspond with the parameters specified to the CreateQueue method when the data queue is created.

StopQueue Method

The **StopQueue** method on an **IEGDataQueue** object suspends send and receive operations for a queue using the Microsoft® Data Queue ActiveX® control.

Syntax

```
object.StopQueue
```

Parameters

None.

UserID Property

The **UserID** property on an **IEGDataQueueCtrl** object indicates the user name used for authentication. This property affects connection and authentication to a host computer using the Microsoft® Data Queue ActiveX® control. This property sets or returns a BSTR and has no default value.

Syntax

```
currentUserName = object.UserID
object.UserID = Dialog.UserName
```

Remarks

The **UserID** property is used to set or return the user name used for authenticating the user on a host computer. A valid user name and password are normally required to access data on a host computer. The user name is case-sensitive.

Host File Transfer ActiveX Control Programmer's Reference

This section provides reference information about specific ActiveX methods, properties, and event notifications supported by the Microsoft Host File Transfer ActiveX control. The function syntax and code examples are based on Microsoft Visual Basic.

In This Section

AppendToEnd Property

The **AppendToEnd** property on an **IEIGFileTransferCtl** object indicates whether a file transfer operation should append to the end of a file if the file exists, or whether a file transfer operation should overwrite the existing contents replacing the data with the new information. This property affects file transfer operations using the Microsoft® Host File Transfer ActiveX® control. This property sets or returns a Long value representing an **eigAnswerYesNoEnum**. The default value for this property is **eigAnswerYes**.

Syntax

```
currentAppendFlag = object.AppendToEnd
object.AppendToEnd = eigAnswerYes
```

Remarks

The **AppendToEnd** property is used to set or return a flag that indicates whether a file transfer operation will append to the end of a file or overwrite the file. This property can be set to one of the following **eigAnswerYesNoEnum** constants:

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the file transfer operation will append to the end of a file if it exists.
eigAnswerNo	1	This value indicates that the file transfer operation will overwrite the existing contents of a file if it exists.

The **AppendToEnd** property and the **OverwriteHostFile** property are mutually exclusive, so it is not possible to enable (set to yes) one of these properties before the opposing property is disabled (set to no). The **AppendToEnd** property takes precedence over the **OverwriteHostFile** property, since **AppendToEnd** defaults to yes and **OverwriteHostFile** defaults to no. Consequently, the order in which these properties are set will affect the outcome. For example, the following order will result in the properties being set correctly:

```
FileTransfer.AppendToEnd = eigAnswerNo         // correctly set to no
FileTransfer.OverwriteHostFile = eigAnswerYes  // correctly set to yes
```

In contrast, setting the properties in the improper order will cause the properties to be set incorrectly as follows:

```
FileTransfer.OverwriteHostFile = eigAnswerYes   // remains at no
// AppendToEnd defaults to eigAnswerYes, so this change is illegal
FileTransfer.AppendToEnd = eigAnswerNo          // correctly set to no
```

In this second case, the **OverwriteHostFile** property cannot be set to yes (enabled) until the **AppendToEnd** property is set to no (disabled).

Cancel Method

The **Cancel** method on an **IEIGFileTransferCtl** object terminates a file transfer operation that is already in progress. This method cancels a file transfer using the Microsoft® Host File Transfer ActiveX® control.

Syntax

```
object.Cancel
```

Parameters

None.

Remarks

The **Cancel** method is used to cancel a file transfer operation that is already in progress. If the **Cancel** method is executed while uploading a file with the **AppendToEnd** property set to yes, this will result in no change to the host file. However, if the **Cancel** method is executed while uploading a file with the **OverwriteHostFile** property set to yes, this will result in an empty host file. The **Cancel** method implies the transfer has been stopped and all the files are at their original values, but this is not really the case when the **OverwriteHostFile** property is set to yes.

CCSID Property

The **CCSID** property on an **IEIGFileTransferCtl** object indicates the character code set identifier (CCSID) that must match the data in the file as represented on the remote host computer. This property affects how data conversion is handled using the Microsoft® Host File Transfer ActiveX® control. This property sets or returns a short value representing a host CCSID for the data file. The default value for this property is 37 representing a CCSID for U.S./Canada.

Syntax

```
current CCSID = object.CCSID
object.CCSID = 37
```

Remarks

The **CCSID** property is used to set or return the character code set identifier (CCSID) matching the data in the file as represented on the remote host computer. This value is used for data conversion of any character data in the host file to the **PCCodePage** property specified representing ANSI or Unicode character data on the Microsoft® Windows® computer.

Connect Method

The **Connect** method on an **IEIGFileTransferCtl** object establishes a connection to the configured host using the Microsoft® Host File Transfer ActiveX® control and reports to the user an indication of the success or failure of the action.

Syntax

```
object.Connect
```

Parameters

None.

Remarks

The **Connect** method is used to establish a connection to the host.

If the Host File Transfer ActiveX control support DLL cannot be loaded, the Win32® **SetErrorMode** function is called with an error value of SEM_NOOPENFILEERRORBOX | SEM_FAILCRITICALERRORS. Other types of errors are returned using the **ISupportErrorInfo** object.

ConnectionState Property

The **ConnectionState** property on an **IEIGFileTransferCtl** object indicates the current state of the connection to the host using the Microsoft® Host File Transfer ActiveX® control. The state of a connection can be unspecified, idle, connecting, connected, or disconnecting. This property returns a Long value representing an **eigConnectionStateEnum**. The default value for this property is **eigConnStateIdle**.

Syntax

```
currentConnectionState = object.ConnectionState
```

Remarks

The **ConnectionState** property is used to return the current state of the connection to the host. This property is read-only and can be one of the following **eigConnectionStateEnum** constants:

Enumeration	Value	Description
eigConnStateUnspecified	-1	This value indicates that the connection state is unspecified.
eigConnStateIdle	0	This value indicates that the connection state is idle and no connection to the host exists.
eigConnStateConnecting	1	This value indicates that the connection state is in the process of connecting to the host.
eigConnStateConnected	2	This value indicates that the connection state is connected indicating a connection to the host.
eigConnStateDisconnecting	3	This value indicates that the connection state is in the process of disconnecting from the host.

ConnectionType Property

The **ConnectionType** property on an **IEIGFileTransferCtl** object indicates the network transport used for this connection. The **ConnectioneType** property designates whether the Microsoft® Host File Transfer ActiveX® control connects via APPC (SNA LU 6.2) or TCP/IP. This property sets or returns a Long value representing an **eigConnectionTypeEnum**. The default value for this property is **eigConnTypeAPPC** indicating an APPC connection using SNA.

Syntax

```
currentConnectionType = object.ConnectionType
object.ConnectionType = eigConnTypeTCPIP
```

Remarks

The **ConnectionType** property is used to set or return the connection type used to connect to the host. This property can be one of the following **eigConnectionTypeEnum** constants:

Enumeration	Value	Description
eigConnTypeUnspecified	-1	This value indicates that the connection type is unspecified.
eigConnTypeAPPC	0	This value indicates an APPC connection to the host using SNA LU 6.2.
eigConnTypeTCPIP	1	This value indicates a TCP/IP connection to the host.

If APPC (SNA) is selected for **ConnectionType**, then values for the **LocalLU**, **ModeName**, and **RemoteLU** properties are required.

If TCP/IP is selected for **ConnectionType**, then values for the **NetAddr** and **NetPort** properties are required.

CreateIfNonExisting Property

The **CreateIfNonExisting** property on a **IEIGFileTransferCtl** object indicates whether a file transfer operation should create a new destination file if one does not already exist. This property affects file transfer operations using the Microsoft® Host File Transfer ActiveX® control. This property sets or returns a Long value representing an **eigAnswerYesNoEnum**. The default value for this property is **eigAnswerNo**.

Syntax

```
currentCreateFlag = object.CreateIfNonExisting
object.CreateIfNonExisting = eigAnswerYes
```

Remarks

The **CreateIfNonExisting** property is used to set or return a flag that indicates whether a file transfer operation should create a new destination file if one does not already exist. This property can be set to one of the following **eigAnswerYesNoEnum** constants:

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the file transfer operation will create a new destination file if the file does not already exist.
eigAnswerNo	1	This value indicates that the file transfer operation will not create a new destination file if the file does not already exist. If the destination file does not already exist, then the file copy operation will not take place.

Disconnect Method

The **Disconnect** method on an **IEIGFileTransferCtl** object terminates an existing connection to a host computer using the Microsoft® Host File Transfer ActiveX® control.

Syntax

```
object.Disconnect
```

Parameters

None.

Remarks

The **Disconnect** method is used to terminate a connection to the host. Errors are returned using the **ISupportErrorInfo** object.

GetFile Method

The **GetFile** method on an **IEIGFileTransferCtl** object copies a file from host storage to local storage using the Microsoft® Host File Transfer ActiveX® control.

Syntax

```
object.GetFile LocalFile, HostFile
```

Parameters

LocalFile

This required parameter specifies the path of a local file that will be written to as a result of this operation.

HostFile

This required parameter specifies the name of the host file that will be copied to the local file.

Remarks

The **GetFile** method can only be called after a connection has been established to the host (when the ConnectionState property is connected). The behavior of the **GetFile** method is affected by the values of the AppendToEnd, CreateIfNonExisting, and OverwriteHostFile properties.

Errors are returned for this method using the **ISupportErrorInfo** object.

LocalLU Property

The **LocalLU** property on an **IEIGFileTransferCtl** object indicates the local LU alias for an APPC (SNA) connection type to the remote host computer using the Microsoft® Host File Transfer ActiveX® control. This property sets or returns a BSTR string value representing the local LU name. The default value for this property is the "LOCAL" string.

Syntax

```
currentLocalLu = object.LocalLU
object.LocalLu = "Local2"
```

Remarks

The **LocalLU** property is used to set or return the local LU alias. When LU 6.2 (SNA) is selected for the ConnectionType property, this property must match the name of the local LU alias configured using SNA Manager.

This property is ignored when TCP/IP is selected for the **ConnectionType** property.

ModeName Property

The **ModeName** property on an **IEIGFileTransferCtl** object indicates the APPC mode used for an APPC (SNA) connection type to the remote host computer using the Microsoft® Host File Transfer ActiveX® control. This property sets or returns a BSTR string value representing the APPC mode. The default value for this property is the "QPCSUPP" string.

Syntax

```
currentAppcMode = object.ModeName
object.ModeName = "QPCSUPP"
```

Remarks

The **ModeName** property is used to set or return the APPC mode. When APPC (LU 6.2 SNA) is selected for the ConnectionType property, this field must bet set to the APPC mode that matches the host configuration and Host Integration Server configuration. This property is ignored when TCP/IP is selected for the **ConnectionType** property.

Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bi-directional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security).

NetAddr Property

The **NetAddr** property on an **IEIGFileTransferCtl** object indicates the IP address of the host computer for a TCP/IP connection type to the remote host computer using the Microsoft® Host File Transfer ActiveX® control. This property sets or returns a BSTR string value representing the IP address of the host computer. This property has no default value.

Syntax

```
currentHostIP = object.NetAddr
object.NetAddr = "207.136.131.30"
```

Remarks

The **NetAddr** property is used to set or return the IP address of the host computer. When TCP/IP is selected for the ConnectionType property, this property must match the IP address of the host computer used where files will be transferred. This property can be an IP address or the name representing the host IP address using the Domain Name System (sna.microsoft.com, for example). This property is ignored when SNA is selected for the **ConnectionType** property.

NetPort Property

The **NetPort** property on an **IEIGFileTransferCtl** object indicates the TCP/IP port used for communication with the host for a TCP/IP connection type to the remote host computer using the Microsoft® Host File Transfer ActiveX® control. This property sets or returns a BSTR string value representing the TCP/IP port used for communication with the host. The default value for this property is the string "446" representing TCP/IP port 446.

Syntax

```
currentIPPort = object.NetPort
object.NetPort = "446"
```

Remarks

The **NetPort** property is used to set or return the TCP/IP port used for communication with the host. When TCP/IP has been selected for the ConnectionType property, this parameter is the TCP/IP port used for communication with the host. This property is ignored when SNA is selected for the **ConnectionType** property.

OverwriteHostFile Property

The **OverwriteHostFile** property on a **IEIGFileTransferCtl** object indicates whether a file transfer operation request to copy a file that will write over an existing file will be executed. This property affects file transfer operations using the Microsoft® Host File Transfer ActiveX® control. This property sets or returns a Long value representing an **eigAnswerYesNoEnum**. The default value for this property is **eigAnswerNo**.

Syntax

```
currentOverwriteFlag = object.OverwriteHostFile
object.OverwriteHostFile = eigAnswerYes
```

Remarks

The **OverwriteHostFile** property is used to set or return a flag that indicates whether a file transfer operation will overwrite an existing file. This property can be set to one of the following **eigAnswerYesNoEnum** constants:

Enumeration	Value	Description
eigAnswerYes	0	This value indicates that the file transfer operation will overwrite an existing host file if it exists.
eigAnswerNo	1	This value indicates that the file transfer operation will not overwrite an existing host file file if it exists.

The **OverwriteHostFile** property and the **AppendToEnd** property are mutually exclusive, so it is not possible to enable (set to yes) one of these properties before the opposing property is disabled (set to no). The **AppendToEnd** property takes precedence over the **OverwriteHostFile** property, since **AppendToEnd** defaults to yes and **OverwriteHostFile** defaults to no. Consequently, the order in which these properties are set will affect the outcome. For example, the following order will result in the properties being set correctly:

```
FileTransfer.AppendToEnd = eigAnswerNo         // correctly set to no
FileTransfer.OverwriteHostFile = eigAnswerYes  // correctly set to yes
```

In contrast, setting the properties in the improper order will cause the properties to be set incorrectly as follows:

```
FileTransfer.OverwriteHostFile = eigAnswerYes   // remains at no
// AppendToEnd defaults to eigAnswerYes, so this change is illegal
FileTransfer.AppendToEnd = eigAnswerNo          // correctly set to no
```

In this second case, the **OverwriteHostFile** property cannot be set to yes (enabled) until the **AppendToEnd** property is set to no (disabled).

Password Property

The **Password** property on an **IEIGFileTransferCtl** object indicates the password used for authentication. This property affects connection and authentication to a host computer using the Microsoft® Host File Transfer ActiveX® control. This property sets or returns a BSTR and has no default value.

Syntax

```
currentUserPassword = object.Password
object.Password = Dialog.UserPassword
```

Remarks

The **Password** property is used to set or return the password used for authenticating the user on a host computer. A valid user name and password are normally required to access files on a host computer. The password is case-sensitive and is normally displayed as asterisks in a dialog box for security purposes.

PCCodePage Property

The **PCCodePage** property on an **IEIGFileTransferCtl** object indicates the code page to be used on the PC. This property affects how data conversion is handled using the Microsoft® Host File Transfer ActiveX® control. This property sets or returns a short value representing the PC code page for the data file. The default value for this property is 1252 representing a PC code page of Latin 1.

Syntax

```
currentPCCodePage = object.PCCodePage
object.PCCodePage = 1252
```

Remarks

The **PCCodePage** property is used to set or return the code page to be used on the PC. This value is used for data conversion of any character data in the host file to ANSI or Unicode character data in the local file on the Microsoft® Windows® computer.

PutFile Method

The **PutFile** method on an **IEIGFileTransferCtl** object copies a file from host storage to local storage using the Microsoft® Host File Transfer ActiveX® control.

Syntax

```
object.PutFile HostFile, LocalFile
```

Parameters

HostFile

This required parameter specifies the name of the host file that will be written to as a result of this operation. This parameter is a BSTR.

LocalFile

This required parameter specifies the path to a local file that will be copied to the host file. This parameter is a BSTR.

Remarks

The **PutFile** method can only be called after a connection has been established to the host (when the ConnectionState property is connected). The behavior of the **PutFile** method is affected by the values of the AppendToEnd, CreateIfNonExisting, and OverwriteHostFile properties.

Errors are returned for this method using the **ISupportErrorInfo** object.

RDBName Property

The **RDBName** property on an **IEIGFileTransferCtl** object indicates the remote database name and the host column description (HCD) file that describes the data types and data conversions used to transfer this file using the Microsoft® Host File Transfer ActiveX® control. This property sets or returns a BSTR string value and has no default value.

Syntax

```
currentRDbName = object.RDBName
object.RDBName = "Inventory"
```

Remarks

The **RDBName** property is used to set or return the name of the remote database name and the host column description (HCD) file that describes the data types and data conversions used to transfer this file. The HCD file describing the data should be located in the system subdirectory below the root directory where Host Integration Server was installed. Setup defaults to the following location: C:\Program Files\Microsoft Host Integration Server

When TCP/IP is selected for the **ConnectionType** property, the **RDBName** must also match the name of the remote database system.

RemoteLU Property

The **RemoteLU** property on an **IEIGFileTransferCtl** object indicates the remote LU alias for an APPC (SNA) connection type to the remote host computer using the Microsoft® Host File Transfer ActiveX® control. This property sets or returns a BSTR string value representing the remote LU name. This property has no default value.

Syntax

```
currentRemoteLu = object.RemoteLU
object.RemoteLu = "Remote10"
```

Remarks

The **RemoteLU** property is used to set or return the remote LU alias. When LU 6.2 (SNA) is selected for the ConnectionType property, this property must match the name of the remote LU alias configured using SNA Manager.

This property is ignored when TCP/IP is selected for the **ConnectionType** property.

UserID Property

The **UserID** property on an **IEIGFileTransferCtl** object indicates the user name used for authentication. This property affects connection and authentication to a host computer using the Microsoft® Host File Transfer ActiveX® control. This property sets or returns a BSTR and has no default value.

Syntax

```
currentUserName = object.UserID
object.UserID = Dialog.UserName
```

Remarks

The **UserID** property is used to set or return the user name used for authenticating the user on a host computer. A valid user name and password are normally required to access files on a host computer. The user name is case-sensitive.

ADO Programmer's Reference

This section provides reference information about specific ActiveX Data Objects (ADO) methods, properties, and collections supported in Host Integration Server 2009 using the following:

- Microsoft OLE DB Provider for AS/400 and VSAM
- Microsoft OLE DB Provider for DB2
- Microsoft ODBC Driver for DB2

For general information about programming with the OLE DB Provider for AS/400 and VSAM, see the OLE DB Provider for AS/400 and VSAM Programmer's Guide in the OLE DB Providers Programmer's Guide section of the SDK.

For general information about programming with the OLE DB Provider for DB2, see the OLE DB Provider for DB2 Programmer's Guide.

For general information about programming with the ODBC Driver for DB2, see the ODBC Driver for DB2 Programmer's Guide in the OLE DB Providers Programmer's Guide section of the SDK.

In This Section

ActiveCommand Property (ADO)

The **ActiveCommand** property on a **Recordset** object indicates which **Command** object created the associated **Recordset** object. This property returns a variant that contains a **Command** object. The default is a **Null** object reference.

Syntax

```
currentCommand = recordset.ActiveCommand
```

Remarks

The **ActiveCommand** property is property is read-only. If a **Command** object was not used to create the current **Recordset**, then a **Null** object reference is returned.

Use this property to find the associated **Command** object when you are given only the resulting **Recordset** object.

ActiveConnection Property (ADO)

The **ActiveConnection** property on a **Command** or **Recordset** object indicates to which **Connection** object the specified **Command** or **Recordset** object currently belongs. This property sets or returns a String that contains the definition for a connection or a **Connection** object. The default is a **Null** object reference.

Syntax

```
command.ActiveConnection = connectionString
activeConnectionString = recordset.ActiveConnection
```

Remarks

The **ActiveConnection** property is used to determine the **Connection** object over which the specified **Command** object will execute or the specified **Recordset** will be opened.

For **Command** objects, the **ActiveConnection** property is read/write.

If you try to call the **Execute** method on a **Command** object before setting the **ActiveConnection** property to an open **Connection** object or valid connection string, an error occurs.

Under Visual Basic, setting the **ActiveConnection** property to **Nothing** disassociates the **Command** object from the current **Connection** and causes the OLE DB provider to release any associated resources on the data source. You can then associate the **Command** object with the same or another **Connection** object. Some providers allow you to change the **ActiveConnection** property setting from one **Connection** to another, without having to first set the property to **Nothing**.

Closing the **Connection** object with which a **Command** object is associated sets the **ActiveConnection** property to **Nothing**. Setting this property to a closed **Connection** object generates an error.

For open **Recordset** objects or for **Recordset** objects whose **Source** property is set to a valid **Command** object, the **ActiveConnection** property is read-only. Otherwise, it is read/write.

You can set the **ActiveConnection** property to a valid **Connection** object or to a valid connection string. In this case, the OLE DB provider creates a new **Connection** object using this definition and opens the connection. Additionally, the provider may set this property to the new **Connection** object to give you a way to access the **Connection** object for extended error information or to execute other commands.

If the *ActiveConnection* parameter of the **Open** method is used to open a **Recordset** object, the **ActiveConnection** property will inherit the value of the argument.

If the **Source** property of the **Recordset** object is set to a valid **Command** object variable, the **ActiveConnection** property of the **Recordset** inherits the setting of the **ActiveConnection** property of the **Command** object.

The information needed to establish a connection to a data source can be set in the **ActiveConnection** property of a **Recordset** object or passed as part of the **Open** method on a **Recordset** object in the *ActiveConnection* parameter. In either case, this information must be in a specific format for use with the Microsoft OLE DB Provider for AS/400 and VSAM, the Microsoft OLE DB Provider for DB2, or the Microsoft ODBC Driver for DB2. This information can be a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons.

ActiveX Data Objects (ADO) supports several standard ADO-defined arguments for the **ActiveConnection** property as listed in the following table.

Argument	**Description**
Data Source	Specifies the name of the data source for the connection. This argument is optional when you use the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

File Name	Specifies the name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed. This argument is not supported by the OLE DB Provider for AS/400 and VSAM.
Location	The remote database name that is used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.
Password	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target host system and has appropriate access rights to the file.
Provider	Specifies the name of the provider to use for the connection. To use the OLE DB Provider for AS/400 and VSAM, the Provider string must be set to "SNAOLEDB". To use the OLE DB Provider for DB2, the Provider string must be set to "DB2OLEDB". To use the ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the ConnectionString because this value is the default for ADO.
User ID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target host system and has appropriate access rights to the file.

ActiveConnection Property Support Using the OLE DB Provider for AS/400 and VSAM

ActiveConnection Property Support Using the OLE DB Provider for DB2

ActiveConnection Property Support Using the ODBC Driver for DB2

ActiveConnection Property Support Using the OLE DB Provider for AS/400 and VSAM

The Microsoft OLE DB Provider for AS/400 and VSAM also supports a number of provider-specific arguments, some of which have default values as specified in the table below. These arguments are listed in the following table.

Argument	Description
BinAsChar	This parameter indicates whether to process binary fields as character fields (default is 0; do not process binary fields as character fields).
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
Default Library	The default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files.
HCD FileName	The fully qualified filename of the DDM host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the SNA system directory. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400.
Local LU	The name of the local LU alias configured in Host Integration Server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
RDB	The remote database name for OS/400. You only need to specify this value if it is different from the remote LU alias configured in Host Integration Server.
Repair Host Keys	This parameter indicates whether the OLE DB provider should repair any host key values set in the registry and defaults to false.
RemoteLU	The name of the remote logical unit (LU) alias configured in Host Integration Server.
StrictVal	This parameter indicates whether strict validation should be used and defaults to false.

Note

Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** for use with the OLE DB Provider for AS/400 and VSAM follows:

```
Conn.Provider="SNAOLEDB"
Conn.ConnectionString = "User ID=USERNAME;Password=password",&_
  "LocalLU=LOCAL;RemoteLU=DATABASE",&_
  "ModeName=QPCSUPP;CCSID=37;PCCodePage=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note

The &_ character combination is used for continuing long lines in Visual Basic.

When opening a connection object in ActiveX® Data Objects (ADO) version 2.0, you must specify the Prompt connection property. For example, the following is valid with ADO version 1.5 and ADO version 2.0 and will prompt the user for **ConnectionString** properties:

```
Conn.ConnectionString = "Provider=SNAOLEDB
Conn.Properties("PROMPT")=adPromptAlways
Conn.Open
```

ActiveConnection Property Support Using the OLE DB Provider for DB2

The Microsoft OLE DB Provider for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by OLE DB Provider for DB2 supplied with Host Integration Server 2009 differ from the arguments supported by the earlier OLE DB Provider for DB2 included with SNA Server 4.0.

The arguments supported by the OLE DB Provider for DB2 supplied with Host Integration Server are listed in the following table.

Argument	**Description**
BinAsChar	When this parameter is set to **true**, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to **false**.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2;SYSIBM;SYSTEM; CURLIB; or USERID depending on platform. This parameter does not have a default value.
InitCat	This parameter is used as the first part of a three-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
LocalLU	The name of the local logical unit (LU) alias configured in Host Integration Server.
ModeName	The Advanced Program-to-Program Communications (APPC) mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.

NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the computer. If this argument is omitted, the default value is set to Latin 1 (1252).
PkgCol	The name of the DRDA target collection (AS/400 library) where the OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter.
RemoteLU	The name of the remote LU alias configured in Host Integration Server.
TPName	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPName is set to 0X07F9F9F9.
UOW	This parameter determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note

Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using the OLE DB Provider for DB2 follows:

```
Conn.Provider="DB2OLEDB"
Conn.ConnectionString = "User ID=USERNAME;Password=password",&_
  "LocalLU=LOCAL;RemoteLU=DATABASE",&_
  "ModeName=QPCSUPP;CCSID=37;PcCodePage=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note

The &_ character combination is used for continuing long lines in Visual Basic.

ActiveConnection Property Support Using the ODBC Driver for DB2

The Microsoft ODBC Driver for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by ODBC Driver for DB2 supplied with Host Integration Server 2009 differ from the arguments supported by the earlier ODBC Driver for DB2 included with SNA Server 4.0.

The arguments supported by the ODBC Driver for DB2 supplied with Host Integration Server are listed in the following table.

Argument	**Description**
BAC	When the *BinAsChar* parameter is set to **true** (1), the ODBC Driver for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The character code set identifier (CCSID) and PCCodePage values are required input parameters.
CCSID	The CCSID matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the BinAsChar value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character code page to use on the computer. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Windows. If this argument is omitted, the default value is set to Latin 1 (1252).
DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.
DS	The Default Schema parameter is the name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (for example, ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
LLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.

MN	When SNA is used for the Network Transport Library (NTL), the Mode Name field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP.
NA	When TCP/IP is used for the Network Transport Library (NTL), the Network Address parameter indicates the IP address or the hostname alias of the host DB2 server.
NP	When TCP/IP is used for the Network Transport Library (NTL), the Network Port parameter indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default value is TCP/IP port 446.
NTL	The Network Transport Library parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for NetAddr and NetPort are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA application requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the Package Collection parameter.
PDS	The Provider Data Source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the ConnectionString since this value is the default for ADO.
PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the Parameter parameter.
RDB	The Remote Database Name parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.

TPN	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPN is set to 0X07F9F9F9.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the User ID parameter.
UOW	Determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note
Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using the ODBC Driver for DB2 supplied with Host Integration Server is as follows:

```
Conn.Provider="MSDASQL"
Conn.ConnectionString = "UID=USERNAME;PWD=password",&_
  "LLU=LOCAL;RLU=DATABASE",&_
  "MN=QPCSUPP;CCSID=37;CP=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note
The &_ character combination is used for continuing long lines in Visual Basic.

ActualSize Property (ADO)

The **ActualSize** property on a **Field** object indicates the actual length of a field's value. This property returns a Long value.

Syntax

```
size = field.ActualSize
```

Remarks

The **ActualSize** property is used to return the actual length of a **Field** object's value. For all fields, the **ActualSize** property is read-only. If ADO cannot determine the length of the **Field** object's value, the **ActualSize** property returns **adUnknown**.

The **ActualSize** and **DefinedSize** properties on a **Field** object can be different. For example, a **Field** object with a declared type of **adVarChar** (variable character data type) and a maximum length of 50 characters returns a **DefinedSize** property value of 50, but the **ActualSize** property value it returns is the length of the data stored in the field for the current record.

AddNew Method (ADO)

The **AddNew** method on a **Recordset** object creates a new record for an updatable **Recordset** object.

Syntax

```
recordset.AddNewFields, Values
```

Parameters

Fields

This optional parameter specifies a single name or an array of names or ordinal positions of the fields in the new record.

Values

This optional parameter specifies a single value or an array of values for the fields in the new record. If *Fields* is an array, *Values* must also be an array with the same number of members; otherwise, an error occurs. The order of field names must match the order of field values in each array.

Remarks

The **AddNew** method is used to create and initialize a new record. The **Supports** method can be used with **adAddNew** to verify whether records can be added to the current **Recordset** object.

After the **AddNew** method is called, the new record becomes the current record and remains current after the **Update** method is called. If the **Recordset** object does not support bookmarks, you may not be able to access the new record after you move to another record. Depending on your cursor type, you may need to call the **Requery** method to make the new record accessible.

If **AddNew** is called while editing the current record or while adding a new record, ADO calls the **Update** method to save any changes and then creates the new record.

The behavior of the **AddNew** method depends on the updating mode of the **Recordset** object and whether or not the *Fields* and *Values* arguments are passed.

In immediate update mode, the OLE DB Provider writes changes to the underlying data source after the **Update** method is called. In immediate update mode, calling the **AddNew** method without arguments sets the **EditMode** property to **adEditAdd**. The OLE DB Provider caches any field value changes locally. Calling the **Update** method posts the new record to the database and resets the **EditMode** property to **adEditNone**. If the *Fields* and *Values* arguments are passed, ADO immediately posts the new record to the database (no **Update** call is necessary) and the **EditMode** property value does not change (**adEditNone**).

In batch update mode, the OLE DB Provider caches multiple changes and writes them to the underlying data source only when the **UpdateBatch** method is called. In batch update mode, calling the **AddNew** method without arguments sets the **EditMode** property to **adEditAdd**. The OLE DB Provider caches any field value changes locally. Calling the **Update** method adds the new record to the current **Recordset** object and resets the **EditMode** property to **adEditNone**, but the OLE DB Provider does not post the changes to the underlying database until the **UpdateBatch** method is called. If the *Fields* and *Values* arguments are passed, ADO sends the new record to the provider for storage in a cache and the **UpdateBatch** method must be called to post the new record to the underlying database.

AppendChunk Method (ADO)

The **AppendChunk** method on a **Field** object appends data to a large text or binary data **Field** object.

Syntax

```
field.AppendChunkData
```

Parameters

Data

This parameter specifies a Variant containing the data to be appended to the **Field** object.

Remarks

The **AppendChunk** method is used on a **Field** object to fill it with long binary or character data. In situations where system memory is limited, the **AppendChunk** method can be used to manipulate long values in portions rather than in their entirety.

If the **adFldLong** bit in the **Attributes** property of a **Field** object is set to **True**, the **AppendChunk** method can be used for that field.

The first **AppendChunk** call on a **Field** object writes data to the field, overwriting any existing data. Subsequent **AppendChunk** calls add to existing data. If you are appending data to one field and then set or read the value of another field in the current record, ActiveX® Data Objects (ADO) assumes that you are finished appending data to the first field. If the **AppendChunk** method is called on the first field again, ADO interprets the call as a new **AppendChunk** operation and overwrites the existing data. Accessing fields in other **Recordset** objects (that are not clones of the first **Recordset** object) will not disrupt **AppendChunk** operations.

If there is no current record when the **AppendChunk** method is called on a **Field** object, an error occurs.

Attributes Property (ADO)

The **Attributes** property on a **Field** object or a **Property** object in a **Properties** collection indicates one or more characteristics of an object. This property returns a Long value.

Syntax

```
attribute = field.Attributes
```

Remarks

The **Attributes** property is used to return characteristics of **Field** objects or **Property** objects.

For a **Field** object, the **Attributes** property is read-only and its value can be the sum of any one or more of the **FieldAttributeEnum** values. The allowable **FieldAttributeEnum** values can be one of the constants in the following table.

Enumeration	Value	Description
adFldMayDefer	0x2	This value indicates that the field is deferred, that is, the field values are not retrieved from the data source with the whole record, but only when you explicitly access them.
adFldUpdatable	0x4	This value indicates that you can write to the field.
adFldUnknownUpdatable	0x8	This value indicates that the provider cannot determine if you can write to the field.
adFldFixed	0x10	This value indicates that the field contains fixed-length data.
adFldIsNullable	0x20	This value indicates that the field accepts Null values.
adFldMayBeNull	0x40	This value indicates that you can read Null values from the field.
adFldLong	0x80	This value indicates that the field is a long binary field. This value also indicates that the **AppendChunk** and **GetChunk** methods on the **Field** object can be used.
adFldRowID	0x100	This value indicates that the field contains some kind of record identifier (record number, unique identifier, and so on).
adFldRowVersion	0x200	This value indicates that the field contains some kind of time or date stamp (often used to track updates).
adFldCacheDeferred	0x1000	This value indicates that the provider caches field values and that subsequent reads are done from the cache.

For a **Property** object, the **Attributes** property is read-only and its value can be the sum of any one or more of the **PropertyAttributesEnum** values. The allowable **PropertyAttributesEnum** values can be one of the constants in the following table.

Enumeration	Value	Description
adPropNotSupported	0	This value indicates that the property is not supported by the provider.

adPropRequired	0x1	This value indicates that the user must specify a value for this property before the data source is initialized.
adPropOptional	0x2	This value indicates that the user does not need to specify a value for this property before the data source is initialized.
adPropRead	0x200	This value indicates that the user can read the property.
adPropWrite	0x400	This value indicates that the user can set the property.

BOF Property (ADO)

The **BOF** property on a **Recordset** object indicates that the current record position is before the first record in a **Recordset** object. This property returns a Boolean value.

Syntax

```
IsBOF = recordset.BOF
```

Remarks

The **BOF** property is used to determine whether a **Recordset** object contains records or whether you have gone beyond the limits of a **Recordset** object when you move from record to record.

The **BOF** property returns **True** if the current record position is before the first record and **False** if the current record position is on or after the first record.

If the **BOF** property is **True**, there is no current record.

If a **Recordset** object is opened containing no records, both the **BOF** and **EOF** properties are set to **True** and the **Recordset** object's **RecordCount** property setting is zero. When a **Recordset** object is opened that contains at least one record, the first record is the current record and the **BOF** and **EOF** properties are **False**.

If the last remaining record in the **Recordset** object is deleted, the **BOF** and **EOF** properties may remain **False** until you attempt to reposition the current record.

This table below indicates which **Move** methods are allowed with different combinations of the **BOF** and **EOF** properties.

	MoveFirst MoveLast	**MovePrevious Move < 0**	**Move 0**	**MoveNext Move > 0**
BOF=True EOF=False	Allowed	Error	Error	Allowed
BOF=False EOF=True	Allowed	Allowed	Error	Error
Both True	Error	Error	Error	Error
Both False	Allowed	Allowed	Allowed	Allowed

Note

Executing a **Move** 0 method when the **BOF** property is **True** does not currently generate an error using the OLE DB Provider for AS/400 and VSAM.

Note

Allowing a **Move** method does not guarantee that the method will successfully locate a record; it only means that calling the specified **Move** method will not generate an error.

The following table shows what happens to the **BOF** and **EOF** property settings when various **Move** methods are called but are unable to successfully locate a record.

	BOF property	**EOF property**
MoveFirst MoveLast	Set to **True**	Set to **True**
Move 0	No change	No change
MovePrevious Move < 0	Set to **True**	No change
MoveNext Move > 0	No change	Set to **True**

Bookmark Property (ADO)

The **Bookmark** property on a **Recordset** object returns a bookmark that uniquely identifies the current record in a **Recordset** object or sets the current record in a **Recordset** object to the record identified by a valid bookmark. This property sets or returns a **Variant** expression that evaluates to a valid bookmark.

Syntax

```
FirstBookmark = recordset.Bookmark
recordset.Bookmark = PreviousBookmark
```

Remarks

The **Bookmark** property is used to save the position of the current record and return to that record at any time. Bookmarks are available only in **Recordset** objects (host tables) that support the bookmark feature.

When a **Recordset** object is opened, each of its records has a unique bookmark. To save the bookmark for the current record, assign the value of the **Bookmark** property to a variable. To quickly return to that record at any time after moving to a different record, set the **Recordset** object's **Bookmark** property to the value of that variable.

The user may not be able to view the value of the bookmark. Also, users should not expect bookmarks to be directly comparable—two bookmarks that refer to the same record may have different values.

If the **Clone** method is used to create a copy of a **Recordset** object, the **Bookmark** property settings for the original and the duplicate **Recordset** objects are identical and you can use them interchangeably. However, you cannot use bookmarks from different **Recordset** objects interchangeably, even if they were created from the same source or command.

Using the OLE DB Provider for AS/400 and VSAM, only some data sources can be bookmarked. Calling the **Supports** method with the **adBookmark** argument will indicate if the data source (table) can be bookmarked.

CacheSize Property (ADO)

The **CacheSize** property on a **Recordset** object indicates the number of records from a **Recordset** object that are cached locally in memory. This property sets or returns a Long value that must be greater than zero. The default value for the **CacheSize** property is 1.

Syntax

```
previousSize = recordset.CacheSize
recordset.CacheSize = 1
```

Remarks

The **CacheSize** property is used to control how many records the provider keeps in its buffer and how many to retrieve at one time into local memory. For example, if the **CacheSize** is 10, after first opening the **Recordset** object, the provider retrieves the first 10 records into local memory. As you move through the **Recordset** object, the provider returns the data from the local memory buffer. As soon as you move past the last record in the cache, the provider retrieves the next 10 records from the data source into the cache.

The value of the **CacheSize** property can be adjusted during the life of the **Recordset** object, but changing this value only affects the number of records in the cache after subsequent retrievals from the data source. Changing the property value alone will not change the current contents of the cache.

If there are fewer records to retrieve than the **CacheSize** property specifies, the provider returns the remaining records; no error occurs.

A **CacheSize** setting of zero is not allowed and returns an error. Non-bookmarkable files cannot have the **CacheSize** property set to greater than one, or an error will occur.

It is strongly recommended that a **CacheSize** of 1 be used with the OLE DB Provider for AS/400 and VSAM. If the **CacheSize** is set greater than 1, it is possible for the local data cached in memory to be out of date from changes made by other users on the host.

CancelBatch Method (ADO)

The **CancelBatch** method on a **Recordset** object cancels a pending batch update.

Syntax

```
recordset.CancelBatchAffectedRecords
```

Parameters

AffectedRecords

This optional parameter specifies an **AffectEnum** value that determines how many records the **CancelBatch** method will affect. The **AffectEnum** value can be one of the constants in the following table.

Enumeration	Value	Description
adAffectCurrent	1	This value cancels pending updates only for the current record.
adAffectGroup	2	This value cancels pending updates for records that satisfy the current Filter property setting. You must set the **Filter** property to one of the valid predefined constants to use this option.
adAffectAll	3	This value cancels pending updates for all the records in the **Recordset** object, including any hidden by the current **Filter** property setting. This value is the default.

Remarks

The **CancelBatch** method is used to cancel any pending updates in a **Recordset** object in batch update mode. If the **Recordset** object is in immediate update mode, calling **CancelBatch** without **adAffectCurrent** generates an error.

If you are editing the current record or are adding a new record when **CancelBatch** is called, ActiveX® Data Objects (ADO) first calls the CancelUpdate Method to cancel any cached changes, and then all pending changes in the recordset are canceled.

It is possible that the current record will be indeterminable after a **CancelBatch** call, especially if you were in the process of adding a new record. For this reason, it is prudent to set the current record position to a known location in the recordset after the **CancelBatch** method is called. For example, call the **MoveFirst** method.

If the attempt to cancel the pending updates fails because of a conflict with the underlying data (for example, a record has been deleted by another user), the provider returns warnings to the **Errors** collection but does not halt program execution. A run-time error occurs only if there are conflicts on all the requested records. The Filter Property (**adFilterAffectedRecords**) and the **Status** property can be used to locate records with conflicts.

CancelUpdate Method (ADO)

The **CancelUpdate** method on a **Recordset** object cancels any changes made to the current record or to a new record prior to calling the **Update** method.

Syntax

```
recordset.CancelUpdate
```

Parameters

None.

Remarks

The **CancelUpdate** method is used to cancel any changes made to the current record or to discard a newly added record. You cannot undo changes to the current record or to a new record after the **Update** method is called unless the changes are part of a batch update that you can cancel with the CancelBatch Method.

If you are adding a new record when the **CancelUpdate** method is called, the record that was current prior to the AddNew Method call becomes the current record again.

If you have not changed the current record or added a new record, calling the **CancelUpdate** method generates an error.

Clear Method (ADO)

The **Clear** method on a **Collection** object removes all of the objects in a collection.

Syntax

```
collection.Clear
```

Parameters

None.

Remarks

The **Clear** method is used on the **Errors** collection to remove all existing **Error** objects from the collection. When an error occurs, ActiveX® Data Objects (ADO) automatically clears the **Errors** collection and fills it with **Error** objects based on the new error. However, some properties and methods return warnings that appear as **Error** objects in the **Errors** collection but do not halt a program's execution. Before calling the **Resync**, **UpdateBatch**, or CancelBatch Methods on a **Recordset** object or before setting the Filter Property on a **Recordset** object, call the **Clear** method on the **Errors** collection. Doing so enables you to read the **Count** property of the **Errors** collection to test for returned warnings as a result of these specific calls.

Clone Method (ADO)

The **Clone** method on a **Recordset** object creates a duplicate **Recordset** object from an existing **Recordset** object.

Syntax

```
rstDuplicate = rstOriginal.Clone
```

Parameters

rstDuplicate

This object variable specifies the duplicate **Recordset** object to be created.

rstOriginal

This object variable specifies the **Recordset** object to be duplicated.

Remarks

The **Clone** method is used on a **Recordset** object to create multiple, duplicate **Recordset** objects, particularly if you want to be able to maintain more than one current record in a given set of records. Using the **Clone** method is more efficient than creating and opening a new **Recordset** object with the same definition as the original.

The current record of a newly created clone is set to the first record.

Changes made to one **Recordset** object are visible in all of its clones regardless of cursor type. However, after you execute **Requery** on the original **Recordset**, the clones will no longer be synchronized to the original.

Closing the original **Recordset** does not close its copies; closing a copy does not close the original or any of the other copies.

You can only clone a **Recordset** object that supports bookmarks. Bookmark values are interchangeable; that is, a bookmark reference from one **Recordset** object refers to the same record in any of its clones.

Close Method (ADO)

The **Close** method on a **Connection** or **Recordset** object closes an open object and any dependent objects.

Syntax

```
recordSet.Close
```

Parameters

None

Remarks

The **Close** method is used to close either a **Connection** object or a **Recordset** object to free any associated system resources. Closing an object does not remove it from memory; you may change its property settings and open it again later. To completely eliminate an object from memory, set the object variable to **Nothing**.

Using the **Close** method to close a **Connection** object also closes any active **Recordset** objects associated with the connection. A **Command** object associated with the **Connection** object you are closing will persist, but it will no longer be associated with a **Connection** object, that is, its **ActiveConnection** property will be set to **Nothing**.

You can later call the **Open** method to reestablish the connection to the same or another data source. While the **Connection** object is closed, calling any methods that require an open connection to the data source generates an error. Closing a **Connection** object while there are open **Recordset** objects on the connection rolls back any pending changes in all of the **Recordset** objects.

Using the **Close** method to close a **Recordset** object releases the associated data and any exclusive access you may have had to the data through this particular **Recordset** object. You can later call the **Open** method to reopen the recordset with the same or modified attributes. While the **Recordset** object is closed, calling any methods that require a live cursor generates an error.

If an edit is in progress while in immediate update mode, calling the **Close** method generates an error. The **Update** or CancelUpdate Methods should be called first. If you close the **Recordset** object during batch updating, everything changes since the last **UpdateBatch** call is lost.

CommandText Property (ADO)

The **CommandText** property on a **Command** object contains the text of a command that you want to issue against a provider. This property sets or returns a String value containing a provider command, such as an AS/400 Command Language (CL) command for execution by the remote OS/400 DDM target server or an SQL command for execution on a DB2 database server. The default value for the **CommandText** property is a zero-length string.

Syntax

```
previousCommandtext = command.CommandText
command.CommandText= "EXEC COMMAND DDMCmd"
```

Remarks

The **CommandText** property is used to set or return the text of a **Command** object. When used with the OLE DB Provider for AS/400 and VSAM, the text can be an AS/400 CL command for execution by the remote OS/400 DDM target server or a request to open a table on a host (a remote DDM Server). When used with the OLE DB Provider for DB2, the text can be an SQL command for execution or a call to a stored procedure.

If the **Prepared** property of the **Command** object is set to **True** and the **Command** object is bound to an open connection when you set the **CommandText** property, ActiveX® Data Objects (ADO) prepares the query when you call the **Execute** or **Open** methods.

Depending on the **CommandType** property setting, ADO may alter the **CommandText** property. The **CommandText** property can be read at any time to see the actual command text that ADO will use during execution.

The **CommandText** property defines the text version of a command. The syntax for the string in the **CommandText** property when used with the OLE DB Provider for AS/400 and VSAM is as follows:

```
EXEC COMMAND DDMCmd
```

where *DDMCmd* represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands allow you to request functions from the OS/400 operating system. Some examples are the DLTF (Delete File) or DSPFFD (Display File Description) commands. These are the same commands that could be issued on the command line if you were connected to an AS/400 via a 5250 terminal session. See the 'OS/400 CL Reference for your platform for a detailed list of possible commands.

With the OLE DB Provider for AS/400 and VSAM, the **Command** object can also be used to open a data file after a **Connection** object has been opened and the **ActiveConnection** property has been set to this open connection. The **CommandText** property defines the data file to open. When used with the OLE DB Provider for AS/400 and VSAM, the syntax for the **CommandText** property string in this case is as follows:

```
EXEC OPEN DataSetName
```

where *DataSetName* represents a valid data file or library member on the host. If you open a host data file from a **Command** object, then the data file is opened as read-only. This results from the limitation that no argument or option is passed by ADO that supplies a parameter describing whether the data set should be opened as read-only or updatable.

The syntax for the string in the **CommandText** property when used with the OLE DB Provider for DB2 can be one of the following:

```
EXEC SQLStatement
```

where SQLStatement represents a valid SQL statement supported by DB2.

```
CALL StoredProcedure
```

where StoredProcedure represents a valid DB2 stored procedure on the database server.

The **CommandType** property specifies the type of command described in the **CommandText** property prior to execution in order to optimize performance. The **CommandType** property must be set to **adCmdText** for use with the OLE DB Provider

for AS/400 and VSAM or the OLE DB Provider for DB2.

CommandType Property (ADO)

The **CommandType** property on a **Command** object Indicates the type of a **Command** object. This property sets or returns a **CommandTypeEnum** value.

Syntax

```
oldType = command.CommandType
command.CommandType= newType
```

Remarks

The **CommandType** property is used to set or return the type of a **Command** object. This property specifies a **CommandTypeEnum** value that can be one of the constants in the following table.

Enumeration	Value	Description
adCmdUnspecified	-1	This value indicates that the **CommandType** property has been unspecified.
adCmdText	1	This value evaluates the **CommandText** property as a textual definition of a command or stored procedure call.
adCmdTable	2	This value evaluates the **CommandText** property as a table name. This value is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adCmdStoredProc	4	This value evaluates the **CommandText** property as a stored procedure. This value is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2. See remarks below regarding using stored procedures using the OLE DB Provider for DB2.
adCmdUnknown	8	This value indicates that the type of command in a **CommandText** property is not known. This is the default value.

The OLE DB Provider for AS/400 and VSAM and the OLE DB Provider for DB2 only support the **adCmdText** type for the **CommandType** property. If any other value for the **CommandType** property is set, errors will occur.

The OLE DB Provider for DB2 supports calling DB2 stored procedures. An application must use the CALL keyword before the SQL statement in order to execute a stored procedure. When using ADO, a **CommandType** property of **adCmdStoredProc** cannot be used for executing a stored procedure since ActiveX® Data Objects (ADO) inserts an EXEC not CALL keyword before the command text. In order to execute a stored procedure using ADO, the **CommandType** property should be set to **adCmdText** and the CALL keyword should be used before the SQL statement containing the stored procedure to be executed.

ConnectionString Property (ADO)

The **ConnectionString** property on a **Connection** object contains the information used to establish a connection to a data source. This property sets or returns a string value.

Syntax

```
oldString = connection.ConnectionString
connection.ConnectionString = newString
```

Remarks

The **ConnectionString** property is used to specify a data source by passing a detailed connection string containing a series of *argument = value* statements separated by semicolons.

Microsoft ActiveX Data Objects (ADO) supports several standard arguments for the **ConnectionString** property. Any other arguments are passed directly to the provider without any processing by ADO. This information must be in a specific format for use with the Microsoft OLE DB Provider for AS/400 and VSAM, the Microsoft OLE DB Provider for DB2 or the Microsoft ODBC Driver for DB2. This information can be a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons. ADO supports several standard ADO-defined arguments for the **ConnectionString** property as listed in the following table.

Argument	**Description**
Data Source	This argument specifies the name of the data source for the connection. This argument is optional when using the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
File Name	This argument specifies the name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed. This argument is not supported by the OLE DB Provider for AS/400 and VSAM.
Location	The remote database name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.
Password	This argument specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target host system and has appropriate access rights to the file.
Provider	This argument specifies the name of the provider to use for the connection. To use the OLE DB Provider for AS/400 and VSAM, the Provider string must be set to "SNAOLEDB". To use the OLE DB Provider for DB2, the Provider string must be set to "DB2OLEDB". To use the ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the ConnectionString since this value is the default for ADO.
Remote Provider	This argument specifies the name of a provider to use when opening a client-side connection (for a Remote Data Service only). This argument is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
Remote Server	This argument specifies the path name of a server to use when opening a client-side connection (for a Remote Data Service only). This argument is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

User ID	This argument specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target host system and has appropriate access rights to the file.

Note
Not all of these parameters are required. The user can also be prompted for this information.

The OLE DB Provider for AS/400 and VSAM also support a number of provider-specific arguments, some of which default have default values as specified in the following table.

Argument	**Description**
BinAsChar	This parameter indicates whether to process binary fields as character fields (default is 0; do not process binary fields as character fields).
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
Default Library	The default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files.
HCDFileName	The fully qualified filename of the DDM host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the SNA system directory. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400.
Local LU	The name of the local LU alias configured in Host Integration Server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
RDB	The remote database name for OS/400. You only need to specify this value if it is different from the remote LU alias configured in Host Integration Server.
Repair Host Keys	This parameter indicates whether the OLE DB provider should repair any host key values set in the registry and defaults to false.

RemoteLU	The name of the remote LU alias configured in Host Integration Server.
StrictVal	This parameter indicates whether strict validation should be used and defaults to false.

Note

Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** for use with the OLE DB Provider for AS/400 and VSAM follows:

```
Conn.Provider="SNAOLEDB"
Conn.ConnectionString = "User ID=USERNAME;Password=password",&_
  "LocalLU=LOCAL;RemoteLU=DATABASE",&_
  "ModeName=QPCSUPP;CCSID=37;PCCodePage=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note

The &_ character combination is used for continuing long lines in Visual Basic.

When opening a connection object in ADO 2.0, you must specify the Prompt connection property. For example, the following is valid with ADO 1.5 and ADO 2.0 and will prompt the user for **ConnectionString** properties:

```
Conn.ConnectionString = "Provider=SNAOLEDB
Conn.Properties("PROMPT")=adPromptAlways
Conn.Open
```

The OLE DB Provider for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by OLE DB Provider for DB2 supplied with Host Integration Server 2009 differ from the arguments supported by the earlier OLE DB Provider for DB2 included with SNA Server 4.0.

The arguments supported by the OLE DB Provider for DB2 supplied with Host Integration Server 2009 are listed in the following table.

Argument	**Description**
BinAsChar	When this parameter is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).

DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2, SYSIBM, SYSTEM, CURLIB, or USERID depending on platform. This parameter does not have a default value.
InitCat	This parameter is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
LocalLU	The name of the local LU alias configured in Host Integration Server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
PkgCol	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter.

RemoteLU	The name of the remote LU alias configured in Host Integration Server.
TPName	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPName is set to 0X07F9F9F9.
UOW	This parameter determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note

Not all of these parameters are required. The user can also be prompted for this information.

The ODBC Driver for DB2 supports a number of provider-specific arguments, some of which have default values as specified in the following tables. The arguments supported by ODBC Driver for DB2 supplied with Host Integration Server 2009 differ from the arguments supported by the earlier ODBC Driver for DB2 included with SNA Server 4.0.

The arguments supported by the ODBC Driver for DB2 supplied with Host Integration Server 2009 are listed in the following table.

Argument	**Description**
BAC	When the *BinAsChar* parameter is set to **true** (1), the ODBC Driver for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The CCSID and PCCodePage values are required input parameters.
CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the BinAsChar value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character code page to use on the PC. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Windows. If this argument is omitted, the default value is set to Latin 1 (1252).

DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.
DS	The Default Schema parameter is the name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (e.g., ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
LLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
MN	When SNA is used for the Network Transport Library (NTL), the Mode Name field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP.
NA	When TCP/IP is used for the Network Transport Library (NTL), the Network Address parameter indicates the IP address or the hostname alias of the host DB2 server.
NP	When TCP/IP is used for the Network Transport Library (NTL), the Network Port parameter indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default value is TCP/IP port 446.
NTL	The Network Transport Library parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for NetAddr and NetPort are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA application requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the Package Collection parameter.

PDS	The Provider Data Source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the ConnectionString since this value is the default for ADO.
PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the Parameter parameter.
RDB	The remote database name parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
TPN	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPN is set to 0X07F9F9F9.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the User ID parameter.
UOW	Determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note

Not all of these parameters are required. The user can also be prompted for this information.

A sample **ConnectionString** using the ODBC Driver for DB2 supplied with Host Integration Server is as follows:

```
Conn.Provider="MSDASQL"
Conn.ConnectionString = "UID=USERNAME;PWD=password",&_
  "LLU=LOCAL;RLU=DATABASE",&_
```

```
  "MN=QPCSUPP;CCSID=37;CP=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

Note

The &_ character combination is used for continuing long lines in Visual Basic.

After the **ConnectionString** property is set and the **Connection** object is opened, the provider may alter the contents of the property, for example, by mapping the ADO-defined argument names to their provider equivalents. Using the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2, three items are stripped from the **ConnectionString** after a **Connection** object is opened: Data Source, User ID, and Password.

The **ConnectionString** property automatically inherits the value used for the *ConnectionString* argument of the **Open** method on a **Connection** object, so you can override the current **ConnectionString** property during the **Open** method call. Therefore, the **ConnectionString** property of the **Connection** object can be set before opening the **Connection** object, or the *ConnectionString* parameter can be used to set or override the current connection parameters during the **Open** method call.

The **ConnectionString** property is read/write when the connection is closed and read-only when it is open.

If user and password information is set in both the **ConnectionString** property and in the optional *UserID* and *Password* parameters to the **Open** method, the results may be unpredictable. Such information should only be passed in either the **ConnectionString** property (or the *ConnectionString* parameter to the **Open** method call) or in the *UserID* and *Password* parameters.

There are a number of different ways to open a connection. The **Open** method can pass all of the appropriate connection information as part of the *ConnectionString* parameter or by setting the **ConnectionString** property of the **Connection** object, if this information is known in advance. The syntax in this case using the **ConnectionString**property is as follows:

```
connection = CreateObject("ADODB.Connection.2.0")
connection.Provider="SNAOLEDB"
connection.ConnectionString = "User ID=USERNAME;Password=password;Local LU=LOCAL;Remote LU=
DATABASE;ModeName=QPCSUPP;CCSID=37;CodePage=437"
Conn.Properties("PROMPT")=adPromptNever
Conn.Open
```

There is a lack of spaces after the semicolons in the string. If spaces are inserted after the semicolons, an error will occur.

The simplest form of a **ConnectionString** property that contains all necessary information is as follows:

```
connection = CreateObject("ADODB.Connection.2.0")
connection.ConnectionString = "Provider=SNAOLEDB;Data Source=REMLU;User ID=USERNAME;Passwor
d=password;ModeName=QPCSUPP"
```

Note

The User ID and Password must be included. Note the lack of spaces after the semicolons in the string. If spaces are inserted after the semicolons, an error will occur.

In the case where you would like the user to input the connection information, the following syntax can be used. This syntax does not specify any connection information except the provider, which is always required unless this is set in the **ConnectionString** or **Provider** property of the **Connection** object:

```
connection = CreateObject("ADODB.Connection.2.0")
connection.ConnectionString = "Provider=SNAOLEDB"
Conn.Properties("PROMPT")=adPromptAlways
connection.Open
```

This method of invoking the **Open** method automatically causes a dialog box to appear asking the user for the user name, password, and other necessary information.

CursorLocation Property (ADO)

The **CursorLocation** property on a **Connection** object or **Recordset** object indicates the location of the cursor engine. This property sets or returns a Long value representing a **CursorLocationEnum**.

Syntax

```
cursor = connection.CursorLocation
connection.CursorLocation= adUseServer
```

Remarks

The **CursorLocation** property is used to set or return the location of the cursor. This property can be set to one of the **CursorLocationEnum** constants listed in the following table.

Enumeration	Value	Description
adUseNone	1	This value indicates no cursor location. This value is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM.
adUseServer	2	This value indicates that the data provider or driver-supplied cursor is used.
adUseClient	3	This value indicates that a client-side cursor supplied by a local cursor library is to be used.
adUseClientBatch	3	For backward compatibility, this value indicates that a client-side cursor supplied by a local cursor library is to be used.

This property setting only affects connections established after the property has been set. Changing the **CursorLocation** property has no effect on existing connections.

This property is read/write on a **Connection** object or a closed **Recordset**, object and read-only on an open **Recordset**.

If the **CursorLocation** property is set to **adUseClient**, the recordset will be accessible as read-only, and recordset updates to the host are not possible. When the CursorLocation property is set to **adUseClient** (use the client cursor engine), the **Find** method, **Filter** property, and **Sort** property will work if MDAC 2.0 or higher is installed, but will not work properly with earlier versions of ADO.

CursorType Property (ADO)

The **CursorType** property on a **Recordset** object indicates the type of the cursor engine. This property sets or returns a Long value representing a **CursorTypeEnum**.

Syntax

```
oldType = recordset.CursorType
recordset.CursorType= newType
```

Remarks

The **CursorType** property is used to set or return the type of the cursor that the provider should use when opening the **Recordset**. This property can be one of the enumerated values for **CursorTypeEnum** listed in the following table.

Enumeration	Value	Description
adOpenUnspecified	-1	This indicates an unspecified value for the *CursorType*. This value is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM or the Microsoft OLE DB Provider for DB2.
adOpenForwardOnly	0	Specifying this value opens a forward-only-type cursor. This *CursorType* is identical to a static cursor, except that you can only scroll forward through records. This improves performance when only one pass through a **Recordset** is needed. This value is not supported by the Microsoft OLE DB Provider for AS/400 and VSAM.
adOpenKeyset	1	Specifying this value opens a keyset-type cursor. This *CursorType is* similar to a dynamic cursor with a few exceptions. Records that other users delete are inaccessible from your **Recordset**. Data changes to existing records by other users are still visible, but records added by other users are not visible (cannot be seen). This value is not supported by the OLE DB Provider for AS/400 and VSAM.
adOpenDynamic	2	Specifying this value opens a dynamic-type cursor. Additions, changes, and deletions by other users are visible, and all types of movement through the recordset are allowed, except for bookmarks if the provider does not support them. A dynamic cursor is the only *CursorType* supported by the OLE DB Provider for AS/400 and VSAM.
adOpenStatic	3	Specifying this value opens a static-type cursor. A static cursor provides a static copy of a set of records that can be used to find data or generate reports. Additions, changes, or deletions by other users are not visible with a static cursor. This value is not supported by the OLE DB Provider for AS/400 and VSAM.

Note that the **Open** method on a **Recordset** object defaults this property to **adOpenForwardOnly**,a value that is mapped to **adOpenDynamic** by the OLE DB provider for AS/400 and VSAM.

This property setting only affects connections established after the property has been set. Changing the **CursorType** property has no effect on existing connections. The **CursorType** property is read/write when the **Recordset** is closed and read-only when it is open.

If a provider does not support the requested cursor type, the provider may return another cursor type. The **CursorType** property will change to match the actual cursor type in use when the **Recordset** object is open. To verify whether a specific returned cursor is supported, use the **Supports** method. When using the OLE DB Provider for AS/400 and VSAM, the **Supports** method returns **adMovePrevious** as true with **CursorType** set to **adOpenDynamic**. After you close the **Recordset**, the **CursorType** property reverts to its original setting.

DefinedSize Property (ADO)

The **DefinedSize** property on a **Field** object indicates the defined size of a field object. This property returns a Long value that reflects the defined size of a field as a number of bytes.

Syntax

```
size = field.DefinedSize
```

Remarks

The **DefinedSize** property is used to return the data capacity or length of a **Field** object. For all fields, the **DefinedSize** property is read-only. If ActiveX® Data Objects (ADO) cannot determine the length of the **Field** object, the **ActualSize** property returns **adUnknown**.

The **ActualSize** and **DefinedSize** properties on a field object can be different. For example, a **Field** object with a declared type of **adVarChar** (variable character data type) and a maximum length of 50 characters returns a **DefinedSize** property value of 50, but the **ActualSize** property value it returns is the length of the data stored in the field for the current record.

Delete Method (ADO)

The **Delete** method on a **Recordset** object deletes the current record or a group of records.

Syntax

```
recordSet.Delete AffectedRecords
```

Parameters

AffectedRecords

This optional parameter specifies an **AffectEnum** value that determines how many records the **Delete** method will affect. The **AffectEnum** value can be one of the constants listed in the following table.

Enumeration	Value	Description
adAffectCurrent	1	This value deletes only the current record.
adAffectGroup	2	This value deletes the records that satisfy the current Filter Property setting. You must set the **Filter** property to one of the valid predefined constants to use this option.

Remarks

The **Delete** method is used to mark the current record or a group of records in a **Recordset** object for deletion. If the **Recordset** object does not allow record deletion, an error occurs. If you are in immediate update mode, deletions occur in the database immediately. Otherwise, the records are marked for deletion from the cache and the actual deletion happens when the **UpdateBatch** method is called. (Use the **Filter** property to view the deleted records.)

Retrieving field values from the deleted record generates an error. After deleting the current record, the deleted record remains current until you move to a different record. After you move away from the deleted record, it is no longer accessible.

If you are in batch update mode, use the CancelBatch Method to cancel a pending deletion or group of pending deletions.

If the attempt to delete records fails because of a conflict with the underlying data (for example, a record has already been deleted by another user), the data provider returns warnings to the **Errors** collection but does not halt program execution. A run-time error occurs only if there are conflicts on all the requested records.

Description Property (ADO)

The **Description** property on an **Error** object describes the **Error** object. This property returns a String value that contains a description of the error.

Syntax

```
errorString = currentError.Description
```

Remarks

The **Description** property on an **Error** object is used to obtain a short description of the error. Applications can display this property to alert the user to an error that the application does not want to handle. The string will come from either ActiveX® Data Objects (ADO) or a data provider such as the Microsoft® OLE DB Provider for AS/400 and VSAM, the Microsoft OLE DB Provider for DB2, or the Microsoft ODBC Driver for DB2. The provider is responsible for passing specific error text to ADO.

ADO adds an **Error** object to the **Errors** collection for each provider error or warning it receives. An application can enumerate the **Errors** collection to trace the errors that the provider passes.

EditMode Property (ADO)

The **EditMode** property on a **Recordset** object indicates the editing status of the current record. This property returns a Long value representing an **EditModeEnum**.

Syntax

```
currentMode = recordset.EditMode
connection.CursorType= newType
```

Remarks

The **EditMode** property is used to return the editing status of the current recordset. This property can be one of the enumerated values for **EditModeEnum** listed in the following table.

Enumeration	Value	Description
adEditNone	0	This value indicates that no editing operation is in progress.
adEditInProgress	1	This value indicates that data in the current record has been modified but not saved.
adEditAdd	2	This value indicates that the **AddNew** method has been called, and the current record in the copy buffer is a new record that has not been saved in the database.
adEditDelete	4	This value indicates that the current record has been deleted.

ActiveX® Data Objects (ADO) maintains an editing buffer associated with the current record. The **EditMode** property indicates whether changes have been made to this buffer, or whether a new record has been created. Use the **EditMode** property to determine the editing status of the current record. You can test for pending changes if an editing process has been interrupted and determine whether you need to use the Update Method or the CancelUpdate Method.

See the AddNew Method for a more detailed description of the **EditMode** property under different editing conditions.

EOF Property (ADO)

The **EOF** property on a **Recordset** object indicates that the current record position is after the last record in a **Recordset** object. This property returns a Boolean value.

Syntax

```
IsEOF = recordset.EOF
```

Remarks

The **EOF** property is used to determine whether a **Recordset** object contains records or whether you have gone beyond the limits of a **Recordset** object when you move from record to record.

The **EOF** property returns **True** if the current record position is after the last record and **False** if the current record position is on or before the last record.

If the **EOF** property is **True**, there is no current record.

If a **Recordset** object is opened containing no records, both the **BOF** and **EOF** properties are set to **True** and the **Recordset** object's **RecordCount** property setting is zero. When a **Recordset** object is opened that contains at least one record, the first record is the current record and the **BOF** and **EOF** properties are **False**.

If the last remaining record in the **Recordset** object is deleted, the **BOF** and **EOF** properties may remain **False** until you attempt to reposition the current record.

This table below indicates which **Move** methods are allowed with different combinations of the **BOF** and **EOF** properties.

	MoveFirst MoveLast	**MovePrevious Move < 0**	**Move 0**	**MoveNext Move > 0**
BOF=True EOF=False	Allowed	Error	Error	Allowed
BOF=False EOF=True	Allowed	Allowed	Error	Error
Both True	Error	Error	Error	Error
Both False	Allowed	Allowed	Allowed	Allowed

Allowing a **Move** method does not guarantee that the method will successfully locate a record; it only means that calling the specified **Move** method will not generate an error.

The following table shows what happens to the **BOF** and **EOF** property settings when various **Move** methods are called, but are unable to successfully locate a record.

	BOF Property	**EOF Property**
MoveFirst MoveLast	Set to **True**	Set to **True**
Move 0	No change	No change
MovePrevious Move < 0	Set to **True**	No change
MoveNext Move > 0	No change	Set to **True**

Execute Method on a Command Object (ADO)

The **Execute** method on a **Command** object executes the statement specified in the **CommandText** property.

Syntax

```
command.Execute(RecordsAffected,Parameters,Options)
set recordSet = command.Execute( RecordsAffected, Parameters,
Options )
```

Parameters

RecordsAffected

This optional parameter specifies a Long variable to which the provider returns the number of records that the operation affected.

Parameters

This optional parameter specifies a Variant array of parameter values passed with an SQL statement and is not used by the OLE DB Provider for AS/400 and VSAM.

Options

This optional parameter specifies a Long value representing a **CommandTypeEnum** value that indicates how the provider should evaluate the **CommandText** property of the **Command** object.

The **CommandTypeEnum** value can be one of the constants listed in the following table.

Enumeration	Value	Description
adCmdUnspecified	-1	This value indicates that the **CommandText** property is unspecified. This value is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM.
adCmdText	1	This value evaluates the **CommandText** property as a as a textual definition of a command or stored procedure call.
adCmdTable	2	This value evaluates the **CommandText** property as a table name. This value is not supported by the OLE DB Provider for AS/400 and VSAM or the Microsoft OLE DB Provider for DB2.
adCmdStoredProc	4	This value evaluates the **CommandText** property as a stored procedure name. This value is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adCmdUnknown	8	This value indicates that the type of command in **CommandText** is not known. This value is the default. This value is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

The default for *Option* is a**dCmdText** under the OLE DB Provider for AS/400 and VSAM and the OLE DB Provider for DB2.

Remarks

When used with the OLE DB Provider for AS/400 and VSAM, the **Execute** method on a **Command** object can be used to open tables or execute DDM commands on a remote DDM server. The *Options* parameter must be set to **adCmdText** for use with the OLE DB Provider for AS/400 and VSAM.

The primary purpose of the **Command** object in the context of the OLE DB Provider for AS/400 and VSAM is to issue AS/400 Command Language (CL) commands for execution by the remote OS/400 DDM target server. To invoke DDM commands on a remote DDM server, the **CommandText** property defines the text version of a command which must have been set to:

```
EXEC COMMAND DDMCmd
```

where *DDMCmd* represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands allow you to request functions from the OS/400 operating system. Some examples are the DLTF (Delete File) or DSPFFD (Display File Description) commands. These are the same commands that could be issued on the command line if you were connected to an AS/400 via a 5250 terminal session. See the 'OS/400 CL Reference for your platform for a detailed list of possible commands.

Note that this method does not return the results or output of a remote DDM CL command. If the results or output of a remote command are to be captured, the ***DDMCmd*** statement to be executed must include syntax to redirect the command output to a file on the AS/400 host and then explicitly open this output file after the command has completed.

The **Execute** method on a **Command** object can also be used to open a data file after a **Connection** object has been opened and the **ActiveConnection** property has been set to this open connection. The **CommandText** property defines the data file to open and must be set to:

```
EXEC OPEN DataSetName
```

where *DataSetName* represents a valid data file or library member on the host. When used in this way, the **Execute** method returns a **Recordset** object. If you open a host data file from a **Command** object, then the data file is opened as read-only. This results from the limitation that no argument or option is passed by ActiveX® Data Objects (ADO) that supplies a parameter describing whether the data set should be opened as read-only or updatable.

When used with the OLE DB Provider for DB2, the **Execute** method on a **Command** object can be used to execute SQL statements or call a stored procedure. The **CommandText** property defines the SQL statements to execute and must be set to one of the following:

```
EXEC SQLStatement
```

where SQLStatement represents a valid SQL statement supported by DB2.

```
CALL StoredProcedure
```

where StoredProcedure represents a valid DB2 stored procedure on the database server.

If errors occur, these can be examined with the **Errors** collection on the **Command** object.

Execute Method on a Connection Object (ADO)

The **Execute** method on a **Connection** object executes the statement specified in the **CommandText** property.

Syntax

```
connection.Execute CommandText, RecordsAffected,Options
set recordset = connection.Execute( CommandText, RecordsAffected,
Options)
```

Parameters

RecordsAffected

This optional parameter specifies a Long variable to which the provider returns the number of records that the operation affected.

Options

This optional parameter specifies a Long value representing a **CommandTypeEnum** value that indicates how the provider should evaluate the **CommandText** property of the Command object.

The **CommandTypeEnum** value can be one of the constants listed in the following table.

Enumeration	Value	Description
adCmdUnspecified	-1	This value indicates that the **CommandText** property is unspecified. This value is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM or the Microsoft OLE DB Provider for DB2.
adCmdText	1	This value evaluates the **CommandText** property as a textual definition of a command or stored procedure call.
adCmdTable	2	This value evaluates the **CommandText** property as a table name. This value is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adCmdStoredProc	4	This value evaluates the **CommandText** property as a stored procedure name. This value is not supported by the OLE DB Provider for AS/400 and VSAM.
adCmdUnknown	8	This value indicates that the type of command in **CommandText** is not known. This value is the default. This value is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

Remarks

The **Execute** method on a **Connection** object can be used to open tables or execute DDM commands on a remote DDM server. The *Options* parameter must be set to **adCmdText** for use with the OLE DB Provider for AS/400 and VSAM.

The **Execute** method on a **Connection** object is primarily used to open a data file after a **Connection** object has been created. The **CommandText** property defines the data file to open and must be set to:

```
EXEC OPEN DataSetName
```

where *DataSetName* represents a valid data file or library member on the host. When used in this way, the **Execute** method returns a **Recordset** object. If you open a host data file from a **Connection** object, then the data file is opened as read-only. This results from the limitation that no argument or option is passed by ActiveX® Data Objects (ADO) that supplies a parameter describing whether the data set should be opened as read-only or updatable. If a **Recordset** object is desired that is

not read-only, then first create a **Recordset** object with the desired property settings, and use the **Recordset** objects **Open** method to return the open **Recordset**.

The **Execute** method on a **Connection** object can also be used to issue AS/400 Command Language (CL) commands for execution by the remote OS/400 DDM target server. To invoke DDM commands on a remote DDM server, the **CommandText** property defines the text version of a command which must have been set to:

```
EXEC COMMAND DDMCmd
```

where *DDMCmd* represents a valid OS/400 control language (CL) command. Note that only OS/400 CL commands are supported. These commands allow you to request functions from the OS/400 operating system. Some examples are the DLTF (Delete File) or DSPFFD (Display File Description) commands. These are the same commands that could be issued on the command line if you were connected to an AS/400 via a 5250 terminal session. See the 'OS/400 CL Reference for your platform for a detailed list of possible commands.

Note that this method does not return the results or output of a remote DDM CL command. If the results or output of a remote command are to be captured, the ***DDMCmd*** statement to be executed must include syntax to redirect the command output to a file on the AS/400 host and then explicitly open this output file after the command has completed.

If errors occur, these can be examined with the **Errors** collection on the **Connection** object.

Filter Property (ADO)

The **Filter** property on a **Recordset** object indicates a filter for data in a **Recordset**. This property sets or returns a Variant value.

Syntax

```
recordset.Filter=Criteria
```

Parameters

Criteria

This parameter specifies a Variant.

It can be either a criteria (a where clause) or one of the enumerated values for **FilterGroupEnum** listed in the following table.

Enumeration	Value	Description
adFilterNone	0	No filter. This value removes the current filter and restores all records to view.
adFilterPendingRecords	1	Use the pending records. This value allows viewing only those records that have changed but have not yet been sent to the server. This value is only applicable for batch update mode.
adFilterAffectedRecords	2	Use only records affected by the last **Delete**, **Resync**, **UpdateBatch**, or **CancelBatch** call.
adFilterFetchedRecords	3	Use the last fetched records. This value allows viewing the records in the current cache returned as a result of the last call to retrieve records (implying a resynchronization).
adFilterConflictingRecords	5	Use the conflicting records. This value allows viewing only those records that failed the last batch update.

Remarks

The **Filter** property is not supported by the Microsoft® OLE DB Provider for DB2 or the Microsoft ODBC Driver for DB2.

The **Filter** property is supported by the Microsoft OLE DB Provider for AS/400 and VSAM on certain files. In order to use the Recordset **Filter** property, an AS/400 logical file, an AS/400 keyed physical file, a mainframe KSDS file with a unique key, or a mainframe RRDS file with a unique key must be used. If this property is used on an AS/400 non-keyed physical file or any other mainframe file type, then the method fails.

When the **Filter** property is used with a criteria, the where clause is a combination of triplets. Each triplet consists of a column name, an operator, and a literal value. These where clause triplets can be combined with **AND**s and **OR**s for more complex logical filters.

If *Criteria* is a single-condition where clause, then any operator can be used. The construction of a single-condition where clause consists of a column name (the database field), an operator (greater than or equal, for example), and a literal value.

Examples of a single-condition where clause is as follows:

- recordset.Filter = "LastName = 'Jones' "
- recordset.Filter ="Salary > 30000.0"

The *Criteria* argument can be a two-condition with the following restrictions:

- If the column name (the database field) is the same in both clauses, then the separate where clauses must define a contiguous range.

- If the column names are different, then the operators must be the same. If the operators are "LIKE", then the filtered region may be unexpected.

Examples of acceptable two-condition where clauses are as follows:

- recordset.Filter = "LastName = 'Jones' **AND** FirstName = 'Tom' "
- recordset.Filter = "Cost = 5000.00 **OR** Cost > 5000.00 "

The *Criteria* argument can be three or more conditions with the following restrictions:

- The operators must be the same for all conditions. If the operators are "LIKE", then the filtered region may be unexpected.

In all cases, if the "=" operator is used, then the column names specified in the where clause must be keyed columns in the file.

One restriction on these combinations is that **OR** clauses can only be used at the highest (major) level of the logical operation.

Examples of acceptable *Criteria* meeting these conditions are:

- recordset.Filter = "(Title='Manager' **AND** Salary>30000) **OR** (Title='Administrator' **AND** Salary>50000)"
- recordset.Filter ="Salary > 30000.0"

An example of illegal *Criteria* is:

- recordset.Filter = "(Title='Associate' **OR** Salary >30000) **AND** (Title='Administrator')"

The operator can also use wildcards (* or %) in character expressions as follows:

- recordset.Filter = "Lastname LIKE '*SMITH*'"

To determine if any records were found meeting the *Criteria*, the application should check the **Recordset EOF** property. If **EOF** is true, then no records were found meeting the where clause specified in the *Criteria* parameter.

If the CursorLocation Property is set to **adUseClient** (use the client cursor engine), the **Filter** property will work if MDAC 2.0 or later is installed but will not work properly with earlier versions of ADO.

When operating on large VSAM files and only querying data on a subset of the records, using the **Filter** property is not desirable because of the performance impact. The entire VSAM file is transferred to the client for filtering. A better solution is to use the server cursor engine and the **Find** method.

Find Method (ADO)

The **Find** method on a **Recordset** object locates or seeks to the next record in a **Recordset** object that meets a particular condition and makes this the current record. This method can be used to seek to a specific record in a **Recordset** object based on a where clause (similar to an SQL where clause) defined by the user.

Syntax

```
recordset.FindCriteria, SkipRecords, SearchDirection, Start
```

Parameters

ActiveX® Data Objects (ADO) supports four arguments for the **Find** method, but the last three arguments are optional and have default values as noted below:

Criteria

This BSTR parameter specifies the criteria used for locating or seeking to a record in a **Recordset** object.

SkipRecords

This optional parameter specifies a Long expression that indicates the number of records to skip (whether to skip the current record) when locating a record in a **Recordset** object. The default value for this argument is 0 (do not skip the current record). The first time a **Find** method is used, this argument is usually set to 0 (the default). On subsequent calls to this method to seek other records that meet the specified condition, this argument would normally be set to 1, to skip one record forward before finding the next record that matches the search *Criteria*. A negative value for this parameter is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM.

SearchDirection

This optional parameter is an enumeration that specifies the direction for the search.

It can be one of the enumerated values for **SearchDirectionEnum** listed in the following table.

Enumeration	Value	Description
adSearchForward	0	Search forward from the current record.
adSearchBackward	1	Search backward from the current record. This option is not supported by the OLE DB Provider for AS/400 and VSAM.

This optional argument defaults to **adSearchForward**.

Start

This optional parameter specifies the starting location for a search, which can be a bookmark or an enumeration indicating the current, first, or last record in a **Recordset** object.

This argument is a Variant and can be either a bookmark or one of the enumerated values for **BookmarkEnum** listed in the following table.

Enumeration	Value	Description
adBookmarkCurrent	0	The current record.
adBookmarkFirst	1	The first record.
adBookmarkLast	2	The last record.

This optional argument defaults to **adBookmarkCurrent**.

Remarks

The **Find** method is not supported by the Microsoft OLE DB Provider for DB2 or the Microsoft ODBC Driver for DB2.

The **Find** method is supported by the Microsoft OLE DB Provider for AS/400 and VSAM on certain files. In order to use the Recordset **Find** method, an AS/400 logical file, an AS/400 keyed physical file, a mainframe KSDS file with a unique key, or a mainframe RRDS file with a unique key must be used. If this method is used on an AS/400 non-keyed physical file or any other mainframe file type, then the method fails.

The first parameter is the only required argument for the **Find** method. All of the other arguments are optional and have default values. This first argument is a single-condition where clause. The construction of a single-condition where clause consists of a column name (the database field), an operator (greater than or equal, for example), and a literal value.

Examples of acceptable single-condition where clauses are as follows:

- recordset.Find, "Cost > 10000.00"
- recordset.Find, "Cost < 100.00"
- recordset.Find, "Cost = 5000.00"
- recordset.Find, "LastName = 'Jones' "

Note that variables cannot be used as substitutes for literal values. If the file has multiple keys in the index, using the "=" operator will always fail since the values of all keys cannot be specified.

If the CursorLocation Property is set to **adUseClient** (use the client cursor engine), the **Filter** method will work if MDAC 2.0 or later is installed, but will not work properly with earlier versions of ADO.

When operating on large VSAM files and only querying data on a subset of the records, using the **Filter** property is not desirable because of the performance impact. The entire VSAM file is transferred to the client for filtering. A better solution is to use the server cursor engine and the **Find** method.

GetChunk Method (ADO)

The **GetChunk** method on a **Field** object returns all or a portion of the contents of a large text or binary data **Field** object.

Syntax

```
variable = field.GetChunk(Size)
```

Parameters

Size

This parameter specifies a Long expression equal to the number of bytes or characters to be retrieved.

Return Value

A Variant.

Remarks

The **GetChunk** method on a **Field** object is used to retrieve part or all of its long binary or character data. In situations where system memory is limited, the **GetChunk** method can be used to manipulate long values in portions rather than in their entirety.

The data that a **GetChunk** method returns is assigned to a variable. If the *Size* parameter is greater than the remaining data, the **GetChunk** method returns only the remaining data without padding the variable with empty spaces. If the **Field** object is empty, the **GetChunk** method returns Null.

Each subsequent **GetChunk** method call retrieves data starting from where the previous **GetChunk** call left off. However, if you are retrieving data from one field and then set or read the value of another field in the current record, ActiveX® Data Objects (ADO) assumes you are finished retrieving data from the first field. If the **GetChunk** method is called on the first field again, ADO interprets the call as a new **GetChunk** operation and starts reading from the beginning of the data. Accessing **Field** objects in other **Recordset** objects (that are not clones of the first **Recordset** object) will not disrupt **GetChunk** operations.

If the **adFldLong** bit in the **Attributes** property of a **Field** object is set to **True**, the **GetChunk** method can be used for that **Field** object.

If there is no current record when the **GetChunk** method is invoked on a **Field** object, error 3021 (no current record) occurs.

GetRows Method (ADO)

The **GetRows** method on a **Recordset** object retrieves multiple records of a recordset into an array.

Syntax

```
array = recordset.GetRows(Rows,Start,Fields)
```

Parameters

Rows

This optional parameter specifies a Long expression indicating the number of records to retrieve. The default value if this parameter is not specified is a **GetRowSetEnum** which is **adGetRowsRest** (value = -1).

Start

This optional parameter specifies the starting location for the record from which the **GetRows** operation should begin, which can be a bookmark or an enumeration indicating the current, first, or last record in a **Recordset** object.

This argument is a Variant and can be either a bookmark or one of the enumerated values for **BookmarkEnum** listed in the following table.

Enumeration	Value	Description
adBookmarkCurrent	0	The current record
adBookmarkFirst	1	The first record
adBookmarkLast	2	The last record

This optional argument defaults to **adBookmarkCurrent**.

Fields

This optional parameter is a Variant and specifies a single field name or ordinal position or an array of field names or ordinal position numbers. ADO returns only the data in these fields.

Return Value

A two-dimensional array.

Remarks

The **GetRows** method is used to copy records from a recordset into a two-dimensional array. The first subscript of the array identifies the field and the second array subscript identifies the record number. The array variable is automatically dimensioned to the correct size when the **GetRows** method returns the data.

If a value is not specified for the *Rows* parameter, the **GetRows** method automatically retrieves all the records in the **Recordset** object. If more records are requested than are available, **GetRows** returns only the number of available records.

If the **Recordset** object supports bookmarks, you can specify at which record the **GetRows** method should begin retrieving data by passing the value of that record's **Bookmark** property.

To restrict the fields that the **GetRows** method returns, you can pass either a single field name/number or an array of field names/numbers in the *Fields* argument.

After the **GetRows** method is called, the next unread record becomes the current record, or the **EOF** property is set to **True** if there are no more records.

IsolationLevel Property (ADO)

The **IsolationLevel** property on a **Connection** object indicates the level of isolation for a **Connection** object. This property sets or returns a Long value representing an **IsolationLevelEnum**. The default value for this property is **adXactChaos.**

Syntax

```
currentIsoLevel = connection.IsolationLevel
connection.IsolationLevel= newIsoLevel
```

Remarks

The **IsolationLevel** property is used to set the type of isolation level placed on a connection that the provider should use when opening the **Connection** object. This property can also be used to return the type of isolation level in use on an open **Connection** object.

This property can be one of the enumerated values for **IsolationLevelEnum** listed in the following table.

Enumeration	Value	Description
adXactUnspecified	-1	This value indicates that the provider is using a different isolation level than specified, but that the level cannot be determined.
adXactChaos	16	This value indicates that pending changes from more highly isolated transactions cannot be overwritten.
adXactBrowse	256	This value indicates that from one transaction you can view uncommitted changes in other transactions.
adXactReadUncommitted	256	Same as **adXactBrowse**.
adXactCursorStability	4096	This value indicates that from one transaction you can view changes in other transactions only after they have been committed.
adXactReadCommitted	4096	Same as **adXactCursorStability**.
adXactRepeatableRead	65536	This value indicates that from one transaction you cannot see changes made in other transactions, but that re-querying can retrieve new **Recordset** objects.
adXactIsolated	1048576	This value indicates that transactions are conducted in isolation of other transactions.
adXactSerializable	1048576	Same as **adXactIsolated**.

This property is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM.

When setting the **IsolationLevel** property, this change does not take effect until the next time that the **BeginTrans** method is called.

If the level of isolation you request is unavailable, the provider may return the next greater level of isolation.

When used with the Microsoft OLE DB Provider for DB2 or the Microsoft OLE DB Driver for DB2, the ActiveX® Data Objects (ADO) **IsolationLevel** property corresponds with the isolation level defined by the ANSI SQL standard and with IBM's DB2 implementation of isolation level. The table below indicates how the ADO **IsolationLevel** property corresponds with the terms used by ANSI SQL for isolation level and with IBM documentation for isolation level in DB2.

ADO IsolationLevel property	ANSI SQL isolation level	IBM documentation
	AUTOCOMMITTED (Note that this applies only to DB2/400 and does not correspond with an ANSI SQL isolation level	COMMIT(*NONE) (NC). This isolation level is used in DB2/400 auto-commit mode only and has no corresponding isolation level on other DB2 platforms or in ANSI SQL.
adXactReadUncommitted	READ UNCOMMITTED	UNCOMMITTED READ (UR). This isolation level corresponds with ANSI SQL READ UNCOMMITTED.
adXactReadCommitted or **adXactCursorStability**	READ COMMITTED	CURSOR STABILITY (CS). This isolation level corresponds with ANSI SQL READ COMMITTED.
adXactRepeatableRead	REPEATABLE READ	READ STABILITY (RS). This isolation level corresponds with ANSI SQL REPEATABLE READ.
adXactSerializable or **adXactIsolated**	SERIALIZABLE	REPEATABLE READ (RR). This isolation level corresponds with ANSI SQL SERIALIZABLE.

When used with the Remote Data Service on a client-side **Connection** object, the **IsolationLevel** property can be set only to **adXactUnspecified**. Because users are working with disconnected **Recordset** objects on a client-side cache, there may be multi-user issues. For instance, when two different users try to update the same record, Remote Data Service simply allows the user who updates the record first to "win." The second user's update request will fail with an error.

Item Method (ADO)

The **Item** method on a **Collection** object returns a specific member object of a collection by name or ordinal number. This method is supported for the **Errors**, **Fields**, and **Properties** collections using the OLE DB Provider for AS/400 and VSAM.

Syntax

```
set Object = collection.Item ( Index )
```

Parameters

Index

This parameter specifies a Variant that evaluates either to the name or to the ordinal number of an object in a collection.

Return Value

An object reference from the collection.

Remarks

The **Item** method is used to return a specific object in a collection. If the method cannot find an object in the collection corresponding to the *Index* parameter, an error occurs. Also, some collections do not support named objects; for these collections, you must use ordinal number references.

The **Item** method is the default method for all collections; therefore, the following syntax forms are interchangeable:

collection.Item (*Index*)

collection (*Index*)

This method is only supported on the **Errors**, **Fields**, and **Properties** collections under the OLE DB Provider for AS/400 and VSAM.

LockType Property (ADO)

The **LockType** property on a **Recordset** object indicates the type of locks placed on records during editing. This property sets or returns a Long value representing a **LockTypeEnum**. The default value for this property is **adLockReadOnly**.

Syntax

```
currentLock = recordset.LockType
recordset.LockType= newtype
```

Remarks

The **LockType** property is used to set the type of locks placed on records that the provider should use when opening the **Recordset**. This property can also be used to return the type of locking in use on an open **Recordset** object. This property can be one of the enumerated values for **LockTypeEnum** as listed in the following table.

Enumeration	Value	Description
adLockUnspecified	-1	This value does not specify a type of lock. For a recordset created with the **Clone** method, the clone is created with the same lock type as the original.
adLockReadOnly	1	This value indicates read-only records where the data cannot be altered.
adLockPessimistic	2	This value indicates pessimistic locking, record by record. The provider does what is necessary to ensure successful editing of the records, usually by locking records at the data source immediately after editing. This lock type is supported by the Microsoft® OLE DB Provider for AS/400 and VSAM and the Microsoft OLE DB Provider for DB2. However, the OLE DB Provider for AS/400 and VSAM internally maps this lock type to **adLockBatchOptimistic**.
adLockOptimistic	3	This value indicates optimistic locking, record by record. The provider uses optimistic locking, locking records only when the **Update** method is called. This lock type is not supported by the OLE DB Provider for DB2.
adLockBatchOptimistic	4	This value indicates optimistic batch updates and is required for batch update mode. This option is not supported by the OLE DB Provider for DB2.

If a provider cannot support the requested **LockType** setting, it will substitute another type of locking. To determine the actual locking options available on a **Recordset** object, use the **Supports** method with **adUpdate** and **adUpdateBatch**.

The **adLockPessimistic** setting is not supported if the **CursorLocation** property is set to **adUseClient**. If an unsupported value is set, then no error will result; the closest supported **LockType** will be used instead.

The **LockType** property is read/write when the **Recordset** is closed and read-only when it is open.

MaxRecords Property (ADO)

The **MaxRecords** property on a **Recordset** indicates the maximum number of records to return to a **Recordset** from a query. This property sets or returns a Long value that indicates the maximum number of records to return. The default value for this property is zero (no limit).

Syntax

```
cntRecords = recordset.MaxRecords
recordset.MaxRecords = count
```

Remarks

The **MaxRecords** property is used to limit the number of records returned from a data source. The default setting of this property is zero, which means that all requested records are returned.

The **MaxRecords** property is read/write when the **Recordset** is closed and read-only when it is open.

Mode Property (ADO)

The **Mode** property on a **Connection** object sets or returns the available permissions for modifying data on a **Connection**.

Syntax

```
currentMode = connection.Mode
connection.Mode = newMode
```

Remarks

The **Mode** property is used to set or return the access permissions in use by the provider on the current connection. The **Mode** property can only be set when the **Connection** object is closed.

Several of the ActiveX® Data Objects (ADO) enumerated values for the mode settings imply that the using certain mode settings will prevent other applications from opening a connection to the file or table. Under the Microsoft® OLE DB provider for AS/400 and VSAM, these mode settings result in a file lock, but do not prevent other applications from opening a connection.

The value for the **Mode** can be one of the enumerated values for **ConnectModeEnum** as listed in the following table.

Enumeration	**Value**	**Description**
adModeUnknown	0	This value indicates that the permissions have not yet been set or cannot be determined.
adModeRead	1	This value indicates read-only permissions.
adModeWrite	2	This value indicates write-only permissions. This value is not supported by the OLE DB provider for AS/400 and VSAM.
adModeReadWrite	3	This value indicates read/write permissions.
adModeShareDenyRead	4	This value prevents others from opening a connection with read permissions.
adModeShareDenyWrite	8	This value prevents others from opening a connection with write permissions. Under the OLE DB provider for AS/400 and VSAM, this mode setting is implemented as a file lock and does not result in excluding other applications from opening a connection. Other applications opening a connection will not receive an error, but the table or file will be locked preventing any changes from other applications.
adModeShareExclusive	0xc	This value prevents others from opening a connection. Under the OLE DB provider for AS/400 and VSAM, this mode setting is implemented as a file lock and does not result in excluding other applications from opening a connection. Other applications opening a connection will not receive an error, but the table or file will be locked preventing any changes from other applications.

adModeShareDenyNone	0x10	This value prevents others from opening a connection with any permissions. Under the OLE DB provider for AS/400 and VSAM this mode setting is implemented as a file lock and does not result in excluding other applications from opening a connection. Other applications opening a connection will not receive an error, but the table or file will be locked preventing any changes from other applications.

The **Mode** property defaults to **adModeUnknown**.

Move Method (ADO)

The **Move** method on a **Recordset** object moves the position of the current record in a **Recordset** object.

Syntax

```
recordset.Move NumRecords, Start
```

Parameters

NumRecords

This parameter specifies a signed Long expression specifying the number of records the current record position moves.

Start

This optional parameter specifies the starting location for the record from which the **Move** operation should begin, which can be a bookmark or an enumeration indicating the current, first, or last record in a **Recordset** object.

This argument is a Variant and can be either a bookmark or one of the enumerated values for **BookmarkEnum** as listed in the following table.

Enumeration	Value	Description
adBookmarkCurrent	0	The current record
adBookmarkFirst	1	The first record
adBookmarkLast	2	The last record

This optional argument defaults to **adBookmarkCurrent**.

Return Value

None.

Remarks

The **Move** method is supported on all **Recordset** objects.

If the *NumRecords* parameter is greater than zero, the current record position moves forward (toward the end of the recordset). If *NumRecords* is less than zero, the current record position moves backward (toward the beginning of the recordset).

If the **Move** method would move the current record position to a point before the first record, ActiveX® Data Objects (ADO) sets the current record to the position before the first record in the recordset (the **BOF** property is set to **True**). An attempt to move backward when the **BOF** property is already **True** generates an error.

If the **Move** call would move the current record position to a point after the last record, ADO sets the current record to the position after the last record in the recordset (the **EOF** property is set to **True**). An attempt to move forward when the **EOF** property is already **True** generates an error.

Invoking the **Move** method from an empty **Recordset** object generates an error.

If the *Start* parameter is specified, the move is relative to the record with this bookmark assuming the **Recordset** object supports bookmarks. If not specified, the move is relative to the current record.

If the **CacheSize** property is set to greater than 1 to locally cache records from the provider, passing a *NumRecords* value that moves the current record position outside of the current group of cached records forces ADO to retrieve a new group of records starting from the destination record. The **CacheSize** property determines the size of the newly retrieved group, and the destination record is the first record retrieved.

If the **Recordset** object is forward-only, a user can still pass a *NumRecords* value less than zero as long as the destination is within the current set of cached records. If the **Move** method call would move the current record position to a record before the first cached record, an error occurs. Thus, you can use a record cache that supports full scrolling over a provider that only supports forward scrolling. Because cached records are loaded into memory, you should avoid caching more records than necessary. Even if a forward-only **Recordset** object supports backward moves in this way, calling the **MovePrevious** method

on any forward-only **Recordset** object still generates an error.

MoveFirst Method (ADO)

The **MoveFirst** method on a **Recordset** object moves to the first record in a specified **Recordset** object and makes that record current.

Syntax

```
recordset.MoveFirst
```

Parameters

None.

Remarks

The **MoveFirst** method is used to move the current record position to the first record in the recordset. The **MoveFirst** method can be invoked on a forward-only **Recordset** object; but doing so may cause the provider to re-execute the command that generated the **Recordset** object.

MoveLast Method (ADO)

The **MoveLast** method on a **Recordset** object moves to the last record in a specified **Recordset** object and makes that record current.

Syntax

```
recordset.MoveLast
```

Parameters

None.

Remarks

The **MoveLast** method is used to move the current record position to the last record in the recordset.

When using a server-side cursor, the **Recordset** object must support bookmarks or backward cursor movement; otherwise, the **MoveLast** method call generates an error.

MoveNext Method (ADO)

The **MoveNext** method on a **Recordset** object moves to the next record in a specified **Recordset** object and makes that record current.

Syntax

```
recordset.MoveLast
```

Parameters

None.

Remarks

The **MoveNext** method is used to move the current record position one record forward (toward the bottom of the recordset). If the last record is the current record and the **MoveNext** method is invoked, ActiveX® Data Objects (ADO) sets the current record to the position after the last record in the recordset (the **EOF** property is set to **True**). An attempt to move forward when the **EOF** property is already **True** generates an error.

MovePrevious Method (ADO)

The **MovePrevious** method on a **Recordset** object moves to the previous record in a specified **Recordset** object and makes that record current.

Syntax

```
recordset.MovePrevious
```

Parameters

None.

Remarks

The **MovePrevious** method is used to move the current record position one record backward (toward the top of the recordset).

When using a server-side cursor, if the **Recordset** object does not support either bookmarks or backward cursor movement, the **MovePrevious** method generates an error.

If the first record is the current record and the **MovePrevious** method is invoked, ADO sets the current record to the position before the first record in the recordset (the **BOF** property is set to **True**). An attempt to move backward when the **BOF** property is already **True** generates an error.

Note that if a **MovePrevious** method is invoked after **Delete** method is invoked, this moves the current record back two records instead of one.

Name Property (ADO)

The **Name** property on a **Command** object sets or returns a string value indicating the name of the object. The **Name** property on a **Field** or **Property** returns a string value indicating the name of the object.

Syntax

```
currentName = command.Name
command.Name = newName
```

Remarks

The **Name** property is used to assign a name to or retrieve the name of a **Command**, **Field**, or **Property** object. This value is read/write on a **Command** object and read-only on a **Property** or **Field** object. Note that the **Name** property on a **Command** object cannot be assigned (set) using the OLE DB Provider for AS/400 and VSAM.

The **Name** property of an object can be retrieved by an ordinal reference, after which you can refer to the object directly by name. For example, if **recordset.Properties(20).Name** yields updatability, you can subsequently refer to this property as **recordset.Properties("Updatability")**.

NativeError Property (ADO)

The **NativeError** property on an **Error** object indicates the provider-specific error code for a given **Error** object. This property returns a Long value that indicates the error code.

Syntax

```
errorCode = currentError.NativeError
```

Remarks

The **NativeError** property on an **Error** object is used to retrieve the database-specific error information for a particular **Error** object. For example, when using the Microsoft® OLE DB Provider for DB2, native error codes that originate from the OLE DB Provider for DB2 pass through ActiveX® Data Objects (ADO) to the ADO **NativeError** property.

Number Property (ADO)

The **Number** property on an **Error** object indicates the number that uniquely identifies an **Error** object. This property returns a Long value that may correspond to one of the **ErrorValueEnum** constants.

Syntax

```
errorNumber = currentError.Number
```

Remarks

The **Number** property on an **Error** object is used to determine which error occurred. The value of the property is a unique number that corresponds to the error condition.

The **Errors** collection returns an HRESULT. These HRESULTs can be raised by underlying components, such as OLE DB or even OLE itself.

The value for the **Number** property on the **Error** object representing an ADO error (not an OLE DB error) can be one of the following enumerated values for **ErrorValueEnum** listed in the table below. Note that three forms of the error number value are listed in the table:

- Positive decimal—The lower two bytes of the full number in decimal format. This number is displayed in the default Microsoft® Visual Basic® error message dialog box. For example, **Run-time error '3707'**.
- Negative decimal—The decimal translation of the full error number.
- Hexadecimal—The hexadecimal representation of the full error number. The Windows facility code is the lowest hexadecimal fourth digit in the upper two bytes of the number. The facility code for ADO error numbers is *A*. For example: 0x800**A**0E7B.

Note that OLE DB errors may be passed to an ADO application. Typically, these OLE DB errors can be identified by a Windows® facility code of *4*. For example, 0x800**4**xxxx. For more information about the possible error numbers returned by OLE DB, see Chapter 16 of the *OLE DB Programmer's Reference*.

Enumeration	Value	Description
adErrBoundToCommand	3707 -2146824581 0x800A0E7B	The application cannot change the **ActiveConnection** property of a **Recordset** object that has a **Command** object as its source.
adErrCannotComplete	3732 -2146824556 0x800A0E94	The server cannot complete the operation.
adErrCantChangeConnection	3748 -2146824540 0x800A0EA4	The connection was denied. The new connection requested has different characteristics than the one already in use.
adErrCantChangeProvider	3220 -2146825068 0X800A0C94	The supplied provider is different from the one already in use.
adErrCantConvertvalue	3724 -2146824564 0x800A0E8C	The data value cannot be converted for reasons other than sign mismatch or data overflow. For example, conversion would have truncated data.
adErrCantCreate	3725 -2146824563 0x800A0E8D	The data value cannot be set or retrieved because the field data type was unknown, or the provider had insufficient resources to perform the operation.
adErrCatalogNotSet	3747 -2146824541 0x800A0EA3	The operation requires a valid **ParentCatalog**.

adErrColumnNotOnThisRow	3726 -2146824562 0x800A0E8E	The record does not contain this field.
adErrDataConversion	3421 -2146824867 0x800A0D5D	The application uses a value of the wrong type for the current operation.
adErrDataOverflow	3721 -2146824567 0x800A0E89	The data value is too large to be represented by the field data type.
adErrDelResOutOfScope	3738 -2146824550 0x800A0E9A	The URL of the object to be deleted is outside the scope of the current record.
adErrDenyNotSupported	3750 -2146824538 0x800A0EA6	The provider does not support sharing restrictions.
adErrDenyTypeNotSupported	3751 -2146824537 0x800A0EA7	The provider does not support the requested kind of sharing restriction.
adErrFeatureNotAvailable	3251 -2146825037 0x800A0CB3	The object or provider is not capable of performing requested operation.
adErrFieldsUpdateFailed	3749 -2146824539 0x800A0EA5	The **Fields** update failed. For further information, examine the **Status** property of individual field objects.
adErrIllegalOperation	3219 -2146825069 0x800A0C93	The operation is not allowed in this context.
adErrIntegrityViolation	3719 -2146824569 0x800A0E87	The data value conflicts with the integrity constraints of the field.
adErrInTransaction	3246 -2146825042 0x800A0CAE	The **Connection** object cannot be explicitly closed while in a transaction.
adErrInvalidArgument	3001 -2146825287 0x800A0BB9	The arguments are of the wrong type, are out of acceptable range, or are in conflict with one another.
adErrInvalidConnection	3709 -2146824579 0x800A0E7D	The operation is not allowed on an object referencing a closed or invalid connection.
adErrInvalidParamInfo	3708 -2146824580 0x800A0E7C	The **Parameter** object is improperly defined. Inconsistent or incomplete information was provided.
adErrInvalidTransaction	3714 -2146824574 0x800A0E82	The coordinating transaction is invalid or has not started.
adErrInvalidURL	3729 -2146824559 0x800A0E91	The URL contains invalid characters. Make sure the URL is typed correctly.
adErrItemNotFound	3265 -2146825023 0x800A0CC1	The item cannot be found in the collection corresponding to the requested name or ordinal.
adErrNoCurrentRecord	3021 -2146825267 0x800A0BCD	Either the **BOF** or **EOF** property is True, or the current record has been deleted. The requested operation requires a current record.

adErrNotExecuting	3715 -2146824573 0x800A0E83	The operation cannot be performed while not executing.
adErrNotReentrant	3710 -2146824578 0x800A0E7E	The operation cannot be performed while processing event.
adErrObjectClosed	3704 -2146824584 0x800A0E78	The operation is not allowed when the object is closed.
adErrObjectInCollection	3367 -2146824921 0x800A0D27	The object is already in collection. Cannot append.
adErrObjectNotSet	3420 -2146824868 0x800A0D5C	The object is no longer valid.
adErrObjectOpen	3705 -2146824583 0x800A0E79	The operation is not allowed when the object is open.
adErrOpeningFile	3002 -2146825286 0x800A0BBA	The file could not be opened.
adErrOperationCancelled	3712 -2146824576 0x800A0E80	The operation has been cancelled by the user.
adErrOutOfSpace	3734 -2146824554 0x800A0E96	The operation cannot be performed. Provider cannot obtain enough storage space.
adErrPermissionDenied	3720 -2146824568 0x800A0E88	Insufficient permission prevents writing to the field.
adErrPropConflicting	3742 -2146824546 0x800A0E9E	Property value conflicts with a related property.
adErrPropInvalidColumn	3739 -2146824549 0x800A0E9B	Property cannot apply to the specified field.
adErrPropInvalidOption	3740 -2146824548 0x800A0E9C	Property attribute is invalid.
adErrPropInvalidValue	3741 -2146824547 0x800A0E9D	Property value is invalid. Make sure the value is typed correctly.
adErrPropNotAllSettable	3743 -2146824545 0x800A0E9F	Property is read-only or cannot be set.
adErrPropNotSet	3744 -2146824544 0x800A0EA0	Optional property value was not set.
adErrPropNotSettable	3745 -2146824543 0x800A0EA1	Read-only property value was not set.
adErrPropNotSupported	3746 -2146824542 0x800A0EA2	Provider does not support the property.

adErrProviderFailed	3000 -2146825288 0x800A0BB8	Provider failed to perform the requested operation.
adErrProviderNotFound	3706 -2146824582 0x800A0E7A	Provider cannot be found. It may not be properly installed.
adErrReadFile	3003 -2146825285 0x800A0BBB	File could not be read.
adErrResourceExists	3731 -2146824557 0x800A0E93	Copy operation cannot be performed. Object named by destination URL already exists. Specify **adCopyOverwrite** to replace the object.
adErrResourceLocked	3730 -2146824558 0x800A0E92	Object represented by the specified URL is locked by one or more other processes. Wait until the process has finished and attempt the operation again.
adErrResourceOutOfScope	3735 -2146824553 0x800A0E97	Source or destination URL is outside the scope of the current record.
adErrSchemaViolation	3722 -2146824566 0x800A0E8A	Data value conflicts with the data type or constraints of the field.
adErrSignMismatch	3723 -2146824565 0x800A0E8B	Conversion failed because the data value was signed and the field data type used by the provider was unsigned.
adErrStillConnecting	3713 -2146824575 0x800A0E81	Operation cannot be performed while connecting asynchronously.
adErrStillExecuting	3711 -2146824577 0x800A0E7F	Operation cannot be performed while executing asynchronously.
adErrTreePermissionDenied	3728 -2146824560 0x800A0E90	Permissions are insufficient to access tree or subtree.
adErrUnavailable	3736 -2146824552 0x800A0E98	Operation failed to complete and the status is unavailable. The field may be unavailable or the operation was not attempted.
adErrUnsafeOperation	3716 -2146824572 0x800A0E84	Safety settings on this computer prohibit accessing a data source on another domain.
adErrURLDoesNotExist	3727 -2146824561 0x800A0E8F	Either the source URL or the parent of the destination URL does not exist.
adErrURLNamedRowDoesNotExist	3737 -2146824551 0x800A0E99	Record named by this URL does not exist.
adErrVolumeNotFound	3733 -2146824555 0x800A0E95	Provider cannot locate the storage device indicated by the URL. Make sure the URL is typed correctly.
adErrWriteFile	3004 -2146825284 0x800A0BBC	Write to file failed.

NumericScale Property (ADO)

The **NumericScale** property on a **Field** object indicates the scale of Numeric values in a **Field** object. This property returns a byte value indicating the number of decimal places to which numeric values will be resolved.

Syntax

```
scale = currentfield.NumericScale
```

Remarks

The **NumericScale** property is used to determine how many digits to the right of the decimal point will be used to represent values for a numeric **Field** object.

The byte value that the **NumericScale** property will return is dependent on the data type of the **Field** object. The value for the ActiveX® Data Objects (ADO) data type of the **Field** object can be one of the enumerated values for **DataTypeEnum** as listed in the following table.

Enumeration	Value	Description
adEmpty	0	This data type indicates that no value was specified (DBTYPE_EMPTY).
adSmallInt	2	This data type indicates a 2-byte (16-bit) signed integer (DBTYPE_I2).
adInteger	3	This data type indicates a 4-byte (32-bit) signed integer (DBTYPE_I4).
adSingle	4	This data type indicates a 4-byte (32-bit) single precision IEEE floating point number (DBTYPE_R4).
adDouble	5	This data type indicates an 8-byte (64-bit) double precision IEEE floating point number (DBTYPE_R8).
adCurrency	6	A data type indicates a currency value (DBTYPE_CY). Currency is a fixed-point number with 4 digits to the right of the decimal point. It is stored in an 8-byte signed integer scaled by 10,000. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adDate	7	This data type indicates a date value stored as a Double, the whole part of which is the number of days since December 30, 1899, and the fractional part of which is the fraction of a day. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBSTR	8	This data type indicates a null-terminated Unicode character string (DBTYPE_BSTR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adIDispatch	9	This data type indicates a pointer to an IDispatch interface on an OLE object (DBTYPE_IDISPATCH). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adError	10	This data type indicates a 32-bit error code (DBTYPE_ERROR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBoolean	11	This data type indicates a Boolean value (DBTYPE_BOOL). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

adVariant	12	This data type indicates an automation variant (DBTYPE_VARIANT). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adIUnknown	13	This data type indicates a pointer to an IUnknown interface on an OLE object (DBTYPE_IUNKNOWN). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adDecimal	14	This data type indicates numeric data with a fixed precision and scale (DBTYPE_DECIMAL).
adTinyInt	16	This data type indicates a single-byte (8-bit) signed integer (DBTYPE_I1). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adUnsignedTinyInt	17	This data type indicates a single-byte (8-bit) unsigned integer (DBTYPE_UI1). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adUnsignedSmallInt	18	This data type indicates a 2-byte (16-bit) unsigned integer (DBTYPE_UI2). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adUnsignedInt	19	This data type indicates a 4-byte (32-bit) unsigned integer (DBTYPE_UI4). This data type is not supported by the OLE DB Provider or the OLE DB Provider for DB2.
adBigInt	20	This data type indicates an 8-byte (64-bit) signed integer (DBTYPE_I8). This data type is not supported by the OLE DB Provider for AS/400 and VSAM.
adUnsignedBigInt	21	This data type indicates an 8-byte (64-bit) unsigned integer (DBTYPE_UI8). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adGUID	72	This data type indicates a globally unique identifier or GUID (DBTYPE_GUID). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBinary	128	This data type indicates fixed-length binary data (DBTYPE_BYTES).
adChar	129	This data type indicates a character string value (DBTYPE_STR).
adWChar	130	This data type indicates a null-terminated Unicode character string (DBTYPE_WSTR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adNumeric	131	This data type indicates numeric data where the precision and scale are exactly as specified (DBTYPE_NUMERIC).
adUserDefined	132	This data type indicates user-defined data (DBTYPE_UDT). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

adDBDate	133	This data type indicates an OLE DB date structure (DBTYPE_DATE).
adDBTime	134	This data type indicates an OLE DB time structure (DBTYPE_TIME).
adDBTimeStamp	135	This data type indicates an OLE DB timestamp structure (DBTYPE_TIMESTAMP).
adVarChar	200	This data type indicates variable-length character data (DBTYPE_STR).
adLongVarChar	201	This data type indicates a long string value.
adVarWChar	202	This data type indicates a Unicode string value. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adLongVarWChar	203	This data type indicates a long Unicode string value. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adVarBinary	204	This data type indicates variable-length binary data (DBTYPE_BYTES).
adLongVarBinary	205	This data type indicates a long binary value.

Open Method on a Connection Object (ADO)

The **Open** method on a **Connection** object opens a connection to a data source.

Syntax

```
connection.Open ConnectionString, UserID, Password
```

Parameters

ConnectionString

This optional parameter specifies a string containing connection information. See the **ConnectionString** property on a **Connection** object for details on valid settings.

UserID

This optional parameter specifies a string containing a user name to use when establishing the connection.

Password

This optional parameter specifies a string containing a password to use when establishing the connection.

Values used for the ConnectionString parameter

The information needed to establish a connection to a data source can be set in the **ConnectionString** property or passed as part of the **Open** method in the *ConnectionString* parameter. In either case, this information must be in a specific format for use with the Microsoft OLE DB Provider for AS/400 and VSAM. This information can be a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons. ActiveX Data Objects (ADO) supports several standard ADO-defined arguments for the **ConnectionString** property as listed in the following table.

Argument	**Description**
Data Source	This argument specifies the name of the data source for the connection. This argument is the Data Source name stored in the registry under the OLE DB Provider for AS/400 and VSAM.
File Name	This argument specifies the name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed. This argument is not supported by the OLE DB Provider for AS/400 and VSAM.
Location	This argument specifies the Remote Database Name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.
Password	This argument specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target host system and has appropriate access rights to the file.
Provider	This argument specifies the name of the provider to use for the connection. To use the OLE DB Provider for AS/400 and VSAM, the Provider string must be set to "SNAOLEDB". To use the Microsoft OLE DB Provider for DB2, the Provider string must be set to "DB2OLEDB". To use the Microsoft ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the **ConnectionString** since this value is the default for ADO.
Remote Provider	This argument specifies the name of a provider to use when opening a client-side connection (for a Remote Data Service only). This argument is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

Remote Server	This argument specifies the path name of a server to use when opening a client-side connection (for a Remote Data Service only). This argument is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
User ID	This argument specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target host system and has appropriate access rights to the file.

The OLE DB Provider for AS/400 and VSAM also supports a number of provider-specific arguments, some of which have default values as specified in the table below. These arguments are listed in the following table.

Argument	**Description**
BinAsChar	This parameter indicates whether to process binary fields as character fields (default is 0; do not process binary fields as character fields).
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
Default Library	The default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files.
HCD FileName	The fully qualified filename of the DDM host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the SNA System directory. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400.
Local LU	The name of the local LU alias configured in Host Integration Server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
RDB	The remote database name for OS/400. You only need to specify this value if it is different from the remote LU alias configured in Host Integration Server.

Repair Host Keys	This parameter indicates whether the OLE DB provider should repair any host key values set in the registry and defaults to false.
RemoteLU	The name of the remote LU alias configured in the Host Integration server.
StrictVal	This parameter indicates whether strict validation should be used and defaults to false.

The OLE DB Provider for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by OLE DB Provider for DB2 supplied with Host Integration Server 2009 differ from the arguments supported by the earlier OLE DB Provider for DB2 included with SNA Server 4.0.

The arguments supported by the OLE DB Provider for DB2 supplied with Host Integration Server 2009 are listed in the following table.

Argument	**Description**
BinAsChar	When this parameter is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2;SYSIBM;SYSTEM; CURLIB; or USERID depending on platform. This parameter does not have a default value.
InitCat	This parameter is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
LocalLU	The name of the local LU alias configured in Host Integration Server.

ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
PkgCol	The name of the DRDA target collection (AS/400 library) where the Microsoft® OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter.
RemoteLU	The name of the remote LU alias configured in Host Integration Server.
TPName	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server 2009 uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPName is set to 0X07F9F9F9.

UOW	This parameter determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note

Not all of these parameters are required. The user can also be prompted for this information.

The ODBC Driver for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by ODBC Driver for DB2 supplied with Host Integration Server 2009 differ from the arguments supported by the earlier ODBC Driver for DB2 included with SNA Server 4.0.

The arguments supported by the ODBC Driver for DB2 supplied with Host Integration Server 2009 are listed in the following table.

Argument	**Description**
BAC	When the *BinAsChar* parameter is set to true (1), the ODBC Driver for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The CCSID and PCCodePage values are required input parameters.
CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the BinAsChar value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character code page to use on the computer. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Windows®. If this argument is omitted, the default value is set to Latin 1 (1252).
DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.

DS	The Default Schema parameter is the name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (e.g., ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at login. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
LLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
MN	When SNA is used for the Network Transport Library (NTL), the Mode Name field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP.
NA	When TCP/IP is used for the Network Transport Library (NTL), the Network Address parameter indicates the IP address or the hostname alias of the host DB2 server.
NP	When TCP/IP is used for the Network Transport Library (NTL), the Network Port parameter indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default value is TCP/IP port 446.
NTL	The Network Transport Library parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for NetAddr and NetPort are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA application requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the Package Collection parameter.
PDS	The Provider Data Source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the **ConnectionString** since this value is the default for ADO.

PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the Parameter parameter.
RDB	The remote database name parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
TPN	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPN is set to 0X07F9F9F9.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the User ID parameter.
UOW	Determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note
Not all of these parameters are required. The user can also be prompted for this information.

Remarks

The **Open** method on a **Connection** object is used to open tables on a remote DDM server. Using the **Open** method on a **Connection** object establishes the physical connection to a data source. After this method successfully completes, the connection is live and other methods can be invoked on the **Connection** object to process results.

The optional *ConnectionString* parameter is used to specify a connection string containing a series of *argument=value* statements separated by semicolons. The **ConnectionString** property on a **Connection** object automatically inherits the value used for the *ConnectionString* parameter. Therefore, the **ConnectionString** property of the **Connection** object can be set before opening the **Connection** object, or the *ConnectionString* parameter can be used to set or override the current connection parameters during the **Open** method call.

If user and password information is set in both the *ConnectionString* parameter and in the optional *UserID* and *Password* parameters, the results may be unpredictable. Such information should only be passed in either the *ConnectionString* parameter or the *UserID* and *Password* parameters.

There are a number of different ways to open a connection. The **Open** method can pass all of the appropriate connection information as part of the *ConnectionString* parameter or by setting the **ConnectionString** property of the **Connection** object, if this information is known in advance. The syntax in this case using the *ConnectionString* parameter for use with the OLE DB Provider for AS/400 and VSAM is as follows:

```
connection = CreateObject("ADODB.Connection.2.0")
connection.Open "Provider=SNAOLEDB;Data Source=REMLU;User ID=USERNAME;Password=password;Loc
al LU=LOCAL;Remote LU=DATABASE;ModeName=QPCSUPP;CCSID=37;CodePage=437"
```

Note that not all of these parameters are required. The registry settings for the Data Source usually have default values set for remote LU, local LU, APPC mode, CCSID, and CodePage. If a data source is specified, this other information is not usually needed. These registry settings are configured by using the Microsoft Management Console snap-in for the OLE DB Provider for AS/400 and VSAM.

The simplest form of an **Open** command that contains all necessary information is as follows:

```
connection = CreateObject("ADODB.Connection.2.0")
connection.Open "Provider=SNAOLEDB;Data Source=REMLU;User ID=USERNAME;Password=password"
```

Note
The Data Source, User ID and Password must be included.

In the case where you would like the user to input the connection information, the following syntax can be used. This syntax does not specify any connection information except the provider, which is always required unless this is set in the **ConnectionString** or **Provider** property of the **Connection** object:

```
connection = CreateObject("ADODB.Connection.2.0")
connection.ConnectionString = "Provider=SNAOLEDB"
connection.Open
```

This method of invoking the **Open** method automatically causes a dialog box to appear asking the user for the data source, user name, and password.

When operations have been concluded over an open **Connection** object, the **Close** method should be invoked on the **Connection** object to free any associated system resources. Closing a **Connection** object does not remove it from memory; you may change its property settings and use the **Open** method to open it again later. To completely eliminate an object from memory, set the **Connection** object variable to **Nothing**.

If errors occur, these can be examined with the **Errors** collection on the **Connection** object.

Open Method on a Recordset Object (ADO)

The **Open** method on a **Recordset** object opens a cursor that represents records from a base table or the results of a query.

Syntax

```
recordset.Open Source, ActiveConnection, CursorType, LockType,
Options
```

Parameters

Source

This optional parameter specifies a Variant that evaluates to a valid **Command** object variable name or a valid string specifying the command text specific to the Microsoft OLE DB Provider for AS/400 and VSAM to open a data file on the host.

ActiveConnection

This optional parameter specifies either a Variant that evaluates to a valid **Connection** object variable name or a String containing connection information equivalent to the **ConnectionString** property of a **Connection** object. Possible values are listed at the end of the **Parameters** section.

CursorType

This optional parameter specifies a **CursorTypeEnum** value that determines the type of cursor that the provider should use when opening the **Recordset**. See the CursorType Property of a **Recordset** object for more information. Possible values are listed at the end of the **Parameters** section.

LockType

This optional parameter specifies a **LockTypeEnum** value that determines what type of locking (concurrency) the provider should use when opening the recordset. See the LockType Property of a **Recordset** object for more information. Possible values are listed at the end of the **Parameters** section.

Options

This optional parameter specifies a Long value representing a **CommandTypeEnum** value that indicates how the provider should evaluate the *Source* parameter.

Values used for the ActiveConnection property

The information needed to establish a connection to a data source can be set in the **ActiveConnection** property of a **Recordset** object or passed as part of the **Open** method on a **Recordset** object in the *ActiveConnection* parameter. In either case, this information must be in a specific format for use with the OLE DB Provider for AS/400 and VSAM. This information can be a data source name (DSN) or a detailed connection string containing a series of *argument=value* statements separated by semicolons. ActiveX Data Objects (ADO) supports several standard ADO-defined arguments for the **ActiveConnection** property as listed in the following table.

Argument	**Description**
Data Source	This argument specifies the name of the data source for the connection. This argument is the optional when used with OLE DB Provider for AS/400 and VSAM or the Microsoft OLE Provider for DB2.
File Name	This argument specifies the name of the provider-specific file containing preset connection information. This argument cannot be used if a *Provider* argument is passed. This argument is not supported by the OLE DB Provider for AS/400 and VSAM.
Location	This argument specifies the Remote Database Name used for connecting to OS/400 systems. This parameter is optional when connecting to mainframe systems.

Password	This argument specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used by Host Integration Server 2009 to validate that the user can log on to the target host system and has appropriate access rights to the file.
Provider	This argument specifies the name of the provider to use for the connection. To use the OLE DB Provider for AS/400 and VSAM, the Provider string must be set to "SNAOLEDB". To use the OLE DB Provider for DB2, the Provider string must be set to "DB2OLEDB". To use the ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the ConnectionString since this value is the default for ADO.
Remote Provider	This argument specifies the name of a provider to use when opening a client-side connection (for a Remote Data Service only). This argument is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
Remote Server	This argument specifies the path name of a server to use when opening a client-side connection (for a Remote Data Service only). This argument is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
User ID	This argument specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used by Host Integration Server to validate that the user can log on to the target host system and has appropriate access rights to the file.

The OLE DB Provider for AS/400 and VSAM also supports a number of provider-specific arguments, some of which have default values as specified in the table below. These arguments are as listed in the following table.

Argument	**Description**
BinAsChar	This parameter indicates whether to process binary fields as character fields (default is 0; do not process binary fields as character fields).
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).
Default Library	The default AS/400 library to be accessed. This parameter is not required for mainframe access and is optional when connecting to AS/400 files.
HCDFileName	The fully qualified file name of the DDM host column description (HCD) file. This parameter can be an UNC string up to 256 characters in length. A path does not need to be included in the name if the HCD file is located in the SNA system directory. This parameter is required when connecting to mainframe systems and is optional when connecting to OS/400.
Local LU	The name of the local LU alias configured in the SNA server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and SNA server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.

NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the computer. If this argument is omitted, the default value is set to Latin 1 (1252).
RDB	The remote database name for OS/400. You only need to specify this value if it is different from the remote LU alias configured in the SNA server.
Repair Host Keys	This parameter indicates whether the OLE DB provider should repair any host key values set in the registry and defaults to false.
RemoteLU	The name of the remote LU alias configured in the SNA server.
StrictVal	This parameter indicates whether strict validation should be used and defaults to false.

Note
Not all of these parameters are required. The user can also be prompted for this information.

The OLE DB Provider for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by OLE DB Provider for DB2 supplied with Host Integration Server differ from the arguments supported by the earlier OLE DB Provider for DB2 included with SNA Server 4.0.

The arguments supported by the OLE DB Provider for DB2 supplied with Host Integration Server are listed in the following table.

Argument	**Description**
BinAsChar	When this parameter is set to true, the OLE DB Provider for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The Host CCSID and PC Code Page values are required input and output parameters. This parameter defaults to false.
CCSID	The Code Character Set Identifier (CCSID) attribute indicates the character set used on the host. If this argument is omitted, the default value is U.S./Canada (37).

DefSch	The name of the default schema (collection/owner) where the system catalogs resides. This parameter can be QSYS2;SYSIBM;SYSTEM; CURLIB; or USERID depending on platform. This parameter does not have a default value.
InitCat	This parameter is used as the first part of a 3-part fully qualified table name. In DB2 (MVS, OS/390), this property is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. In DB2/400, this parameter is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then one can be created using the Add option. In DB2 Universal Database, this property is referred to as DATABASE. This parameter has no default value.
LocalLU	The name of the local LU alias configured in Host Integration Server.
ModeName	The APPC mode (must be set to a value that matches the host configuration and Host Integration Server configuration). Legal values for the APPC mode include QPCSUPP (5250), #NTER (interactive), #NTERSC (interactive), #BATCH (batch), #BATCHSC (batch), and custom modes.
NetAddr	When TCP/IP has been selected for the Network Transport Library, this parameter indicates the IP address of the host.
NetPort	When TCP/IP has been selected for the Network Transport Library, this parameter is the TCP/IP port used for communication with the source. The default value is TCP/IP port 446.
NetLib	This parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA.
PCCodePage	The character code page to use on the PC. If this argument is omitted, the default value is set to Latin 1 (1252).
PkgCol	The name of the DRDA target collection (AS/400 library) where the Microsoft OLE DB Provider for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft OLE DB Provider for DB2 uses packages to issue dynamic and static SQL statements. The OLE DB Provider will create packages dynamically in the location to which the user points using the Package Collection parameter.

RemoteLU	The name of the remote LU alias configured in Host Integration Server.
TPName	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPName is set to 0X07F9F9F9.
UOW	This parameter determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note

Not all of these parameters are required. The user can also be prompted for this information.

The ODBC Driver for DB2 also supports a number of provider-specific arguments, some of which have default values as specified in the tables below. The arguments supported by ODBC Driver for DB2 supplied with Host Integration Server differ from the arguments supported by the earlier ODBC Driver for DB2 included with SNA Server 4.0.

The arguments supported by the ODBC Driver for DB2 supplied with Host Integration Server are listed in the following table.

Argument	**Description**
BAC	When the *BinAsChar* parameter is set to **true** (1), the ODBC Driver for DB2 treats binary data type fields (with a CCSID of 65535) as character data type fields on a per-data source basis. The **CCSID** and **PCCodePage** values are required input parameters.
CCSID	The character code set identifier (CCSID) matching the DB2 data as represented on the remote computer. The CCSID property is required when processing binary data as character data. Unless the **BinAsChar** value is set, character data is converted based on the DB2 column CCSID and default ANSI code page. If this argument is omitted, this parameter defaults to U.S./Canada (37).
CP	The character code page to use on the PC. This parameter is required when processing binary data as character data. Unless the Binary as Character (BAC) value is set, character data is converted based on the default ANSI code page configured in Windows. If this argument is omitted, the default value is set to Latin 1 (1252).

DESC	A field to provide a comment describing this ODBC data source. The description is an optional parameter and may be left blank.
DS	The Default Schema parameter is the name of the Collection where the ODBC Driver for DB2 looks for catalog information. The Default Schema is the "SCHEMA" name for the target collection of tables and views. The ODBC driver uses Default Schema to restrict results sets for popular operations, such as enumerating a list of tables in a target collection (for example, ODBC Catalog SQLTables). For DB2, the Default Schema is the target AUTHENTICATION (User ID or "owner"). For DB2/400, the Default Schema is the target COLLECTION name. For DB2 Universal Database (UDB), the Default Schema is the SCHEMA name. If the user does not provide a value for Default Schema, then the ODBC driver uses the USER_ID provided at logon. For DB2/400, the driver will use QSYS2 if there is no collection found matching the USER_ID value. Obviously, this default is inappropriate in many cases, therefore it is essential that the Default Schema value in the data source be defined.
DSN	The data source name is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file, which is stored in the Program Files\Common Files\ODBC\Data Sources directory.
LLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
MN	When SNA is used for the Network Transport Library (NTL), the Mode Name field is the APPC mode and must be set to a value that matches the host configuration and Host Integration Server configuration. Legal values for the APPC mode include QPCSUPP (common system default often used by 5250), #INTER (interactive), #INTERSC (interactive with minimal routing security), #BATCH (batch), #BATCHSC (batch with minimal routing security), #IBMRDB (DB2 remote database access), and custom modes. The following modes that support bidirectional LZ89 compression are also legal: #INTERC (interactive with compression), INTERCS (interactive with compression and minimal routing security), BATCHC (batch with compression), and BATCHCS (batch with compression and minimal routing security). This parameter normally defaults to QPCSUPP.
NA	When TCP/IP is used for the Network Transport Library (NTL), the Network Address parameter indicates the IP address or the hostname alias of the host DB2 server.
NP	When TCP/IP is used for the Network Transport Library (NTL), the Network Port parameter indicates the TCP/IP port used for communication with the target DB2 DRDA service. The default value is TCP/IP port 446.
NTL	The Network Transport Library parameter determines whether TCP/IP or SNA APPC is used for network communication. The possible values for this parameter are TCPIP or SNA. This value defaults to SNA. If the default SNA is selected, then values for LLU, MN, and RLU are required. If TCP/IP is selected, then values for NetAddr and NetPort are required.
PC	The name of the DRDA target collection (AS/400 library) where the Microsoft ODBC Driver for DB2 should store and bind DB2 packages. This could be same as the Default Schema. The Microsoft ODBC Driver for DB2, which is implemented as an IBM DRDA application requester, uses packages to issue dynamic and static SQL statements. The ODBC driver will create packages dynamically in the location to which the user points using the Package Collection parameter.
PDS	The Provider Data Source is a required parameter that is used to define the data source. The ODBC driver manager uses this attribute value to load the correct ODBC data source configuration from the registry or from a file. For File data sources, this field is used to name the DSN file, which is stored in the Program Files\Common Files\ODBC\Data Sources directory.

PROV	Specifies the name of the provider to use for the connection. To use the ODBC Driver for DB2, the Provider string must be set to "MSDASQL" or not used as part of the **ConnectionString** since this value is the default for ADO.
PWD	Specifies a valid mainframe or AS/400 password to use when opening the connection. This password is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. Note that this parameter is the same as the Parameter parameter.
RDB	The remote database name parameter is used as the first part of a three-part, fully qualified DB2 table name. This parameter is referred to by different names depending on the DB2 platform. In DB2 on MVS and OS/390, this parameter is referred to as LOCATION. The SYSIBM.LOCATIONS table lists all the accessible locations. To find the location of the DB2 to which you need to connect on these platforms, ask the administrator to look in the TSO Clist DSNTINST under the DDF definitions. These definitions are provided in the DSNTIPR panel in the DB2 Installation manual. In DB2/400 on OS/400, this property is referred to as RDBNAM. The RDBNAM value can be determined by invoking the WRKRDBDIRE command from the console to the OS/400 system. If there is no RDBNAM value, then a value can be created using the **Add** option. In DB2 Universal Database, this property is referred to as DATABASE.
RLU	When SNA is used for the network transport, this field is the name of the remote LU alias configured in Host Integration Server.
TPN	The Transaction Program (TP) Name parameter represents the default transaction program name for the DB2 DRDA application server (AS) which is 07F6DB (DB2DRDA). However, some DB2 installations may be configured to use an alternate TP name. Host Integration Server uses the alternate TP name in the off-line demo configuration (DRDADEMO.UDL). In that case, TPN is set to 0X07F9F9F9.
UID	Specifies a valid mainframe or AS/400 user name to use when opening the connection. This user name is used to validate that the user can log on to the target DB2 host system and has appropriate access rights to the database. This parameter is the same as the User ID parameter.
UOW	Determines whether two-phase commit is enabled. The possible values for this parameter are DUW (distributed unit of work) or RUW (remote unit of work). This value defaults to RUW. When this parameter is set to RUW, two-phase commit is disabled. When this parameter is set to DUW, two-phase commit is enabled in the OLE DB Provider for DB2. Distributed transactions are handled using Microsoft Transaction Server, Microsoft Distributed Transaction Coordinator, and the SNA LU 6.2 Resync Service. This option works only with DB2 for OS/390 v5R1 or later. This option also requires that SNA (LU 6.2) service is selected as the network transport and Microsoft Transaction Server (MTS) is installed.

Note

Not all of these parameters are required. The user can also be prompted for this information. **Values used for the CursorType parameter**

Thisparameter can be one of the enumerated values for **CursorTypeEnum** as listed in the following table.

Enumeration	Value	Description

adOpenUnspecified	-1	This indicates an unspecified value for the *CursorType*. This value is not supported by the Microsoft OLE DB Provider for AS/400 and VSAM or the Microsoft OLE DB Provider for DB2.
adOpenForwardOnly	0	Specifying this value opens a forward-only-type cursor. This *CursorType* is identical to a static cursor, except that you can only scroll forward through records. This improves performance when only one pass through a **Recordset** is needed. This value is not supported by the Microsoft OLE DB Provider for AS/400 and VSAM.
adOpenKeyset	1	Specifying this value opens a keyset-type cursor. This *CursorType is* similar to a dynamic cursor with a few exceptions. Records that other users delete are inaccessible from your **Recordset**. Data changes to existing records by other users are still visible, but records added by other users are not visible (cannot be seen). This value is not supported by the OLE DB Provider for AS/400 and VSAM.
adOpenDynamic	2	Specifying this value opens a dynamic-type cursor. Additions, changes, and deletions by other users are visible, and all types of movement through the recordset are allowed, except for bookmarks if the provider does not support them. A dynamic cursor is the only *CursorType* supported by the OLE DB Provider for AS/400 and VSAM.
adOpenStatic	3	Specifying this value opens a static-type cursor. A static cursor provides a static copy of a set of records that can be used to find data or generate reports. Additions, changes, or deletions by other users are not visible with a static cursor. This value is not supported by the OLE DB Provider for AS/400 and VSAM.

This optional argument defaults to **adOpenForwardOnly**, a value that is mapped to **adOpenDynamic** by the OLE DB provider for AS/400 and VSAM.

Values used for the LockType parameter

This parameter can be one of the enumerated values for **LockTypeEnum** as listed in the following table.

Enumeration	Value	Description
adLockUnspecified	-1	Indicates an unspecified value for the *LockType*. This value is not supported by the OLE DB Provider for AS/400 and VSAM.
adLockReadOnly	1	Specifying this value opens a **Recordset** object read-only and data cannot be altered.
adLockPessimistic	2	Specifying this value opens a recordset with pessimistic locking. Record-by-record, the OLE DB Provider does whatever is necessary to ensure successful editing of the records, usually by locking records at the data source immediately upon editing. This lock type is supported by the OLE DB Provider for AS/400 and VSAM and the OLE DB Provider. However, the OLE DB Provider for AS/400 and VSAM internally maps this lock type to **adLockBatchOptimistic**.
adLockOptimistic	3	Specifying this value opens a recordset with optimistic locking. Record-by-record, the OLE DB Provider locks records only when the **Update** method is invoked on a **Recordset** object. This lock type is not supported by the OLE DB Provider for DB2.

adLockBatchOptimistic	4	Specifying this value opens a **Recordset** with batch optimistic locking. This value is required for batch update mode as opposed to immediate update. This lock type is not supported by the OLE DB Provider for DB2.

This optional argument defaults to **adLockReadOnly**.

Values used by the Optionsproperty

The **CommandTypeEnum** value can be one of the constants listed in the following table.

Enumeration	Value	Description
adCmdUnspecified	-1	This value indicates that the **CommandText** property is unspecified. This value is not supported by the OLE DB Provider for AS/400 and VSAM.
adCmdText	1	This value evaluates the **CommandText** property as a textual definition of a command or stored procedure call.
adCmdTable	2	This value evaluates the **CommandText** property as a table name. This value is not supported by the OLE DB Provider for AS/400 and VSAM.
adCmdStoredProc	4	This value evaluates the **CommandText** property as a stored procedure name. This value is not supported by the OLE DB Provider for AS/400 and VSAM.
adCmdUnknown	8	This value indicates that the type of command in **CommandText** property is not known. This is the default value. This value is not supported by the OLE DB Provider for AS/400 and VSAM.

Remarks

The **Open** method on a **Recordset** object is used to open tables on a remote DDM server. Using the **Open** method on a **Recordset** object establishes the physical connection to a data source and opens a cursor that represents records from a base table or the results of a query. After this method successfully completes, the **Recordset** object is live and other methods can be invoked on the **Recordset** object to process results.

The optional *Source* parameter is used to specify the command text required to open a data file on the host using the OLE DB Provider for AS/400 and VSAM. The syntax in this case is as follows:

```
recordset = CreateObject("ADODB.Recordset.2.0")
recordset.Open "EXEC OPEN LIBRARY/FILE", connection, adOpenDynamic, adLockOptimistic, adCmd
Text
```

Using the OLE DB Provider for AS/400 and VSAM, the *Source* parameter represents a table name and uses one of the following host file naming conventions.

Host file type	File naming convention
VSAM Data Sets	DATASETNAME.FILENAME
Partitioned Data Sets	DATASETNAME.FILENAME(MEMBER)
OS/400 Files	LIBRARY/FILE
OS/400 Files	LIBRARY/FILE.NAME
OS/400 File Members	LIBRARY/FILE(MEMBER)

OS/400 File Members	LIBRARY/FILE.NAME(MEMBER)

Note that if a member of a library contains a dot in the member name, the member name must be surrounded by double quotes. For example, if the member name is NAMES.DAT, the proper syntax for command text used for the **Recordset.Open** method is:

```
recordset = CreateObject("ADODB.Recordset.2.0")
recordset.Open "EXEC OPEN LIBRARY/FILE(""NAMES.DAT"")", connection, adOpenDynamic, adLockOp
timistic, adCmdText
```

Note the doubled quotes are required surrounding the member name in this example since the member name contains a period. The full path to the mainframe data set must be specified when using the OLE DB Provider for AS/400 and VSAM. In the example above, there are two path elements (LIBRARY/FILE) and one name element (NAMES.DAT).

Whenever a VSAM data set is allocated, it is given a unique name composed of one or more segments. Each segment of the data set name is joined by periods and represents a level of qualification. For example, the following data set has four segments that comprise the fully-qualified data set name (three path elements and one name element):

```
SAMPLES.DEMO.KSDS.TITLES
```

The high-level qualifier is SAMPLES. The low-level qualifier is TITLES. Each segment can be from 1-8 characters in length (the first character must be alphabetic, while the remainder can be alphanumeric or hyphens). The full data set name must be no more than 44 characters in length and contain no more than 22 segments.

The optional *ActiveConnection* parameter corresponds to the **ActiveConnection** property on a **Recordset** object and specifies on which connection to open the **Recordset** object. If a connection string definition is passed for this argument, ADO opens a new connection using the specified parameters. The value of this **ActiveConnection** property can be changed after opening the **Recordset** to send updates to another provider. The **ActiveConnection** property is set to **Nothing** (in Microsoft® Visual Basic®) to disconnect the recordset from the OLE DB Provider. If the optional *ActiveConnection* parameter is used to specify a connection string, this string must contain a series of *argument=value* statements separated by semicolons.

The **ActiveConnection** property on a **Recordset** object automatically inherits the value used for the *ActiveConnection* parameter. Therefore, the **ActiveConnection** property of the **Recordset** object can be set before opening the **Recordset** object, or the *ActiveConnection* parameter can be used to set or override the current connection parameters during the **Open** method call.

The *CursorType* parameter cannot be omitted using the OLE DB Provider for AS/400 and VSAM since this parameter defaults to **adOpenForwardOnly**, a *CursorType* that is not supported on the OLE DB Provider. The *CursorType* parameter must be set to **adOpenDynamic**, otherwise an error will occur and results will be unpredictable.

There are a number of different ways to open a recordset and connect to a data source. The **Open** method of the **Recordset** object can pass all of the appropriate connection information as part of the *ActiveConnection* parameter or by setting the **ActiveConnection** property of the **Recordset** object, if this information is known in advance. The syntax, in this case using the *ActiveConnection* parameter and the OLE DB Provider for AS/400 and VSAM, is as follows:

```
recordset = CreateObject("ADODB.Recordset.2.0")
recordset.Open "EXEC OPEN LIBRARY/FILE","Provider=SNAOLEDB;Data Source=REMLU;User ID=USERNA
ME;Password=password;Local LU=LOCAL;Remote LU=DATABASE;ModeName=QPCSUPP;CCSID=37;CodePage=4
37", adOpenDynamic, adLockOptimistic, adCmdText
```

Note

Not all of these parameters are required. The registry settings for the Data Source usually have default values set for remote LU, local LU, APPC mode, CCSID, and CodePage. If a data source is specified, this other information is not usually needed. The se registry settings are configured by using the Microsoft Management Console snap-in for the OLE DB Provider for AS/400 and VSAM.

For the other parameters that correspond directly to the properties of a **Recordset** object (*Source*, *CursorType*, and *LockType*), the relationships of the parameters to the properties are:

- The property is read/write before the **Recordset** object is opened.
- The property settings are used unless the corresponding parameters are passed when executing the **Open** method. If a parameter is passed, it overrides the corresponding property setting, and the property setting is updated with the parameter value.
- After the **Recordset** object is opened, these properties become read-only.

Note
For **Recordset** objects whose **Source** property is set to a valid **Command** object, the **ActiveConnection** property is read-only, even if the **Recordset** object is not open.

If a **Command** object is passed in the *Source* parameter and an *ActiveConnection* parameter is also passed, an error occurs. The **ActiveConnection** property of the **Command** object must already be set to a valid **Connection** object or connection string.

If a **Command** object is not passed in the *Source* argument, the *Options* argument must be set to **adCmdText**. If the *Options* argument is not defined, you may experience diminished performance because ADO must make calls to the OLE DB Provider to determine if the argument is a command statement. If you know what *Source* type you are using, setting the *Options* argument instructs ADO to jump directly to the relevant code.

If the data source returns no records, the provider sets both the **BOF** and **EOF** properties on the **Recordset** object to **True**, and the current record position is undefined. You can still add new data to this empty **Recordset** object if the cursor type allows it.

When operations have been concluded over an open **Recordset** object, the **Close** method should be invoked on the **Recordset** object to free any associated system resources. Closing a **Recordset** object does not remove it from memory; you may change its property settings and use the **Open** method to open it again later. To completely eliminate an object from memory, set the **Recordset** object variable to **Nothing**.

If errors occur, these can be examined with the **Errors** collection on the **Recordset** object.

OpenSchema Method (ADO)

The **OpenSchema** method on a **Connection** object obtains database schema information from the provider.

Syntax

```
recordset = connection.OpenSchema ( QueryType, Criteria, SchemaID )
```

Parameters

QueryType

This parameter specifies a **SchemaEnum** value that indicates the type of schema query to run.

The **SchemaEnum** values supported by the Microsoft® OLE DB Provider for AS/400 and VSAM can be one of the constants listed in the table following the Parameters section.

Criteria

This optional parameter specifies an array of query constraints for each *QueryType* option, as listed below.

The values supported by the OLE DB Provider for AS/400 and VSAM can be one of the constants listed in the table following the Parameters section. This value depends on the *QueryType*.

Note

The **adSchemaindexes** TYPE restriction is not supported by the OLE DB Provider for DB2.

Note

The **adSchemaProcedures** PROCEDURE_SCHEMA, and **adSchemaProcedureParameters** PROCEDURE_SCHEMA restrictions are not supported when connecting to DB/2 on OS/390 platforms.

SchemaID

This optional parameter specifies the GUID for a provider-schema schema query not defined by the OLE DB specification. This parameter is required if the *QueryType* parameter is set to **adSchemaProviderSpecific**; otherwise, it is not used. This parameter is not supported by the OLE DB Provider for AS/400 and VSAM.

Values for QueryType

Enumeration	Value	Description
adSchemaColumns	4	This value indicates that the *QueryType* is requesting column information for tables on the server (not supported when connecting to mainframes).
adSchemaIndexes	12	This value indicates that the *QueryType* is requesting index information about the tables on the server (not supported when connecting to mainframes).
adSchemaTables	20	This value indicates that the *QueryType* is requesting information about the tables on the server.
adSchemaProviderTypes	22	This value indicates that the *QueryType* is requesting provider-type information.

The **SchemaEnum** values supported by the Microsoft OLE DB Provider for DB2 and the Microsoft ODBC Driver for DB2 can be one of the constants listed in the following table.

Enumeration	Value	Description
adSchemaColumns	4	This value indicates that the *QueryType* is requesting column information for tables on the server (not supported when connecting to mainframes).

adSchemaIndexes	12	This value indicates that the *QueryType* is requesting index information about the tables on the server (not supported when connecting to mainframes).
adSchemaProcedures	16	This value indicates that the *QueryType* is requesting information about stored procedures on the server.
adSchemaTables	20	This value indicates that the *QueryType* is requesting information about the tables on the server.
adSchemaProviderTypes	22	This value indicates that the *QueryType* is requesting provider-type information.
adSchemaProcedureParameters	26	This value indicates that the *QueryType* is requesting information about parameters used by stored procedures on the server.
adSchemaPrimaryKeys	28	This value indicates that the *QueryType* is requesting information about the primary keys for tables on the server.

Return Value

Returns a **Recordset** object that contains schema information requested.

Remarks

The **OpenSchema** method on a **Connection** object is used to return information about the data source, such as information about the tables on the server and the columns in the tables.

The *Criteria* argument is an array of values that can be used to limit the results of a schema query. Each schema query supports a different set of parameters. The actual schemas are defined by the OLE DB specification under the **IDBSchemaRowset** interface. The schema queries supported in ActiveX® Data Objects (ADO) version 1.5 and later by the OLE DB Provider for AS/400 and VSAM are listed above.

The **OpenSchema** method allows an application to pass at run time the target library of a Partitioned Data Set (PDS/PDSE), a dataset, or a member name as one of the *Criteria* array arguments to retrieve the schema.

Providers are not required to support all of the OLE DB standard schema *QueryType* values. Specifically, only **adSchemaTables**, **adSchemaColumns**, and **adSchemaProviderTypes** are required by the OLE DB specification. However, the provider is not required to support the *Criteria* constraints listed above for those schema queries. Support for other schema *QueryType* values is optional.

The schema information specified in OLE DB is based on the assumption that providers support the concepts of a catalog and a schema. The ANSI SQL 92 specification defines them as follows:

- A catalog contains one or more schemas, but always contains a schema named INFORMATION_SCHEMA which contains the views and domains of the information schema. In Microsoft SQL Server™ and Microsoft Access terms, a catalog is a database; in ODBC 2.*x* terms, a catalog is a qualifier.

- A schema is a collection of database objects that are owned or have been created by a particular user. In Microsoft SQL Server and ODBC 2.*x* terms, a schema is an owner; there is no equivalent to a schema in a Microsoft Access database.

Schema information in ADO and OLE DB is retrieved using predefined schema rowsets.

adSchemaColumns

The **adSchemaColumns** *QueryType* identifies the columns of tables defined in the catalog that are accessible to a given user. This *QueryType* is supported by the Microsoft OLE DB Provider for AS/400 and VSAM and the Microsoft OLE DB Provider for DB2.

The rowset returned by an **adSchemaColumns** *QueryType* contains the columns listed in the following table.

Column name	Type indicator	Description
TABLE_CATALOG	DBTYPE_WSTR	Catalog name. NULL if the provider does not support catalogs.
TABLE_SCHEMA	DBTYPE_WSTR	Unqualified schema name. NULL if the provider does not support schemas.
TABLE_NAME	DBTYPE_WSTR	Table name.
COLUMN_NAME	DBTYPE_WSTR	The name of the column; this might not be unique. If this cannot be determined, a NULL is returned. This column, together with the COLUMN_GUID and COLUMN_PROPID columns, forms the column ID. One or more of these columns will be NULL depending on which elements of the DBID structure the provider uses. If possible, the resulting column ID should be persistent. However, some providers do not support persistent identifiers for columns. The column ID of a base table should be invariant under views.
COLUMN_GUID	DBTYPE_GUID	Column GUID.
COLUMN_PROPID	DBTYPE_UI4	Column property ID.

ORDINAL_POSITION	DBTYPE_UI4	The ordinal of the column. Columns are numbered starting from one. NULL if there is no stable ordinal value for the column.
COLUMN_HASDEFAULT	DBTYPE_BOOL	VARIANT_TRUE: The column has a default value. VARIANT_FALSE: The column does not have a default value or it is unknown whether the column has a default value.
COLUMN_DEFAULT	DBTYPE_WSTR	Default value of the column. A provider may expose DBCOLUMN_DEFAULTVALUE but not DBCOLUMN_HASDEFAULT (for SQL 92 tables) in the rowset returned by **IColumnsRowset::GetColumnsRowset**. If the default value is the NULL value, COLUMN_HASDEFAULT is VARIANT_TRUE, and the COLUMN_DEFAULT column is a NULL value.
COLUMN_FLAGS	DBTYPE_UI4	A bitmask that describes column characteristics. The DBCOLUMNFLAGS enumerated type specifies the bits in the bitmask. For information about DBCOLUMNFLAGS, see **IColumnsInfo::GetColumnInfo**. This column cannot contain a NULL value.
IS_NULLABLE	DBTYPE_BOOL	VARIANT_TRUE: The column might be nullable. VARIANT_FALSE: The column is known not to be nullable.
DATA_TYPE	DBTYPE_UI2	The indicator of the columns data type. If the data type of the column varies from row to row, this must be DBTYPE_VARIANT.
TYPE_GUID	DBTYPE_GUID	The GUID of the columns data type.
CHARACTER_MAXIMUM_LENGTH	DBTYPE_UI4	The maximum possible length of a value in the column. For character, binary, or bit columns, this is one of the following: The maximum length of the column in characters, bytes, or bits, respectively, if one is defined. For example, a CHAR(5) column in an SQL table has a maximum length of five (5). The maximum length of the data type in characters, bytes, or bits, respectively, if the column does not have a defined length. Zero (0) if neither the column nor the data type has a defined maximum length. NULL for all other types of columns.

CHARACTER_OCTET_LENGTH	DBTYPE_UI4	Maximum length in octets (bytes) of the column, if the type of the column is character or binary. A value of zero means the column has no maximum length. NULL for all other types of columns.
NUMERIC_PRECISION	DBTYPE_UI2	If the columns data type is numeric, this is the maximum precision of the column. The precision of columns with a data type of DBTYPE_DECIMAL or DBTYPE_NUMERIC depends on the definition of the column. If the columns data type is not numeric, this is NULL.
NUMERIC_SCALE	DBTYPE_I2	If columns type indicator is DBTYPE_DECIMAL or DBTYPE_NUMERIC, this is the number of digits to the right of the decimal point. Otherwise, this is NULL.
DATETIME_PRECISION	DBTYPE_UI4	Datetime precision (number of digits in the fractional seconds portion) of the column if the column is a datetime or interval type.
CHARACTER_SET_CATALOG	DBTYPE_WSTR	Catalog name in which the character set is defined. NULL if the provider does not support catalogs or different character sets.
CHARACTER_SET_SCHEMA	DBTYPE_WSTR	Unqualified schema name in which the character set is defined. NULL if the provider does not support schemas or different character sets.
CHARACTER_SET_NAME	DBTYPE_WSTR	Character set name. NULL if the provider does not support different character sets.
COLLATION_CATALOG	DBTYPE_WSTR	Catalog name in which the collation is defined. NULL if the provider does not support catalogs or different collations.
COLLATION_SCHEMA	DBTYPE_WSTR	Unqualified schema name in which the collation is defined. NULL if the provider does not support schemas or different collations.

COLLATION_NAME	DBTYPE_WSTR	Collation name. NULL if the provider does not support different collations.
DOMAIN_CATALOG	DBTYPE_WSTR	Catalog name in which the domain is defined. NULL if the provider does not support catalogs or domains.
DOMAIN_SCHEMA	DBTYPE_WSTR	Unqualified schema name in which the domain is defined. NULL if the provider does not support schemas or domains.
DOMAIN_NAME	DBTYPE_WSTR	Domain name. NULL if the provider does not support domains.
DESCRIPTION	DBTYPE_WSTR	Human-readable description of the column. For example, the description for a column named Name in the Employee table might be "Employee name."

The default sort order for the **adSchemaColumns** rowset is TABLE_CATALOG, TABLE_SCHEMA, and TABLE_NAME.

adSchemaIndexes

The **adSchemaIndexes** *QueryType* identifies the indexes defined in the catalog that are owned by a given user. This *QueryType* is supported by the Microsoft OLE DB Provider for AS/400 and VSAM and the Microsoft OLE DB Provider for DB2.

The rowset returned by an **adSchemaIndexes** *QueryType* contains the columns listed in the following table.

Column name	Type indicator	Description
TABLE_CATALOG	DBTYPE_WSTR	Catalog name. NULL if the provider does not support catalogs.
TABLE_SCHEMA	DBTYPE_WSTR	Unqualified schema name. NULL if the provider does not support schemas.
TABLE_NAME	DBTYPE_WSTR	Table name.

INDEX_CATALOG	DBTYPE_WSTR	Catalog name. NULL if the provider does not support catalogs.
INDEX_SCHEMA	DBTYPE_WSTR	Unqualified schema name. NULL if the provider does not support schemas.
INDEX_NAME	DBTYPE_WSTR	Index name.
PRIMARY_KEY	DBTYPE_BOOL	Whether the index represents the primary key on the table. NULL if this is not known.
UNIQUE	DBTYPE_BOOL	Whether index keys must be unique. One of the following: VARIANT_TRUE: The index keys must be unique. VARIANT_FALSE: Duplicate keys are allowed.

CLUSTERED	DBTYPE_BOOL	Whether an index is clustered. One of the following: VARIANT_TRUE: The leaf nodes of the index contain full rows, not bookmarks. This is a way to represent a table clustered by key value. VARIANT_FALSE: The leaf nodes of the index contain bookmarks of the base table rows whose key value matches the key value of the index entry.
TYPE	DBTYPE_UI2	The type of the index. One of the following: DBPROPVAL_IT_BTREE: The index is a B+-tree. DBPROPVAL_IT_HASH: The index is a hash file using, for example, linear or extensible hashing. DBPROPVAL_IT_CONTENT: The index is a content index. DBPROPVAL_IT_OTHER: The index is some other type of index.
FILL_FACTOR	DBTYPE_I4	For a B+-tree index, this property represents the storage utilization factor of page nodes during the creation of the index. The value is an integer from 1 to 100 representing the percentage of use of an index node. For a linear hash index, this property represents the storage utilization of the entire hash structure (the ratio of used area to total allocated area) before a file structure expansion occurs.
INITIAL_SIZE	DBTYPE_I4	The total amount of bytes allocated to this structure at creation time.
NULLS	DBTYPE_I4	Whether null keys are allowed. One of the following: DBPROPVAL_IN_DISALLOWNULL: The index does not allow entries where the key columns are NULL. If the consumer attempts to insert an index entry with a NULL key, then the provider returns an error. DBPROPVAL_IN_IGNORENULL: The index does not insert entries containing NULL keys. If the consumer attempts to insert an index entry with a NULL key, then the provider ignores that entry and no error code is returned. DBPROPVAL_IN_IGNOREANYNULL: The index does not insert entries where some column key has a NULL value. For an index having a multicolumn search key, if the consumer inserts an index entry with NULL value in some column of the search key, then the provider ignores that entry and no error code is returned.
SORT_BOOKMARKS	DBTYPE_BOOL	How the index treats repeated keys. One of the following: VARIANT_TRUE: The index sorts repeated keys by bookmark. VARIANT_FALSE: The index does not sort repeated keys by bookmark.

AUTO_UPDATE	DBTYPE_BOOL	Whether the index is maintained automatically when changes are made to the corresponding base table. One of the following: VARIANT_TRUE: The index is automatically maintained. VARIANT_FALSE: The index must be maintained by the consumer through explicit calls to **IRowsetChange**. Ensuring consistency of the index as a result of updates to the associated base table is the responsibility of the consumer.
NULL_COLLATION	DBTYPE_I4	How NULLs are collated in the index. One of the following: DBPROPVAL_NC_END: NULLs are collated at the end of the list, regardless of the collation order. DBPROPVAL_NC_START: NULLs are collated at the start of the list, regardless of the collation order. DBPROPVAL_NC_HIGH: NULLs are collated at the high end of the list. DBPROPVAL_NC_LOW: NULLs are collated at the low end of the list.
ORDINAL_POSITION	DBTYPE_UI4	Ordinal position of the column in the index, starting with one.
COLUMN_NAME	DBTYPE_WSTR	Column name. This column, together with the COLUMN_GUID and COLUMN_PROPID columns, forms the column ID. One or more of these columns will be NULL depending on which elements of the DBID structure the provider uses.
COLUMN_GUID	DBTYPE_GUID	Column GUID.

COLUMN_PROPID	DBTYPE_UI4	Column property ID.
COLLATION	DBTYPE_I2	One of the following: DB_COLLATION_ASC: The sort sequence for the column is ascending. DB_COLLATION_DESC: The sort sequence for the column is descending. NULL: A column sort sequence is not supported.
CARDINALITY	DBTYPE_I4	Number of unique values in the index.
PAGES	DBTYPE_I4	Number of pages used to store the index.
FILTER_CONDITION	DBTYPE_WSTR	The WHERE clause identifying the filtering restriction.

The default sort order for the **adSchemaIndexes** rowset is UNIQUE, TYPE, INDEX_CATALOG, INDEX_SCHEMA, INDEX_NAME, and ORDINAL_POSITION.

adSchemaPrimaryKeys

The **adSchemaPrimaryKeys** *QueryType* identifies the primary key columns defined in the catalog by a given user. This *QueryType* is supported by the Microsoft OLE DB Provider for DB2.

The rowset returned by an **adSchemaPrimaryKeys** *QueryType* contains the columns listed in the following table.

Column name	Type indicator	Description
TABLE_CATALOG	DBTYPE_WSTR	Catalog name in which the table is defined. NULL if the provider does not support catalogs.
TABLE_SCHEMA	DBTYPE_WSTR	Unqualified schema name in which the table is defined. NULL if the provider does not support schemas.
TABLE_NAME	DBTYPE_WSTR	Table name.
COLUMN_NAME	DBTYPE_WSTR	Primary key column name. This column, together with the COLUMN_GUID and COLUMN_PROPID columns, forms the column ID. One or more of these columns will be NULL depending on which elements of the DBID structure the provider uses.
COLUMN_GUID	DBTYPE_GUID	Primary key column GUID.
COLUMN_PROPID	DBTYPE_UI4	Primary key column property ID.
ORDINAL	DBTYPE_UI4	The order of the column names (and GUIDs and property IDs) in the key.
PK_NAME	DBTYPE_WSTR	Primary key name. NULL if the provider does not support primary key constraints.

The default sort order for the **adSchemaPrimaryKeys** rowset is UNIQUE, TABLE_CATALOG, TABLE_SCHEMA, and TABLE_NAME.

adSchemaProcedures

The **adSchemaProcedures** *QueryType* identifies information about the columns of rowsets returned by procedures. This *QueryType* is supported by the Microsoft OLE DB Provider for DB2.

The rowset returned by an **adSchemaProcedures** *QueryType* contains the columns listed in the following table.

Column name	Type indicator	Description
PROCEDURE_CATALOG	DBTYPE_WSTR	Catalog name. NULL if the provider does not support catalogs.
PROCEDURE_SCHEMA	DBTYPE_WSTR	Unqualified schema name. NULL if the provider does not support schemas.
PROCEDURE_NAME	DBTYPE_WSTR	Table name.
COLUMN_NAME	DBTYPE_WSTR	The name of the column; this might not be unique. If this cannot be determined, a NULL is returned. This column, together with the COLUMN_GUID and COLUMN_PROPID columns, forms the column ID. One or more of these columns will be NULL depending on which elements of the DBID structure the provider uses. If possible, the resulting column ID should be persistent. However, some providers do not support persistent identifiers for columns. The column ID of a base table should be invariant under views.
COLUMN_GUID	DBTYPE_GUID	Column GUID.
COLUMN_PROPID	DBTYPE_UI4	Column property ID.

ROWSET_NUMBER	DBTYPE_UI4	Number of the rowset containing the column. This is greater than one only if the procedure returns multiple rowsets.
ORDINAL_POSITION	DBTYPE_UI4	The ordinal of the column. Columns are numbered starting from one. NULL if there is no stable ordinal value for the column.
IS_NULLABLE	DBTYPE_BOOL	VARIANT_TRUE: The column might be nullable. VARIANT_FALSE: The column is known not to be nullable.
DATA_TYPE	DBTYPE_UI2	The indicator of the columns data type. If the data type of the column varies from row to row, this must be DBTYPE_VARIANT.
TYPE_GUID	DBTYPE_GUID	The GUID of the columns data type.
CHARACTER_MAXIMUM_LENGTH	DBTYPE_UI4	The maximum possible length of a value in the column. For character, binary, or bit columns, this is one of the following: The maximum length of the column in characters, bytes, or bits, respectively, if one is defined. For example, a CHAR(5) column in an SQL table has a maximum length of five (5). The maximum length of the data type in characters, bytes, or bits, respectively, if the column does not have a defined length. Zero (0) if neither the column nor the data type has a defined maximum length. NULL for all other types of columns.
CHARACTER_OCTET_LENGTH	DBTYPE_UI4	Maximum length in octets (bytes) of the column, if the type of the column is character or binary. A value of zero means the column has no maximum length. NULL for all other types of columns.
NUMERIC_PRECISION	DBTYPE_UI2	If the columns data type is numeric, this is the maximum precision of the column. The precision of columns with a data type of DBTYPE_DECIMAL or DBTYPE_NUMERIC depends on the definition of the column. If the columns data type is not numeric, this is NULL.

NUMERIC_SCALE	DBTYPE_I2	If columns type indicator is DBTYPE_DECIMAL or DBTYPE_NUMERIC, this is the number of digits to the right of the decimal point. Otherwise, this is NULL.
DESCRIPTION	DBTYPE_WSTR	Human-readable description of the column. For example, the description for a column named Name in the Employee table might be "Employee name."

The default sort order for the **adSchemaProcedures** rowset is PROCEDURE_CATALOG, PROCEDURE_SCHEMA, and PROCEDURE_NAME.

adSchemaProcedureParameters

The **adSchemaProcedureParameters** *QueryType* identifies information about the parameters and return codes of procedures. This *QueryType* is supported by the Microsoft OLE DB Provider for DB2.

The rowset returned by an **adSchemaProcedureParameters** *QueryType* contains the columns listed in the following table.

Column name	Type indicator	Description
PROCEDURE_CATALOG	DBTYPE_WSTR	Catalog name. NULL if the provider does not support catalogs.
PROCEDURE_SCHEMA	DBTYPE_WSTR	Unqualified schema name. NULL if the provider does not support schemas.
PROCEDURE_NAME	DBTYPE_WSTR	Table name.
PARAMETER_NAME	DBTYPE_WSTR	Parameter name. NULL if the parameter is not named.
ORDINAL_POSITION	DBTYPE_UI2	If the parameter is an input, input/output, or output parameter, this is the one-based ordinal position of the parameter in the procedure call. If the parameter is the return value, this is zero.
PARAMETER_TYPE	DBTYPE_UI2	One of the following: DBPARAMTYPE_INPUT—The parameter is an input parameter. DBPARAMTYPE_INPUTOUTPUT—The parameter is an input/output parameter. DBPARAMTYPE_OUTPUT—The parameter is an output parameter. DBPARAMTYPE_RETURNVALUE—The parameter is a procedure return value. If the provider cannot determine the parameter type, this is NULL.
PARAMETER_HASDEFAULT	DBTYPE_BOOL	VARIANT_TRUE: The parameter has a default value. VARIANT_FALSE: The parameter does not have a default value or it is unknown whether the parameter has a default value.
PARAMETER_DEFAULT	DBTYPE_WSTR	Default value of the parameter. If the default value is the NULL value, PARAMETER_HASDEFAULT is VARIANT_TRUE, and the PARAMETER_DEFAULT value is a NULL value.
IS_NULLABLE	DBTYPE_BOOL	VARIANT_TRUE: The parameter might be nullable. VARIANT_FALSE: The parameter is not nullable.
DATA_TYPE	DBTYPE_UI2	The indicator of the parameters data type.

CHARACTER_MAXIMUM_LENGTH	DBTYPE_UI4	The maximum possible length of a value in the parameter. For character, binary, or bit columns, this is one of the following: The maximum length of the parameter in characters, bytes, or bits, respectively, if one is defined. For example, a CHAR(5) column in an SQL table has a maximum length of five (5). The maximum length of the data type in characters, bytes, or bits, respectively, if the parameter does not have a defined length. Zero (0) if neither the parameter nor the data type has a defined maximum length. NULL for all other types of parameters.
CHARACTER_OCTET_LENGTH	DBTYPE_UI4	Maximum length in octets (bytes) of the parameter, if the type of the parameter is character or binary. A value of zero means the parameter has no maximum length. NULL for all other types of parameter.
NUMERIC_PRECISION	DBTYPE_UI2	If the parameters data type is numeric, this is the maximum precision of the parameter. The precision of parameters with a data type of DBTYPE_DECIMAL or DBTYPE_NUMERIC depends on the definition of the parameters. If the parameters data type is not numeric, this is NULL.
NUMERIC_SCALE	DBTYPE_I2	If parameters type indicator is DBTYPE_DECIMAL or DBTYPE_NUMERIC, this is the number of digits to the right of the decimal point. Otherwise, this is NULL.
DESCRIPTION	DBTYPE_WSTR	Human-readable description of the parameter. For example, the description for a parameter named Name in a procedure that adds a new employee might be "Employee name."
TYPE_NAME	DBTYPE_WSTR	Provider-specific data type name.
LOCAL_TYPE_NAME	DBTYPE_WSTR	Localized version of TYPE_NAME. NULL is returned if a localized name is not supported by the data provider.

The default sort order for the **adSchemaProcedureParameters** rowset is PROCEDURE_CATALOG, PROCEDURE_SCHEMA, and PROCEDURE_NAME.

adSchemaProviderTypes

The **adSchemaProviderTypes** *QueryType* identifies the data types supported by the data provider. This *QueryType* is supported by the Microsoft OLE DB Provider for AS/400 and VSAM and the Microsoft OLE DB Provider for DB2.

The rowset returned by an **adSchemaProviderType** *QueryType* contains the columns listed in the following table.

Column name	Type indicator	Description
TYPE_NAME	DBTYPE_WSTR	Provider-specific data type name.
DATA_TYPE	DBTYPE_UI2	The indicator of the data type.
COLUMN_SIZE	DBTYPE_UI4	The length of a non-numeric column or parameter refers to either the maximum or the defined length for this type by th e provider. For character data, this is the maximum or defined length in characters. If the data type is numeric, this is the upper bound on the maximum precision of the data type.
LITERAL_PREFIX	DBTYPE_WSTR	Character or characters used to prefix a literal of this type in a text command.

LITERAL_SUFFIX	DBTYPE_WSTR	Character or characters used to suffix a literal of this type in a text command.
CREATE_PARAMS	DBTYPE_WSTR	The creation parameters are specified by the consumer when creating a column of this data type. For example, the SQL data type DECIMAL needs a precision and a scale. In this case, the creation parameters might be the string "precision,scale". In a text command, to create a DECIMAL column with a precision of 10 and a scale of 2, the value of the TYPE_NAME column might be DECIMAL() and the complete type specification would be DECIMAL(10,2). The creation parameters appear as a comma-separated list of values, in the order they are to be supplied, with no surrounding parentheses. If a creation parameter is length, maximum length, precision, or scale, "length", "max length", "precision", and "scale" should be used, respectively. If the creation parameters are some other value, it is provider-specific what text is used to describe the creation parameter. If the data type requires creation parameters, "()" generally appears in the type name. This indicates the position at which to insert the creation parameters. If the type name does not include "()", the creation parameters are enclosed in parentheses and appended to the end of the data type name.
IS_NULLABLE	DBTYPE_BOOL	VARIANT_TRUE: The data type is nullable. VARIANT_FALSE: The data type is not nullable. NULL: It is not known whether the data type is nullable.
CASE_SENSITIVE	DBTYPE_BOOL	VARIANT_TRUE: The data type is a character type and is case-sensitive. VARIANT_FALSE: The data type is not a character type or is not case-sensitive.
SEARCHABLE	DBTYPE_UI4	If the provider supports **ICommandText**, then this column is an integer indicating the searchability of a data type, otherwise this column is NULL. One of the following: DB_UNSEARCHABLE: The data type cannot be used in a WHERE clause. DB_LIKE_ONLY: The data type can be used in a WHERE clause only with the LIKE predicate. DB_ALL_EXCEPT_LIKE: The data type can be used in a WHERE clause with all comparison operators except LIKE. DB_SEARCHABLE: The data type can be used in a WHERE clause with any comparison operator.

UNSIGNED_ATTRIBUTE	DBTYPE_BOOL	VARIANT_TRUE: The data type is unsigned. VARIANT_FALSE: The data type is signed. NULL: Not applicable to data type.
FIXED_PREC_SCALE	DBTYPE_BOOL	VARIANT_TRUE: The data type has a fixed precision and scale. VARIANT_FALSE: The data type does not have a fixed precision and scale.
AUTO_UNIQUE_VALUE	DBTYPE_BOOL	VARIANT_TRUE: Values of this type can be auto-incrementing. VARIANT_FALSE: Values of this type cannot be auto-incrementing.

LOCAL_TYPE_NAME	DBTYPE_WSTR	Localized version of TYPE_NAME. NULL is returned if a localized name is not supported by the data provider.
MINIMUM_SCALE	DBTYPE_I2	If the type indicator is DBTYPE_DECIMAL or DBTYPE_NUMERIC, this is the minimum number of digits allowed to the right of the decimal point. Otherwise, this is NULL.
MAXIMUM_SCALE	DBTYPE_I2	If the type indicator is DBTYPE_DECIMAL or DBTYPE_NUMERIC, this is the maximum number of digits allowed to the right of the decimal point. Otherwise, this is NULL.
GUID	DBTYPE_GUID	The GUID of the type. All types supported by a provider are described in a type library, so each type has a corresponding GUID.

TYPELIB	DBTYPE_WSTR	The type library containing the description of this type. All types supported by a provider are described in one or more type libraries.
VERSION	DBTYPE_WSTR	The version of the type definition. Providers may want to version type definitions. Different providers may use different version schemes, such as a timestamp or number (integer or float). NULL if not supported.
IS_LONG	DBTYPE_BOOL	VARIANT_TRUE: The data type is a BLOB that contains very long data; the definition of very long data is provider-specific. VARIANT_FALSE: The data type is a BLOB that does not contain very long data or is not a BLOB. This value determines the setting of the DBCOLUMNFLAGS_ISLONG flag returned by **GetColumnInfo** in **IColumnsInfo** and **GetParameterInfo** in **ICommandWithParameters**. For more information, see **GetColumnInfo** and **GetParameterInfo**.
BEST_MATCH	DBTYPE_BOOL	VARIANT_TRUE: The data type is the best match between all data types in the data source and the OLE DB data type indicated by the value in the DATA_TYPE column. VARIANT_FALSE: The data type is not the best match. For each set of rows in which the value of the DATA_TYPE column is the same, the BEST_MATCH column is set to VARIANT_TRUE in only one row.

The default sort order for the **adSchemaProviderTypes** rowset is DATA_TYPE.

adSchemaTables

The **adSchemaTables** *QueryType* identifies the tables defined in the catalog that are accessible to a given user. This *QueryType* is supported by the Microsoft OLE DB Provider for AS/400 and VSAM and the Microsoft OLE DB Provider for DB2.

The rowset returned by an **adSchemaTables** *QueryType* contains the columns listed in the following table.

Column name	Type indicator	Description
TABLE_CATALOG	DBTYPE_WSTR	Catalog name. NULL if the provider does not support catalogs.
TABLE_SCHEMA	DBTYPE_WSTR	Unqualified Schema Name. NULL if the provider does not support schemas.
TABLE_NAME	DBTYPE_WSTR	Table name.
TABLE_TYPE	DBTYPE_WSTR	Table type. One of the following or a provider-specific value. "ALIAS" "TABLE" "SYNONYM" "SYSTEM TABLE" "VIEW" "GLOBAL TEMPORARY" "LOCAL TEMPORARY"
TABLE_GUID	DBTYPE_GUID	GUID that uniquely identifies the table. Providers that do not use GUIDs to identify tables should return NULL in this column.
DESCRIPTION	DBTYPE_WSTR	Human-readable description of the table.

The default sort order for the **adSchemaTables** rowset is TABLE_TYPE, TABLE_CATALOG, TABLE_SCHEMA, and TABLE_NAME.

OriginalValue Property (ADO)

The **OriginalValue** property on a **Field** object indicates the value of a **Field** that existed in the record before any changes were made. This property returns a Variant.

Syntax

```
oldValue = currentfield.OriginalValue
```

Remarks

The **OriginalValue** property is used to return the original field value for a field from the current record.

In immediate update mode (the provider writes changes to the underlying data source once the **Update** method is called), the **OriginalValue** property returns the field value that existed prior to any changes (that is, since the last **Update** method call). This is the same value that the **CancelUpdate** method uses to replace the **Value** property.

In batch update mode (the provider caches multiple changes and writes them to the underlying data source only when the **UpdateBatch** method is called), the **OriginalValue** property returns the field value that existed prior to any changes (that is, since the last **UpdateBatch** method call). This is the same value that the **CancelBatch** method uses to replace the **Value** property. When this property is used with the **UnderlyingValue** property, you can resolve conflicts that arise from batch updates.

Precision Property (ADO)

The **Precision** property on a **Field** object indicates the degree of precision for Numeric values for numeric **Field** objects. This property returns a byte value indicating the maximum number of digits used to represent numeric values in a **Field** object.

Syntax

```
numericPrecision = currentfield.Precision
```

Remarks

The **Precision** property is used to return the precision of a numeric field object.

The byte value that the **Precision** property will return is dependent on the data type of the **Field** object. The value for the ActiveX® Data Objects (ADO) data type of the **Field** object can be one of the enumerated values for **DataTypeEnum** as listed in the following table.

Enumeration	Value	Description
adEmpty	0	This data type indicates that no value was specified (DBTYPE_EMPTY).
adSmallInt	2	This data type indicates a 2-byte (16-bit) signed integer (DBTYPE_I2).
adInteger	3	This data type indicates a 4-byte (32-bit) signed integer (DBTYPE_I4).
adSingle	4	This data type indicates a 4-byte (32-bit) single precision IEEE floating point number (DBTYPE_R4).
adDouble	5	This data type indicates an 8-byte (64-bit) double precision IEEE floating point number (DBTYPE_R8).
adCurrency	6	A data type indicates a currency value (DBTYPE_CY). Currency is a fixed-point number with 4 digits to the right of the decimal point. It is stored in an 8-byte signed integer scaled by 10,000. This data type is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM or the Microsoft OLE DB Provider for DB2.
adDate	7	This data type indicates a date value stored as a Double, the whole part of which is the number of days since December 30, 1899, and the fractional part of which is the fraction of a day. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBSTR	8	This data type indicates a null-terminated Unicode character string (DBTYPE_BSTR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adIDispatch	9	This data type indicates a pointer to an IDispatch interface on an OLE object (DBTYPE_IDISPATCH). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adError	10	This data type indicates a 32-bit error code (DBTYPE_ERROR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBoolean	11	This data type indicates a Boolean value (DBTYPE_BOOL). This data type is not supported by the OLE DB Provider for AS/400 and VSAM.

adVariant	12	This data type indicates an automation variant (DBTYPE_VARIANT). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adIUnknown	13	This data type indicates a pointer to an IUnknown interface on an OLE object (DBTYPE_IUNKNOWN). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adDecimal	14	This data type indicates numeric data with a fixed precision and scale (DBTYPE_DECIMAL).
adTinyInt	16	This data type indicates a single-byte (8-bit) signed integer (DBTYPE_I1). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adUnsignedTinyInt	17	This data type indicates a single-byte (8-bit) unsigned integer (DBTYPE_UI1). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adUnsignedSmallInt	18	This data type indicates a 2-byte (16-bit) unsigned integer (DBTYPE_UI2). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adUnsignedInt	19	This data type indicates a 4-byte (32-bit) unsigned integer (DBTYPE_UI4). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBigInt	20	This data type indicates an 8-byte (64-bit) signed integer (DBTYPE_I8). This data type is not supported by the OLE DB Provider for AS/400 and VSAM.
adUnsignedBigInt	21	This data type indicates an 8-byte (64-bit) unsigned integer (DBTYPE_UI8). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adGUID	72	This data type indicates a globally unique identifier or GUID (DBTYPE_GUID). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBinary	128	This data type indicates fixed-length binary data (DBTYPE_BYTES).
adChar	129	This data type indicates a character string value (DBTYPE_STR).
adWChar	130	This data type indicates a null-terminated Unicode character string (DBTYPE_WSTR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adNumeric	131	This data type indicates numeric data where the precision and scale are exactly as specified (DBTYPE_NUMERIC).
adUserDefined	132	This data type indicates user-defined data (DBTYPE_UDT). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

adDBDate	133	This data type indicates an OLE DB date structure (DBTYPE_DATE).
adDBTime	134	This data type indicates an OLE DB time structure (DBTYPE_TIME).
adDBTimeStamp	135	This data type indicates an OLE DB timestamp structure (DBTYPE_TIMESTAMP).
adVarChar	200	This data type indicates variable-length character data (DBTYPE_STR).
adLongVarChar	201	This data type indicates a long string value.
adVarWChar	202	This data type indicates a Unicode string value. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adLongVarWChar	203	This data type indicates a long Unicode string value. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adVarBinary	204	This data type indicates variable-length binary data (DBTYPE_BYTES).
adLongVarBinary	205	This data type indicates a long binary value.

Note that the **Precision** property returns values that differ from the precision of the host data type for the ActiveX® Data Objects (ADO) data types as listed in the following table.

ADO data type	Comments
adSmallInt	The precision on the host is 4, but the OLE DB Provider returns a precision of 5.
adInteger	The precision on the host is 8, but the OLE DB Provider returns a precision of 10.
adSingle	The precision on the host is 9, but the OLE DB Provider returns a precision of 7.
adDouble	The precision on the host is 17, but the OLE DB Provider returns a precision of 15.

Provider Property (ADO)

The **Provider** property on a **Connection** object indicates the name of the provider. This property sets or returns a String value.

Syntax

```
oldProvider = currentConnection.Provider
currentConnection.Provider = "SNAOLEDB"
```

Remarks

The **Provider** property is used to set or return the name of the provider for the connection. This property can also be set by the contents of **ConnectionString** property or the **ConnectionString** argument of the **Open** method. However, specifying a provider in more than one place while calling the **Open** method can have unpredictable results. If no provider is specified, the property will default to MSDASQL (Microsoft® OLE DB Provider for ODBC).

The Microsoft OLE DB Provider for AS/400 and VSAM requires "SNAOLEDB" as the **Provider** property string.

The Microsoft OLE DB Provider for DB2 requires "DB2OLEDB" as the **Provider** property string.

The **Provider** property is read/write when the connection is closed and read-only when it is open. The setting does not take effect until either the **Connection** object is opened or the **Properties** collection of the **Connection** object is accessed. If the setting is invalid, an error occurs.

Refresh Method (ADO)

The **Refresh** method on a **Collection** object updates the objects in a collection to reflect objects available from and specific to the OLE DB provider.

Syntax

```
collection.Refresh
```

Parameters

None.

Remarks

This method is only supported on the **Field**s and **Properties** collections under the Microsoft® OLE DB Provider for AS/400 and VSAM.

The **Refresh** method accomplishes different tasks depending on the collection object on which it is called.

Using the **Refresh** method on the **Field**s collection has no visible effect. To retrieve changes from the underlying database structure, either the **Requery** method must be used or, if the **Recordset** object does not support bookmarks, the **MoveFirst** method must be used.

Using the **Refresh** method on a **Properties** collection of some objects populates the collection with the dynamic properties the provider exposes. These properties provide information about features specific to the provider beyond the built-in properties ActiveX® Data Objects (ADO) supports. The OLE DB Data Provider for AS/400 and VSAM does not support any provider-specific properties.

Requery Method (ADO)

The **Requery** method on a **Recordset** object updates the data in a **Recordset** object by re-executing the query on which the object is based.

Syntax

```
recordset.Requery
```

Parameters

None.

Remarks

The **Requery** method is used to refresh the entire contents of a **Recordset** object from the data source by reissuing the original command and retrieving the data a second time. Calling this method is equivalent to calling the **Close** and **Open** methods in succession. If you are editing the current record or adding a new record, an error occurs.

While the **Recordset** object is open, the properties that define the nature of the cursor (**CursorType**, **LockType**, **MaxRecords**, and other properties) are read-only. Thus, the **Requery** method can only refresh the current cursor. To change any of the cursor properties and view the results, the **Close** method must be used so that the properties become read/write again. You can then change the property settings and call the **Open** method to reopen the cursor.

Save Method (ADO)

The **Save** method on a **Recordset** object saves the Recordset in a file or Stream object.

Syntax

```
recordset.Save Destination, Persistent Format
```

Parameters

Destination

This optional parameter specifies a Variant representing the complete path name of the file where the **Recordset** is to be saved, or a reference to a **Stream** object.

Persistent Format

This optional parameter specifies a Long integer value representing a **PersistFormatEnum** value that specifies the format in which the **Recordset** is to be saved (XML or ADTG). The default value is **adPersistADTG**.

The **PersistFormatEnum** value can be one of the constants listed in the following table.

Enumeration	Value	Description
adPersistADTG	0	This value indicates Microsoft Advanced Data TableGram (ADTG) format.
adPersistXML	1	This value indicates Extensible Markup Language (XML) format.

Remarks

The **Save** method can only be invoked on an open **Recordset**. Use the **Open** method to later restore the **Recordset** from *Destination*.

When using the Microsoft® OLE DB Provider for AS/400 and VSAM and the Filter property is in effect for the **Recordset**, then only the rows accessible under the filter are saved.

The first time you save the **Recordset**, it is optional to specify *Destination*. If the *Destination* parameter is omitted, a new file will be created with a name set to the value of the Source Property of the **Recordset**. See the topic Source Property on a Recordset Object (ADO) for more information.

The *Destination* parameter should be omitted when you subsequently call **Save** after the first save, or a run-time error will occur. If you subsequently call **Save** with a new *Destination*, the **Recordset** is saved to the new destination. However, the new destination and the original destination will both be open.

Save does not close the **Recordset** or *Destination*, so you can continue to work with the **Recordset** and save your most recent changes. *Destination* remains open until the **Recordset** is closed, during which time other applications can read but not write to *Destination*.

For reasons of security, the **Save** method permits only the use of low and custom security settings from a script executed by Microsoft Internet Explorer. For a more detailed explanation of security issues, see "ADO and RDS Security Issues in Microsoft Internet Explorer" found in the ActiveX® Data Objects (ADO) Technical Articles of the Microsoft Data Access Technical Articles.

If the **Save** method is called while an asynchronous **Recordset** fetch, execute, or update operation is in progress, then **Save** waits until the asynchronous operation is complete.

Records are saved beginning with the first row of the **Recordset**. When the **Save** method is finished, the current row position is moved to the first row of the **Recordset**.

For best results, set the CursorLocation Property property to **adUseClient** with **Save**. If your provider does not support all of the features necessary to save **Recordset** objects, the Cursor Service will provide these features.

When a **Recordset** is persisted with the **CursorLocation** property set to **adUseServer**, the update capability for the **Recordset** is limited. Typically, only single-table updates, insertions, and deletions are allowed (dependent on features supported by the provider). The **Resync** method is also unavailable in this configuration.

Note that saving a **Recordset** with **Fields** of type **adVariant**, **adIDispatch**, or **adIUnknown** is not supported by ADO and can cause unpredictable results.

Because the *Destination* parameter can accept any object that supports the OLE DB IStream interface, a **Recordset** can be saved directly to the ASP Response object. For more information, see the XML Recordset Persistence Scenario in the *ADO Programmer's Reference*.

Sort Property (ADO)

The **Sort** property on a **Recordset** object indicates that a recordset should be sorted.

Syntax

```
Recordset.Sort BSTR Criteria
```

Parameters

Criteria

This parameter specifies the criteria used for sorting the **Recordset** object. This **Sort** property contains a comma-delimited list of column names and a direction specifier (ascending or descending) to be used for sorting records in a **Recordset** object. The direction specifier is a string (ASC or DESC). When a direction is not specified, the direction defaults to ascending.

An example of a **Sort** property criteria is as follows:

"LastName ASC, FirstName DESC, Initial"

Remarks

The **Sort** property is not supported by the OLE DB Provider for DB2 or the ODBC Driver for DB2.

The **Sort** property is used with an open **Recordset** object based on an AS/400 physical file. The **Sort** property allows the user to indicate which logical view to apply to an AS/400 physical file. The logical view must be a valid index specified in the description of the AS/400 physical file. The logical view is provided by the AS/400 logical file. The Microsoft® OLE DB Provider for AS/400 and VSAM responds to a **Sort** request by first closing the open physical file, and then opening the logical file that points back to the data in the physical file.

The **Recordset Sort** property is only supported on AS/400 hosts. If the user opens a **Recordset** object based on an AS/400 logical file, then there is likely no need to use **Recordset**.**Sort**. For performance reasons, applications should be written to open the AS/400 logical file first, because the overhead is so much greater when opening a physical file first.

If the CursorLocation Property property is set to **adUseClient** (use the client cursor engine), the **Sort** property will work if MDAC 2.0 or later is installed but will not work properly with earlier versions of ADO.

Source Property on an Error Object (ADO)

The **Source** property on an **Error** object indicates the name of the object or application that originally generated an error. This property returns a String value that indicates the name of an object or application.

Syntax

```
errorSource = currentError.Source
```

Remarks

The **Source** property on an **Error** object is used to determine the name of the object or application that originally generated an error. This could be the object's class name or programmatic ID.

For errors in ADO, the property value will be **ADODB.***ObjectName*, where *ObjectName* is the name of the object that triggered the error. For ADOX and ADO MD, the value will be **ADOX.***ObjectName* and **ADOMD.***ObjectName*, respectively.

Based on the error documentation from the **Source**, Number Property (ADO), and Description Property (ADO) for **Error** objects, you can write code that will handle the error appropriately.

The **Source** property is read-only for **Error** objects.

Source Property on a Recordset Object (ADO)

The **Source** property on a **Recordset** object indicates the data source for the Recordset object. This property sets a String value or **Command** object reference or returns only a String value that indicates the source of the **Recordset**.

Syntax

```
currentSource = currentRecordset.Source
recordset.Source = newSource
```

Remarks

The **Source** property on a Recordset is used to specify a data source for a **Recordset** object.

Using the Microsoft® OLE DB Provider for AS/400 and VSAM, the **Source** property can be either a **Command** object variable or a table name.

Using the Microsoft OLE DB Provider for DB2, the Source property can be one of the following: a **Command** object variable, an SQL statement, or a stored procedure. If the **Source** property is an SQL statement or a stored procedure, you can optimize performance by passing the appropriate *Options* argument with the **Open** method call.

If you set the **Source** property to a **Command** object, the **ActiveConnection** property of the **Recordset** object will inherit the value of the **ActiveConnection** property for the specified **Command** object. However, reading the **Source** property does not return a **Command** object; instead, it returns the **CommandText** property of the **Command** object to which you set the **Source** property.

The **Source** property is read/write for closed **Recordset** objects and read-only for open **Recordset** objects.

State Property (ADO)

The **State** property on a **Connection**, **Command**, or **Recordset** object describes the current state of an object. This property sets or returns a Long value.

Syntax

```
oldState = currentConnection.State
currentConnection.State = adStateClosed
```

Remarks

The **State** property is used to set or return the current state of an object. The value of the **State** property can be one of the enumerated values listed in the following table.

Enumeration	Value	Description
adStateClosed	0	This value indicates that the object is closed. This is the default value.
adStateOpen	1	This value indicates that the object is open.

The **State** property can be used to determine the current state of a given object at any time.

Status Property (ADO)

The **Status** property on a **Recordset** object indicates the status of the current record with respect to batch updates or other bulk operations. This property returns a Long value.

Syntax

```
oldStatus = currentRecordset.Status
```

Remarks

The **Status** property is used to return the current status of a recordset object at any time. The value of the **Status** property returns a sum of the **RecordStatusEnum** enumerated values listed in the following table.

Enumeration	Value	Description
adRecOK	0	This value indicates that the recordset object was successfully updated.
adRecNew	0x1	This value indicates that the recordset object is new.
adRecModified	0x2	This value indicates that the recordset object was modified.
adRecDeleted	0x4	This value indicates that the recordset object was deleted.
adRecUnmodified	0x8	This value indicates that the recordset object was not modified.
adRecInvalid	0x10	This value indicates that the recordset object was not saved because its bookmark is invalid.
adRecMultipleChanges	0x40	This value indicates that the recordset object was not saved because it would have affected multiple records.
adRecPendingChanges	0x80	This value indicates that the recordset object was not saved because it refers to a pending insert.
adRecCanceled	0x100	This value indicates that the recordset object was not saved because the operation was canceled.
adRecCantRelease	0x400	This value indicates that the new recordset object was not saved because of existing record locks.
adRecConcurencyViolation	0x800	This value indicates that the recordset object was not saved because optimistic concurrency was in use.
adRecIntegrityViolation	0x1000	This value indicates that the recordset object was not saved because the user violated integrity constraints.
adRecMaxChangesExceeded	0x2000	This value indicates that the recordset object was not saved because there were too many pending changes.
adRecObjectOpen	0x4000	This value indicates that the recordset object was not saved because of a conflict with an open storage object.
adRecOutOfMemory	0x8000	This value indicates that the recordset object was not saved because the computer has run out of memory.

adRecPermissionDenied	0x10000	This value indicates that the recordset object was not saved because the user has insufficient permissions.
adRecSchemaViolation	0x20000	This value indicates that the recordset object was not saved because it violates the structure of the underlying database.
adRecDBDeleted	0x40000	This value indicates that the recordset object has already been deleted from the data source.

Use the **Status** property to see what changes are pending for records modified during batch updating. You can also use the **Status** property to view the status of records that fail during bulk operations such as when you call the **Resync**, **UpdateBatch**, or **CancelBatch** methods on a recordset object, or set the **Filter** property on a recordset object to an array of bookmarks. With this property, you can determine how a given record failed and resolve it accordingly.

Supports Method (ADO)

The **Supports** method on a **Recordset** object determines whether a specified **Recordset** object supports a particular type of feature.

Syntax

```
boolean = recordset.Supports ( CursorOptions )
```

Parameters

CursorOptions

This parameter specifies a Long expression that consists of one or more of the **CursorOptionEnum** values indicating which feature is being queried.

The **CursorOptionEnum** value can be one of the constants listed in the table following the Parameters section.

Values for CursorOptions

Enumeration	Value	Description
adAddNew	0x1000400	This value indicates whether the **AddNew** method can be used to add new records.
adApproxPosition	0x4000	This value indicates whether the **AbsolutePosition** and **AbsolutePage** properties can read and set.
adBookMark	0x2000	This value indicates whether the **Bookmark** property can be used to access specific records.
adDelete	0x1000800	This value indicates whether the **Delete** method can be used to delete records.
adFind	0x80000	This value indicates whether the **Find** method can be used to locate a row in a **Recordset**.
adHoldRecords	0x100	This value indicates whether you can retrieve more records or change the next retrieve position without committing all pending changes.
adIndex	0x100000	This value indicates whether the **Index** property can be name an index.
adMovePrevious	0x200	This value indicates whether the **MoveFirst** and **MovePrevious** methods, and **Move** or **GetRows** methods can be used to move the current record position backward without requiring bookmarks.
adNotify	0x40000	This value indicates that the underlying data provider supports notifications (which determines whether **Recordset** events are supported).
adResync	0x20000	This value indicates whether the recordset cursor can be updated with the data visible in the underlying database using the **Resync** method.
adSeek	0x200000	This value indicates whether the **Seek** method can be used to locate a row in a **Recordset**.

adUpdate	0x10080000	This value indicates whether the **Update** method can be used to modify existing data.
adUpdateBatch	0x10000	This value indicates whether batch updating can be used on the recordset (the **UpdateBatch** and **CancelBatch** methods) to transmit changes to the provider in groups.

Return Value

Returns a Boolean value that indicates whether all of the features identified by the *CursorOptions* argument are supported by the provider.

Remarks

The **Supports** method is used to determine what types of features (methods and properties) a **Recordset** object supports. If the **Recordset** object supports the features whose corresponding constants are in *CursorOptions*, the **Supports** method returns **True**. Otherwise, it returns **False**.

Although the **Supports** method may return **True** for a given feature, it does not guarantee that the OLE DB Provider can make the feature available under all circumstances. The **Supports** method simply returns whether the provider can support the specified function assuming certain conditions are met. For example, the **Supports** method may indicate that a **Recordset** object supports updates even though the cursor is based on a multi-table join, some columns of which are not updatable.

Type Property (ADO)

The **Type** property on a **Field** object indicates the operational type or data type for **Field** or **Property** objects. This property sets or returns a **DataTypeEnum** value.

Syntax

```
datatype = currentfield.Type
```

Remarks

The **Type** property is used to return the data type of a numeric field object.

The value returned by the **Type** property on a **Field** object can be one of the enumerated values for **DataTypeEnum** listed in the following table.

Enumeration	Value	Description
adEmpty	0	This data type indicates that no value was specified (DBTYPE_EMPTY).
adSmallInt	2	This data type indicates a 2-byte (16-bit) signed integer (DBTYPE_I2).
adInteger	3	This data type indicates a 4-byte (32bit) signed integer (DBTYPE_I4).
adSingle	4	This data type indicates a 4-byte (32-bit) single-precision IEEE floating-point number (DBTYPE_R4).
adDouble	5	This data type indicates an 8-byte (64-bit) double-precision IEEE floating-point number (DBTYPE_R8).
adCurrency	6	A data type indicates a currency value (DBTYPE_CY). Currency is a fixed-point number with four digits to the right of the decimal point. It is stored in an 8-byte signed integer scaled by 10,000. This data type is not supported by the Microsoft® OLE DB Provider for AS/400 and VSAM or the Microsoft OLE DB Provider for DB2.
adDate	7	This data type indicates a date value stored as a Double, the whole part of which is the number of days since December 30, 1899, and the fractional part of which is the fraction of a day. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBSTR	8	This data type indicates a null-terminated Unicode character string (DBTYPE_BSTR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adIDispatch	9	This data type indicates a pointer to an **IDispatch** interface on an OLE object (DBTYPE_IDISPATCH). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adError	10	This data type indicates a 32-bit error code (DBTYPE_ERROR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBoolean	11	This data type indicates a Boolean value (DBTYPE_BOOL). This data type is not supported by the OLE DB Provider for AS/400 and VSAM.

adVariant	12	This data type indicates an Automation variant (DBTYPE_VARIANT). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adIUnknown	13	This data type indicates a pointer to an **IUnknown** interface on an OLE object (DBTYPE_IUNKNOWN). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adDecimal	14	This data type indicates numeric data with a fixed precision and scale (DBTYPE_DECIMAL).
adTinyInt	16	This data type indicates a single-byte (8-bit) signed integer (DBTYPE_I1). This data type is not supported by the OLE DB Provider.
adUnsignedTinyInt	17	This data type indicates a single-byte (8-bit) unsigned integer (DBTYPE_UI1). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adUnsignedSmallInt	18	This data type indicates a 2-byte (16-bit) unsigned integer (DBTYPE_UI2). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adUnsignedInt	19	This data type indicates a 4-byte (32-bit) unsigned integer (DBTYPE_UI4). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBigInt	20	This data type indicates an 8-byte (64-bit) signed integer (DBTYPE_I8). This data type is not supported by the OLE DB Provider for AS/400 and VSAM.
adUnsignedBigInt	21	This data type indicates an 8-byte (64-bit) unsigned integer (DBTYPE_UI8). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adGUID	72	This data type indicates a globally unique identifier or GUID (DBTYPE_GUID). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adBinary	128	This data type indicates fixed-length binary data (DBTYPE_BYTES).
adChar	129	This data type indicates a character string value (DBTYPE_STR).
adWChar	130	This data type indicates a null-terminated Unicode character string (DBTYPE_WSTR). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adNumeric	131	This data type indicates numeric data where the precision and scale are exactly as specified (DBTYPE_NUMERIC).
adUserDefined	132	This data type indicates user-defined data (DBTYPE_UDT). This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.

adDBDate	133	This data type indicates an OLE DB date structure (DBTYPE_DATE).
adDBTime	134	This data type indicates an OLE DB time structure (DBTYPE_TIME).
adDBTimeStamp	135	This data type indicates an OLE DB timestamp structure (DBTYPE_TIMESTAMP).
adVarChar	200	This data type indicates variable-length character data (DBTYPE_STR).
adLongVarChar	201	This data type indicates a long string value.
adVarWChar	202	This data type indicates a Unicode string value. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adLongVarWChar	203	This data type indicates a long Unicode string value. This data type is not supported by the OLE DB Provider for AS/400 and VSAM or the OLE DB Provider for DB2.
adVarBinary	204	This data type indicates variable-length binary data (DBTYPE_BYTES).
adLongVarBinary	205	This data type indicates a long binary value.

The corresponding OLE DB type indicator is shown in parentheses in the description column of the above table. For more information on OLE DB data types, see the *OLE DB 2.0 Programmer's Reference*.

UnderlyingValue Property (ADO)

The **UnderlyingValue** property on a **Field** object indicates the **Field** object's current value in the database. This property returns a Variant.

Syntax

```
actualValue = currentfield.UnderlyingValue
```

Remarks

The **UnderlyingValue** property is used to return the current field value from the database. The field value in the **UnderlyingValue** property is the value that is visible to your transaction and may be the result of a recent update by another transaction. This may differ from the **OriginalValue** property, which reflects the value that was originally returned to the **Recordset**.

This is similar to the affect of calling the **Resync** method, however the **UnderlyingValue** property returns only the value for a specific field from the current record. This is the same value that the **Resync** method uses to replace the **Value** property.

When this property is used with the **OriginalValue** property, you can resolve conflicts that arise from batch updates.

Update Method (ADO)

The **Update** method on a **Recordset** object saves any changes you make to the current record of a **Recordset** object.

Syntax

```
recordset.Update Fields, Values
```

Parameters

Fields

This optional parameter specifies a Variant representing a single name or a Variant array representing names or ordinal positions of the field or fields you want to modify.

Values

This optional parameter specifies a Variant representing a single value or a Variant array representing values for the field or fields in the new record.

Remarks

The **Update** method is used to save any changes you make to the current record of a **Recordset** object since calling the **AddNew** method or since changing any field values in an existing record. The **Recordset** object must support updates for the **Update** method to be used successfully.

To set field values, do one of the following:

- Assign values to a **Field** object's **Value** property and call the **Update** method.
- Pass a field name and a value as arguments with the **Update** call.
- Pass an array of field names and an array of values with the **Update** call.

When arrays of fields and values are used, there must be an equal number of elements in both arrays. Also, the order of field names must match the order of field values. If the number and order of fields and values do not match, an error occurs.

If the **Recordset** object supports batch updating, then multiple changes to one or more records can be cached locally when the **UpdateBatch** method is called. If you are editing the current record or adding a new record when the **UpdateBatch** method is called, ActiveX® Data Objects (ADO) will automatically call the **Update** method to save any pending changes to the current record before transmitting the batched changes to the OLE DB Provider.

If you move from the record you are adding or editing before calling the **Update** method, ADO will automatically call **Update** to save the changes. The **CancelUpdate** method must be called if you want to cancel any changes made to the current record or to discard a newly added record.

The current record remains current after the **Update** method is called.

UpdateBatch Method (ADO)

The **UpdateBatch** method on a **Recordset** object writes all pending batch updates to the host.

Syntax

```
recordset.UpdateBatch AffectedRecords
```

Parameters

AffectedRecords

This optional parameter specifies an **AffectEnum** value that determines how many records the **UpdateBatch** method will affect.

The **AffectEnum** value can be one of the constants listed in the following table.

Enumeration	Value	Description
adAffectCurrent	1	This value writes pending changes only for the current record.
adAffectGroup	2	This value writes pending changes for the records that satisfy the current Filter property setting. You must set the **Filter** property to one of the valid predefined constants to use this option.
adAffectAll	3	This value writes pending changes for all the records in the **Recordset** object, including any hidden by the current **Filter** property setting. This value is the default.

Remarks

The **UpdateBatch** method is used when modifying a **Recordset** object in batch update mode to transmit all changes made in a **Recordset** object to the underlying database.

If the **Recordset** object supports batch updating, then multiple changes to one or more records can be cached locally until the **UpdateBatch** method is called. If you are editing the current record or adding a new record when the **UpdateBatch** method is called, ADO will automatically call the **Update** method to save any pending changes to the current record before transmitting the batched changes to the provider.

If the attempt to transmit changes fails because of a conflict with the underlying data (for example, a record has already been deleted by another user), the provider returns warnings to the **Errors** collection but does not halt program execution. A run-time error occurs only if there are conflicts on all the requested records. Use the **Filter** property (**adFilterAffectedRecords**) and the **Status** property to locate records with conflicts.

To cancel all pending batch updates, use the **CancelBatch** method.

Value Property (ADO)

The **Value** property on a **Field** object indicates the value assigned to a **Field** or **Property** object. This property sets or returns a Variant value. The default value depends on the **Type** property of the **Field** object.

Syntax

```
oldValue = currentfield.Value
currentField.Value = newValue
```

Remarks

The **Value** property is used to set or return data from **Field** objects or to set or return property settings with **Property** objects. Whether the **Value** property is read/write or read-only depends upon numerous factors. For a **Field** object, this includes whether the **Recordset** was opened as read-only or read/write.

ActiveX® Data Objects (ADO) allows setting and returning long binary data with the **Value** property from the database.

Version Property (ADO)

The **Version** property on a **Connection** object indicates the ActiveX® Data Objects (ADO) version number. This property returns a String value.

Syntax

```
versionADO = currentConnection.Version
```

Remarks

The **Version** property is used to return the version number of the ADO implementation. The version of the provider will be available as a dynamic property in the **Properties** collection.

Network Integration Programmer's Reference

This section of Host Integration Server 2009 Help describes the objects, methods, properties, controls, and other interfaces that enable you to integrate Host Integration Server network technologies into your application.

This section of Host Integration Server 2009 Help provides information about the verbs, extensions, and return codes that make up the APPC programming interface.

For general information about programming for APPC, see the APPC Programmer's Guide section of the SDK.

For sample code using APPC, see APPC Samples.

In This Section

APPC Management Verbs

This section describes the Advanced Program-to-Program Communications (APPC) management verbs. The management verbs enable you to establish APPC LU 6.2 session limits, obtain configuration information and current operating values for the SNA node, and activate or deactivate sessions. The description of each verb provides:

- A definition of the verb.
- The structure defining the verb control block (VCB) used by the verb. The structure is contained in the WINAPPC.H file. The length of each VCB field is in bytes. Fields beginning with reserv (for example, reserv2) are reserved.
- The parameters (VCB fields) supplied to and returned by APPC. A description of each parameter is provided, along with its possible values and other information.
- The conversation state(s) in which the verb can be issued.
- The state(s) to which the conversation can change upon return from the verb. Conditions that do not cause a state change are not noted. For example, parameter checks and state checks do not cause a state change.
- Additional information describing the verb.

Most parameters supplied to and returned by APPC are hexadecimal values. To simplify coding, these values are represented by meaningful symbolic constants, which are established by **#define** statements in the WINAPPC.H header file. For example, the **opcode** (operation code) member of the **mc_send_data** structure used by the **MC_SEND_DATA** verb is the hexadecimal value represented by the symbolic constant AP_M_SEND_DATA. Use only the symbolic constants when writing transaction programs (TPs).

In This Section

ACTIVATE_SESSION

The **ACTIVATE_SESSION** verb requests Microsoft® Host Integration Server to activate a session between the local logical unit (LU) and a specified partner LU, using a specified mode. This verb completes either when the specified session has become active or when it has failed.

The following structure describes the verb control block used by the **ACTIVATE_SESSION** verb.

Syntax

```
typedef struct activate_session {
    unsigned short  opcode;
    unsigned char   reserv2[2];
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   reserv3[8];
    unsigned char   lu_alias[8];
    unsigned char   plu_alias[8];
    unsigned char   mode_name[8];
    unsigned char   fqplu_name[17];
    unsigned char   polarity;
    unsigned char   session_id[8];
    unsigned long   conv_group_id;
    unsigned char   reserv4[1];
    unsigned char   type;
    HANDLE          deactivation_event;
    unsigned short* p_deactivation_status;
    unsigned char   reserv5[10];
} ACTIVATE_SESSION;
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_ACTIVATE_SESSION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

reserv3

A reserved field.

lu_alias

Supplied parameter. Provides the 8-byte ASCII name used locally for the LU. If the default local LU is to be used, fill this parameter with spaces.

plu_alias

Supplied parameter. Provides the 8-byte ASCII name used locally for the partner LU. If the default remote LU is to be used, fill this parameter with spaces. If the partner LU is to be specified with the **fqplu_name** parameter, fill this parameter with binary zeros.

mode_name

Supplied parameter. Specifies the EBCDIC (type A) mode name.

fqplu_name

Supplied parameter. Provides the partner LU name in EBCDIC (type A) when no **plu_alias** name is defined at the local node and the partner LU is located at a different node. This parameter is ignored if **plu_alias** is specified.

polarity

Supplied parameter. Specifies the polarity for the session. The possible values are:

AP_POL_EITHER

If AP_POL_EITHER is set, ACTIVATE_SESSION activates a first speaker session if available; otherwise a bidder session is activated.

AP_POL_FIRST_SPEAKER

If AP_POL_FIRST_SPEAKER is set, ACTIVATE_SESSION only succeeds if a session of the requested polarity is available.

AP_POL_BIDDER

If AP_POL_BIDDER is set, ACTIVATE_SESSION only succeeds if a session of the requested polarity is available.

session_id

Returned parameter. Provides the 8-byte identifier of the activate session.

conv_group_id

Returned parameter. Provides the conversation group identifier. This parameter can be specified on **ALLOCATE** and **MC_ALLOCATE** verbs to start conversations on this particular session.

reserv4

A reserved field.

type

Supplied parameter. Specifies the type of activation. Possible values are:

AP_ACT_ACTIVE

If AP_ACT_ACTIVE is specified, then Host Integration Server will attempt to start the required session (by sending the BIND or INIT-SELF).

AP_ACT_PASSIVE

If AP_ACT_PASSIVE is specified, then Host Integration Server will not attempt to start the session and the verb will complete when the partner has started the session.

deactivation_event

Supplied parameter. Provides an event handle that APPC is to signal when the session is deactivated. The event handle should be obtained by calling either the **CreateEvent** or **OpenEvent** Win32® function.

p_deactivation_status

Returned parameter. A pointer to a value that is set when the deactivation event is signaled to provide completion status. The following values can be returned.

AP_SESSION_DEACTIVATED

AP_COMM_SUBSYSTEM_ABENDED

reserv5

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully. The secondary return code indicates the polarity of the established session. The following values can be returned.

AP_POL_FIRST_SPEAKER

AP_POL_BIDDER

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_INVALID_LU_ALIAS

Secondary return code; APPC cannot find the specified **lu_alias** among those defined.

AP_INVALID_PLU_ALIAS

Secondary return code; APPC did not recognize the specified **plu_alias**.

AP_INVALID_MODE_NAME

Secondary return code; APPC did not recognize the specified **mode_name**.

AP_INVALID_FQPLU_NAME

Secondary return code; APPC did not recognize the specified **fqplu_name**.

AP_INVALID_POLARITY

Secondary return code; APPC did not recognize the specified **polarity**.

AP_INVALID_TYPE

Secondary return code; APPC did not recognize the specified **type**.

AP_ACTIVATION_FAIL_NO_RETRY

Primary return code; the session could not be activated because of a condition that requires action (such as a configuration mismatch or a session protocol error).

AP_ACTIVATION_FAIL_RETRY

Primary return code; the session could not be activated because of a temporary condition (such as a link failure).

AP_SESSION_LIMITS_EXCEEDED

Primary return code; the session could not be activated because the session limits have been exceeded.

AP_SESSION_LIMITS_CLOSED

Primary return code; the session could not be activated because the session limits are closed (that is, zero).

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions occurred:

The node used by this conversation encountered an ABEND.

The connection between the TP and the PU 2.1 node has been broken (local area network error occurred).

The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

Remarks

This verb supports both active and passive activation.

The active form of this verb results in Host Integration Server trying to initiate the session (by sending a BIND for independent LUs or an INIT-SELF for dependent LUs). The active form of this verb will also result in the following behavior:

- If the connection to the partner LU is inactive and is configured as on-demand, the Node will attempt to start the

connection.

- If dynamic partnering is being used, the Node will set up the LU-LU/MODE partnership.
- If CNOS has not run, the Node will start CNOS (but will not change any of the session limits).

The passive form does not attempt to start the session, but completes when the LU is started by a BIND from its partner LU. For independent LUs, multiple passive **ACTIVATE_SESSION** verbs can be queued up for the same LU-LU/MODE, and complete in turn as new sessions are started.

This verb also includes a deactivation event, which is posted when the session is deactivated by any method other than a **DEACTIVATE_SESSION** verb (for example, an unsolicited UNBIND from its partner LU results in this event being posted).

CNOS

The **CNOS** (Change Number of Sessions) verb establishes APPC LU 6.2 session limits.

The following structure describes the verb control block used by the **CNOS** verb.

Syntax

```
typedef struct cnos {
    unsigned short  opcode;
    unsigned char   reserv2[2];
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   key[8];
    unsigned char   lu_alias[8];
    unsigned char   plu_alias[8];
    unsigned char   fqplu_name[17];
    unsigned char   reserv3;
    unsigned char   mode_name[8];
    unsigned int    mode_name_select:1;
    unsigned int    set_negotiable:1;
    unsigned int    reserv4:6;
    unsigned int    reserv5:8;
    unsigned short  plu_mode_sess_lim;
    unsigned short  min_conwinners_source;
    unsigned short  min_conwinners_target;
    unsigned short  auto_act;
    unsigned int    drain_target:1;
    unsigned int    drain_source:1;
    unsigned int    responsible:1;
    unsigned int    reserv6:5;
    unsigned int    reserv7:8;
} CNOS;
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_CNOS.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

key

Supplied parameter. Specifies either the master or service key in ASCII, if the keylock feature has been secured.

lu_alias

Supplied parameter. Provides the 8-byte ASCII name used locally for the LU.

plu_alias

Supplied parameter. Provides the 8-byte ASCII name used locally for the partner LU.

fqplu_name

Supplied parameter. Provides the partner logical unit (LU) name in EBCDIC (type A) when no **plu_alias** name is defined at the local node and the partner LU is located at a different node.

mode_name

Supplied parameter. Specifies the EBCDIC (type A) mode name to be used when the value of **mode_name_select** is AP_ONE.

mode_name_select

Supplied parameter. Specifies the mode name select for which your program is setting or resetting the session limits and contention-winner polarities. Allowed values are AP_ALL or AP_ONE.

set_negotiable

Supplied parameter. Specifies whether APPC is to change the current setting for the maximum negotiable session limit. Allowed values are AP_YES and AP_NO.

reserv4

A 6-bit reserved field.

reserv5

An 8-bit reserved field.

plu_mode_sess_lim

Supplied parameter. Specifies the session limit when the value for **set_negotiable** is YES. Allowed values are 0 to 32767.

min_conwinners_source

Supplied parameter. Specifies the number of sessions of which the LU is guaranteed to be the contention winner. Allowed values are 0 to 32767.

min_conwinners_target

Supplied parameter. Specifies the minimum number of sessions of which the target LU is guaranteed to be the contention winner. Allowed values are 0 to 32767.

auto_act

Supplied parameter. Specifies the number of the local LUs contention-winner sessions for APPC to activate automatically. Allowed values are 0 to 32767. See the Remarks section of this topic before using this parameter.

drain_target

Supplied parameter. Specifies whether the target LU can drain its waiting (outbound) allocation requests. Allowed values are AP_YES and AP_NO.

drain_source

Supplied parameter. Specifies whether the source LU can drain its waiting (outbound) allocation requests. Allowed values are AP_YES and AP_NO.

responsible

Supplied parameter. Specifies which LU is responsible for deactivating the sessions as a result of resetting the session limit for parallel-session connections. Allowed values are AP_SOURCE and AP_TARGET.

reserv6

A 5-bit reserved field.

reserv7

An 8-bit reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_CNOS_ACCEPTED

Secondary return code; APPC accepts the session limits and responsibility as specified.

AP_CNOS_NEGOTIATED

Secondary return code; APPC accepts the session limits and responsibility as negotiable by the partner LU. Values that can be

Secondary return code; APPC accepts the session limits and responsibility as negotiable by the partner LU. Values that can be negotiated are:

plu_mode_session_limit

min_conwinners_source

min_conwinners_target

responsible

drain_target

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after ALLOCATE or MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CNOS_LOCAL_RACE_REJECT

Primary return code; APPC is currently processing a **CNOS** verb issued by a local LU.

AP_CNOS_PARTNER_LU_REJECT

Primary return code; the partner LU rejected a **CNOS** request from the local LU.

AP_CNOS_MODE_CLOSED

Secondary return code; the local LU cannot negotiate a nonzero session limit because the local maximum session limit at the partner LU is zero.

AP_CNOS_MODE_NAME_REJECT

Secondary return code; the partner LU does not recognize the specified mode name.

AP_CNOS_COMMAND_RACE_REJECT

Secondary return code; the local LU is currently processing a **CNOS** verb issued by the partner LU.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

The node used by this conversation encountered an ABEND.

The connection between the transaction program (TP) and the PU 2.1 node has been broken (a local area network error).

The SnaBase at the TPs computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_INVALID_KEY

Primary return code; the supplied key was incorrect.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_ALL_MODE_MUST_RESET

Secondary return code; APPC does not permit a nonzero session limit when the **mode_name_select** parameter indicates AP_ALL.

AP_AUTOACT_EXCEEDS_SESSLIM

Secondary return code; on the **CNOS** verb, the value for **auto_act** is greater than the value for **plu_mode_sess_lim**.

AP_BAD_LU_ALIAS

Secondary return code; APPC cannot find the specified **lu_alias** among those defined.

AP_BAD_PARTNER_LU_ALIAS

Secondary return code; APPC did not recognize the supplied **plu_alias**.

AP_BAD_SNASVCMG_LIMITS

Secondary return code; your program specified invalid settings for **plu_mode_sess_lim**, **min_conwinners_source**, or **min_conwinners_target** when **mode_name** was supplied.

AP_CHANGE_SRC_DRAINS

Secondary return code; APPC does not permit **mode_name_select** (ONE) and **drain_source** (YES) when **drain_source** (NO) is currently in effect for the specified mode.

AP_CNOS_IMPLICIT_PARALLEL

Secondary return code; APPC does not permit a program to change the session limit for a mode other than the SNASVCMG mode for the implicit partner template when the template specifies parallel sessions. (The term "template" is used because many of the actual values are yet to be filled in.)

AP_CPSVCMG_MODE_NOT_ALLOWED

Secondary return code; the mode named CPSVCMG cannot be specified as the **mode_name** on the deactivate session verb.

AP_EXCEEDS_MAX_ALLOWED

Secondary return code; your program issued a **CNOS** verb, specifying a **plu_mode_sess_lim** number and **set_negotiable** (AP_NO).

AP_MIN_GT_TOTAL

Secondary return code; the sum of **min_conwinners_source** and **min_conwinners_target** specifies a number greater than **plu_mode_sess_lim**.

AP_MODE_CLOSED

Secondary return code; the local LU cannot negotiate a nonzero session limit because the local maximum session limit at the partner LU is zero.

AP_RESET_SNA_DRAINS

Secondary return code; SNASVCMG does not support the drain parameter values.

AP_SINGLE_NOT_SRC_RESP

Secondary return code; for a single-session **CNOS** verb, APPC permits only the local (source) LU to be responsible for deactivating sessions.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_CANT_RAISE_LIMITS

Secondary return code; APPC does not permit setting session limits to a nonzero value unless the limits currently are zero.

AP_LU_DETACHED

Secondary return code; a command has reset the definition of the local LU before **CNOS** tried to specify the LU.

AP_SNASVCMG_RESET_NOT_ALLOWED

Secondary return code; your local program attempted to issue the **CNOS** verb for the mode named SNASVCMG, specifying a session limit of zero.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC verb from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

CNOS identifies an LU by alias alone. If the same local LU alias is used multiple times in a domain (for backup or other purposes) and that LU alias is specified through **CNOS**, the verb can flow to a different LU than the one intended.

If CNOS is not issued to set the mode session limit before a program issues its first APPC ALLOCATE, MC_ALLOCATE, SEND_CONVERSATION, or MC_SEND_CONVERSATION, or Common Programming Interface for Communications (CPI-C) Allocate call for a given partner LU and mode, APPC will internally generate a session limit using the value from the mode definition.

When setting the limits for a parallel-session connection, the two LUs negotiate the mode session limits, drain settings, and responsibility values. APPC updates these parameters in **CNOS** to reflect the settings agreed to by both LUs during negotiation. Your program can issue DISPLAY to obtain the negotiated values for the mode session limit.

No **CNOS** negotiation occurs when setting the limits for a single session (that is, the two LUs do not negotiate drain settings or responsibility values). Therefore, coordinate the mode definition parameter settings between partner LUs using a single-session connection by defining a single session mode at each node.

As part of setting up the initial limits, **CNOS** also sets the guaranteed (that is, the minimum) number of contention-winner and contention-loser sessions and sets the automatic activation count for the source LUs contention-winner sessions. The action of **CNOS** normally affects only the group of sessions with the specified mode name between the source LU and the target LU. Alternatively, one **CNOS** can reset the session limits of all modes for a partner LU.

APPC enforces the new mode session limit and the contention-winner polarities until one side or the other changes them by issuing a subsequent **CNOS** verb. The **CNOS** transaction is invisible at the target LU's API, regardless of which LU is the target. The results of the **CNOS** transaction can be obtained using **DISPLAY**.

Setting a Session Limit to Zero

After **CNOS** raises the session limit above zero, it can reset the limit to zero only. It cannot set the session limit to a value that is not zero, and it cannot redistribute the number of sessions allocated as the contention winners and losers. Therefore, your program cannot change the mode session limits if the two logical units (LUs) have already set the limits to a nonzero value, regardless of which LU initiated the **CNOS** transaction.

A program can change the session limits from a nonzero value, as long as the program first changes the session limit to zero. For example, if the session limit is 8, a program can change it to 6 by first issuing **CNOS** and changing the session limit to zero, and then issuing **CNOS** again and setting the session limit to 6.

APPC can activate one or more LU-LU sessions with the specified mode name as a result of initializing the session limit. You cannot use **CNOS** to activate sessions between two LUs on the same server. APPC deactivates all LU-LU sessions for the specified mode name (or for all mode names for a partner LU) as a result of resetting the session limit to zero. APPC deactivates each session as it becomes free and does not interrupt active conversations.

A separate value, the maximum negotiable session limit, is used in **CNOS** negotiations. If the **set_negotiable** value is AP_YES, the mode session limit value given in this **CNOS** verb also sets the maximum negotiable session limit.

The **lu_alias** and **plu_alias** parameters are 8-byte ASCII character strings. If the name is fewer than eight bytes, it must be padded on the right with ASCII spaces.

You can specify the SNA-defined mode name SNASVCMG for **mode_name**. Use this mode only in a **CNOS** transaction when the source LU and the target LU use parallel user sessions. However, when resetting the session limits to zero for the SNASVCMG PU 2.1 node, the session limits of all other modes between the two LUs must be reset first. The PU 2.1 mode name is a type A EBCDIC character string. A mode name consisting of all spaces is supported. The SNA-defined mode name CPSVCMG is not allowed.

When specifying **plu_mode_sess_lim**, if the mode session limit is currently greater than zero, the value of this parameter must be zero. **CNOS** can raise the limit above zero, but the next **CNOS** must set the value to zero. A single **CNOS** cannot change the mode session limit from one nonzero number to another.

When raising the mode session limit above zero for a parallel-session connection, the target LU can negotiate its parameter to a value greater than zero and less than the specified session limit. The specified or negotiated limit then becomes the new mode session limit and is returned in this field.

The value specified for this parameter must be greater than or equal to the sum of the values specified in the **CNOS min_conwinners_source** and **min_conwinners_target** parameters.

Do not reset the SNASVCMG session limit to zero until all other mode session limits between the two LUs are reset to zero and the count of active sessions for all modes (except SNASVCMG) for the partner LU is zero.

The mode session limit should be large enough to accommodate all active conversations in the mode for all TPs.

For **min_conwinners_source** and **min_conwinners_target**, the sum of both parameters cannot exceed the mode session limit. For single-session connections, these parameters specify the desired contention-winner sessions for the target and source LUs. For the SNASVCMG mode name (with a mode session limit of 2 or 1), the specified minimum number of contention-winner sessions for the target LU must be 1. For the source LU, with a mode session limit of 2, the number must be 1; with a mode session limit of 1, the number must be 0. APPC uses these parameters only when the mode session limit is set to a nonzero value.

APPC uses auto_act only when the mode session limit is set to a nonzero value. If the value is greater than the min_conwinners_source value, APPC uses the new minimum number of contention winners for the source LU as the autoactivation limit.

⚠**Caution**
The **auto_act** parameter can conflict with the on-demand definition of a connection. Autoactivations by either peer partner c an re-establish sessions and connections, possibly resulting in a thrashing situation. Therefore, avoid specifying autoactivatio n between peer PU 2.1 nodes using on-demand connections.

Whether an LU deactivates a session immediately after the current conversation or after all queued conversations are complete depends on the **drain_source** and **drain_target** parameters.

If an LU is to drain its waiting (outbound) allocation requests, it continues to allocate conversations to active sessions. The responsible LU deactivates a session only when the conversation allocated to the session is deallocated and no request is waiting for allocation to any session with the specified mode name between the two LUs. The allocation of a waiting request takes precedence over the deactivation of a session.

If an LU is not to drain its waiting (outbound) allocation requests, the responsible LU deactivates a session as soon as the conversation allocated to the session is deallocated. If no conversation is allocated to the session, the responsible LU deactivates the session immediately. However, this verb does not force deallocation of active conversations.

The **responsible** and **mode_name_select** parameters are interrelated as follows:

- APPC ignores the **responsible** parameter for mode names for which the session limit is currently zero if this **CNOS** verb specifies **mode_name_select** (AP_ALL).

- If CNOS specifies **mode_name_select** (AP_ONE) with a mode session limit of zero, and the current session limit for that mode name is already zero, the **responsible** parameter must specify the same LU (SOURCE or TARGET) that is currently responsible for deactivating sessions. APPC uses this parameter only when **CNOS** specifies a mode session limit of zero.

For parallel-session connections, the **drain_source** and **mode_name_select** parameters are interrelated as follows:

- If **CNOS** specifies **mode_name_select** (AP_ALL) and **drain_source** (AP_YES), APPC ignores **drain_source** for those mode names for which the session limit is currently zero.

- If **CNOS** specifies **mode_name_select** (AP_ALL) and **drain_source** (AP_NO), APPC accepts **drain_source** for all mode names. APPC ends draining for any mode currently draining its requests.

- If **CNOS** specifies **mode_name_select** (AP_ONE), and **drain_source** (AP_YES) is currently in effect, **drain_source** (AP_NO) directs APPC to end the draining at the source LU for requests for the specified mode name.

- If **CNOS** specifies **mode_name_select** (AP_ONE) and **drain_source** (AP_NO) is currently in effect, your program must specify **drain_source** (AP_NO) again.

For parallel-session connections, the **drain_target** parameter and the **mode_name_select** parameter are interrelated as follows:

- If **CNOS** specifies **mode_name_select** (AP_ALL) and **drain_target** (AP_YES), APPC ignores **drain_target** for the mode names for which the session limit is currently zero.

- If **CNOS** specifies **mode_name_select** (AP_ALL) and **drain_target** (AP_NO), APPC accepts **drain_target** for all mode names, regardless of the current session limit. Any draining of waiting (outbound) allocation requests at the target LU is ended.

- If **CNOS** specifies **mode_name_select** (AP_ONE) and **drain_target** (AP_YES) is currently in effect, **drain_target** (AP_NO) ends the target LUs draining.

- If **CNOS** specifies **mode_name_select** (AP_ONE) and **drain_target** (AP_YES), and **drain_target** (AP_NO) is currently in effect, the target LU can either accept **drain_target** (AP_YES) or negotiate the parameter to AP_NO. After the target LU accepts the **drain_target** (AP_YES) parameter, it can drain any remaining waiting (outbound) allocation requests.

DEACTIVATE_SESSION

The **DEACTIVATE_SESSION** verb requests Microsoft® Host Integration Server to deactivate a particular session between the local logical unit (LU) and a specified partner LU, or all sessions on a particular mode.

The following structure describes the verb control block used by the **DEACTIVATE_SESSION** verb.

Syntax

```
typedef struct deactivate_session {
    unsigned short  opcode;
    unsigned char   reserv2[2];
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   reserv3[8];
    unsigned char   lu_alias[8];
    unsigned char   session_id[8];
    unsigned char   plu_alias[8];
    unsigned char   mode_name[8];
    unsigned char   type;
    unsigned char   reserv4[3];
    unsigned short  sense_data;
    unsigned char   fqplu_name[17];
    unsigned char   reserv5[19];
} DEACTIVATE_SESSION;
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_DEACTIVATE_SESSION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

reserv3

A reserved field.

lu_alias

Supplied parameter. Provides the 8-byte ASCII name used locally for the LU.

session_id

Supplied parameter. Provides the 8-byte identifier of the session to deactivate (returned on the **ACTIVATE_SESSION** verb). If this field is set to 8 binary zeros, Host Integration Server deactivates all sessions for the partner LU and mode.

plu_alias

Supplied parameter. Provides the 8-byte ASCII name used locally for the partner LU. If the default remote LU is to be used, fill this parameter with spaces. If the partner LU is to be specified with the **fqplu_name** parameter, fill this parameter with binary zeros.

mode_name

Supplied parameter. Specifies the EBCDIC (type A) mode name.

type

Supplied parameter. Specifies the type of deactivation. Possible values are:

AP_DEACT_CLEANUP

Deactivate the session immediately, without waiting for sessions to end.

AP_DEACT_NORMAL

Do not deactivate the session until all conversations using the session have ended.

sense_data

Returned parameter. Specifies the deactivation sense data for the session.

reserv4

A reserved field.

fqplu_name

Supplied parameter. Provides the partner LU name in EBCDIC (type A) when no **plu_alias** name is defined at the local node and the partner LU is located at a different node. This parameter is ignored if **plu_alias** is specified.

reserv5

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully. The secondary return code indicates the polarity of the established session. The following values can be returned.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error, specified by one of the following secondary return codes:

AP_INVALID_LU_ALIAS

Secondary return code; APPC cannot find the specified **lu_alias** among those defined.

AP_INVALID_PLU_ALIAS

Secondary return code; APPC did not recognize the specified **plu_alias**.

AP_INVALID_SESSION_ID

Secondary return code; APPC did not recognize the specified **session_id**.

AP_INVALID_MODE_NAME

Secondary return code; APPC did not recognize the specified **mode_name**.

AP_INVALID_FQPLU_NAME

Secondary return code; APPC did not recognize the specified **fqplu_name**.

AP_INVALID_TYPE

Secondary return code; APPC did not recognize the specified **type**.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions occurred:

The node used by this conversation encountered an ABEND.

The connection between the TP and the PU 2.1 node has been broken (a local area network error occurred).

The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus,

communication could not take place. Contact the system administrator for corrective action.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

DISPLAY

The **DISPLAY** verb returns configuration information and current operating values for the SNA node.

It is recommended that you use the GetAppcConfig Windows extension function to obtain system configuration information relating to APPC LUs. Users of 5250 emulators, in particular, should use the **GetAPPCConfig** Windows extension.

Note

Because of the nature of client/server architecture, the implementation of the **DISPLAY** verb on Host Integration Server 2009 contains important differences from the IBM Extended Services for OS/2 version 1.0 (IBM ES for OS/2 version 1.0) on which it was based.

Note

For applications that use the APPC **DISPLAY** verb in IBM ES for OS/2 version 1.0 compatibility mode and that do not use the Host Integration Server extensions for enumerating all active servers and connections, Host Integration Server will randomly choose a default **DISPLAY** connection, unless a specific default **DISPLAY** connection has been configured in SNA Manager. This connection is used as the basis for all **DISPLAY** requests. For information about specifying the default **DISPLAY** connection, see Host Integration Server 2009 Help.

The following structure describes the verb control block used by the **DISPLAY** verb.

Syntax

```
struct display {
    unsigned short  opcode;
    unsigned char   reserv2[2];
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned long   init_sect_len;
    unsigned long   buffer_len;
    unsigned char FAR * buffer_ptr;
    unsigned long  num_sections;
    unsigned long  display_len;
    unsigned long  area_needed;
    unsigned char  sna_global_info;
    unsigned char  lu62_info;
    unsigned char  am_info;
    unsigned char  tp_info;
    unsigned char  sess_info;
    unsigned char  link_info;
    unsigned char  lu_0_3_info;
    unsigned char  gw_info;
    unsigned char  x25_physical_link_info;
    unsigned char  sys_def_info;
    unsigned char  adapter_info;
    unsigned char  lu_def_info;
    unsigned char  plu_def_info;
    unsigned char  mode_def_info;
    unsigned char  link_def_info;
    unsigned char  ms_info;
    struct sna_global_info_sect FAR * sna_global_info_ptr;
    struct lu62_info_sect FAR * lu62_info_ptr;
    struct am_info_sect FAR * am_info_ptr;
    struct tp_info_sect FAR * tp_info_ptr;
    struct sess_info_sect FAR * sess_info_ptr;
    struct link_info_sect FAR * link_info_ptr;
    struct lu_0_3_info_sect FAR * lu_0_3_info_ptr;
    struct gw_info_sect FAR * gw_info_ptr;
    struct x25_physical_link_info_sect FAR * x25_physical_link_info_ptr;
    struct sys_def_info_sect FAR * sys_def_info_ptr;
    struct adapter_info_sect FAR * adapter_info_ptr;
    struct lu_def_info_sect FAR * lu_def_info_ptr;
```

```
    struct plu_def_info_sect FAR * plu_def_info_ptr;
    struct mode_def_info_sect FAR * mode_def_info_ptr;
    struct link_def_info_sect FAR * link_def_info_ptr;
    struct ms_info_sect FAR * ms_info_ptr;
} DISPLAY;
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_DISPLAY.

reserv2

A reserved field, this value must be set to NULL.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

init_sect_len

Supplied parameter. Specifies the number of bytes in the initial section of the VCB, up to the beginning of information pointers. This parameter and the **num_sections** parameter must be set to specific values depending on the format being requested. See the notes below for details.

buffer_len

Supplied parameter. Specifies the length (0 to 65535 bytes) of the passed display data buffer.

buffer_ptr

Supplied parameter. Provides the address of the display data buffer that will contain the requested information.

num_sections

Supplied parameter. Specifies the maximum number of information sections that can be returned by the verb. This parameter and the **init_sect_len** parameter must be set to specific values depending on the format being requested. See the notes below for details.

display_len

Returned parameter. Provides the total number of bytes used that are returned into the display data buffer.

area_needed

Returned parameter. Provides the total number of bytes needed for all of the displayed data.

sna_global_info

Supplied parameter. Specifies if global information is requested. Allowed values are AP_YES and AP_NO.

lu62_info

Supplied parameter. Specifies if information on all active LUs, their partners, and their modes is requested. Allowed values are AP_YES and AP_NO.

am_info

Supplied parameter. Specifies if Attach Manager information on the defined TP is requested. Allowed values are AP_YES and AP_NO.

Note
This option is not supported by Host Integration Server and this parameter must be set to AP_NO.

tp_info

Supplied parameter. Specifies if information on the active TPs and any active conversations is requested. Allowed values are AP_YES and AP_NO.

Note
This option is not supported by Host Integration Server and this parameter must be set to AP_NO.

sess_info

Supplied parameter. Specifies if information on sessions is requested. Allowed values are AP_YES and AP_NO.

link_info

Supplied parameter. Specifies if information on the active SNA logical lines is requested. Allowed values are AP_YES and AP_NO.

lu_0_3_info

Supplied parameter. Specifies if information on logical units type 0, 1, 2, and 3 is requested. Allowed values are AP_YES and AP_NO.

gw_info

Supplied parameter. Specifies if information on the SNA gateway is requested. Allowed values are AP_YES and AP_NO.

x25_physical_link_info

Supplied parameter. Specifies if X.25 information is required. Allowed values are AP_YES and AP_NO.

Note
This option is not supported by Host Integration Server and this parameter must be set to AP_NO.

sys_def_info

Supplied parameter. Specifies if information about the default LU, node names, and default parameters for inbound and outbound implicit partners is requested. Allowed values are AP_YES and AP_NO.

adapter_info

Supplied parameter. Specifies if information about the configured communications adapters is requested. Allowed values are AP_YES and AP_NO. This parameter must be set to AP_NO when NS/2 format is requested.

lu_def_info

Supplied parameter. Specifies if information about the defined LUs is requested. Allowed values are AP_YES and AP_NO.

plu_def_info

Supplied parameter. Specifies if information about the defined partner LUs is requested. Allowed values are AP_YES and AP_NO.

mode_def_info

Supplied parameter. Specifies if information about the defined nodes is requested. Allowed values are AP_YES and AP_NO.

link_def_info

Supplied parameter. Specifies if information about the defined logical links is requested. Allowed values are AP_YES and AP_NO.

ms_info

Supplied parameter. Specifies if information about management services is requested. Allowed values are AP_YES and AP_NO. This parameter must be set to AP_NO when NS/2 format is requested.

sna_global_info_ptr

Returned parameter. Indicates the address of the beginning of SNA global information in the data buffer.

lu62_info_ptr

Returned parameter. Indicates the address of the beginning of LU 6.2 information in the data buffer.

am_info_ptr

Returned parameter. Indicates the address of the beginning of the Attach Manager information in the data buffer.

Note
This option is not supported by Host Integration Server.

tp_info_ptr

Returned parameter. Indicates the address of the beginning of TP information in the data buffer.

Note
This option is not supported by Host Integration Server.

sess_info_ptr

Returned parameter. Indicates the address of the beginning of session information in the data buffer.

link_info_ptr

Returned parameter. Indicates the address of the beginning of link information in the data buffer.

lu_0_3_info_ptr

Returned parameter. Indicates the address of the beginning of LU information in the data buffer.

gw_info_ptr

Returned parameter. Indicates the address of the beginning of gateway information in the data buffer.

x25_physical_link_info_ptr

Returned parameter. Indicates the address of the beginning of X.25 information in the data buffer.

Note
This option is not supported by Host Integration Server.

sys_def_info_ptr

Returned parameter. Indicates the address of the beginning of system default information in the data buffer.

adapter_info_ptr

Returned parameter. Indicates the address of the beginning of adapter information in the data buffer.

lu_def_info_ptr

Returned parameter. Indicates the address of the beginning of local LU definition information in the data buffer.

plu_def_info_ptr

Returned parameter. Indicates the address of the beginning of partner LU definition information in the data buffer.

mode_def_info_ptr

Returned parameter. Indicates the address of the beginning of mode definition information in the data buffer.

link_def_info_ptr

Returned parameter. Indicates the address of the beginning of link definition information in the data buffer.

ms_info_ptr

Returned parameter. Indicates the address of the beginning of management services information in the data buffer.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_DISPLAY_INVALID_CONSTANT

Secondary return code; the value supplied for NUM_SECTIONS or INIT_SEC_LEN is invalid.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_DISPLAY_INFO_EXCEEDS_LEN

Secondary return code; the returned **DISPLAY** information did not fit in the buffer.

AP_INVALID_DATA_SEGMENT

Secondary return code; the segment containing the data buffer is too small for the specified data length.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

The node used by this conversation has encountered an ABEND.

The connection between the TP and the node type 2.1 has been broken (a LAN error).

The SnaBase at the TPs computer has encountered an ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

DISPLAY identifies an LU by alias alone. If the same local LU alias is used multiple times in a domain (for backup or other purposes) and that LU alias is specified through **DISPLAY**, the verb can flow to a different LU than the one intended.

For the **DISPLAY** verb to return successfully, a specific connection must be defined in the SNA Manager program **Display Verb** dialog box. IBM originally defined the **DISPLAY** verb with the IBM OS/2 Extended Edition product which assumed a single connection. However, because Host Integration Server supports multiple connections, the specific connection associated with the **DISPLAY** verb must be configured.

The **DISPLAY** verb requires a user-supplied buffer for the return of system information. If the buffer is not large enough, APPC returns the AP_DISPLAY_INFO_EXCEEDS_LEN return code, along with the size actually needed at the time of the request (in the **area_needed** parameter). One possible strategy for the use of this verb follows:

- If the **buffer_len** value is less than the **area_needed** value returned by APPC, and the required length is less than 64 kilobytes (KB), then increase the size of the display buffer to equal or greater than the **area_needed** value.

- If the **area_needed** value is greater than 64KB, you can choose to request each information section individually. Or, you can take the following steps:

    1. Process the information sections with complete information, whose total number displayed equals the total actual number.

2. Choose a subset of the information sections you requested that contains incomplete information, and reissue the verb requesting those information sections.

3. Repeat steps a and b as needed.

Note
If an individual information section is greater than 64 KB, then you cannot get all of the requested information from AP PC.

The **DISPLAY** verb should not be executed from different threads of the same process, since it is not thread-safe.

The **DISPLAY** verb returns AP_DISPLAY_INVALID_CONSTANT if the following values are not set for the supplied parameters for **init_sect_len** and **num_sections**:

	NS/2 format	**IBM EE format**	**NS/2 format (Windows 2000 only)**	**IBM EE format (Windows 2000 only)**
init_sect_len	50	44	52	48
num_sections	16	9	16	9

The AP_DISPLAY_INVALID_CONSTANT is also returned when the following parameters are not set properly:

- **reserv2** must be set to NULL.
- **am_info** must be set to AP_NO.
- **tp_info** must be set to AP_NO.
- **adapter_info** must be set to AP_NO if NS/2 format is requested.
- **ms_info** must be set to AP_NO if NS/2 format is requested.

Differences by Information Type

Host Integration Server Extensions

The Host Integration Server **DISPLAY** verb is compatible with the IBM ES for OS/2 version 1.0 **DISPLAY** verb. However, since IBM ES for OS/2 version 1.0 is a single-server system and Host Integration Server supports multiple-server systems, the **DISPLAY** verb has been extended to allow the user to target a specific server running Host Integration Server by which the **DISPLAY** verb will be processed.

To direct a **DISPLAY** verb at a particular server running Host Integration Server, place the ASCII string CSEXTNID, followed by the computer name of the server running Host Integration Server at the start of the buffer pointed to by **buffer_ptr**. The computer name is a 32-byte ASCII string and can be zero or padded with spaces.

Because the local node identifier is configured on a per-node basis for IBM ES for OS/2 version 1.0 and can be different for each connection in Host Integration Server, Host Integration Server also allows you to specify an optional connection name. This is an 8-byte ASCII string, which is placed after the 32-byte computer name. Again, the string can be zero or padded with spaces. The following example illustrates the CSEXTNID extension:

csextnid computername 0000000000000000000 name

If you do not specify a connection name, Host Integration Server returns information about the first connection configured for the Host Integration Server system.

If you do not specify a computer name, Host Integration Server will randomly choose a default **DISPLAY** computer and connection, unless a specific default **DISPLAY** connection has been configured on the server. These parameters can be configured with the SNA Manager or the Host Integration Server Administrator Client when using Host Integration Server 2009. **DISPLAY** will behave as if you specified the connection and the computer name of the server that owns the verb. For additional information about using default LUs, see Host Integration Server 2009 Help.

Host Integration Server also allows you to use **DISPLAY** to return a list of active servers. To do so, place the string CSEXTNIDCSLISTND in the **DISPLAY** buffer and set the supplied parameters **sna_global_info**, **lu62_info**, and so on, to AP_NO. The information is returned in the **DISPLAY** buffer in the following format.

Syntax

```
#activenodes            - 2 bytes
  node_name 1           - 8 bytes
  box_name 1            - 32 bytes
  .
  node_name m
  box_name m
```

Remarks

In the current version of Host Integration Server, **node_name** is always SNASERVR and **box_name** is the computer name of the server.

Differences by Information Type

Differences in the implementation of the **DISPLAY** verb between Host Integration Server 2009 and IBM ES for OS/2 are described in this section by information type. For each information type, there is a topic that describes:

- The information defined by IBM ES for OS/2 version 1.0.
- The information returned by Host Integration Server.

Note
Host Integration Server does not support all of the information types supported by IBM ES for OS/2 version 1.0. If an information type is not listed in this section, it is not supported by Host Integration Server.

In This Section

SNA Global Information

SNA global information is defined or returned as described here.

Defined by IBM ES for OS/2 version 1.0

Information on SNA global information is provided in the **sna_global_info_sect** structure as defined below.

```
typedef struct sna_global_info_sect {
    unsigned char version;
    unsigned char release;
    unsigned char net_name[8];
    unsigned char pu_name[8];
    unsigned char node_id[4];
    type_product_set_id product_set_id;
    unsigned char alias_cp_name[8];
    unsigned char node_type;
    unsigned char cp_nau_addr;
    unsigned char corr_serv_disk;
    unsigned char reserved;
    unsigned char appc_version;
    unsigned char appc_release;
    unsigned char appc_fixlevel;
} SNA_GLOBAL_INFO_SECT;
```

Members

version

Communications Manager Extended Edition version number.

release

Communications Manager Extended Edition release number.

net_name

Network name, first part of fully qualified control program (CP) name, in EBCDIC (type A).

pu_name

PU name, second part of fully qualified CP name, in EBCDIC (type A).

node_id

4-byte hexadecimal exchange identifier.

product_set_id

Computer product data.

alias_cp_name

Node name (local name for CP) in ASCII.

node_type

AP_NN, AP_EN, or AP_LEN.

cp_nau_addr

CP NAU address where 0 means not used (an independent LU). Other legal values are 1 to 254.

corr_serv_disk

Last four digits of corrective service disk number.

reserved

Reserved field.

appc_version

APPC version number.

appc_release

APPC release number.

appc_fixlevel

APPC patch number.

Returned by Host Integration Server

Information on SNA global information is provided in the **sna_global_info_sect** structure defined below.

```
typedef struct sna_global_info_sect {
    unsigned char version;
    unsigned char release;
    unsigned char net_name[8];
    unsigned char pu_name[8];
    unsigned char node_id[4];
    type_product_set_id product_set_id;
    unsigned char alias_cp_name[8];
    unsigned char node_type;
    unsigned char cp_nau_addr;
    unsigned char corr_serv_disk;
    unsigned char reserved;
    unsigned char appc_version;
    unsigned char appc_release;
    unsigned char appc_fixlevel;
} SNA_GLOBAL_INFO_SECT;
```

Members

version

Major operating system (OS) version number.

release

Minor OS version number.

net_name

Node network name in EBCDIC (type A).

pu_name

PU name in EBCDIC (type A) associated with connection.

node_id

Node identifier to send.

product_set_id

Set to EBCDIC zeros.

alias_cp_name

Node name, local name for the control program (CP), in ASCII.

node_type

Set to AP_LEN.

cp_nau_addr

CP NAU address where 0 means not used (an independent LU). Other legal values are 1 to 254.

corr_serv_disk

Reserved field set to zero.

reserved

Reserved field set to zero.

appc_version

Host Integration Server major version number.

appc_release

Host Integration Server minor version number.

appc_fixlevel

Host Integration Server patch number.

Remarks

Host Integration Server returns **version** and **release** as the major and minor OS version numbers from **GetVersion**. Because Host Integration Server 2009 has no information on the computer type, serial number, and manufacturer, **product_set_id** is set to EBCDIC zeros.

Host Integration Server does not support APPN node types, so the node type is returned as 1 (an AP_LEN node), and not 2 or 3 (AP_NN or AP_EN nodes), as defined by IBM ES for OS/2 version 1.0.

LU 6.2 Information

Information on LUs is provided in the **lu62_info_sect** structure as defined below.

Syntax

```
typedef struct lu62_info_sect {
    unsigned long  lu62_init_sect_len;
    unsigned short num_lu62s;
    unsigned short total_lu62s;
} LU62_INFO_SECT;
```

Members

lu62_init_sect_len

Structure length.

num_lu62s

Number of configured LUs displayed.

total_lu62s

Total number of configured LUs.

For each configured LU, an **lu62_overlay** structure is provided as defined below.

Syntax

```
typedef struct lu62_overlay {
    unsigned long  lu62_entry_len;
    unsigned long  lu62_overlay_len;
    unsigned char  lu_name[8];
    unsigned char  lu_alias[8];
    unsigned short num_plus;
    unsigned char  fqlu_name[17];
    unsigned char  default_lu;
    unsigned char  reserv3;
    unsigned char  lu_local_addr;
    unsigned short lu_sess_lim;
    unsigned char  max_tps;
    unsigned char  lu_type;
} LU62_OVERLAY;
```

Members

lu62_entry_len

Size of this LU entry.

lu62_overlay_len

This value contains **sizeof(**struct **lu62_overlay)**–**sizeof(lu62_entry_len)**.

lu_name

LU name (EBCDIC type A).

lu_alias

LU alias (ASCII).

num_plus

Number of partner LUs.

fqlu_name

Fully qualified LU name (EBCDIC type A).

default_lu

For local LU group, an LU equal to the **default_lu** is used if none is specified. Legal values are AP_NO and AP_YES.

On Host Integration Server, there is no concept of a default local LU. Therefore, the **default_lu** flag, which is set to AP_YES for the node in IBM ES for OS/2 version 1.0, is set to AP_NO for Host Integration Server.

lu_local_addr

NAU address, 0–254.

lu_sess_lim

Configured session limit, 0–255.

max_tps

Maximum number of TPs, 1–255.

lu_type

Always LU type 6.2.

For each configured LU, a **plu_62_overlay** structure for the partner LU is provided as defined below.

Syntax

```
typedef struct plu62_overlay {
    unsigned long  plu62_entry_len;
    unsigned long  plu62_overlay_len;
    unsigned char  plu_alias[8];
    unsigned short num_modes;
    unsigned char  plu_un_name[8];
    unsigned char  fqplu_name[17];
    unsigned char  reserv3;
    unsigned char  plu_sess_lim;
    unsigned char  dlc_name[8];
    unsigned char  adapter_num;
    unsigned char  dest_addr_len;
    unsigned char  dest_addr[32];
    unsigned int   par_sess_supp:1;
    unsigned int   reserv4:7;
    unsigned int   def_already_ver:1;
    unsigned int   def_conv_sec:1;
    unsigned int   def_sess_sec:1;
    unsigned int   reserv5:5;
    unsigned int   act_already_ver:1;
    unsigned int   act_conv_sec:1;
    unsigned int   reserv6:6;
    unsigned int   implicit_part:1;
    unsigned int   reserv7:7;
} PLU62_OVERLAY;
```

Members

plu62_entry_len

Size of this partner LU entry.

plu62_overlay_len

This value contains **sizeof(**struct **plu62_overlay)**–**sizeof(plu62_entry_len)**.

plu_alias

Partner LU alias (ASCII).

num_modes

Number of modes.

plu_un_name

Partner LU uninterpreted name (EBCDIC).

fqplu_name

Fully qualified partner LU name (EBCDIC type A).

reserv3

Reserved field set to zero.

plu_sess_lim

Partner LU session limit, 0–255.

dlc_name

DLC name (ASCII).

adapter_num

DLC adapter number.

dest_addr_len

Length of destination adapter address.

dest_addr

Destination adapter address.

par_sess_supp

Bit 15 of a bitfield specifying parallel sessions. Valid values are AP_NOT_SUPPORTED and AP_SUPPORTED.

reserv4

Bits 8–14 of a bitfield specifying a reserved field set to zero.

def_already_ver

Bit 7 of a bitfield specifying whether the configured already verified option is supported. Valid values are AP_NOT_SUPPORTED and AP_SUPPORTED.

def_conv_sec

Bit 6 of a bitfield specifying whether the configured conversation security option is supported. Valid values are AP_NOT_SUPPORTED and AP_SUPPORTED.

def_sess_sec

Bit 5 of a bitfield specifying whether the configured session security option is supported. Valid values are AP_NOT_SUPPORTED and AP_SUPPORTED.

reserv5

Bits 0–4 of a bitfield specifying a reserved field set to zero.

act_already_ver

Bit 15 of a bitfield specifying whether the active already verified option is supported. Valid values are AP_NOT_SUPPORTED and AP_SUPPORTED.

act_conv_sec

Bit 14 of a bitfield specifying whether the active conversation security option is supported. Valid values are AP_NOT_SUPPORTED and AP_SUPPORTED.

reserv6

Bits 8–13 of a bitfield specifying a reserved field set to zero.

implicit_part

Bit 7 of a bitfield specifying whether this is an implicit partner. Valid values are AP_NO and AP_YES.

For partner LU group, **implicit_part** indicates the partner LU group was configured as an implicit primary logical unit (PLU).

reserv7

Bits 0–6 of a bitfield specifying a reserved field set to zero.

Remarks

Host Integration Server returns information on all the configured LU 6.2s in the system, including the implicit PLU and all instances of implicit modes. IBM ES for OS/2 version 1.0 only returns information on those that are in use or have been in use.

For partner LU group, **implicit_part** indicates the partner LU group was configured as an implicit primary logical unit (PLU).

For mode group, **implicit_mode** bitfield returned in the **mode_overlay** structure indicates the mode group was configured as an implicit mode.

Session Information

Information on session information is provided in the **sess_info_sect** structure as defined below.

Syntax

```
typedef struct sess_info_sect {
    unsigned long  sess_sect_len;
    unsigned short num_sessions;
    unsigned short total_sessions;
} SESS_INFO_SECT;
```

Members

sess_sect_len

The length of the initial session information section, including this parameter, up to the first session group. The length does not include any previous information sections.

num_sessions

The number of session groups returned by the **DISPLAY** verb into your program's buffer. This is the number of times the session group is repeated.

total_sessions

The total number of session groups. This number is the same as the number returned in the **num_sessions** member except when APPC has more information about session groups than it can place in the supplied buffer, in which case this number is larger.

For each session group, a **sess_overlay** structure for the session is provided as defined below.

Syntax

```
typedef struct sess_overlay {
    unsigned long  sess_entry_len;
    unsigned long  reserv3;
    unsigned char  sess_id[8];
    unsigned long  conv_id[8];
    unsigned char  lu_alias[8];
    unsigned char  plu_alias[8];
    unsigned char  mode_name[8];
    unsigned short send_ru_size;
    unsigned short rcv_ru_size;
    unsigned short send_pacing_size;
    unsigned short rcv_pacing_size;
    unsigned char  link_id[12];
    unsigned char  daf;
    unsigned char  oaf;
    unsigned char  odai;
    unsigned char  sess_type;
    unsigned char  conn_type;
    unsigned char  reserv4;
    FPCID_OVERLAY  fpcid;
    unsigned char  cgid[4];
    unsigned char  fqlu_name[17];
    unsigned char  fqplu_name[17];
    unsigned char  pacing_type;
    unsigned char  reserv5;
 } SESS_OVERLAY;
```

Defined by IBM ES for OS/2 version 1.0

Members

sess_entry_len

Size of this session group entry.

sess_id

The internal identifier of the session for which this information is displayed.

conv_id

The unique four-byte ID of the conversation currently using this session.

lu_alias

LU alias (ASCII).

plu_alias

Partner LU alias (ASCII).

mode_name

The name of the mode (EBCDIC).

send_ru_size

The maximum RU size used on this session and this **mode_name** for sending RUs.

rcv_ru_size

The maximum RU size used on this session and this **mode_name** for receiving RUs.

send_pacing_size

The size of the send pacing window on this session.

rcv_pacing_size

The size of the receive pacing window on this session.

link_id

Name of local logical link station.

daf

The destination address field for this session.

oaf

The origin address field for this session.

odai

The origin destination address indicator field for this session.

sess_type

The type of the session. The session type can be one of the following:

SSCP_PU_SESSION

This session is between a workstation physical unit and a host system services control point. This type of session exists if the local node contains a dependent LU, or if the session has been solicited in order to send alerts to the host.

SSCP_LU_SESSION

This session is between a dependent LU and a host system services control point.

LU_LU _SESSION

This session is between two LUs.

conn_type

Indicates whether the session activation protocol follows the rules for an independent LU or a dependent LU. The connection type can be one of the following:

AP_HOST_SESSION

For dependent LU protocols, the workstation LU is defined as dependent at the host, the host LU sends the session activation request (BIND), and each workstation LU can support only one session at a time.

AP_PEER_SESSION

For independent LU protocols, an LU can send a BIND, and can have multiple sessions to different partners, or parallel sessions to the same partner LU.

fq_pc_id

Fully qualified procedure correlation identifier of the session.

cgid

Unique identifier for the conversation group of the session.

fqlu_name

The fully-qualified LU name in EBCDIC (type A).

fqplu_name

The fully-qualified partner LU name in EBCDIC (type A).

pacing_type

The pacing type can be one of the following:

AP_FIXED

Fixed pacing.

AP_ADAPTIVE

Adaptive pacing.

Returned by Host Integration Server

Members
sess_entry_len

Size of this session group entry.

sess_id

The internal identifier of the session for which this information is displayed.

conv_id

The unique four-byte ID of the conversation currently using this session.

lu_alias

LU alias (ASCII).

plu_alias

Partner LU alias (ASCII).

mode_name

The name of the mode (EBCDIC).

mode_name

The name of the mode (EBCDIC).

send_ru_size

The maximum RU size used on this session and this **mode_name** for sending RUs.

rcv_ru_size

The maximum RU size used on this session and this **mode_name** for receiving RUs.

send_pacing_size

The size of the send pacing window on this session.

rcv_pacing_size

The size of the receive pacing window on this session.

link_id

Connection name.

daf

The destination address field for this session.

oaf

The origin address field for this session.

odai

The origin destination address indicator field for this session.

sess_type

The type of the session. The session type can be one of the following:

SSCP_PU_SESSION

This session is between a workstation physical unit and a host system services control point. This value is never returned by Host Integration Server.

SSCP_LU_SESSION

This session is between a dependent LU and a host system services control point.

LU_LU _SESSION

This session is between two LUs.

conn_type

Indicates whether the session activation protocol follows the rules for an independent LU or a dependent LU. The connection type can be one of the following:

AP_HOST_SESSION

For dependent LU protocols, the workstation LU is defined as dependent at the host, the host LU sends the session activation request (BIND), and each workstation LU can support only one session at a time.

AP_PEER_SESSION

For independent LU protocols, an LU can send a BIND, and can have multiple sessions to different partners, or parallel sessions to the same partner LU.

AP_BOTH_SESSION

Connections can support both Dependent and Independent LUs.

fq_pc_id

Set to zero.

cgid

Set to zero.

type_of_pacing

The pacing type can be one of the following:

AP_FIXED

Fixed pacing.

AP_ADAPTIVE

Adaptive pacing. This value is never returned by Host Integration Server.

Active Link Information

Active link information is provided in the **link_info_sect** structure as defined below.

Syntax

```
typedef struct link_info_sect {
    unsigned long  link_init_sect_len;
    unsigned short num_links;
    unsigned short total_links;
} LINK_INFO_SECT;
```

Members

link_init_sect_len

The length of the initial active link information section, including this parameter, up to the first link overlay group. The length does not include any previous information sections.

num_links

The number of active links returned by the **DISPLAY** verb into your program's buffer. This is the number of times the link overlay group is repeated.

total_links

The total number of active links. This number is the same as the number returned in the **num_links** member except when APPC has more information about active links than it can place in the supplied buffer, in which case this number is larger.

For each active link, a **link_overlay** structure for the active link is provided as defined below.

Syntax

```
typedef struct link_overlay {
    unsigned long  link_entry_len;
    unsigned char  link_id[12];
    unsigned long  dlc_name[8];
    unsigned char  adapter_num;
    unsigned char  dest_addr_len;
    unsigned char  dest_addr[32];
    unsigned char  inbound_outbound;
    unsigned char  state;
    unsigned char  deact_link_flag;
    unsigned char  reserv3;
    unsigned short num_sessions;
    unsigned short ru_size;
    unsigned short reserv4;
    unsigned char  adj_fq_cp_name[17];
    unsigned char  adj_node_type;
    unsigned char  reserv5;
    unsigned char  cp_cp_sess_spt;
    unsigned char  conn_type;
    unsigned char  ls_role;
    unsigned char  line_type;
    unsigned char  tg_number;
    unsigned long  eff_capacity;
    unsigned char  conn_cost;
    unsigned char  byte_cost;
    unsigned char  propagation_delay;
    unsigned char  user_def_1;
    unsigned char  user_def_2;
    unsigned char  user_def_3;
    unsigned char  security;
    unsigned char  reserv6;
 } LINK_OVERLAY;
```

Defined by IBM ES for OS/2 version 1.0

Members

link_entry_len

Size of this link entry.

link_id

Local logical link station name (EBCDIC).

dlc_name

Data link control (DLC) name set to one of the following:

ETHERAND

IBMTRNET

IBMPCNET

SDLC

TWINAX (Not supported by Host Integration Server 2009)

X25DLC

adapter_num

Adapter number used by this link to connect to the adjacent node.

dest_addr_len

Length of the destination adapter address.

dest_addr

The destination adapter address.

inbound_outbound

The direction of the link. Values can be:

AP_OUTBOUND

The link is outbound.

AP_INBOUND

The link is inbound.

state

The state of the link. The link state can be one of the following:

AP_CONALS_PND

The process to bring up the link has started but XID negotiation has not started.

AP_XID_PND

XID negotiation is in process.

AP_CONTACT_PND

XID negotiation has been completed but the final response from the DLC has not been received.

AP_CONTACTED

The link is fully functioning.

AP_DISC_PND

A request to disconnect the link has been issued to the DLC.

AP_DISC_RQ

The operator has requested that the link be disconnected.

deact_link_flag

Deactivate logical link.

reserv3

A reserved field.

num_sessions

Number of active sessions.

ru_size

RU size.

reserv4

A reserved field.

adj_fq_cp_name

Fully qualified **cp_name** in adjacent node.

adj_node_type

The adjacent node type (NN, EN, or LEN).

cp_cp_sess_spt

Specifies whether the link supports CP-CP sessions.

conn_type

Indicates whether the session activation protocol follows the rules for an independent LU or a dependent LU. The connection type can be one of the following:

AP_HOST_SESSION

For dependent LU protocols, the workstation LU is defined as dependent at the host, the host LU sends the session activation request (BIND), and each workstation LU can support only one session at a time.

AP_PEER_SESSION

For independent LU protocols, an LU can send a BIND, and can have multiple sessions to different partners, or parallel sessions to the same partner LU.

AP_BOTH_SESSION

Connections can support both Dependent and Independent LUs.

ls_role

Specifies the link station role.

line_type

The line type.

tg_number

Transmission group number.

eff_capacity

Highest bit rate transmission effective capacity supported.

conn_cost

Relative cost per connection time using this link.

byte_cost

Relative cost of transmitting a byte over link.

propagation_delay

Indicates amount of time for signal to travel length of link. Set to one of the following:

AP_PROP_DELAY_MINIMUM

AP_PROP_DELAY_LAN

AP_PROP_DELAY_TELEPHONE

AP_PROP_DELAY_PKT_SWITCHED_NET

AP_PROP_DELAY_SATELLITE

AP_PROP_DELAY_MAXIMUM

user_def_1

User-defined TG characteristics.

user_def_2

User-defined TG characteristics.

user_def_3

User-defined TG characteristics.

security

The security value for this link. Set to one of the following:

AP_SEC_NONSECURE

AP_SEC_PUBLIC_SWITCHED_NETWORK

AP_SEC_UNDERGROUND_CABLE

AP_SEC_SECURE_CONDUIT

AP_SEC_GUARDED_CONDUIT

AP_SEC_ENCRYPTED

AP_SEC_GUARDED_RADIATION

reserv6

A reserved field.

Returned by Host Integration Server

Members

link_entry_len

Size of this link entry.

link_id

Connection name.

dlc_name

DLC name set to one of the following:

IBMTRNET

SDLC

X25DLC

adapter_num

Adapter number used by this link to connect to the adjacent node. Always set to zero.

dest_addr_len

Length of the destination adapter address.

dest_addr

The destination adapter address.

inbound_outbound

The direction of the link. Values can be:

AP_OUTBOUND

The link is outbound.

AP_INBOUND

The link is inbound.

state

The state of the link. The link state can be one of the following:

AP_CONALS_PND

The process to bring up the link has started but XID negotiation has not started.

AP_XID_PND

XID negotiation is in process.

AP_CONTACT_PND

XID negotiation has been completed but the final response from the DLC has not been received.

AP_CONTACTED

The link is fully functioning.

AP_DISC_PND

A request to disconnect the link has been issued to the DLC.

AP_DISC_RQ

The operator has requested that the link be disconnected.

deact_link_flag

Deactivate logical link.

num_sessions

Number of active sessions.

ru_size

RU size.

adj_fq_cp_name

Fully qualified **cp_name** in adjacent node. Always set to EBCDIC spaces.

adj_node_type

The adjacent node type. Always set to AP_LEN.

cp_cp_sess_spt

Specifies whether the link supports CP-CP sessions. Always set to AP_NO.

conn_type

Indicates whether the session activation protocol follows the rules for an independent LU or a dependent LU. The connection type can be one of the following:

AP_HOST_SESSION

For dependent LU protocols, the workstation LU is defined as dependent at the host, the host LU sends the session activation request (BIND), and each workstation LU can support only one session at a time.

AP_PEER_SESSION

For independent LU protocols, an LU can send a BIND, and can have multiple sessions to different partners, or parallel sessions to the same partner LU.

ls_role

Specifies the link station role.

line_type

The line type.

tg_number

Transmission group number. Always set to zero.

effective_capacity

Highest bit rate transmission effective capacity supported. Always set to zero.

conn_cost

Relative cost per connection time using this link. Always set to zero.

byte_cost

Relative cost of transmitting a byte over link. Always set to zero.

propagation_delay

Indicates amount of time for signal to travel length of link. This parameter is always set to AP_PROP_DELAY_MAXIMUM.

user_def_1

User-defined TG characteristics. Always set to zero.

user_def_2

User-defined TG characteristics. Always set to zero.

user_def_3

User-defined TG characteristics. Always set to zero.

security

The security value for this link. Always set to AP_SEC_NONSECURE.

LU 0 to 3 Information

LU 0 to 3 information is provided in the **lu_0_3_info_sect** structure as defined below.

Syntax

```
typedef struct lu_0_3_info_sect {
    unsigned long  lu_0_3_init_sect_len;
    unsigned short num_lu_0_3s;
} LU_0_3_ INFO_SECT;
```

Members

lu_0_3_init_sect_len

The length of the initial LU 0 to 3 information section, including this parameter, up to the first link overlay group. The length does not include any previous information sections.

num_lu_0_3s

The number of LU groups. This is the number of times the lu_0_3 overlay group is repeated.

For each configured LU, an **lu_0_3_overlay** structure for the LU is provided as defined below.

Syntax

```
typedef struct lu_0_3_overlay {
    unsigned long  lu_0_3_entry_len;
    unsigned char  access_type;
    unsigned char  lu_type;
    unsigned char  lu_daf;
    unsigned char  lu_short_name;
    unsigned char  lu_long_name[8];
    unsigned char  session_id[8];
    unsigned long  dlc_name[8];
    unsigned char  adapter_num;
    unsigned char  dest_addr_len;
    unsigned char  dest_addr[32];
    unsigned char  sscp_lu_sess_state;
    unsigned char  lu_lu_sess_state;
    unsigned char  link_id[12];
 } LU_0_3_OVERLAY;
```

Defined by IBM ES for OS/2 version 1.0

Members

lu_0_3_entry_len

Size of this LU entry.

access_type

The access type (AP_3270 or AP_LUA).

lu_type

The LU type (AP_LU0, AP_LU1, AP_LU2, or AP_LU3).

lu_daf

The network addressable unit of the LU for which the information is displayed.

lu_short_name

The 1-byte LU short name (ASCII).

lu_long_name

The 8-byte ASCII LU long name.

session_id

The LU-LU session ID.

dlc_name

DLC name set to one of the following:

ETHERAND

IBMTRNET

IBMPCNET

SDLC

TWINAX (Not supported by Host Integration Server 2009)

X25DLC

adapter_num

The DLC adapter number for host link.

dest_addr_len

Length of the destination adapter address.

dest_addr

The destination adapter address.

sscp_lu_sess_state

Specifies the state of the SSCP-LU session.

lu_lu_sess_state

Specifies the state of the LU-LU session. The state can be one of the following:

AP_NOT_BOUND

The LU-LU session is not bound.

AP_BOUND

The LU-LU session is bound.

AP_BINDING

The LU-LU session is in the process of binding.

AP_UNBINDING

The LU-LU session is in the process of unbinding.

link_id

Name of local logical link station being used.

Returned by Host Integration Server
Members
lu_0_3_entry_len

Size of this LU entry.

access_type

The access type (AP_3270 or AP_LUA).

lu_type

The LU type (AP_LU0, AP_LU1, AP_LU2, or AP_LU3).

lu_daf

The network addressable unit of the LU for which the information is displayed.

lu_short_name

The 1 byte ASCII LU short name.

lu_long_name

The 8 byte ASCII LU long name.

session_id

The LU-LU session ID.

dlc_name

DLC name set to one of the following:

IBMTRNET

SDLC

TWINAX (Not supported by Host Integration Server 2009)

X25DLC

adapter_num

The DLC adapter number for host link. Always set to zero.

dest_addr_len

Length of the destination adapter address.

dest_addr

The destination adapter address.

sscp_lu_sess_state

Specifies the state of the SSCP-LU session.

lu_lu_sess_state

Specifies the state of the LU-LU session. The state can be one of the following:

AP_NOT_BOUND

The LU-LU session is not bound.

AP_BOUND

The LU-LU session is bound.

AP_BINDING

The LU-LU session is in the process of binding.

AP_UNBINDING

The LU-LU session is in the process of unbinding.

link_id

Name of connection.

System Default Information

System default information is defined or returned as described here.

Defined by IBM ES for OS/2 version 1.0
Members
default_mode_name

Mode name used for undefined mode name is sent or received.

default_local_lu_name

Alias or local default LU.

implicit_partner_lu_support

Indicates if implicit partner LU support is enabled.

maximum_held_alerts

Number of alerts that will be held by NS/2 if there is no active link to a focal point.

default_tp_conversation_security_rqd

Specifies if conversation security is used for default TPs.

maximum_mc_ll_send_size

Maximum length of a logical record used on a mapped conversation for sending data to either the inbound or outbound implicit remote LU.

directory_for_inbound_attaches

Name of OS/2 directory used by Attach Manager.

default_tp_operation

Set to one of the following:

QUEUED_OPERATOR_STARTED

QUEUED_OPERATOR_PRELOADED

QUEUED_AM_STARTED

NONQUEUED_AM_STARTED

default_tp_program_type

Set to one of the following:

BACKGROUND

FULL_SCREEN

PRESENTATION_MANAGER

VIO_WINDOWABLE

Returned by Host Integration Server
Members
default_mode_name

Always set to NULL.

default_local_lu_name

Always set to spaces.

implicit_partner_lu_support

Always set to NO.

maximum_held_alerts

Always set to zero.

default_tp_conversation_security_rqd

Always set to NO.

maximum_mc_ll_send_size

Always set to 16384.

directory_for_inbound_attaches

Always returned * and indicates that the current path should be used.

default_tp_operation

Always set to QUEUED_AM_STARTED.

default_tp_program_type

Always set to FULL_SCREEN.

LU 6.2 Definition Information

There are no differences for this information type.

Partner Definition Information

Partner definition information is defined or returned as described here.

Defined by IBM ES for OS/2 version 1.0

Members

maximum_mc_ll_send_size

Maximum length of a logical record used on a mapped conversation for sending data to the partner LU.

number_of_alternate_aliases

Specifies number of alternate aliases configured.

Returned by Host Integration Server

maximum_mc_ll_send_size

Always set to 16384.

number_of_alternate_aliases

Always set to zero.

Mode Definition Information

Mode definition information is defined or returned as described here.

Defined by IBM ES for OS/2 version 1.0

Members
cos_name

Name of class of service.

Returned by Host Integration Server

Members
cos_name

Set to EBCDIC spaces.

Link Definition Information

Link definition information is provided in the **link_def_info_sect** structure as defined below.

Syntax

```
typedef struct link_def_info_sect {
    unsigned long  link_def_init_sect_len;
    unsigned short num_link_def;
    unsigned short total_link_def;
} LINK_DEF_INFO_SECT;
```

Members

link_def_init_sect_len

The length of the initial link definition information section, including this parameter, up to the first link definition overlay group. The length does not include any previous information sections.

num_link_def

The number of link definitions returned by the **DISPLAY** verb into your program's buffer. This is the number of times the link definition overlay is repeated.

total_link_def

The total number of link definitions. This number is the same as the number returned in the **num_link_def** member except when APPC has more information about link definitions than it can place in the supplied buffer, in which case this number is larger.

For each link definition, a **link_def_overlay** structure for the link definition is provided as defined below.

Syntax

```
typedef struct link_def_overlay {
    unsigned long  link_def_entry_len;
    unsigned char  link_name[8];
    unsigned char  adj_fq_cp_name[17];
    unsigned char  adj_node_type;
    unsigned long  dlc_name[8];
    unsigned char  adapter_num;
    unsigned char  dest_addr_len;
    unsigned char  dest_addr[32];
    unsigned char  preferred_nn_server;
    unsigned char  auto_act_link;
    unsigned char  tg_number;
    unsigned char  lim_res;
    unsigned char  solicit_sscp_session;
    unsigned char  initself;
    unsigned char  bind_support;
    unsigned char  ls_role;
    unsigned char  line_type;
    unsigned long  eff_capacity;
    unsigned char  conn_cost;
    unsigned char  byte_cost;
    unsigned char  propagation_delay;
    unsigned char  user_def_1;
    unsigned char  user_def_2;
    unsigned char  user_def_3;
    unsigned char  security;
    unsigned char  reserv;
 } LINK_OVERLAY;
```

Defined by IBM ES for OS/2 version 1.0

Members

link_def_entry_len

Size of this link definition entry.

link_name

Local logical link station name (EBCDIC).

dlc_name

Data link control (DLC) name set to one of the following:

ETHERAND

IBMTRNET

IBMPCNET

SDLC

TWINAX (Not supported by Host Integration Server 2009)

X25DLC

adj_fq_cp_name

Fully qualified **cp_name** in adjacent node.

adj_node_type

The adjacent node type (AP_ADJACENT_NN, AP_LEARN, or AP_LEN).

adapter_num

DLC adapter number used by this link.

dest_addr_len

Length of the destination adapter address.

dest_addr

The destination adapter address.

cp_cp_sess_spt

Specifies whether the link supports CP-CP sessions.

preferred_nn_server

Indicates if this is the preferred NN server.

auto_act_link

Indicates if the link should be automatically activated.

tg_number

Transmission group number.

lim_res

Indicates if this is a limited resource.

solicit_sscp_session

Indicates whether to solicit an SSCP session.

initself

Indicates if the node supports receiving INIT_SELF over this link.

bind_support

Indicates whether BIND support is available.

ls_role

Specifies the link station role.

line_type

The line type.

eff_capacity

Highest bit rate transmission effective capacity supported.

conn_cost

Relative cost per connection time using this link.

byte_cost

Relative cost of transmitting a byte over link.

propagation_delay

Indicates amount of time for signal to travel length of link. Set to one of the following:

AP_PROP_DELAY_MINIMUM

AP_PROP_DELAY_LAN

AP_PROP_DELAY_TELEPHONE

AP_PROP_DELAY_PKT_SWITCHED_NET

AP_PROP_DELAY_SATELLITE

AP_PROP_DELAY_MAXIMUM

user_def_1

User-defined TG characteristics.

user_def_2

User-defined TG characteristics.

user_def_3

User-defined TG characteristics.

security

The security value for this link. Set to one of the following:

AP_SEC_NONSECURE

AP_SEC_PUBLIC_SWITCHED_NETWORK

AP_SEC_UNDERGROUND_CABLE

AP_SEC_SECURE_CONDUIT

AP_SEC_GUARDED_CONDUIT

AP_SEC_ENCRYPTED

AP_SEC_GUARDED_RADIATION

Returned by Host Integration Server
Members
link_def_entry_len

Size of this link definition entry.

link_name

Local logical link station name (EBCDIC).

dlc_name

Data link control (DLC) name set to one of the following:

IBMTRNET

SDLC

X25DLC

adj_fq_cp_name

Fully qualified **cp_name** in adjacent node. Always set to EBCDIC spaces.

adj_node_type

The adjacent node type. Always set to AP_LEN.

adapter_num

DLC adapter number used by this link. Always set to zero.

dest_addr_len

Length of the destination adapter address.

dest_addr

The destination adapter address.

cp_cp_sess_spt

Specifies whether the link supports CP-CP sessions. Always set to AP_NO.

preferred_nn_server

Indicates if this is the preferred NN server.

auto_act_link

Indicates if the link should be automatically activated.

tg_number

Transmission group number. Always set to zero.

lim_res

Indicates if this is a limited resource.

solicit_sscp_session

Indicates whether to solicit an SSCP session.

initself

Indicates if the node supports receiving INIT_SELF over this link.

bind_support

Indicates whether BIND support is available.

ls_role

Specifies the link station role.

line_type

The line type.

effective_capacity

Highest bit rate transmission effective capacity supported. Always set to zero.

conn_cost

Relative cost per connection time using this link. Always set to zero.

byte_cost

Relative cost of transmitting a byte over link. Always set to zero.

propagation_delay

Indicates amount of time for signal to travel length of link. Set to one of the following: Always set to AP_PROP_DELAY_MAXIMUM.

user_def_1

User-defined TG characteristics. Always set to zero.

user_def_2

User-defined TG characteristics. Always set to zero.

user_def_3

User-defined TG characteristics. Always set to zero.

security

The security value for this link. Always set to AP_SEC_NONSECURE.

Management Services Information

Information on management services is provided in the **ms_info_sect** structure as defined below.

Syntax

```
typedef struct ms_info_sect {
    unsigned long  ms_init_sect_len;
    unsigned char  held_mds_mu_alerts;
    unsigned char  held_nmvt_alerts;
    unsigned short num_fps;
    unsigned short total_fps;
    unsigned short num_ms_appls;
    unsigned short total_ms_appls;
    unsigned short num_act_trans;
    unsigned short total_act_trans;
} MS_INFO_SECT;
```

Members

ms_init_sect_len

The length of the initial MS information section, including this parameter, up to the first MS focal point group. The length does not include any previous information sections.

held_mds_mu_alerts

The number of management service MDS alerts being held that will be sent to the management service alert focal point (FP) when one becomes available.

held_nmvt_alerts

The number of management service NMVT alerts being held that will be sent to the management service alert focal point (FP) when one becomes available.

num_fps

The number of management service focal points (MS FPs) for which the information listed under MS Focal Point Group is returned. This is the number of times the information group is repeated.

total_fps

The total number of management service focal points for which APPC has information. This number is the same as the number returned in the **num_fps** member except when APPC has more information about management service focal points than it can place in the supplied buffer, in which case this number is larger.

num_ms_appls

The number of registered MS applications for which the information listed under Registered MS Application Group is returned. This is the number of times the information group is repeated.

total_ms_appls

The total number of registered MS applications for which APPC has information. This number is the same as the number returned in the **num_ms_appls** member except when APPC has more information about registered MS applications than it can place in the supplied buffer, in which case this number is larger.

num_act_trans

The number of MS active transactions for which the information listed under MS Active Transaction Group is returned. This is the number of times the information group is repeated.

total_act_trans

The number or MS active transactions for which APPC has information. This number is the same as the number returned in the **num_act_trans** member except when APPC has more information about registered MS active transactions than it can place in the supplied buffer, in which case this number is larger.

For each local and remote management service focal point group, an **ms_fp_overlay** structure for the focal point group is provided as defined below.

Syntax

```
typedef struct ms_fp_overlay {
    unsigned long  ms_fp_entry_len;
    unsigned char  ms_appl_name[8];
    unsigned char  ms_category[4];
    unsigned char  fp_fq_cp_name[17];
    unsigned char  bkup_appl_name[8];
    unsigned char  bkup_fp_fq_cp_name[17];
    unsigned char  reserv1;
    unsigned char  fp_type;
    unsigned char  fp_status;
    unsigned char  fp_routing;
} MS_FP_OVERLAY;
```

Members

ms_fp_entry_len

Size of this management service focal point information entry.

ms_appl_name

The management service application name of the current active focal point (EBCDIC).

ms_category

The management service category.

fp_fq_cp_name

The fully qualified control point name of the node on which the current (active) management service focal point is located (EBCDIC). If the local node has no focal point, a value of all EBCDIC space characters (0x40) is returned.

bkup_appl_name

The management service application name of the backup focal point, if one is known (EBCDIC).

bkup_fp_fq_cp_name

The fully qualified control point name of the node on which the backup management service focal point is located, if one is known (EBCDIC). If the local node has no backup focal point, a value of all EBCDIC space characters (0x40) is returned.

fp_type

The type of the focal point for the local management service entry point node. The focal point type depends on how the focal point-end point relationship was established, and on whether the local node is configured as an NN, EN, or LEN node (an EN without CP-CP session support). The type can be one of the following:

AP_EXPLICIT_PRIMARY_FP

The current focal point type is explicit primary.

AP_BACKUP_FP

The current focal point type is back up.

AP_DEFAULT_PRIMARY_FP

The current focal point type is default primary.

AP_DOMAIN_FP

The current focal point type is domain.

AP_HOST_FP

The current focal point type is host.

AP_NO_FP

Currently the local node has no focal point.

fp_status

The status of the management service focal point. The status can be one of the following:

AP_NOT_ACTIVE

The focal point has been acquired, but has since become unavailable.

AP_ACTIVE

The remote focal point has been acquired and is available.

AP_PENDING

A request has been sent to a remote primary or backup focal point to acquire that FP, and its reply has not yet been received.

AP_NEVER_ACTIVE

The focal point has never been acquired, but one or more registered management service applications have requested focal point information.

fp_routing

The routing used to send unsolicited requests to the management service focal point when the local node is an EN. Note that requests from an NN are always sent directly to the focal point.

The routing can be one of the following:

AP_DEFAULT

Unsolicited management service requests destined for the focal point are sent from the EN to its serving NN for forwarding to the focal point.

AP_DIRECT

Unsolicited management service requests destined for the focal point are sent directly to the focal point.

Remarks

When a program registers a management service application name, it can request focal point information. When APPC acquires the focal point, it passes the program the focal point information, which includes the type of routing to use to send unsolicited management service requests to the focal point.

APPC TP Verbs

This section describes the Advanced Program-to-Program Communications (APPC) transaction program (TP) verbs. The description of each verb provides:

- A definition of the verb.
- The structure defining the verb control block (VCB) used by the verb. The structure is contained in the WINAPPC.H file. The length of each VCB field is in bytes. Fields beginning with reserv (for example, reserv2) are reserved.
- The parameters (VCB fields) supplied to and returned by APPC. A description of each parameter is provided, along with its possible values and other information.
- The conversation state(s) in which the verb can be issued.
- The state(s) to which the conversation can change upon return from the verb. Conditions that do not cause a state change are not noted. For example, parameter checks and state checks do not cause a state change.
- Additional information describing the verb.

Most parameters supplied to and returned by APPC are hexadecimal values. To simplify coding, these values are represented by meaningful symbolic constants, which are established by **#define** statements in the WINAPPC.H header file. For example, the **opcode** (operation code) member of the **mc_send_data** structure used by the **MC_SEND_DATA** verb is the hexadecimal value represented by the symbolic constant AP_M_SEND_DATA. Use only the symbolic constants when writing TPs.

In This Section

GET_TP_PROPERTIES

The **GET_TP_PROPERTIES** verb returns attributes of the transaction program (TP) and the current transaction.

The following structure describes the verb control block used by the **GET_TP_PROPERTIES** verb.

Syntax

```
struct get_tp_properties {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned char   tp_name[64];
    unsigned char   lu_alias[8];
    unsigned char   luw_id[26];
    unsigned char   fqlu_name[17];
    unsigned char   reserve3[10];
    unsigned char   user_id[10];
    unsigned char   prot_luw_id[26];
    unsigned char   pwd[10];
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_GET_TP_PROPERTIES.

opext

Supplied parameter. Specifies the verb operation extension. If the AP_EXTD_VCB bit is set, this indicates that the **get_tp_properties** structure includes the **prot_luw_id** member used for Sync Point support. Otherwise the verb control block ends immediately after the **user_id** member.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

tp_name

Returned parameter. Supplies the TP name of the TP that issued the verb. The name is returned as a 64-byte EBCDIC string, padded on the right with EBCDIC spaces.

lu_alias

Returned parameter. Supplies the alias name assigned to the local LU. It is returned as an 8-byte ASCII string padded on the right with ASCII spaces.

luw_id

Returned parameter. Supplies the unprotected logical unit-of-work identifier for the transaction in which the TP is participating. Several TPs can be involved in a transaction. This identifier, which is assigned on behalf of the TP initiating the

transaction, allows the conversation that makes up the transaction to be logically connected.

The **luw_id** can be represented as an **luw_id_overlay** structure with the following fields:

```
typedef struct luw_id_overlay { unsigned char fqla_name_len; unsigned char fqla_name[17]; nsigned char
instance[6]; unsigned char sequence[2];} LUW_ID_OVERLAY;
```

luw_id.fqla_name_len

A 1-byte length of the fully qualified LU name for the LU of the originating TP.

luw_id.fqla_name

The fully qualified name of the LU for the originating TP. The name is returned as a 17-byte EBCDIC string, consisting of the NETID, a period, and the LU name. If the length of the name is fewer than 17 bytes, the **instance** and **sequence** numbers follow immediately. (Note that because of this, you should not use the fields of the **luw_id_overlay** structure to access those values. These are provided for compatibility only.)

luw_id.instance

A 6-byte string uniquely generated by the LU for the originating TP.

luw_id.sequence

A 2-byte number that indicates the segment of unit-of-work. (This is always set to 1, if Sync Point is not supported.)

If the **luw_id** length is fewer than 26 bytes, it is padded on the right with EBCDIC spaces.

fqlu_name

Returned parameter. Supplies the fully qualified name of the local LU. The name is returned as a 17-byte EBCDIC string, consisting of the NETID, a period, and the LU name. The name is padded on the right with EBCDIC spaces.

reserve3

A reserved field.

user_id

Supplied parameter. Indicates the **user_id** supplied by the initiating TP in the allocation request. The name is supplied as a 10-byte EBCDIC string, padded on the right with EBCDIC spaces.

prot_luw_id

Returned parameter. Contains the protected logical unit-of-work identifier for the transaction in which the TP is participating, if the conversation was allocated with **synclevel** Sync Point.

Several TPs can be involved in a transaction. This identifier, which is assigned on behalf of the TP initiating the transaction, allows the conversation that makes up the transaction to be logically connected.

The **prot_luw_id** can be represented as an **luw_id_overlay** structure with the following fields:

```
typedef struct luw_id_overlay { unsigned char fqla_name_len; unsigned char fqla_name[17]; nsigned char
instance[6]; unsigned char sequence[2];} LUW_ID_OVERLAY;
```

luw_id.fqla_name_len

A 1-byte length of the fully qualified LU name for the LU of the originating TP.

luw_id.fqla_name

The fully qualified name of the LU for the originating TP. The name is returned as a 17-byte EBCDIC string, consisting of the NETID, a period, and the LU name. If the length of the name is fewer than 17 bytes, the **instance** and **sequence** numbers follow immediately. (Note that because of this, you should not use the fields of the **luw_id_overlay** structure to access those values. These are provided for compatibility only).

luw_id.instance

A 6-byte string uniquely generated by the LU for the originating TP.

luw_id.sequence

A 2-byte number that indicates the segment of unit-of-work. (This is always set to 1, if Sync Point is not supported.)

If the **prot_luw_id** length is fewer than 26 bytes, it is padded on the right with EBCDIC spaces.

pwd

Supplied parameter. Contains the password of the **user_id** of the initiating TP in the allocation request. The password is supplied as a 10-byte EBCDIC string, padded on the right with EBCDIC spaces.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_TP_BUSY

Primary return code; the local TP has issued a call to APPC while APPC was processing another call for the same TP. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **tp_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

This verb relates to the TP rather than a specification conversation, so the TP can issue the verb in any state. There is no state change.

The **luw_id** member contains fields for **fqla_name_len** (the length of the fully qualified LU name of the LU originating the TP), **fqla_name** (the fully qualified name of the LU originating the TP), **instance** (generated uniquely by the LU originating the TP), and **sequence** (always set to 1 and indicating the segment of unit-of-work).

SET_TP_PROPERTIES

The **SET_TP_PROPERTIES** verb enables a transaction program (TP) to set its logical unit-of-work identifiers (LUWIDs) to either an existing value, by providing the LUWIDs, or request that the SNA server generate new ones and use them from then on. When the LUWID is generated by the SNA server, it is guaranteed to be unique. This verb is used only if Sync Point support is enabled.

The following structure describes the verb control block (VCB) used by the **SET_TP_PROPERTIES** verb.

Syntax

```
struct set_tp_properties {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned char   set_prot_id;
    unsigned char   new_prot_id;
    unsigned char   prot_id[26];
    unsigned char   set_unprot_id;
    unsigned char   new_unprot_id;
    unsigned char   unprot_id[26];
    unsigned char   set_user_id;
    unsigned char   reserv3;
    unsigned char   user_id[10];
    unsigned char   reserv4[10];
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_SET_TP_PROPERTIES.

opext

Supplied parameter. Specifies the verb operation extension. The AP_EXTD_VCB bit must be set to indicate that the **set_tp_properties** structure requires Sync Point support.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

set_prot_id

Supplied parameter. Indicates whether the **prot_id** member should be modified. Legal values are AP_YES or AP_NO.

new_prot_id

Supplied parameter. Indicates whether Microsoft® Host Integration Server should use the supplied **prot_id** LUWID member or create a new LUWID. Legal values are AP_YES (create a new LUWID) or AP_NO (use the supplied LUWID).

prot_id

This member is the protected logical unit-of-work identifier for the transaction in which the TP is participating. It is ignored if **set_prot_id** is AP_NO. It is a supplied parameter if **new_unprot_id** is AP_NO or a returned parameter if **new_unprot_id** is AP_YES.

Several TPs can be involved in a transaction. This identifier, which is assigned on behalf of the TP initiating the transaction, allows the conversation that makes up the transaction to be logically connected.

The **prot_id** can be represented as an **luw_id_overlay** structure with the following fields:

```
typedef struct luw_id_overlay { unsigned char fqla_name_len; unsigned char fqla_name[17]; nsigned char
instance[6]; unsigned char sequence[2];} LUW_ID_OVERLAY;
```

luw_id.fqla_name_len

A 1-byte length of the fully qualified LU name for the LU of the originating TP.

luw_id.fqla_name

The fully qualified name of the LU for the originating TP. The name is returned as a 17-byte EBCDIC string, consisting of the NETID, a period, and the LU name. If the length of the name is fewer than 17 bytes, the **instance** and **sequence** numbers follow immediately. (Note that because of this, you should not use the fields of the **luw_id_overlay** structure to access those values. These are provided for compatibility only).

luw_id.instance

A 6-byte string uniquely generated by the LU for the originating TP.

luw_id.sequence

A 2-byte number that indicates the segment of unit-of-work. (This is always set to 1 if Sync Point is not supported.)

If the **luw_id** length is fewer than 26 bytes, it is padded on the right with EBCDIC spaces.

set_unprot_id

Supplied parameter. Indicates whether the **unprot_id** member should be modified. Legal values are AP_YES or AP_NO.

new_unprot_id

Supplied parameter. Indicates whether Host Integration Server should use the supplied **unprot_id** LUWID member or create a new LUWID. Legal values are AP_YES (create a new LUWID) or AP_NO (use the supplied LUWID).

unprot_id

This member is the unprotected logical unit-of-work identifier for the transaction in which the TP is participating. It is ignored if **set_unprot_id** is AP_NO. It is a supplied parameter if **new_unprot_id** is AP_NO or a returned parameter if **new_unprot_id** is AP_YES.

Several TPs can be involved in a transaction. This identifier, which is assigned on behalf of the TP initiating the transaction, allows the conversation that makes up the transaction to be logically connected.

The **prot_id** can be represented as an **luw_id_overlay** structure with the following fields:

```
typedef struct luw_id_overlay { unsigned char fqla_name_len; unsigned char fqla_name[17]; nsigned char
instance[6]; unsigned char sequence[2];} LUW_ID_OVERLAY;
```

luw_id.fqla_name_len

A 1-byte length of the fully qualified LU name for the LU of the originating TP.

luw_id.fqla_name

The fully qualified name of the LU for the originating TP. The name is returned as a 17-byte EBCDIC string, consisting of the NETID, a period, and the LU name. If the length of the name is fewer than 17 bytes, the **instance** and **sequence** numbers follow immediately. (Note that because of this, you should not use the fields of the **luw_id_overlay** structure to access those values. These are provided for compatibility only.)

luw_id.instance

A 6-byte string uniquely generated by the LU for the originating TP.

luw_id.sequence

A 2-byte number that indicates the segment of unit-of-work. (This is always set to 1 if Sync Point is not supported.)

If the **luw_id** length is fewer than 26 bytes, it is padded on the right with EBCDIC spaces.

set_user_id

Supplied parameter. Indicates whether the **user_id** member should be modified. Legal values are AP_YES or AP_NO.

reserve3

A reserved field.

user_id

Supplied parameter. Indicates the **user_id** that should be used by the initiating TP in the allocation request. The name is a 10-byte EBCDIC string, padded on the right with EBCDIC spaces. This parameter is ignored if **set_user_id** is AP_NO.

reserve4

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_TP_BUSY

Primary return code; the local TP has issued a call to APPC while APPC was processing another call for the same TP. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **tp_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

This verb relates to the TP rather than a specification conversation, so the TP can issue the verb in any state. There is no state change.

The **prot_id** and **unprot_id** members contain fields for **fqla_name_len** (the length of the fully qualified LU name of the LU

originating the TP), **fqla_name** (the fully qualified name of the LU originating the TP), **instance** (generated uniquely by the LU originating the TP), and **sequence** (always set to 1 and indicating the segment of unit-of-work).

It is the responsibility of the application (the Sync Point support component) to transmit the new LUWID PS header to the partner Sync Point support when the protected LUWID is changed. Similarly, when the new LUWID PS header is received, the application must inform the LU by issuing a **SET_TP_PROPERTIES** verb.

TP_ENDED

The **TP_ENDED** verb is issued by both the invoking and invoked transaction program (TP), and notifies APPC that the TP is ending.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use the WinAsyncAPPC function rather than the blocking version of this call.

The following structure describes the verb control block (VCB) used by the **TP_ENDED** verb.

Syntax

```
struct tp_ended {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned char   type;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_TP_ENDED.

opext

Supplied parameter. Specifies the verb operation extension. This field is not used by the **TP_ENDED** verb.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

type

Supplied parameter. Specifies the type of termination to be performed. The following are allowed values:

- AP_HARD indicates that all active verbs for the TP are terminated; the session(s) being used by the conversation(s) are ended. Both the local TP and the partner TP can receive conversation failure return codes (AP_DEALLOC_ABEND for mapped conversations and AP_DEALLOC_ABEND_PROG for basic conversations).

- AP_SOFT indicates that the TP waits for all active verbs to complete; the session being used by the conversation remains active.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_TP_ID

Secondary return code; APPC did not recognize the **tp_id** as an assigned TP identifier.

AP_BAD_TYPE

Secondary return code; the specified **type** value was not recognized by APPC.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_TP_BUSY

Primary return code; the local TP has issued a call to APPC while APPC was processing another call for the same TP. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **tp_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

In response to **TP_ENDED**, APPC frees the resources used by the TP. After this verb executes, the TP identifier is no longer valid; the TP cannot issue any more APPC conversation verbs.

The conversation can be in any state when the TP issues this verb.

If the conversation is in SEND state, **TP_ENDED** performs the function of DEALLOCATE or MC_DEALLOCATE with **dealloc_type** set to AP_FLUSH.

If the conversation is in a state other than RESET or SEND, **TP_ENDED** performs the function of **DEALLOCATE** or **MC_DEALLOCATE** with **dealloc_type** set to AP_ABEND (for a mapped conversation) or AP_ABEND_PROG (for a basic conversation).

After successful execution (**primary_rc** is AP_OK), there is no APPC state.

TP_STARTED

The **TP_STARTED** verb is issued by the invoking transaction program (TP), and notifies APPC that the TP is starting.

For the Microsoft® Windows® version 3.*x* system, it is recommended that you use the WinAsyncAPPC function rather than the blocking version of this call.

The following structure describes the verb control block used by the **TP_STARTED** verb.

Syntax

```
struct tp_started {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   lu_alias[8];
    unsigned char   tp_id[8];
    unsigned char   tp_name[64];
    unsigned char   syncpoint_rqd;
};
```

Remarks

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_TP_STARTED.

opext

Supplied parameter. Specifies the verb operation extension. If the AP_EXTD_VCB bit is set, this indicates that the **tp_started** structure includes the **syncpoint_rqd** member used for Sync Point support. Otherwise, the verb control block ends immediately after the **tp_name** member.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

lu_alias

Supplied parameter. Specifies the alias by which the local LU is known to the local TP.

The name must match an LU alias established during configuration. APPC checks the LU alias against the current Host Integration Server configuration file. Due to the client/server architecture used by Host Integration Server, however, this parameter is not validated until an ALLOCATE or MC_ALLOCATE is performed.

This parameter is an 8-byte ASCII character string. It can consist of the following ASCII characters:

- Uppercase letters
- Numerals from 0 through 9
- Spaces
- Special characters $, #, % and @

The first character of this string cannot be a space.

If the value of this parameter is fewer than eight bytes in length, pad it on the right with ASCII spaces (0x20).

To use an LU from the default LU pool, set this field to eight hexadecimal zeros. For more information, see Default LUs.

tp_id

Returned parameter. Identifies the newly established TP.

tp_name

Supplied parameter. Specifies the name of the local TP.

Under the Host Integration Server implementation of APPC, this parameter is ignored when issued by **TP_STARTED**. However, this parameter is required if the program runs under the IBM ES for OS/2 version 1.0 implementation of APPC.

This parameter is a 64-byte EBCDIC character string and is case-sensitive. The **tp_name** parameter can consist of the following EDCDIC characters:

- Uppercase and lowercase letters
- Numerals from 0 through 9
- Special characters $, #, @, and period (.)

If the TP name is fewer than 64 bytes in length, use EBCDIC spaces (0x40) to pad it on the right.

The SNA convention for a service TP name is up to four characters. The first character is a hexadecimal byte between 0x00 and 0x3F.

syncpoint_rqd

This optional parameter is only applicable if the AP_EXTD_VCB bit is set in the **opext** parameter and Sync Point services are required.

- AP_YES if Sync Point is required.
- AP_NO if Sync Point is not required.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_TP_BUSY

Primary return code; the local TP has issued a call to APPC while APPC was processing another call for the same TP.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

In response to **TP_STARTED**, APPC generates a TP identifier for the invoking TP. This identifier is a required parameter for subsequent APPC verbs issued by the invoking TP.

This must be the first APPC verb issued by the invoking TP. Consequently, no prior APPC state exists.

If the verb executes successfully (**primary_rc** is AP_OK), the state changes to RESET.

In This Section

- Default LUs

Default LUs

Any LU can be configured to be in a pool of default local LUs available for use by invoking transaction programs (TPs).

For a user or group who will be using TPs, 5250 emulators, and/or APPC applications, you can assign a default local APPC LU and a default remote APPC LU. If the invoking TP specifies the LU alias that it uses (in TP_STARTED), that LU alias must match a local APPC LU alias on the supporting SNA server. If the invoking TP leaves the LU alias blank in **TP_STARTED**, one of two methods for designating a default LU must be carried out on the supporting SNA server:

- Assign a default local APPC LU to the user or group that starts the invoking TP (that is, the user or group logged on at the system from which **TP_STARTED** is issued).

  —or—

- Designate one or more LUs as members of the default outgoing local APPC LU pool. The SNA server first attempts to determine the default local APPC LU of the associated user or group, then attempts to assign an available LU from the default outgoing local APPC LU pool; if these attempts fail, the SNA server rejects the request.

AS/400 Environment

In AS/400 environments, the ability to assign default APPC LUs to users or groups is especially useful because it gives the administrator centralized control over these LU assignments. In such environments, for each user or group, assign both a default local APPC LU and a default remote APPC LU. Assigning a default local APPC LU for each user fulfills the normal AS/400 procedure of assigning local LUs on a per-user basis. Assigning a default remote APPC LU is equivalent to assigning a default AS/400 for the user to connect to, since the remote LU designates the AS/400. By making these assignments, the administrator can centrally control the default AS/400 that a 5250 emulator user connects to.

TP_STARTED

APPC Conversation Verbs

This section describes the Advanced Program-to-Program Communications (APPC) conversation verbs. The description of each verb provides:

- A definition of the verb.
- The structure defining the verb control block (VCB) used by the verb. The structure is contained in the WINAPPC.H file. The length of each VCB field is in bytes. Fields beginning with reserv (for example, reserv2) are reserved.
- The parameters (VCB fields) supplied to and returned by APPC. A description of each parameter is provided, along with its possible values and other information.
- The conversation state(s) in which the verb can be issued.
- The state(s) to which the conversation can change upon return from the verb. Conditions that do not cause a state change are not noted. For example, parameter checks and state checks do not cause a state change.
- Additional information describing the verb.

Mapped conversation verbs are preceded by an **MC_** designator. For example, the mapped conversation verb **MC_ALLOCATE** corresponds to the basic conversation verb **ALLOCATE**.

Most parameters supplied to and returned by APPC are hexadecimal values. To simplify coding, these values are represented by meaningful symbolic constants, which are established by **#define** statements in the WINAPPC.H header file. For example, the **opcode** (operation code) member of the **mc_send_data** structure used by the **MC_SEND_DATA** verb is the hexadecimal value represented by the symbolic constant AP_M_SEND_DATA. Use only the symbolic constants when writing transaction programs (TPs).

ALLOCATE

The **ALLOCATE** verb is issued by the invoking transaction program (TP). It allocates a session between the local logical unit (LU) and partner LU and (in conjunction with RECEIVE_ALLOCATE) establishes a conversation between the invoking TP and the invoked TP. After this verb executes successfully, APPC generates a conversation identifier (**conv_id**). The **conv_id** is a required parameter for all other APPC conversation verbs.

The following structure describes the verb control block used by the **ALLOCATE** verb.

Syntax

```
struct allocate {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    conv_type;
    unsigned char    synclevel;
    unsigned char    reserv3[2];
    unsigned char    rtn_ctl;
    unsigned char    reserv4;
    unsigned long    conv_group_id;
    unsigned long    sense_data;
    unsigned char    plu_alias[8];
    unsigned char    mode_name[8];
    unsigned char    tp_name[64];
    unsigned char    security;
    unsigned char    reserv5[11];
    unsigned char    pwd[10];
    unsigned char    user_id[10];
    unsigned short   pip_dlen;
    unsigned char FAR * pip_dptr;
    unsigned char    reserv7;
    unsigned char    fqplu_name[17];
    unsigned char    reserv8[8];
    unsigned long    proxy_user;
    unsigned long    proxy_domain;
    unsigned char    reserv9[16];
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_ALLOCATE.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION. If the AP_EXTD_VCB bit is set, this indicates that an extended version of the verb control block is used. In this case, the **ALLOCATE** structure includes Sync Point support or privileged proxy feature support.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED.

conv_id

Returned parameter. Identifies the conversation established between the two TPs.

conv_type

Supplied parameter. Used only by **ALLOCATE** to specify the type of conversation to allocate and is either AP_BASIC_CONVERSATION or AP_MAPPED_CONVERSATION.

If **ALLOCATE** establishes a mapped conversation, the local TP must issue basic-conversation verbs and provide its own mapping layer to convert data records to logical records and logical records to data records. The partner TP can issue basic-conversation verbs and provide the mapping layer, or it can use mapped-conversation verbs (if the partner TP is using an implementation of APPC that supports mapped-conversation verbs). For more information, see your IBM SNA manual(s).

synclevel

Supplied parameter. Specifies the synchronization level of the conversation. It determines whether the TPs can request confirmation of receipt of data and confirm receipt of data.

- AP_NONE specifies that confirmation processing will not be used in this conversation.
- AP_CONFIRM_SYNC_LEVEL specifies that the TPs can use confirmation processing in this conversation.
- AP_SYNCPT specifies that TPs can use Sync Point Level 2 confirmation processing in this conversation.

reserv3

A reserved field.

rtn_ctl

Supplied parameter. Specifies when the local LU, acting on a session request from the local TP, should return control to the local TP. For information about sessions, see About Transaction Programs.

- AP_IMMEDIATE specifies that the LU allocates a contention-winner session, if one is immediately available, and returns control to the TP.
- AP_WHEN_SESSION_ALLOCATED specifies that the LU does not return control to the TP until it allocates a session or encounters one of the errors documented in Return Codes in this topic. (If the session limit is zero, the LU returns control immediately.) If a session is not available, the TP waits for one.
- AP_WHEN_SESSION_FREE specifies that the LU allocates a contention-winner or contention-loser session, if one is available or able to be activated, and returns control to the TP. If an error occurs, (as documented in Return Codes in this topic) the call will return immediately with the error in the **primary_rc** and **secondary_rc** fields.
- AP_WHEN_CONWINNER_ALLOCATED specifies that the LU does not return control until it allocates a contention-winner session or encounters one of the errors documented in Return Codes in this topic. (If the session limit is zero, the LU returns control immediately.) If a session is not available, the TP waits for one.
- AP_WHEN_CONV_GROUP_ALLOCATED specifies that the LU does not return control to the TP until it allocates the session specified by **conv_group_id**or encounters one of the errors documented in Return Codes in this topic. If a session is not available, the TP waits for it to become free.

Note
AP_IMMEDIATE is the only value for **rtn_ctl** that never causes a new session to start. For values other than AP_IMMEDIATE, if an appropriate session is not immediately available, Host Integration Server 2009 tries to start one. This causes the on-demand connection to be activated.

reserv4

A reserved field.

conv_group_id

Supplied/returned parameter. Specifies the identifier of the conversation group from which the session should be allocated. The **conv_group_id** is required only if **rtn_ctl**is set to WHEN_CONV_GROUP_ALLOC. When**rtn_ctl** specifies a different value and the **primary_rc** is AP_OK, this is a returned value.

sense_data

Returned parameter. Indicates an allocation error (retry or no-retry) and contains sense data.

plu_alias

Supplied parameter. Specifies the alias by which the partner LU is known to the local TP.

The **plu_alias** must match the name of a partner LU established during configuration.

The parameter is an 8-byte ASCII character string. It can consist of the following ASCII characters:

- Uppercase letters
- Numerals 0 through 9
- Spaces
- Special characters $, #, %, and @

The first character of this string cannot be a space.

If the value of this parameter is fewer than eight bytes, pad it on the right with ASCII spaces (0x20).

If you want to specify the partner LU with the **fqplu_name** parameter, fill this parameter with binary zeros.

For a user or group using TPs, 5250 emulators, and/or APPC applications, the system administrator can assign default local and remote LUs. In this case, the field is left blank or null and the default LUs are accessed when the user or group member starts an APPC program. For more information on default LUs, see Microsoft Host Integration Server 2009 Help.

mode_name

Supplied parameter. Specifies the name of a set of networking characteristics defined during configuration.

The value of **mode_name** must match the name of a mode associated with the partner LU during configuration.

The parameter is an 8-byte EBCDIC character string. It can consist of characters from the type A EBCDIC character set:

- Uppercase letters
- Numerals 0 through 9
- Special characters $, #, and @

The first character in the string must be an uppercase letter or a special character.

Do not use SNASVCMG in a mapped conversation. SNASVCMG is a reserved **mode_name** used internally by APPC. Using this name in a basic conversation is not recommended.

tp_name

Supplied parameter. Specifies the name of the invoked TP. The value of **tp_name** specified by **ALLOCATE** in the invoking TP must match the value of **tp_name** specified by RECEIVE_ALLOCATE in the invoked TP.

The parameter is a 64-byte EBCDIC character string and is case-sensitive. The **tp_name** parameter can consist of the following EBCDIC characters:

- Uppercase and lowercase letters

- Numerals 0 through 9
- Special characters $, #, @, and period (.)

If **tp_name** is fewer than 64 bytes, use EBCDIC spaces (0x40) to pad it on the right.

The SNA convention is that a service TP name can have up to four characters. The first character is a hexadecimal byte between 0x00 and 0x3F. The other characters are from the type AE EBCDIC character set.

security

Supplied parameter. Provides the information that the partner LU requires to validate access to the invoked TP.

Based on the conversation security established for the invoked TP during configuration, use one of the following values:

- AP_NONE for an invoked TP that uses no conversation security.
- AP_PGM for an invoked TP that uses conversation security and thus requires a user identifier and password. Supply this information through the **user_id** and **pwd** parameters.
- AP_PROXY_PGM for an invoked TP with privileged proxy that uses conversation security and thus requires a user identifier and password. Pointers must be set up for **proxy_user** and **proxy_domain** to point to Unicode strings containing the user name and domain name of the user to be impersonated. The application does not need to set the **user_id** and **pwd** fields.
- AP_PROXY_SAME for a TP that has been invoked using privileged proxy with a valid user identifier and password supplied by the proxy, which in turn invokes another TP. Pointers must be set up for **proxy_user** and **proxy_domain** to point to Unicode strings containing the user name and domain name of the user to be impersonated. The application does not need to set the **user_id** and **pwd** fields.

For example, assume that TP A invokes TP B with a valid user identifier and password supplied by the privileged proxy, and TP B in turn invokes TP C. If TP B specifies the value AP_PROXY_SAME, APPC will send the LU for TP C the user identifier from TP A and an already-verified indicator. This indicator tells TP C to not require the password (if TP C is configured to accept an already-verified indicator).

- AP_PROXY_STRONG for an invoked TP with privileged proxy that uses conversation security and thus requires a user identifier and password provided by the privileged proxy mechanism. Pointers must be set up for **proxy_user** and **proxy_domain** to point to Unicode strings containing the user name and domain name of the user to be impersonated. The application does not need to set the **user_id** and **pwd** fields. AP_PROXY_STRONG differs from AP_PROXY_PGM in that AP_PROXY_STRONG does not allow clear-text passwords. If the remote system does not support encrypted passwords (strong conversation security), then this call fails.
- AP_SAME for a TP that has been invoked with a valid user identifier and password, which in turn invokes another TP.

For example, assume that TP A invokes TP B with a valid user identifier and password, and TP B in turn invokes TP C. If TP B specifies the value AP_SAME, APPC will send the LU for TP C the user identifier from TP A and an already-verified indicator. This indicator tells TP C to not require the password (if TP C is configured to accept an already-verified indicator).

When AP_SAME is used in an **ALLOCATE** verb, your application must always provide values for the **user_id** and **pwd** parameters in the verb control block. Depending on the properties negotiated between the SNA server and the peer LU, the **ALLOCATE** verb will send one of three kinds of Attach (FMH-5) messages, in this order of precedence:

1. If the LUs have negotiated "already verified" security, then the Attach sent by the SNA server will not include the contents of the **pwd** parameter field specified in the VCB.
2. If the LUs have negotiated "persistent verification" security, then the Attach sent by the SNA server will include the **pwd** parameter specified in the VCB, but only when the Attach is the first for the specified **user_id** parameter since the start of the LU-LU session, and will omit the **pwd** parameter on all subsequent Attaches (issued by your application or any other application using this LU-LU-mode triplet).

3. If the LUs have not negotiated either of the above, then the Attach sent by the SNA server will omit both the **user_id** and **pwd** parameters on all Attaches.

   Your application cannot tell which mode of security has been negotiated between the LUs, nor can it tell whether the **ALLOCATE** verb it is issuing is the first for that LU-LU-mode triplet. So your application must always set the **user_id** and **pwd** parameter fields in the VCB when **security** is set to AP_SAME.

   For more information on persistent verification and already verified security, see the SNA Formats Guide, section "FM Header 5: Attach (LU 6.2)".

- AP_STRONG for an invoked TP that uses conversation security and thus requires a user identifier and password. Supply this information through the **user_id** and **pwd** parameters. AP_STRONG differs from AP_PGM in that AP_STRONG does not allow clear-text passwords. If the remote system does not support encrypted passwords (strong conversation security), then this call fails.

  If the APPC automatic logon feature is to be used, **security** must be set to AP_PGM. See the Remarks section for details.

reserv5

A reserved field.

pwd

Supplied parameter. Specifies the password associated with **user_id**.

The **pwd** parameter is required only if **security** is set to AP_PGM or AP_SAME. It must match the password for **user_id** that was established during configuration.

The **pwd** parameter is a 10-byte EBCDIC character string and is case-sensitive. It can consist of the following EBCDIC characters:

- Uppercase and lowercase letters
- Numerals 0 through 9
- Special characters $, #, @, and period (.)

If the password is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

If the APPC automatic logon feature is to be used, the **pwd** character string must be hard-coded to MS$SAME. See the Remarks section for details.

user_id

Supplied parameter. Specifies the user identifier required to access the partner TP. It is required only if the security parameter is set to AP_PGM or AP_SAME.

The **user_id** parameter is a 10-byte EBCDIC character string and is case-sensitive. It must match one of the user identifiers configured for the partner TP.

The parameter can consist of the following EBCDIC characters:

- Uppercase and lowercase letters
- Numerals 0 through 9
- Special characters $, #, @, and period (.)

If **user_id** is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

If the APPC automatic logon feature is to be used, the **user_id** character string must be hard-coded to MS$SAME. See the Remarks section for details.

pip_dlen

Supplied parameter. Specifies the length of the program initialization parameters (PIP) to be passed to the partner TP. The range is from 0 through 32767.

pip_dptr

Supplied parameter. Specifies the address of the buffer containing PIP data. Use this parameter only if **pip_dlen** is greater than zero.

PIP data can consist of initialization parameters or environmental setup information required by a partner TP or remote operating system. The PIP data must follow the general data stream (GDS) format. For more information, see *SNA LU6.2 Reference: Peer Protocols* published by IBM.

For Microsoft Windows® 2000, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

reserv7

A reserved field.

fqplu_name

Supplied parameter. Specifies the fully qualified name of the partner LU. This must match the fully qualified name of the local LU defined in the remote node. The parameter consists of two type A EBCDIC character strings for the NETID and the LU name of the partner LU. The names are separated by an EBCDIC period (.).

This name must be provided if no **plu_alias** is specified. It can consist of the following EBCDIC characters:

- Uppercase letters
- Numerals 0 through 9
- Special characters $, #, and @

If the value of this parameter is fewer than 17 bytes, pad it on the right with EBCDIC spaces (0x40).

reserv8

A reserved field.

proxy_user

Supplied parameter. Specifies a LPWSTR pointing to a Unicode string containing the user name to be impersonated using the privileged proxy feature. This field can only be used when the AP_EXTD_VCB bit is set on the **opext** field, indicating an extended VCB.

proxy_domain

Supplied parameter. Specifies a LPWSTR pointing to a Unicode string containing the domain name of the user to be impersonated using the privileged proxy feature. This field can only be used when the AP_EXTD_VCB bit is set on the **opext** field, indicating an extended VCB.

reserv9

A reserved field.

Return Codes
AP_OK

Primary return code; the verb executed successfully.

AP_UNSUCCESSFUL

Primary return code; the supplied parameter **rtn_ctl** specified immediate (AP_IMMEDIATE) return of control to the TP, and the local LU did not have an available contention-winner session.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_RETURN_CONTROL

Secondary return code; the value specified for **rtn_ctl** was invalid.

AP_BAD_SECURITY

Secondary return code; the value specified for **security** was invalid.

AP_BAD_SYNC_LEVEL

Secondary return code; the value specified for **sync_level** was invalid.

AP_BAD_TP_ID

Secondary return code; the value specified for **tp_id** was invalid.

AP_PIP_LEN_INCORRECT

Secondary return code; the value of **pip_dlen** was greater than 32767.

AP_UNKNOWN_PARTNER_MODE

Secondary return code; the value specified for **mode_name** was invalid.

AP_BAD_PARTNER_LU_ALIAS

Secondary return code; APPC did not recognize the supplied **partner_lu_alias**.

AP_BAD_CONV_TYPE (for a basic conversation)

Secondary return code; the value specified for **conv_type** was invalid.

AP_NO_USE_OF_SNASVCMG (for a mapped conversation)

Secondary return code; SNASVCMG is not a valid value for **mode_name**.

AP_INVALID_DATA_SEGMENT

Secondary return code; the PIP data was longer than the allocated data segment, or the address of the PIP data buffer was wrong.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after **ALLOCATE**.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with **ALLOCATE**, it can indicate that no communications system could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for system configured with multiple nodes using Host Integration Server, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

ALLOCATE can establish either a basic or mapped conversation.

The conversation state is RESET when the TP issues this verb. After successful execution (**primary_rc** is AP_OK), the state changes to SEND. If the verb does not execute, the state remains unchanged.

Several parameters of **ALLOCATE** are EBCDIC or ASCII strings. A TP can use the common service verb (CSV) CONVERT to translate a string from one character set to the other.

To send the **ALLOCATE** request immediately, the invoking TP can issue FLUSH or CONFIRM immediately after **ALLOCATE**. Otherwise, the **ALLOCATE** request accumulates with other data in the local LU's send buffer until the buffer is full.

By issuing **CONFIRM** after **ALLOCATE**, the invoking TP can immediately determine whether the allocation was successful (if **synclevel** is set to AP_CONFIRM_SYNC_LEVEL).

Normally, the value of the **ALLOCATE** verb's **mode_name** parameter must match the name of a mode configured for the invoked TP's node and associated during configuration with the partner LU.

If one of the modes associated with the partner LU on the invoked TP's node is an implicit mode, the session established between the two LUs will be of the implicit mode when no mode name associated with the partner LU matches the value of **mode_name**.

Host Integration Server supports a feature called password substitution. This is a security feature supported by the latest version of the OS/400 operating system (V3R1) which encrypts any password that flows between two nodes on an Attach message. A password flows on an Attach whenever someone invokes an APPC transaction program specifying a user identifier and password. For example, this happens whenever anyone logs on to an AS/400.

Support for password substitution is indicated by setting bit 5 in byte 23 of the BIND request to 1 (which indicates that password substitution is supported). If the remote system sets this bit in the BIND response, the SNA server automatically encrypts the LU 6.2 conversation security password included in the FMH-5 Attach message. APPC applications using Host Integration Server 2009 automatically take advantage of this feature by setting the security field of the VCB to AP_PGM or AP_STRONG in the **ALLOCATE** request.

If an APPC application wants to force an encrypted password to flow, the application can specify AP_STRONG for the security field in the VCB in the **ALLOCATE** request. This option is implemented as defined in OS/400 V3R1, and is documented in the OS/400 CPI-C programmer reference as CM_SECURITY_PROGRAM_STRONG, where the LU 6.2 **pwd** (password) field is encrypted before it flows over the physical network.

The password substitution features is currently only supported by OS/400 V3R1 or later. If the remote system does not support this feature, the SNA server will UNBIND the session with the sense code of 10060006. The two nodes negotiate whether or not they support this feature in the BIND exchange. Host Integration Server sets a bit in the BIND, and also adds some random data on the BIND for encryption. If the remote node supports password substitution, it sets the same bit in the BIND response, and adds some (different) random data for decryption.

Host Integration Server 2009 supports automatic logon for APPC applications. This feature requires specific configuration by the network administrator: The APPC application must be invoked on the LAN side from a client of Host Integration Server 2009. The client must be logged into a Windows 2000 domain, but the client can be running on any operating system supported by the Host Integration Server 2009 APPC APIs.

The client application is coded to use "program" level security, with a special hard-coded APPC user name MS$SAME and password MS$SAME. When this session allocation flows from client to SNA server, the server looks up the host account and password corresponding to the Windows 2000 account under which the client is logged in, and substitutes the host account information into the APPC attach message it sends to the host.

Note
It is illegal for the remote node to set the bit specifying password substitution and not add the random data.

According to IBM, there are implementations of LU 6.2 password substitution that do not support password substitution but do echo the password substitution bit back to Host Integration Server 2009, without specifying any random data. When they do this, the SNA server will UNBIND the session with the sense code 10060006.This sense code is interpreted as:

- 1006 = Required field or parameter missing.
- 0006 = A required subfield of a control vector was omitted.

Host Integration Server should also log an Event 17 (APPC session activation failure: BIND negative response sent).

The correct solution is for the failing implementation to be fixed. However, as a short-term workaround, the following Host Integration Server service registry setting can be set:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\snaservr\parameters\NOPWDSUB: REG_SZ: YES

When this parameter is specified in the registry, password substitution support will be disabled.

Several updates have been made to Host Integration Server to allow a privileged APPC application to open an APPC conversation using the Single Sign-On feature on behalf of any defined Windows 2000 user. This is referred to as the privileged proxy feature. An extension has been added to the APPC **ALLOCATE** verb to invoke this feature.

An APPC application becomes privileged by being started in a Windows 2000 user account that is a member of a special Windows 2000 group. When a Host Security Domain is configured, SNA Manager will define a second Windows 2000 group for use with the host security features of Host Integration Server 2009. If the user account under which the actual client is running is a member of this second Windows 2000 group, the client is privileged to initiate an APPC conversation on behalf of any user account defined in the Host Account Cache.

The following illustrates how the privileged proxy feature works:

The Host Integration Server 2009 administrator creates a Host Security Domain called APP. SNA Manager now creates two

Windows 2000 groups. The first group is called APP and the second is called APP_PROXY for this example. Users that are assigned to the APP group are enabled for Single Sign-On. Users assigned to the APP_PROXY group are privileged proxies. The administrator adds the Windows 2000 user AppcUser to the APP_PROXY group using the Users button on the Host Security Domain property dialog box in SNA Manager.

The administrator then sets up an APPC application on the Host Integration Server to run as a Windows 2000 service called APPCAPP and that service has been set up to operate under the AppcUser user account. When APPCAPP runs, it opens an APPC session via an **ALLOCATE** verb using the extended VCB format and specifies the Windows 2000 user name of the desired user, UserA (for example).

The SNA Service sees the session request coming from a connection that is a member of the Host Security Domain APP. The Client/Server interface tells the SNA Service that the actual client is AppcUser.

The SNA Service checks to see if AppcUser is a member of the APP_PROXY group. Because AppcUser is a member of APP_PROXY, the SNA Service inserts the Username/Password for UserA in the APPC Attach (FMH-5) command and sends it off to the partner TP.

In order to support the privileged proxy feature, the APPC application must implement the following program logic:

The APPC application must determine the Windows 2000 user ID and domain name that it wishes to impersonate.

The APPC application must set the following parameters before calling the **ALLOCATE** verb:

Enable the use of the extended **ALLOCATE** verb control block structure by setting the AP_EXTD_VCB flag in the **opext** field.

Set security to AP_PROXY_SAME, AP_PROXY_PGM or AP_PROXY_STRONG.

Set up the pointers for **proxy_user** and **proxy_domain** to point to Unicode strings containing the user name and domain name of the user to be impersonated.

Note
The application does not need to set up the **user_id** and **pwd** fields in the **ALLOCATE** VCB.

When the APPC application performs the above steps and issues the **ALLOCATE** verb, the Host Integration Server 2009 server will perform a lookup in the host security domain for the specified Windows 2000 user and set the user ID and password fields in the FMH-5 Attach message sent to the remote system.

CONFIRM

The **CONFIRM** verb sends the contents of the local logical unit's (LU) send buffer and a confirmation request to the partner transaction program (TP).

The following structure describes the verb control block used by the **CONFIRM** verb.

Syntax

```
struct confirm {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned long   conv_id;
    unsigned char   rts_rcvd;
};
```

Remarks

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_CONFIRM.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED.

conv_id

Returned parameter. Identifies the conversation established between the two TPs.

rts_rcvd

Returned parameter. Indicates whether the partner TP issued REQUEST_TO_SEND, which requests the local TP to change the conversation to RECEIVE state.

To change to RECEIVE state operating on Microsoft Windows 2000 the local TP can use PREPARE_TO_RECEIVE, RECEIVE_AND_WAIT, or RECEIVE_AND_POST.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_CONFIRM_ON_SYNC_LEVEL_NONE

Secondary return code; the local TP attempted to use **CONFIRM** in a conversation with a synchronization level of AP_NONE. The synchronization level, established by ALLOCATE, must be AP_CONFIRM_SYNC_LEVEL.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_CONFIRM_BAD_STATE

Secondary return code; the conversation was not in SEND state.

AP_CONFIRM_NOT_LL_BDY

Secondary return code; the conversation for the local TP was in SEND state, and the local TP did not finish sending a logical record.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after **ALLOCATE**.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE, AP_CONFIRM_SYNC_LEVEL, or AP_SYNCPT) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer has encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued SEND_ERROR with **err_type** set to AP_PROG. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND_PROG

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued DEALLOCATE with **dealloc_type**set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_PURGING

Primary return code; the partner TP (or partner LU) issued SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

Remarks

In response to **CONFIRM**, the partner TP normally issues CONFIRMED to confirm that it has received the data without error. (If the partner TP encounters an error, it issues SEND_ERROR or abnormally deallocates the conversation.)

The TP can issue **CONFIRM** only if the conversation's synchronization level, established by ALLOCATE, is AP_CONFIRM_SYNC_LEVEL.

The conversation must be in SEND state when the TP issues this verb. State changes, summarized in the following table, are based on the value of the **primary_rc**.

primary_rc	**New state**
AP_OK	No change
AP_ALLOCATION_ERROR	RESET
AP_COMM_SUBSYSTEM_ABENDED AP_COMM_SUBSYSTEM_NOT_LOADED	RESET RESET
AP_CONV_FAILURE_RETRY AP_CONV_FAILURE_NO_RETRY	RESET RESET
AP_DEALLOC_ABEND AP_DEALLOC_ABEND_PROG AP_DEALLOC_ABEND_SVC AP_DEALLOC_ABEND_TIMER	RESET RESET RESET RESET
AP_PROG_ERROR_PURGING AP_SVC_ERROR_PURGING	RECEIVE RECEIVE

CONFIRM waits for a response from the partner TP. A response is generated by one of the following verbs in the partner TP:

- CONFIRMED
- SEND_ERROR
- DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER
- TP_ENDED

By issuing **CONFIRM** afterALLOCATE, the invoking TP can immediately determine whether the allocation was successful (if **synclevel** is set to AP_CONFIRM_SYNC_LEVEL).

Normally, the value of the **ALLOCATE** verb's **mode_name** parameter must match the name of a mode configured for the invoked TP's node and associated during configuration with the partner LU.

If one of the modes associated with the partner LU on the invoked TP's node is an implicit mode, the session established between the two LUs will be of the implicit mode when no mode name associated with the partner LU matches the value of **mode_name**. For more information, see Host Integration Server 2009 Help.

Several parameters of **ALLOCATE** are EBCDIC or ASCII strings. A TP can use the common service verb (CSV) CONVERT to translate a string from one character set to the other.

To send the **ALLOCATE** request immediately, the invoking TP can issue FLUSH or **CONFIRM** immediately after **ALLOCATE**. Otherwise, the **ALLOCATE** request accumulates with other data in the local LU's send buffer until the buffer is full.

CONFIRMED

The **CONFIRMED** verb responds to a confirmation request from the partner transaction program (TP). It informs the partner TP that the local TP has not detected an error in the received data. Because the TP issuing the confirmation request waits for a confirmation, **CONFIRMED** synchronizes the processing of the two TPs.

The following structure describes the verb control block (VCB) used by the **CONFIRMED** verb.

Syntax

```
struct confirmed {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned long   conv_id;
    unsigned char   rts_rcvd;
};
```

Remarks

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_CONFIRMED.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTEDin the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Identifies the conversation established between the two TPs. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

rts_rcvd

Returned parameter. Indicates whether the partner TP issued MC_REQUEST_TO_SEND, which requests the local TP to change the conversation to RECEIVE state.

To change to RECEIVE state the local TP can use MC_PREPARE_TO_RECEIVE, MC_RECEIVE_AND_WAIT, or MC_RECEIVE_AND_POST.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_CONFIRMED_BAD_STATE

Secondary return code; the conversation is not in CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation must be in one of the following states when the TP issues this verb:

- CONFIRM

- CONFIRM_SEND
- CONFIRM_DEALLOCATE

The new state is determined by the old state—the state of the conversation when the local TP issued **CONFIRMED**. The old state is indicated by the value of the **what_rcvd** parameter of the preceding receive verb. The following state changes are possible:

Old state	New state
CONFIRM	RECEIVE
CONFIRM_SEND	SEND
CONFIRM_DEALLOCATE	RESET

Confirmation Requests

A confirmation request is issued by one of the following verbs in the partner TP:

- CONFIRM
- PREPARE_TO_RECEIVE if **ptr_type** is set to AP_SYNC_LEVEL and the conversation's synchronization level (established by ALLOCATE) is AP_CONFIRM_SYNC_LEVEL
- DEALLOCATE if **dealloc_type** is set to AP_SYNC_LEVEL and the conversation's synchronization level (established by **ALLOCATE**) is AP_CONFIRM_SYNC_LEVEL
- SEND_DATA if type is set to AP_SEND_DATA_CONFIRM and the conversation's synchronization level (established by **ALLOCATE**) is AP_CONFIRM_SYNC_LEVEL

A confirmation request is received by the local TP through the **what_rcvd** parameter of one of the following verbs:

- RECEIVE_IMMEDIATE
- RECEIVE_AND_WAIT
- RECEIVE_AND_POST

CONFIRMED is issued by the local TP only if **what_rcvd** contains one of the following values:

- AP_CONFIRM_WHAT_RECEIVED
- AP_CONFIRM_SEND
- AP_CONFIRM_DEALLOCATE

If the **rtn_status** parameter is set to AP_YES, **what_rcvd** can also contain the following values:

- AP_DATA_COMPLETE_CONFIRM
- AP_DATA_COMPLETE_CONFIRM_SEND
- AP_DATA_COMPLETE_CONFIRM_DEALL

For basic conversations, **what_rcvd** can also contain the following values:

- AP_DATA_CONFIRM
- AP_DATA_CONFIRM_SEND
- AP_DATA_CONFIRM_DEALLOCATE

DEALLOCATE

The **DEALLOCATE** verb deallocates a conversation between two transaction programs (TPs).

The following structure describes the verb control block (VCB) used by the **DEALLOCATE** verb.

Syntax

```
struct deallocate {
    unsigned short       opcode;
    unsigned char        opext;
    unsigned char        reserv2;
    unsigned short       primary_rc;
    unsigned long        secondary_rc;
    unsigned char        tp_id[8];
    unsigned long        conv_id;
    unsigned char        reserv3;
    unsigned char        dealloc_type;
    unsigned short       log_dlen;
    unsigned char FAR *  log_dptr;
    void                 (WINAPI *callback)();
    void                 *correlator;
    unsigned char        reserv6[4];
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_DEALLOCATE.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Identifies the conversation established between the two TPs. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv3

A reserved field.

dealloc_type

Supplied parameter. Specifies how to perform the deallocation.

Using one of the following values deallocates the conversation abnormally:

- AP_ABEND_PROG

- AP_ABEND_SVC
- AP_ABEND_TIMER

If the conversation is in SEND state when the local TP issues **DEALLOCATE**, APPC sends the contents of the local logical unit's (LU) send buffer to the partner TP before deallocating the conversation. If the conversation is in RECEIVE or PENDING_POST state, APPC purges any incoming data before deallocating the conversation.

An application or service TP should specify AP_ABEND_PROG when it encounters an error preventing the successful completion of a transaction.

A service TP should specify AP_ABEND_SVC when it encounters an error caused by its partner service TP (for example, a format error in control information sent by the partner service TP). A service TP should specify AP_ABEND_TIMER when it encounters an error requiring immediate deallocation (for example, an operator ending the program prematurely).

AP_FLUSH sends the contents of the local LU's send buffer to the partner TP before deallocating the conversation. This value is allowed only if the conversation is in SEND state.

AP_SYNC_LEVEL uses the conversation's synchronization level (established by ALLOCATE) to determine how to deallocate the conversation. This value is allowed only if the conversation is in SEND state.

If the synchronization level of the conversation is AP_NONE, APPC sends the contents of the local LU's send buffer to the partner TP before deallocating the conversation.

If the synchronization level is AP_CONFIRM_SYNC_LEVEL, APPC sends the contents of the local LU's send buffer and a confirmation request to the partner TP. Upon receiving confirmation from the partner TP, APPC deallocates the conversation. If, however, the partner TP reports an error, the conversation remains allocated.

log_dlen

Supplied parameter. Specifies the number of bytes of data to be sent to the error log file. The range is from 0 through 32767.

You can set this parameter to a number greater than zero if **dealloc_type** is set to AP_ABEND_PGM, AP_ABEND_SVC, or AP_ABEND_TIMER. Otherwise, this parameter must be zero.

log_dptr

Supplied parameter. Provides the address of the data buffer containing error information. The data is sent to the local error log and to the partner LU.

This parameter is used by **DEALLOCATE** if **log_dlen** is greater than zero.

For Microsoft Windows 2000, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For OS/2, the log data buffer must reside on an unnamed, shared segment, which is allocated by the function **DosAllocSeg** with Flags equal to 1. The log data buffer must fit entirely on the segment.

The TP must format the error data as a GDS error log variable. For more information, see your IBM SNA manual(s).

callback

Supplied parameter. Only present if the AP_EXTD_VCB bit is set in the **opext** member, indicating support for Sync Point. This parameter is the address of a user-supplied callback function. If this field is NULL, no notification will be provided.

The prototype of the callback routine is as follows:

```
void WINAPI callback_proc(
    struct appc_hdr *vcb,
    unsigned char tp_id[8],
    unsigned long conv_id,
    unsigned short type,
    void *correlator
   );
```

The callback procedure can take any name, since the address of the procedure is passed to the APPC DLL. The parameters passed to the function are as follows:

vcb

A pointer to the **DEALLOCATE** verb control block that caused the conversation to be deallocated.

tp_id

The TP identifier of the TP that owned the deallocated conversation.

conv_id

The conversation identifier of the deallocated conversation.

type

The type of the message flow that caused the callback to be invoked. Possible values are:

AP_DATA_FLOW

Normal data flow on the session.

AP_UNBIND

The session was unbound normally.

AP_FAILURE

The session terminated due to an outage.

correlator

This value is the **correlator** specified on the **DEALLOCATE** verb.

correlator

Supplied parameter. Only present if the AP_EXTD_VCB bit is set in the **opext** member, indicating support for the Sync Point API. This **correlator** field allows the TP to specify a value it can use to correlate a call to the callback function with, for example, its own internal data structures. This value is returned to the TP as one of the parameters of the callback routine when it is invoked.

reserv4

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_DEALLOC_BAD_TYPE

Secondary return code; the **dealloc_type** parameter was not set to a valid value.

AP_DEALLOC_LOG_LL_WRONG

Secondary return code; the LL field of the GDS error log variable did not match the actual length of the log data.

AP_INVALID_DATA_SEGMENT

Secondary return code; the error data for the log file was longer than the segment allocated to contain the error data, or the address of the error data buffer was wrong.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_DEALLOC_CONFIRM_BAD_STATE

Secondary return code; the conversation was not in SEND state, and the TP attempted to flush the send buffer and send a confirmation request. This attempt occurred because the value of **dealloc_type** was AP_SYNC_LEVEL and the synchronization level of the conversation was AP_CONFIRM_SYNC_LEVEL.

AP_DEALLOC_FLUSH_BAD_STATE

Secondary return code; the conversation was not in SEND state and the TP attempted to flush the send buffer. This attempt occurred because the value of **dealloc_type** was AP_FLUSH or because the value of **dealloc_type** was AP_SYNC_LEVEL and the synchronization level of the conversation was AP_NONE. In either case, the conversation must be in SEND state.

AP_DEALLOC_NOT_LL_BDY

Secondary return code; the conversation was in SEND state, and the TP did not finish sending a logical record. The **dealloc_type** parameter was set to AP_SYNC_LEVEL or AP_FLUSH.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued SEND_ERROR with **err_type** set to AP_PROG. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND_PROG

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type**

set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_PURGING

Primary return code; the partner TP (or partner LU) issued **SEND_ERROR** with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

Remarks

Depending on the value of the **dealloc_type** parameter, the conversation can be in one of the states indicated in the following table when the TP issues **DEALLOCATE**.

dealloc_type	**Allowed state**
AP_FLUSH	SEND
AP_SYNC_LEVEL	SEND
AP_ABEND	Any except RESET
AP_ABEND_PROG	Any except RESET
AP_ABEND_SVC	Any except RESET
AP_ABEND_TIMER	Any except RESET

State changes, summarized in the following table, are based on the value of the **primary_rc**.

primary_rc	**New state**
AP_OK	RESET
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE

Before deallocating the conversation, this verb performs the equivalent of one of the following:

- FLUSH, by sending the contents of the local LU's send buffer to the partner LU (and TP).
- CONFIRM, by sending the contents of the local LU's send buffer and a confirmation request to the partner TP.

After this verb has successfully executed, the conversation identifier is no longer valid.

LU 6.2 Sync Point can use an optimization of the message flows known as implied forget. When the protocol specifies that a FORGET PS header is required, the next data flow on the session implies that a FORGET has been received. In the normal situation, the TP is aware of the next data flow when data is received or sent on one of its Sync Point conversations.

However, it is possible that the last message to flow is caused by the conversation being deallocated. In this case, the TP is unaware when the next data flow on the session occurs. To provide the TP with this notification, the **DEALLOCATE** verb is modified to allow the TP to register a callback function which will be called:

- On the first normal flow transmission (request or response) over the session used by the conversation.
- If the session is unbound before any other data flows.
- If the session is terminated abnormally due to a DLC outage.

The **DEALLOCATE** verb also contains a **correlator** field member that is returned as one of the parameters when the callback function is invoked. The application can use this parameter in any way (for example, as a pointer to a control block within the application).

The TP can use the *type* parameter passed to the callback function to determine whether the message flow indicates an implied forget has been received.

Note that the **DEALLOCATE** verb will probably complete before the callback routine is called. The conversation is considered to be in RESET state and no further verbs can be issued using the conversation identifier. If the application issues a TP_ENDED verb before the next data flow on the session, the callback routine will not be invoked.

Host Integration Server 2009 allows TPs to deallocate conversations immediately after sending data by specifying the **type** parameter on SEND_DATA as AP_SEND_DATA_DEALLOC_*. However, the SEND_DATA verbs do not contain the implied forget callback function. TPs that want to receive implied forget notification must issue **DEALLOCATE** explicitly.

FLUSH

The **FLUSH** verb sends the contents of the local logical unit's (LU) send buffer to the partner LU and transaction program (TP). If the send buffer is empty, no action takes place.

The following structure describes the verb control block (VCB) used by the **FLUSH** verb.

Syntax

```
struct flush {
    unsigned short   opcode;
        unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_FLUSH.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_FLUSH_NOT_SEND_STATE

Secondary return code; the conversation was not in SEND state.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

Data processed by SEND_DATA accumulates in the local LU's send buffer until one of the following happens:

- The local TP issues **FLUSH** (or other verb that flushes the LU's send buffer).
- The buffer is full.

The request generated by ALLOCATE is also buffered.

The conversation must be in SEND state when the TP issues this verb.

There is no state change.

GET_ATTRIBUTES

The **GET_ATTRIBUTES** verb returns the attributes of the conversation.

The following structure describes the verb control block (VCB) used by the **GET_ATTRIBUTES** verb.

Syntax

```
struct get_attributes {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    reserv3;
    unsigned char    sync_level;
    unsigned char    mode_name[8];
    unsigned char    net_name[8];
    unsigned char    lu_name[8];
    unsigned char    lu_alias[8];
    unsigned char    plu_alias[8];
    unsigned char    plu_un_name[8];
    unsigned char    reserv4[2];
    unsigned char    fqplu_name[17];
    unsigned char    reserv5;
    unsigned char    user_id[10];
    unsigned long    conv_group_id;
    unsigned char    conv_corr_len;
    unsigned char    conv_corr[8];
    unsigned char    reserv6[13];
NOTE: The following fields are present when the high bit of opext is set (opext & AP_EXTD_V
CB) != 0.
    unsigned char    luw_id[26];
    unsigned char    sess_id[8];
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_GET_ATTRIBUTES.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local transaction program (TP). The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

sync_level

Returned parameter. Specifies the level of synchronization processing for the conversation. This parameter determines whether the TPs can request confirmation of receipt of data and confirm receipt of data.

- AP_NONE indicates that confirmation processing will not be used in this conversation.
- AP_CONFIRM_SYNC_LEVEL indicates that TPs can use confirmation processing in this conversation.
- AP_SYNCPT indicates that TPs can use Sync Point Level 2 confirmation processing in this conversation.

mode_name

Returned parameter. Specifies the name of a set of networking characteristics. It is a type A EBCDIC character string.

net_name

Returned parameter. Specifies the name of the SNA network containing the local logical unit (LU) used by this TP. It is a type A EBCDIC character string.

lu_name

Returned parameter. Provides the name of the local LU.

lu_alias

Returned parameter. Provides the alias by which the local LU is known to the local TP. It is an ASCII character string.

plu_alias

Returned parameter. Provides the alias by which the partner LU is known to the local TP. It is an ASCII character string.

plu_un_name

Returned parameter. Specifies the uninterpreted name of the partner LU—the name of the partner LU as defined to the system services control point (SSCP). It is a type AE EBCDIC character string. This parameter is returned only if the local LU is dependent.

fqplu_name

Returned parameter. Provides the fully qualified name of the partner LU. It is a type A EBCDIC character string. The field contains the network name, an EBCDIC period, and the partner-LU name.

user_id

Returned parameter. Specifies the user identifier sent by the invoking TP through ALLOCATE to access the invoked TP (if applicable). It is a type AE EBCDIC character string. The field contains the user identifier if the following conditions are true:

- The invoked TP requires conversation security.
- **GET_ATTRIBUTES** was issued by the invoked TP.

Otherwise, the field contains spaces.

conv_group_id

Returned parameter. Specifies the conversation group identifier for the session to which the conversation has been allocated. This is also returned on ALLOCATE and RECEIVE_ALLOCATE.

conv_corr_len

Returned parameter. Specifies the length of the conversation correlator identifier that is returned.

conv_corr

Returned parameter. Specifies the conversation correlator identifier (if any) that the source LU assigns to identify the conversation, which is unique for the source/partner LU pair. It is sent by the source LU on the allocation request.

Note
The following fields are present when the high bit of **opext** is set(**opext** & AP_EXTD_VCB) != 0.These fields are only present when using Sync Point Level 2 support.

luw_id

Logical unit-of-work identifier.

sess_id

Session identifier.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any state except RESET when the TP issues this verb.

There is no state change.

GET_LU_STATUS

The **GET_LU_STATUS** verb returns the status of a particular logical unit (LU). This conversation verb is only available when Sync Point conversations are supported.

The following structure describes the verb control block (VCB) used by the **GET_LU_STATUS** verb.

Syntax

```
struct get_type {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned char    plu_alias[8];
    unsigned short   active_sess;
    unsigned char    zero_sess;
    unsigned char    local_only;
    unsigned char    synchpoint;
    unsigned char    pool_member;
    unsigned char    reserv3[7];
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_GET_LU_STATUS.

opext

This field is unused by the **GET_LU_STATUS** verb.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local transaction program (TP). The value of this parameter was returned by TP_STARTED in the invoking TP, or by RECEIVE_ALLOCATE or RECEIVE_ALLOCATE_EX in the invoked TP.

plu_alias

Supplied parameter. Provides the identifier for the LU about which this TP is inquiring. The value of this parameter was returned by MC_ALLOCATE or ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

Not required if local_only is set to AP_YES

active_sess

Returned parameter. Supplies the number of active sessions on this LU.

zero_sess

Returned parameter. Indicates whether a zero session is on this LU. Values are AP_YES or AP_NO.

active_sess

Returned parameter.

zero_sess

Returned parameter.

local_only

If this field is set to AP_YES then the plu_alias does not need to be specified and the verb only returns the local LU information - syncpoint and default_pool.

synchpoint

Returned parameter.

pool_member

If this field is set to AP_YES then the plu_alias does not need to be specified and the verb only returns the local LU information - syncpoint and default_pool.

reserv3

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_LU_ALIAS

Secondary return code; the value of **plu_alias** did not match any LUs assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any state except RESET when the TP issues this verb.

There is no state change.

The current version of GET_LU_STATUS allows for an application to retrieve configuration parameters for a Local APPC LU.

To check the configuration of a particular Local LU before issuing a RECEIVE_ALLOCATE_EX verb, the following verb sequence should be issued:

- TP_STARTED (specifying the Local LU of interest)
- GET_LU_STATUS (with local_only set to AP_YES)
- TP_ENDED (AP_SOFT)

GET_STATE

The **GET_STATE** verb returns the state of a particular conversation.

The following structure describes the verb control block (VCB) used by the **GET_STATE** verb.

Syntax

```
struct get_state {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    conv_state;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_GET_STATE.

opext

This field is unused by the **GET_STATE** verb.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local transaction program (TP). The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the identifier for the conversation about which this TP is inquiring. The value of this parameter was returned by MC_ALLOCATE or ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

conv_state

Returned parameter. Indicates the state of the conversation. The **conv_state** parameter can be one of the following values:

AP_RESET_STATE

The conversation is in the RESET state.

AP_SEND_STATE

The conversation is in the SEND state.

AP_RECEIVE_STATE

The conversation is in the RECEIVE state.

AP_CONFIRM_STATE

The conversation is in the CONFIRM state.

AP_CONFIRM_SEND_STATE

The conversation is in the CONFIRM_SEND state.

AP_CONFIRM_DEALL_STATE

The conversation is in the CONFIRM_DEALLOCATE state.

AP_PEND_POST_STATE

The conversation has a **POST** verb pending.

AP_PEND_DEALL_STATE

The conversation has a **DEALLOCATE** verb pending.

AP_END_CONV_STATE

The conversation is in the END_CONVERSATION state.

AP_SEND_PENDING_STATE

The conversation is in the SEND_PENDING state.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any state when the TP issues this verb.

There is no state change.

GET_TYPE

The **GET_TYPE** verb returns the conversation type (basic or mapped) of a particular conversation so the transaction program (TP) can decide whether to use basic or mapped conversation verbs.

The following structure describes the verb control block (VCB) used by the **GET_TYPE** verb.

Syntax

```
struct get_type {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    conv_type;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_GET_TYPE.

opext

This field is unused by the **GET_TYPE** verb.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the identifier for the conversation about which this TP is inquiring. The value of this parameter was returned by MC_ALLOCATE or ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

conv_type

Returned parameter. Supplies the type of conversation, either AP_BASIC_CONVERSATION or AP_MAPPED_CONVERSATION.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any state except RESET when the TP issues this verb.

There is no state change.

MC_ALLOCATE

The **MC_ALLOCATE** verb is issued by the invoking transaction program (TP). It allocates a session between the local logical unit (LU) and partner LU and (in conjunction with RECEIVE_ALLOCATE) establishes a conversation between the invoking TP and the invoked TP. After this verb executes successfully, APPC generates a conversation identifier (**conv_id**). The **conv_id** is a required parameter for all other APPC conversation verbs.

The following structure describes the verb control block (VCB) used by the **MC_ALLOCATE** verb.

Syntax

```
struct mc_allocate {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    reserv3;
    unsigned char    synclevel;
    unsigned char    reserv4[2];
    unsigned char    rtn_ctl;
    unsigned char    reserv5;
    unsigned long    conv_group_id;
    unsigned long    sense_data;
    unsigned char    plu_alias[8];
    unsigned char    mode_name[8];
    unsigned char    tp_name[64];
    unsigned char    security;
    unsigned char    reserv6[11];
    unsigned char    pwd[10];
    unsigned char    user_id[10];
    unsigned short   pip_dlen;
    unsigned char FAR * pip_dptr;
    unsigned char    reserv7;
    unsigned char    fqplu_name[17];
    unsigned char    reserv8[8];
    unsigned long    proxy_user;
    unsigned long    proxy_domain;
    unsigned char    reserv9[16];
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code; AP_M_ALLOCATE.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION. If the AP_EXTD_VCB bit is set, this indicates that an extended version of the verb control block is used. In this case, the **MC_ALLOCATE** structure includes Sync Point support or privileged proxy feature support.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED.

conv_id

Returned parameter. Identifies the conversation established between the two TPs.

reserv3

A reserved field.

synclevel

Supplied parameter. Specifies the synchronization level of the conversation. It determines whether the TPs can request confirmation of receipt of data and confirm receipt of data.

- AP_NONE specifies that confirmation processing will not be used in this conversation.
- AP_CONFIRM_SYNC_LEVEL specifies that the TPs can use confirmation processing in this conversation.
- AP_SYNCPT specifies that TPs can use Sync Point Level 2 confirmation processing in this conversation.

reserv4

A reserved field.

reserv5

A reserved field.

rtn_ctl

Supplied parameter. Specifies when the local LU, acting on a session request from the local TP, should return control to the local TP. For information about sessions, see Transaction Programs Overview.

- AP_IMMEDIATE specifies that the LU allocates a contention-winner session, if one is immediately available, and returns control to the TP.
- AP_WHEN_SESSION_ALLOCATED specifies that the LU does not return control to the TP until it allocates a session or encounters one of the errors documented in Return Codes in this topic. (If the session limit is zero, the LU returns control immediately.) If a session is not available, the TP waits for one.
- AP_WHEN_SESSION_FREE specifies that the LU allocates a contention-winner or contention-loser session, if one is available or able to be activated, and returns control to the TP. If an error occurs, (as documented in Return Codes in this topic) the call will return immediately with the error in the **primary_rc** and **secondary_rc** fields.
- AP_WHEN_CONWINNER_ALLOC specifies that the LU does not return control until it allocates a contention-winner session or encounters one of the errors documented in Return Codes in this topic. (If the session limit is zero, the LU returns control immediately.) If a session is not available, the TP waits for one.
- AP_WHEN_CONV_GROUP_ALLOC specifies that the LU does not return control to the TP until it allocates the session specified by **conv_group_id**or encounters one of the errors documented in Return Codes in this topic. If a session is not available, the TP waits for it to become free.

Note
AP_IMMEDIATE is the only value for **rtn_ctl** that never causes a new session to start. For values other than AP_IMMEDIATE, if an appropriate session is not immediately available, Microsoft® Host Integration Server tries to start one. This causes the on-demand connection to be activated.

conv_group_id

Supplied/returned parameter. Specifies the identifier of the conversation group from which the session should be allocated.

The **conv_group_id** is required only if **rtn_ctl**is set to WHEN_CONV_GROUP_ALLOC. When**rtn_ctl** specifies a different value and the **primary_rc** is AP_OK, this is a returned value.

sense_data

Returned parameter. Indicates an allocation error (retry or no-retry) and contains sense data.

plu_alias

Supplied parameter. Specifies the alias by which the partner LU is known to the local TP.

The **plu_alias** must match the name of a partner LU established during configuration.

The parameter is an 8-byte ASCII character string. It can consist of the following ASCII characters:

- Uppercase letters
- Numerals 0 through 9
- Spaces
- Special characters $, #, %, and @

The first character of this string cannot be a space.

If the value of this parameter is fewer than eight bytes, pad it on the right with ASCII spaces (0x20).

If you want to specify the partner LU with the **fqplu_name** parameter, fill this parameter with binary zeros.

For a user or group using TPs, 5250 emulators, and/or APPC applications, the system administrator can assign default local and remote LUs. In this case, the field is left blank or null and the default LUs are accessed when the user or group member starts an APPC program. For more information on default LUs, see Host Integration Server 2009 Help.

mode_name

Supplied parameter. Specifies the name of a set of networking characteristics defined during configuration.

The value of **mode_name** must match the name of a mode associated with the partner LU during configuration.

The parameter is an 8-byte EBCDIC character string. It can consist of characters from the type A EBCDIC character set:

- Uppercase letters
- Numerals 0 through 9
- Special characters $, #, and @

The first character in the string must be an uppercase letter or a special character.

Do not use SNASVCMG in a mapped conversation. SNASVCMG is a reserved **mode_name** used internally by APPC.

tp_name

Supplied parameter. Specifies the name of the invoked TP. The value of **tp_name** specified by **MC_ALLOCATE** in the invoking TP must match the value of **tp_name** specified by RECEIVE_ALLOCATE in the invoked TP.

The parameter is a 64-byte EBCDIC character string and is case-sensitive. The **tp_name** parameter can consist of the following EBCDIC characters:

- Uppercase and lowercase letters
- Numerals 0 through 9
- Special characters $, #, @, and period (.)

If **tp_name** is fewer than 64 bytes, use EBCDIC spaces (0x40) to pad it on the right.

The SNA convention is that a service TP name can have up to four characters. The first character is a hexadecimal byte between 0x00 and 0x3F. The other characters are from the type AE EBCDIC character set.

security

Supplied parameter. Provides the information that the partner LU requires to validate access to the invoked TP. See the section **Possible values for the Security parameter** in this topic.

Reserv6

A reserved field.

pwd

Supplied parameter. Specifies the password associated with **user_id**.

The **pwd** parameter is required only if **security** is set to AP_PGM or AP_SAME. It must match the password for **user_id** that was established during configuration.

The **pwd** parameter is a 10-byte EBCDIC character string and is case-sensitive. It can consist of the following EBCDIC characters:

- Uppercase and lowercase letters
- Numerals 0 through 9
- Special characters $, #, @, and period (.)

If the password is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

If the APPC automatic logon feature is to be used, the **pwd** character string must be hard-coded to MS$SAME. See the Remarks section for details.

user_id

Supplied parameter. Specifies the user identifier required to access the partner TP. It is required only if the security parameter is set to AP_PGM or AP_SAME.

The **user_id** parameter is a 10-byte EBCDIC character string and is case-sensitive. It must match one of the user identifiers configured for the partner TP.

The parameter can consist of the following EBCDIC characters:

- Uppercase and lowercase letters
- Numerals 0 through 9
- Special characters $, #, @, and period (.)

If **user_id** is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

If the APPC automatic logon feature is to be used, the **user_id** character string must be hard-coded to MS$SAME. See the Remarks section for details.

pip_dlen

Supplied parameter. Specifies the length of the program initialization parameters (PIP) to be passed to the partner TP. The range is from 0 through 32767.

pip_dptr

Supplied parameter. Specifies the address of the buffer containing PIP data. Use this parameter only if **pip_dlen** is greater than zero.

PIP data can consist of initialization parameters or environmental setup information required by a partner TP or remote operating system. The PIP data must follow the general data stream (GDS) format. For more information, see your IBM SNA manual(s).

For Microsoft Windows 2000, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

reserv7

A reserved field.

fqplu_name

Supplied parameter. Specifies the fully qualified name of the partner LU. This must match the fully qualified name of the local LU defined in the remote node. The parameter consists of two type A EBCDIC character strings for the NETID and the LU name of the partner LU. The names are separated by an EBCDIC period (.).

This name must be provided if no **plu_alias** is specified. It can consist of the following EBCDIC characters:

- 18Uppercase letters
- Numerals 0 through 9
- Special characters $, #, and @

If the value of this parameter is fewer than 17 bytes, pad it on the right with EBCDIC spaces (0x40).

reserv8

A reserved field.

proxy_user

Supplied parameter. Specifies a LPWSTR pointing to a Unicode string containing the user name to be impersonated using the privileged proxy feature. This field can only be used when the AP_EXTD_VCB bit is set on the **opext** field, indicating an extended VCB.

proxy_domain

Supplied parameter. Specifies a LPWSTR pointing to a Unicode string containing the domain name of the user to be impersonated using the privileged proxy feature. This field can only be used when the AP_EXTD_VCB bit is set on the **opext** field, indicating an extended VCB.

reserv9

A reserved field.

Possible Values for the Security Parameter

Based on the conversation security established for the invoked TP during configuration, use one of the following values:

- AP_NONE for an invoked TP that uses no conversation security.
- AP_PGM for an invoked TP that uses conversation security and thus requires a user identifier and password. Supply this information through the **user_id** and **pwd** parameters.
- AP_PROXY_PGM for an invoked TP with privileged proxy that uses conversation security and thus requires a user identifier and password. Pointers must be set up for **proxy_user** and **proxy_domain** to point to Unicode strings containing the user name and domain name of the user to be impersonated. The application does not need to set the **user_id** and **pwd** fields.
- AP_PROXY_SAME for a TP that has been invoked using privileged proxy with a valid user identifier and password supplied by the proxy, which in turn invokes another TP. Pointers must be set up for **proxy_user** and **proxy_domain** to point to Unicode strings containing the user name and domain name of the user to be impersonated. The application does not need to set the **user_id** and **pwd** fields.

  For example, assume that TP A invokes TP B with a valid user identifier and password supplied by the privileged proxy, and TP B in turn invokes TP C. If TP B specifies the value AP_PROXY_SAME, APPC will send the LU for TP C the user identifier from TP A and an already-verified indicator. This indicator tells TP C to not require the password (if TP C is configured to accept an already-verified indicator).

- AP_PROXY_STRONG for an invoked TP with privileged proxy that uses conversation security and thus requires a user identifier and password provided by the privileged proxy mechanism. Pointers must be set up for **proxy_user** and **proxy_domain** to point to Unicode strings containing the user name and domain name of the user to be impersonated. The application does not need to set the **user_id** and **pwd** fields. AP_PROXY_STRONG differs from AP_PROXY_PGM in that AP_PROXY_STRONG does not allow clear-text passwords. If the remote system does not support encrypted passwords (strong conversation security), then this call fails.

- AP_SAME for a TP that has been invoked with a valid user identifier and password, which in turn invokes another TP.

  For example, assume that TP A invokes TP B with a valid user identifier and password, and TP B in turn invokes TP C. If TP B specifies the value AP_SAME, APPC will send the LU for TP C the user identifier from TP A and an already-verified indicator. This indicator tells TP C to not require the password (if TP C is configured to accept an already-verified indicator).

  When AP_SAME is used in an **MC_ALLOCATE** verb, your application must always provide values for the **user_id** and **pwd** parameters in the verb control block. Depending on the properties negotiated between Host Integration Server 2009 and the peer LU, the **MC_ALLOCATE** verb will send one of three kinds of Attach (FMH-5) messages, in this order of precedence:

  1. If the LUs have negotiated "already verified" security, then the Attach sent by Host Integration Server 2009 will not include the contents of the **pwd** parameter field specified in the VCB.

  2. If the LUs have negotiated "persistent verification" security, then the Attach sent by Host Integration Server will include the **pwd** parameter specified in the VCB, but only when the Attach is the first for the specified **user_id** parameter since the start of the LU-LU session, and will omit the **pwd** parameter on all subsequent Attaches (issued by your application or any other application using this LU-LU-mode triplet).

  3. If the LUs have not negotiated either of the above, then the Attach sent by Host Integration Server will omit both the **user_id** and **pwd** parameters on all Attaches.

     Your application cannot tell which mode of security has been negotiated between the LUs, nor can it tell whether the **MC_ALLOCATE** verb it is issuing is the first for that LU-LU-mode triplet. So your application must always set the **user_id** and **pwd** parameter fields in the VCB when **security** is set to AP_SAME.

     For more information on persistent verification and already verified security, see the SNA Formats Guide, section "FM Header 5: Attach (LU 6.2)".

- AP_STRONG for an invoked TP that uses conversation security and thus requires a user identifier and password. Supply this information through the **user_id** and **pwd** parameters. AP_STRONG differs from AP_PGM in that AP_STRONG does not allow clear-text passwords. If the remote system does not support encrypted passwords (strong conversation security), then this call fails.

  If the APPC automatic logon feature is to be used, **security** must be set to AP_PGM. See the Remarks section for details.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_UNSUCCESSFUL

Primary return code; the supplied parameter **rtn_ctl** specified immediate (AP_IMMEDIATE) return of control to the TP, and the local LU did not have an available contention-winner session.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_RETURN_CONTROL

Secondary return code; the value specified for **rtn_ctl** was not valid.

AP_BAD_SECURITY

Secondary return code; the value specified for **security** was not valid.

AP_BAD_SYNC_LEVEL

Secondary return code; the value specified for **sync_level** was not valid.

AP_BAD_TP_ID

Secondary return code; the value specified for **tp_id** was not valid.

AP_PIP_LEN_INCORRECT

Secondary return code; the value of **pip_dlen** was greater than 32767.

AP_UNKNOWN_PARTNER_MODE

Secondary return code; the value specified for **mode_name** was not valid.

AP_BAD_PARTNER_LU_ALIAS

Secondary return code; APPC did not recognize the supplied **partner_lu_alias**.

AP_NO_USE_OF_SNASVCMG

Secondary return code; SNASVCMG is not a valid value for **mode_name**.

AP_INVALID_DATA_SEGMENT

Secondary return code; the PIP data was longer than the allocated data segment, or the address of the PIP data buffer was wrong.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after **MC_ALLOCATE**.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with **MC_ALLOCATE**, it can indicate that no communications system could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can

satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Host Integration Server system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

MC_ALLOCATE establishes a mapped conversation.

The conversation state is RESET when the TP issues this verb. After successful execution (**primary_rc** is AP_OK), the state changes to SEND. If the verb does not execute, the state remains unchanged.

Several parameters of **MC_ALLOCATE** are EBCDIC or ASCII strings. A TP can use the CSV CONVERT to translate a string from one character set to the other.

To send the **MC_ALLOCATE** request immediately, the invoking TP can issue MC_FLUSH or MC_CONFIRM immediately after **MC_ALLOCATE**. Otherwise, the **MC_ALLOCATE** request accumulates with other data in the local LU's send buffer until the buffer is full.

By issuing **MC_CONFIRM** after **MC_ALLOCATE**, the invoking TP can immediately determine whether the allocation was successful (if **synclevel** is set to AP_CONFIRM_SYNC_LEVEL).

Normally, the value of the **MC_ALLOCATE** verb's **mode_name** parameter must match the name of a mode configured for the invoked TP's node and associated during configuration with the partner LU.

If one of the modes associated with the partner LU on the invoked TP's node is an implicit mode, the session established between the two LUs will be of the implicit mode when no mode name associated with the partner LU matches the value of **mode_name**.

Host Integration Server 2009 supports a feature called password substitution. This is a security feature supported by the latest version of the OS/400 operating system (V3R1) that encrypts any password that flows between two nodes on an Attach message. A password flows on an Attach whenever someone invokes an APPC transaction program specifying a user identifier and password. For example, this happens whenever anyone logs on to an AS/400.

Support for password substitution is indicated by setting bit 5 in byte 23 of the BIND request to 1 (which indicates that password substitution is supported). If the remote system sets this bit in the BIND response, Host Integration Server automatically encrypts the LU 6.2 conversation security password included in the FMH-5 Attach message. Host Integration Server APPC applications automatically take advantage of this feature by setting the **security** field of the VCB to AP_PGM or AP_STRONG in the **MC_ALLOCATE** request.

If an APPC application wants to force an encrypted password to flow, the application can specify AP_STRONG for the **security** field in the VCB in the **MC_ALLOCATE** request. This option is implemented as defined in OS/400 V3R1, and is documented in the OS/400 CPI-C programmer reference as CM_SECURITY_PROGRAM_STRONG, where the LU 6.2 **pwd** (password) field is encrypted before it flows over the physical network.

The password substitution feature is currently only supported by OS/400 V3R1 or later. If the remote system does not support this feature, Host Integration Server will UNBIND the session with the sense code of 10060006. The two nodes negotiate whether or not they support this feature in the BIND exchange. Host Integration Server sets a bit in the BIND, and also adds some random data on the BIND for encryption. If the remote node supports password substitution, it sets the same bit in the BIND response, and adds some (different) random data for decryption.

Host Integration Server 2009 supports automatic logon for APPC applications. This feature requires specific configuration by the network administrator: The APPC application must be invoked on the LAN side from a client of Host Integration Server. The client must be logged into a Windows 2000 domain, but can be any platform that supports the Host Integration Server 2009 APPC APIs.

The client application is coded to use "program" level security, with a special hard-coded APPC user name MS$SAME and password MS$SAME. When this session allocation flows from client to Host Integration Server, the Host Integration Server server looks up the host account and password corresponding to the Windows 2000 account under which the client is logged in, and substitutes the host account information into the APPC attach message it sends to the host.

Note
It is illegal for the remote node to set the bit specifying password substitution and not add the random data.

According to IBM, there are implementations of LU 6.2 password substitution that do not support password substitution but do echo the password substitution bit back to Host Integration Server, without specifying any random data. When they do this, Host Integration Server will UNBIND the session with the sense code 10060006.This sense code is interpreted as:

- 1006 = Required field or parameter missing.
- 0006 = A required subfield of a control vector was omitted.

Host Integration Server should also log an Event 17 (APPC session activation failure: BIND negative response sent).

The correct solution is for the failing implementation to be fixed. However, as a short-term workaround, the following Host Integration Server SNA Service registry setting can be set:
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\snaservr\parameters\NOPWDSUB: REG_SZ: YES

When this parameter is specified in the registry, Host Integration Server password substitution support will be disabled.

Several updates have been made to Host Integration Server to allow a privileged APPC application to open an APPC conversation using the Single Sign-On feature on behalf of any defined Windows 2000 user. This is referred to as the privileged proxy feature. An extension has been added to the APPC **MC_ALLOCATE** verb to invoke this feature.

An APPC application becomes privileged by being started in a Windows 2000 user account that is a member of a special Windows 2000 group. When a Host Security Domain is configured, SNA Manager will define a second Windows 2000 group for use with the host security features of Host Integration Server. If the user account under which the actual client is running is a member of this second Windows 2000 group, the client is privileged to initiate an APPC conversation on behalf of any user account defined in the Host Account Cache.

The following illustrates how the privileged proxy feature works:

The Host Integration Server administrator creates a Host Security Domain called APP. SNA Manager now creates two Windows 2000 groups. The first group is called APP and the second is called APP_PROXY for this example. Users that are assigned to the APP group are enabled for Single Sign-On. Users assigned to the APP_PROXY group are privileged proxies. The administrator adds the Windows 2000 user AppcUser to the APP_PROXY group using the Users button on the Host Security Domain property dialog box in SNA Manager.

The administrator then sets up an APPC application on the Host Integration Server server to run as a Windows 2000 service called APPCAPP, and that service has been set up to operate under the AppcUser user account. When APPCAPP runs, it opens an APPC session via an **ALLOCATE** verb using the extended VCB format and specifies the Windows 2000 user name of the desired user, UserA (for example).

The SNA Service sees the session request coming from a connection that is a member of the Host Security Domain APP. The Client/Server interface tells the SNA Service that the actual client is AppcUser.

The SNA Service checks to see if AppcUser is a member of the APP_PROXY group. Because AppcUser is a member of APP_PROXY, the SNA Service inserts the Username/Password for UserA in the APPC Attach (FMH-5) command and sends it off to the partner TP.

In order to support the privileged proxy feature, the APPC application must implement the following program logic:

The APPC application must determine the Windows 2000 user ID and domain name that it wishes to impersonate.

The APPC application must set the following parameters before calling the **MC_ALLOCATE** verb:

Enable the use of the extended **MC_ALLOCATE** verb control block structure by setting the AP_EXTD_VCB flag in the **opext** field.

Set security to AP_PROXY_SAME, AP_PROXY_PGM, or AP_PROXY_STRONG.

Set up the pointers for **proxy_user** and **proxy_domain** to point to Unicode strings containing the user name and domain name of the user to be impersonated.

Note
The application does not need to set up the **user_id** and **pwd** fields in the **MC_ALLOCATE** VCB.

When the APPC application performs the above steps and issues the **MC_ALLOCATE** verb, the Host Integration Server server will perform a lookup in the host security domain for the specified Windows 2000 user and set the user ID and password fields in the FMH-5 Attach message sent to the remote system.

MC_CONFIRM

The **MC_CONFIRM** verb sends the contents of the local logical unit's (LU) send buffer and a confirmation request to the partner transaction program (TP).

The following structure describes the verb control block (VCB) used by the **MC_CONFIRM** verb.

Syntax

```
struct mc_confirm {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned long   conv_id;
    unsigned char   rts_rcvd;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_CONFIRM.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED.

conv_id

Returned parameter. Identifies the conversation established between the two TPs.

rts_rcvd

Returned parameter. Indicates whether the partner TP issued MC_REQUEST_TO_SEND, which requests the local TP to change the conversation to RECEIVE state.

To change to RECEIVE state the local TP can use MC_PREPARE_TO_RECEIVE, MC_RECEIVE_AND_WAIT, or MC_RECEIVE_AND_POST.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_CONFIRM_ON_SYNC_LEVEL_NONE

Secondary return code; the local TP attempted to use **MC_CONFIRM** in a conversation with a synchronization level of AP_NONE. The synchronization level, established by MC_ALLOCATE, must be AP_CONFIRM_SYNC_LEVEL.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_CONFIRM_BAD_STATE

Secondary return code; the conversation was not in SEND state.

AP_CONFIRM_NOT_LL_BDY

Secondary return code; the conversation for the local TP was in SEND state, and the local TP did not finish sending a logical record.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after **MC_ALLOCATE**.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE, AP_CONFIRM_SYNC_LEVEL, or AP_SYNCPT) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer has encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued MC_SEND_ERROR. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE with**dealloc_type**set to AP_ABEND.

- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

Remarks

In response to **MC_CONFIRM**, the partner TP normally issues MC_CONFIRMED to confirm that it has received the data without error. (If the partner TP encounters an error, it issues MC_SEND_ERROR or abnormally deallocates the conversation.)

The TP can issue **MC_CONFIRM** only if the conversation's synchronization level, established by MC_ALLOCATE, is AP_CONFIRM_SYNC_LEVEL.

The conversation must be in SEND state when the TP issues this verb. State changes, summarized in the following table, are based on the value of the **primary_rc**.

primary_rc	**New state**
AP_OK	No change
AP_ALLOCATION_ERROR	RESET
AP_COMM_SUBSYSTEM_ABENDED AP_COMM_SUBSYSTEM_NOT_LOADED	RESET RESET
AP_CONV_FAILURE_RETRY AP_CONV_FAILURE_NO_RETRY	RESET RESET
AP_DEALLOC_ABEND AP_DEALLOC_ABEND_PROG AP_DEALLOC_ABEND_SVC AP_DEALLOC_ABEND_TIMER	RESET RESET RESET RESET
AP_PROG_ERROR_PURGING AP_SVC_ERROR_PURGING	RECEIVE RECEIVE

MC_CONFIRM waits for a response from the partner TP. A response is generated by one of the following verbs in the partner TP:

- MC_CONFIRMED
- MC_SEND_ERROR
- MC_DEALLOCATE with **dealloc_type** set to AP_ABEND
- TP_ENDED

By issuing **MC_CONFIRM** afterMC_ALLOCATE, the invoking TP can immediately determine whether the allocation was successful (if **synclevel** is set to AP_CONFIRM_SYNC_LEVEL).

Normally, the value of the **MC_ALLOCATE** verb's **mode_name** parameter must match the name of a mode configured for the invoked TP's node and associated during configuration with the partner LU.

If one of the modes associated with the partner LU on the invoked TP's node is an implicit mode, the session established between the two LUs will be of the implicit mode when no mode name associated with the partner LU matches the value of **mode_name**. For more information, see Host Integration Server 2009 Help.

Several parameters of **MC_ALLOCATE** are EBCDIC or ASCII strings. A TP can use the common service verb (CSV) CONVERT to translate a string from one character set to the other.

To send the **MC_ALLOCATE** request immediately, the invoking TP can issue MC_FLUSH or **MC_CONFIRM** immediately after **MC_ALLOCATE**. Otherwise, the **MC_ALLOCATE** request accumulates with other data in the local LU's send buffer until the buffer is full.

MC_CONFIRMED

The **MC_CONFIRMED** verb responds to a confirmation request from the partner transaction program (TP). It informs the partner TP that the local TP has not detected an error in the received data. Because the TP issuing the confirmation request waits for a confirmation, **MC_CONFIRMED** synchronizes the processing of the two TPs.

The following structure describes the verb control block (VCB) used by the **MC_CONFIRMED** verb.

Syntax

```
struct mc_confirmed {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned long   conv_id;
    unsigned char   rts_rcvd;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_CONFIRMED.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTEDin the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Identifies the conversation established between the two TPs. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

rts_rcvd

Returned parameter. Indicates whether the partner TP issued MC_REQUEST_TO_SEND, which requests the local TP to change the conversation to RECEIVE state.

To change to RECEIVE state the local TP can use MC_PREPARE_TO_RECEIVE, MC_RECEIVE_AND_WAIT, or MC_RECEIVE_AND_POST.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_CONFIRMED_BAD_STATE

Secondary return code; the conversation is not in CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation must be in one of the following states when the TP issues this verb:

- CONFIRM
- CONFIRM_SEND
- CONFIRM_DEALLOCATE

The new state is determined by the old state—the state of the conversation when the local TP issued **MC_CONFIRMED**. The old state is indicated by the value of the **what_rcvd** parameter of the preceding receive verb. The following state changes are possible:

Old state	New state
CONFIRM	RECEIVE
CONFIRM_SEND	SEND
CONFIRM_DEALLOCATE	RESET

Confirmation Requests

A confirmation request is issued by one of the following verbs in the partner TP:

- MC_CONFIRM
- MC_PREPARE_TO_RECEIVE if **ptr_type** is set to AP_SYNC_LEVEL and the conversation's synchronization level (established by MC_ALLOCATE) is AP_CONFIRM_SYNC_LEVEL
- MC_DEALLOCATE if **dealloc_type** is set to AP_SYNC_LEVEL and the conversation's synchronization level (established by MC_ALLOCATE) is AP_CONFIRM_SYNC_LEVEL
- MC_SEND_DATA if type is set to AP_SEND_DATA_CONFIRM and the conversation's synchronization level (established by MC_ALLOCATE) is AP_CONFIRM_SYNC_LEVEL

A confirmation request is received by the local TP through the **what_rcvd** parameter of one of the following verbs:

- MC_RECEIVE_IMMEDIATE
- MC_RECEIVE_AND_WAIT
- MC_RECEIVE_AND_POST

MC_CONFIRMED is issued by the local TP only if **what_rcvd** contains one of the following values:

- AP_CONFIRM_WHAT_RECEIVED
- AP_CONFIRM_SEND
- AP_CONFIRM_DEALLOCATE

If the **rtn_status** parameter is set to AP_YES, **what_rcvd** can also contain the following values:

- AP_DATA_COMPLETE_CONFIRM
- AP_DATA_COMPLETE_CONFIRM_SEND
- AP_DATA_COMPLETE_CONFIRM_DEALL

MC_DEALLOCATE

The **MC_DEALLOCATE** verb deallocates a conversation between two transaction programs (TP).

The following structure describes the verb control block (VCB) used by the **MC_DEALLOCATE** verb.

Syntax

```
struct mc_deallocate {
    unsigned short   opcode;
    unsigned char    opext;
     unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    reserv3;
    unsigned char    dealloc_type;
    unsigned char    reserv4[2];
    unsigned char    reserv5[4];
    void             (WINAPI *callback)();
    void             *correlator;
    unsigned char    reserv6[4];
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_DEALLOCATE.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Identifies the conversation established between the two TPs. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv3

A reserved field.

dealloc_type

Supplied parameter. Specifies how to perform the deallocation.

For **MC_DEALLOCATE**, use AP_ABEND to deallocate the conversation abnormally. If the conversation is in SEND state when the local TP issues **MC_DEALLOCATE**, APPC sends the contents of the local logical unit's (LU) send buffer to the partner TP before deallocating the conversation. If the conversation is in RECEIVE or PENDING_POST state, APPC purges any incoming

data before deallocating the conversation.

A TP should specify AP_ABEND when it encounters an error preventing the successful completion of a transaction.

AP_FLUSH sends the contents of the local LU's send buffer to the partner TP before deallocating the conversation. This value is allowed only if the conversation is in SEND state.

AP_SYNC_LEVEL uses the conversation's synchronization level (established by MC_ALLOCATE) to determine how to deallocate the conversation. This value is allowed only if the conversation is in SEND state.

If the synchronization level of the conversation is AP_NONE, APPC sends the contents of the local LU's send buffer to the partner TP before deallocating the conversation.

If the synchronization level is AP_CONFIRM_SYNC_LEVEL, APPC sends the contents of the local LU's send buffer and a confirmation request to the partner TP. Upon receiving confirmation from the partner TP, APPC deallocates the conversation. If, however, the partner TP reports an error, the conversation remains allocated.

callback

Supplied parameter. Only present if the AP_EXTD_VCB bit is set in the **opext** member indicating support for Sync Point. This parameter is the address of a user-supplied callback function. If this field is NULL, no notification will be provided.

The prototype of the callback routine is as follows:

```
void WINAPI callback_proc(
    struct appc_hdr *vcb,
    unsigned char tp_id[8],
    unsigned long conv_id,
    unsigned short type,
    void *correlator
   );
```

The callback procedure can take any name, since the address of the procedure is passed to the APPC DLL. The parameters passed to the function are as follows:

vcb

A pointer to the **MC_DEALLOCATE** verb control block that caused the conversation to be deallocated.

tp_id

The TP identifier of the TP that owned the deallocated conversation.

conv_id

The conversation identifier of the deallocated conversation.

type

The type of the message flow that caused the callback to be invoked. Possible values are:

AP_DATA_FLOW

Normal data flow on the session.

AP_UNBIND

The session was unbound normally.

AP_FAILURE

The session terminated due to an outage.

correlator

This value is the **correlator** specified on the **MC_DEALLOCATE** verb.

correlator

Supplied parameter. Only present if the AP_EXTD_VCB bit is set in the **opext** member indicating support for the Sync Point API. This **correlator** field allows the TP to specify a value it can use to correlate a call to the callback function with, for example, its own internal data structures. This value is returned to the TP as one of the parameters of the callback routine when it is invoked.

reserv4

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_DEALLOC_BAD_TYPE

Secondary return code; the **dealloc_type** parameter was not set to a valid value.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_DEALLOC_CONFIRM_BAD_STATE

Secondary return code; the conversation was not in SEND state, and the TP attempted to flush the send buffer and send a confirmation request. This attempt occurred because the value of **dealloc_type** was AP_SYNC_LEVEL and the synchronization level of the conversation was AP_CONFIRM_SYNC_LEVEL.

AP_DEALLOC_FLUSH_BAD_STATE

Secondary return code; the conversation was not in SEND state and the TP attempted to flush the send buffer. This attempt occurred because the value of **dealloc_type** was AP_FLUSH or because the value of **dealloc_type** was AP_SYNC_LEVEL and the synchronization level of the conversation was AP_NONE. In either case, the conversation must be in SEND state.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued MC_SEND_ERROR. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued **MC_DEALLOCATE** with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

Remarks

Depending on the value of the **dealloc_type** parameter, the conversation can be in one of the states indicated in the following table when the TP issues **MC_DEALLOCATE**.

Dealloc_type	**Allowed state**
AP_FLUSH	SEND
AP_SYNC_LEVEL	SEND
AP_ABEND	Any state except RESET
AP_ABEND_PROG	Any state except RESET
AP_ABEND_SVC	Any state except RESET
AP_ABEND_TIMER	Any state except RESET

State changes, summarized in the following table, are based on the value of the **primary_rc**.

Primary_rc	**New state**
AP_OK	RESET
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_PROG_ERROR_PURGING	RECEIVE

Before deallocating the conversation, this verb performs the equivalent of one of the following:

- MC_FLUSH, by sending the contents of the local LU's send buffer to the partner LU (and TP).
- MC_CONFIRM, by sending the contents of the local LU's send buffer and a confirmation request to the partner TP.

After this verb has successfully executed, the conversation identifier is no longer valid.

LU 6.2 Sync Point can use an optimization of the message flows known as implied forget. When the protocol specifies that a FORGET PS header is required, the next data flow on the session implies that a FORGET has been received. In the normal situation, the TP is aware of the next data flow when data is received or sent on one of its Sync Point conversations.

However, it is possible that the last message to flow is caused by the conversation being deallocated. In this case, the TP is unaware when the next data flow on the session occurs. In order to provide the TP with this notification, the **MC_DEALLOCATE** verb is modified to allow the TP to register a callback function which will be called:

- On the first normal flow transmission (request or response) over the session used by the conversation.
- If the session is unbound before any other data flows.
- If the session is terminated abnormally due to a DLC outage.

The **MC_DEALLOCATE** verb also contains a **correlator** field member that is returned as one of the parameters when the callback function is invoked. The application can use this parameter in any way (for example, as a pointer to a control block within the application).

The TP can use the *type* parameter passed to the callback function to determine whether the message flow indicates an implied forget has been received.

Note that the **MC_DEALLOCATE** verb will probably complete before the callback routine is called. The conversation is considered to be in RESET state and no further verbs can be issued using the conversation identifier. If the application issues a TP_ENDED verb before the next data flow on the session, the callback routine will not be invoked.

Host Integration Server 2009 allows TPs to deallocate conversations immediately after sending data by specifying the type parameter on MC_SEND_DATA as AP_SEND_DATA_DEALLOC_*. However, the **MC_SEND_DATA** verbs do not contain the implied forget callback function. TPs wishing to receive implied forget notification must issue **MC_DEALLOCATE** explicitly.

MC_FLUSH

The **MC_FLUSH** verb sends the contents of the local logical unit's (LU) send buffer to the partner LU and transaction program (TP). If the send buffer is empty, no action takes place.

The following structure describes the verb control block (VCB) used by the **MC_FLUSH** verb.

Syntax

```
struct mc_flush {
    unsigned short  opcode;
    unsigned char   opext;
    unsigned char   reserv2;
    unsigned short  primary_rc;
    unsigned long   secondary_rc;
    unsigned char   tp_id[8];
    unsigned long   conv_id;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_FLUSH.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_FLUSH_NOT_SEND_STATE

Secondary return code; the conversation was not in SEND state.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

Data processed by MC_SEND_DATA accumulates in the local LU's send buffer until one of the following happens:

- The local TP issues **MC_FLUSH** (or other verb that flushes the LU's send buffer).
- The buffer is full.

The request generated by MC_ALLOCATE is also buffered.

The conversation must be in SEND state when the TP issues this verb.

There is no state change.

MC_GET_ATTRIBUTES

The **MC_GET_ATTRIBUTES** verb returns the attributes of the conversation.

The following structure describes the verb control block (VCB) used by the **MC_GET_ATTRIBUTES** verb.

Syntax

```
struct mc_get_attributes {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    reserv3;
    unsigned char    sync_level;
    unsigned char    mode_name[8];
    unsigned char    net_name[8];
    unsigned char    lu_name[8];
    unsigned char    lu_alias[8];
    unsigned char    plu_alias[8];
    unsigned char    plu_un_name[8];
    unsigned char    reserv4[2];
    unsigned char    fqplu_name[17];
    unsigned char    reserv5;
    unsigned char    user_id[10];
    unsigned long    conv_group_id;
    unsigned char    conv_corr_len;
    unsigned char    conv_corr[8];
    unsigned char    reserv6[13];
//  NOTE: The following fields are present
//  when the high bit of opext is set
//  (opext & AP_EXTD_VCB) != 0.
    unsigned char    luw_id[26];
    unsigned char    sess_id[8];
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_GET_ATTRIBUTES.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local transaction program (TP). The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

sync_level

Returned parameter. Specifies the level of synchronization processing for the conversation. This parameter determines whether the TPs can request confirmation of receipt of data and confirm receipt of data.

AP_NONE indicates that confirmation processing will not be used in this conversation.

AP_CONFIRM_SYNC_LEVEL indicates that TPs can use confirmation processing in this conversation.

AP_SYNCPT indicates that TPs can use Sync Point Level 2 confirmation processing in this conversation.

mode_name

Returned parameter. Specifies the name of a set of networking characteristics. It is a type A EBCDIC character string.

net_name

Returned parameter. Specifies the name of the SNA network containing the local logical unit (LU) used by this TP. It is a type A EBCDIC character string.

lu_name

Returned parameter. Provides the name of the local LU.

lu_alias

Returned parameter. Provides the alias by which the local LU is known to the local TP. It is an ASCII character string.

plu_alias

Returned parameter. Provides the alias by which the partner LU is known to the local TP. It is an ASCII character string.

plu_un_name

Returned parameter. Specifies the uninterpreted name of the partner LU—the name of the partner LU as defined to the system services control point (SSCP). It is a type AE EBCDIC character string. This parameter is returned only if the local LU is dependent.

fqplu_name

Returned parameter. Provides the fully qualified name of the partner LU. It is a type A EBCDIC character string. The field contains the network name, an EBCDIC period, and the partner-LU name.

user_id

Returned parameter. Specifies the user identifier sent by the invoking TP through MC_ALLOCATE to access the invoked TP (if applicable). It is a type AE EBCDIC character string. The field contains the user identifier if the following conditions are true:

- The invoked TP requires conversation security.
- **MC_GET_ATTRIBUTES** was issued by the invoked TP.

Otherwise, the field contains spaces.

conv_group_id

Returned parameter. Specifies the conversation group identifier for the session to which the conversation has been allocated. This is also returned on MC_ALLOCATE and RECEIVE_ALLOCATE.

conv_corr_len

Returned parameter. Specifies the length of the conversation correlator identifier that is returned.

conv_corr

Returned parameter. Specifies the conversation correlator identifier (if any) that the source LU assigns to identify the conversation, which is unique for the source/partner LU pair. It is sent by the source LU on the allocation request.

Note

The following fields are present when the high bit of opext is set (opext & AP_EXTD_VCB) != 0.These fields are only present when using Sync Point Level 2 support.

luw_id

Logical unit-of-work identifier.

sess_id

Session identifier.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any state except RESET when the TP issues this verb.

There is no state change.

MC_POST_ON_RECEIPT

The **MC_POST_ON_RECEIPT** verb allows the application to register to receive a notification when data or status arrives at the local logical unit (LU) without actually receiving it at the same time. This verb can only be issued while in RECEIVE state and it never causes a change in conversation state.

When the transaction program (TP) issues this verb, APPC returns control to the TP immediately. When the specified conditions are satisfied, the Win32® event specified by the **sema** parameter is signaled and the verb completes. Then the TP looks at the return code in the verb control block (VCB) to determine whether or not any data or status notification has arrived at the local LU and issues an MC_RECEIVE_IMMEDIATE or MC_RECEIVE_AND_WAIT verb to actually receive the data or status notification.

The **MC_POST_ON_RECEIPT** verb implements both the **POST_ON_RECEIPT** and **TEST** verbs as described in the IBM Transaction Programmer's manual for LU Type 6.2.

The following structure describes the verb control block used by the **MC_POST_ON_RECEIPT** verb.

Syntax

```
struct mc_post_on_receipt {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv1;
    unsigned char    primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned short   reserv2;
    unsigned char    reserv3;
    unsigned char    reserv4;
    unsigned short   max_len;
    unsigned short   reserv5;
    unsigned char *  reserv6;
    unsigned char    reserv7[5];
    unsigned long    sema;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_POST_ON_RECEIPT.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv1

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or byRECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv2

A reserved field.

reserv3

A reserved field.

reserv4

A reserved field.

max_len

Supplied parameter. Specifies the length of data that triggers APPC to post a notification to the TP.

reserv5

A reserved field.

reserv6

A reserved field.

reserv7

A reserved field.

sema

Supplied parameter. Specifies the handle of a Win32 event. The event should have been created by the TP and the TP is responsible for ensuring that it is reset before a call is made and after the verb completes.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_DATA

Secondary return code; data is available for the program to receive.

AP_NOT_DATA

Secondary return code; information other than data is available for the program to receive.

AP_CANCELLED

Primary return code; the verb was canceled.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_INVALID_SEMAPHORE_HANDLE

Secondary return code; the **sema** parameter was not set to a valid value.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_DEALLOC_ABEND_PROG

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE.

- The partner TP has encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

AP_DEALLOC_NORMAL

Primary return code; the partner TP has deallocated the conversation without requesting confirmation and issued MC_DEALLOCATE with **dealloc_type** set to one of the following:

- AP_CONFIRM_SYNC_LEVEL
- AP_FLUSH
- AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

AP_PROG_ERROR_NO_TRUNC

Primary return code; the partner TP has issued MC_SEND_ERROR while the conversation was in SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued MC_SEND_ERROR. Data sent but not yet received is purged.

AP_PROG_ERROR_TRUNC

Primary return code; the partner TP has issued MC_SEND_ERROR while the conversation was in SEND state. Data was truncated.

AP_SVC_ERROR_NO_TRUNC

Primary return code; the partner TP (or partner LU) issued MC_SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP was not truncated.

AP_SVC_ERROR_PURGING

Primary return code; the partner TP (or partner LU) issued MC_SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

AP_SVC_ERROR_TRUNC

Primary return code; the partner TP (or partner LU) issued MC_SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been truncated.

Remarks

While an **MC_POST_ON_RECEIPT** verb is outstanding, the following verbs can be issued on the same conversation:

GET_ATTRIBUTES

GET_TYPE

MC_DEALLOCATE

MC_RECEIVE_AND_WAIT

MC_RECEIVE_IMMEDIATE

MC_REQUEST_TO_SEND

MC_SEND_ERROR

MC_TEST_RTS

TP_ENDED

Issuing any of the following verbs prior to completion of the asynchronous **MC_POST_ON_RECEIPT** verb causes the

MC_POST_ON_RECEIPT verb to be canceled (the Win32 event is signaled and the primary return code in the verb control block is set to AP_CANCELLED).

MC_DEALLOCATE

MC_RECEIVE_AND_WAIT

MC_RECEIVE_IMMEDIATE

MC_SEND_ERROR

TP_ENDED

MC_PREPARE_TO_RECEIVE

The **MC_PREPARE_TO_RECEIVE** verb changes the state of the conversation for the local transaction program (TP) from SEND to RECEIVE.

The following structure describes the verb control block (VCB) used by the **MC_PREPARE_TO_RECEIVE** verb.

Syntax

```
struct mc_prepare_to_receive {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    primary_rc;
    unsigned short   reserv2;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    ptr_type;
    unsigned char    locks;
};
```

Remarks

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_PREPARE_TO_RECEIVE.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or byRECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

ptr_type

Supplied parameter. Specifies how to perform the state change.

Use AP_FLUSH to send the contents of the local logical unit's (LU) send buffer to the partner LU (and TP) before changing the conversation's state to RECEIVE.

The AP_SYNC_LEVEL value uses the conversation's synchronization level (established by **MC_ALLOCATE**) to determine how to perform the state change.

If the synchronization level of the conversation is AP_NONE, APPC sends the contents of the local LU's send buffer to the partner TP before changing the conversation's state to RECEIVE. If the synchronization level is AP_CONFIRM_SYNC_LEVEL, APPC sends the contents of the local LU's send buffer and a confirmation request to the partner TP. Upon receiving

confirmation from the partner TP, APPC changes the conversation's state to RECEIVE. If, however, the partner TP reports an error, the state changes to RECEIVE or RESET. See the Remarks in this topic.

locks

Supplied parameter. Specifies when APPC should return control to the local TP.

Use this parameter only if **ptr_type** is set to AP_SYNC_LEVEL and the synchronization level of the conversation, established by **MC_ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. (Otherwise, the parameter is ignored.)

- AP_LONG indicates that APPC returns control to the local TP when the confirmation and subsequent data from the partner TP arrive at the local LU. (This method results in more efficient use of the network but requires a longer time to return control to the local TP.)

- AP_SHORT indicates that APPC returns control to the local TP when the confirmation from the partner TP arrives at the local LU.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_P_TO_R_INVALID_TYPE

Secondary return code; the **ptr_type** parameter was not set to a valid value.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_P_TO_R_NOT_SEND_STATE

Secondary return code; the conversation was not in SEND state.

AP_P_TO_R_NOT_LL_BDY

Secondary return code; the local TP did not finish sending a logical record.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued MC_SEND_ERROR. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

Remarks

Before changing the conversation state, this verb performs the equivalent of one of the following:

- MC_FLUSH, by sending the contents of the local LU's send buffer to the partner LU (and TP).
- MC_CONFIRM, by sending the contents of the local LU's send buffer and a confirmation request to the partner TP.

After this verb has successfully executed, the local TP can receive data.

The conversation must be in SEND state when the TP issues this verb.

State changes, summarized in the following table, are based on the value of **primary_rc**.

primary_rc	**New state**
AP_OK	RECEIVE
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE

The conversation does not change to SEND state for the partner TP until the partner TP receives one of the following values through the **what_rcvd** parameter of a subsequent receive verb:

- AP_SEND
- AP_CONFIRM_SEND and replies with MC_CONFIRMED
- AP_DATA_COMPLETE_CONFIRM_SEND and replies with **MC_CONFIRMED**
- AP_DATA_CONFIRM_SEND and replies with **MC_CONFIRMED**

The receive verbs are MC_RECEIVE_AND_POST, MC_RECEIVE_IMMEDIATE, and MC_RECEIVE_AND_WAIT.

MC_RECEIVE_AND_POST

The **MC_RECEIVE_AND_POST** verb receives application data and status information asynchronously. This allows the local transaction program (TP) to proceed with processing while data is still arriving at the local logical unit (LU).

While an asynchronous **MC_RECEIVE_AND_POST** is outstanding, the following verbs can be issued on the same conversation:

- GET_TYPE
- MC_GET_ATTRIBUTES
- MC_REQUEST_TO_SEND
- MC_SEND_ERROR
- MC_TEST_RTS
- TP_ENDED

This allows an application to use an asynchronous **MC_RECEIVE_AND_POST** to receive data. While the **MC_RECEIVE_AND_POST** is outstanding, it can still use **MC_SEND_ERROR** and **REQUEST_TO_SEND**. It is recommended that you use this feature for full asynchronous support. For information on how a TP receives data and how to use this verb, see Remarks in this topic.

The following structure describes the verb control block (VCB) used by the **MC_RECEIVE_AND_POST** verb.

Syntax

```
struct mc_receive_and_post {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      what_rcvd;
    unsigned char       rtn_status;
    unsigned char       reserv4;
    unsigned char       rts_rcvd;
    unsigned char       reserv5;
    unsigned short      max_len;
    unsigned short      dlen;
    unsigned char FAR * dptr;
    unsigned char FAR * sema;
    unsigned char       reserv6;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_RECEIVE_AND_POST.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary

depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or byRECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

what_rcvd

Returned parameter. Indicates whether data or conversation status was received.

- AP_CONFIRM_DEALLOCATE indicates that the partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_SYNC_LEVEL. The conversation's synchronization level, established by MC_ALLOCATE, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues MC_CONFIRMED.

- AP_CONFIRM_SEND indicates that the partner TP issued MC_PREPARE_TO_RECEIVE with ptr_type set to AP_SYNC_LEVEL. The conversation's synchronization level, established by **MC_ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues **MC_CONFIRMED**, and begins to send data.

- AP_CONFIRM_WHAT_RECEIVED indicates that the partner TP issued MC_CONFIRM. Upon receiving this value, the local TP normally issues **MC_CONFIRMED**.

- AP_DATA_COMPLETE indicates, for **MC_RECEIVE_AND_POST**, that the local TP has received a complete data record or the last part of a data record. Upon receiving this value, the local TP normally reissues **MC_RECEIVE_AND_POST** or issues another receive verb. If the partner TP has sent more data, the local TP begins to receive a new unit of data. Otherwise, the local TP examines status information.

  If **primary_rc** contains AP_OK and **what_rcvd** contains AP_SEND, AP_CONFIRM_SEND, AP_CONFIRM_DEALLOCATE, or AP_CONFIRM_WHAT_RECEIVED, see the description of the value (in this section) for the next action the local TP normally takes.

  If primary_rc contains AP_DEALLOC_NORMAL, the conversation has been deallocated in response to the MC_DEALLOCATE issued by the partner TP.

- AP_DATA_INCOMPLETE indicates, for **MC_RECEIVE_AND_POST**, that the local TP has received an incomplete data record. The **max_len** parameter specified a value less than the length of the data record (or less than the remainder of the data record if this is not the first receive verb to read the record). Upon receiving this value, the local TP normally reissues **MC_RECEIVE_AND_POST** (or issues another receive verb) to receive the next part of the record.

- AP_NONE indicates that the TP did not receive data or conversation status indicators.

- AP_SEND indicates, for the partner TP, that the conversation has entered RECEIVE state. For the local TP, the conversation is now in SEND state. Upon receiving this value, the local TP normally uses MC_SEND_DATA to begin sending data.

rtn_status

Supplied parameter. Indicates whether both data and conversation status indicators should be returned within one API call.

- AP_NO specifies that indicators should be returned individually on separate invocations of the verb.

- AP_YES specifies that indicators should be returned together, provided both are available. Both can be returned when:

The receive buffer is large enough to hold all of the data that precedes the status indicator.

The data is the last data record before the status indicator.

rts_rcvd

Returned parameter. Indicates whether the partner TP issued MC_REQUEST_TO_SEND.

- AP_YES indicates that the partner TP issued **MC_REQUEST_TO_SEND**, which requests that the local TP change the conversation to RECEIVE state.
- AP_NO indicates that the partner TP has not issued **MC_REQUEST_TO_SEND**.

Max_len

Supplied parameter. Specifies the maximum number of bytes of data the local TP can receive. The range is from 0 through 65535.

The value must not exceed the length of the buffer to contain the received data. The offset of **dptr** plus the value of **max_len** must not exceed the size of the data segment.

dlen

Returned parameter. Specifies the number of bytes of data received. Data is stored in the buffer specified by **dptr**. A length of zero indicates that no data was received.

dptr

Supplied parameter. Provides the address of the buffer to contain the data received by the local LU.

For the Microsoft® Windows® 2000 operating system, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For the OS/2 operating system, the data buffer must reside on an unnamed, shared segment, which is allocated by the **DosAllocSeg** function with Flags equal to 1. The data buffer must fit entirely on the data segment.

sema

Supplied parameter. Provides the address of the semaphore that APPC is to clear when the asynchronous receiving operation is finished. The **sema** parameter is an event handle obtained by calling either the **CreateEvent** or **OpenEvent** Win32 function.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

When **rtn_status** is AP_YES, the preceding return code or one of the following return codes can be returned.

AP_DATA_COMPLETE_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_SEND.

AP_DATA_COMPLETE_CONFIRM_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_SEND.

AP_DATA_COMPLETE_CONFIRM

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_WHAT_RECEIVED.

AP_DATA_COMPLETE_CONFIRM_DEALL

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_DEALLOCATE.

AP_DEALLOC_NORMAL

Primary return code; the partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_FLUSH or AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE.

If **rtn_status** is AP_YES, examine **what_rcvd** also.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_RETURN_STATUS_WITH_DATA

Secondary return code; the specified **rtn_status** value was not recognized by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_INVALID_SEMAPHORE_HANDLE

Secondary return code; the address of the RAM semaphore or system semaphore handle was invalid.

Note
APPC cannot trap all invalid semaphore handles. If the TP passes a bad RAM semaphore handle, a protection violation results.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_RCV_AND_POST_BAD_STATE

Secondary return code; the conversation was not in RECEIVE or SEND state when the TP issued this verb.

AP_RCV_AND_POST_NOT_LL_BDY

Secondary return code; the conversation was in SEND state; the TP began but did not finish sending a logical record.

AP_CANCELED

Primary return code; the local TP issued one of the following verbs, which canceled **MC_RECEIVE_AND_POST**:

MC_DEALLOCATE with **dealloc_type** set to AP_ABEND

MC_SEND_ERROR

TP_ENDED

Issuing one of these verbs causes the semaphore to be cleared.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the

allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_NO_TRUNC

Primary return code; the partner TP issued MC_SEND_ERROR while the conversation was in SEND state. Data was not

truncated.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **MC_SEND_ERROR**. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

Remarks

The local TP receives data through the following process:

1. The local TP issues a receive verb until it finishes receiving a complete unit of data. The data received is one data record.

   The local TP may need to issue the receive verb several times in order to receive a complete unit of data. After a complete unit of data has been received, the local TP can manipulate it. The receive verbs are **MC_RECEIVE_AND_POST**, MC_RECEIVE_AND_WAIT, and MC_RECEIVE_IMMEDIATE.

2. The local TP issues the receive verb again. This has one of the following effects:

   - If the partner TP has sent more data, the local TP begins to receive a new unit of data.
   - If the partner TP has finished sending data or is waiting for confirmation, status information (available through **what_rcvd**) indicates the next action the local TP normally takes.

The following procedure shows tasks performed by the local TP in using **MC_RECEIVE_AND_POST**.

To use MC_RECEIVE_AND_POST

1. For the Windows® 2000 operating system, the TP retrieves the WinAsyncAPPC message number by calling the **RegisterWindowMessage** API or allocating a semaphore. The **sema** field should be set to NULL if the application expects to be notified through the Windows message mechanism.

   APPC sends the Windows message or clears the semaphore when the local TP finishes receiving data.

   For the OS/2 operating system, the TP uses the **DosSemSet** function to set the semaphore pointed to by **sema**.

   The semaphore will remain set while the local TP receives data asynchronously. APPC will clear the semaphore when the local TP finishes receiving data.

2. The TP issues **MC_RECEIVE_AND_POST**.
3. The TP checks the value of **primary_rc**.

If **primary_rc** is AP_OK, the receive buffer (pointed to by **dptr**) is asynchronously receiving data from the partner TP. While receiving data asynchronously, the local TP can:

- Perform tasks not related to this conversation.
- Issue MC_REQUEST_TO_SEND.
- Gather information about this conversation by issuing GET_TYPE, MC_GET_ATTRIBUTES, or MC_TEST_RTS.
- Prematurely cancel **MC_RECEIVE_AND_POST** by issuing MC_DEALLOCATE with **dealloc_type** set to AP_ABEND; MC_SEND_ERROR; or TP_ENDED.

If, however, **primary_rc** is not AP_OK, **MC_RECEIVE_AND_POST** has failed. In this case, the local TP does not perform the next two tasks.

4. For the Windows 2000 operating system, when the TP finishes receiving data asynchronously, APPC issues the WinAsyncAPPC Windows message or clears the semaphore.

   For the OS/2 operating system, the TP uses the **DosSemWait** function to wait for APPC to clear the semaphore pointed to by **sema**. When the TP finishes receiving data asynchronously, APPC clears the semaphore. To prevent the local TP from waiting, have it test the semaphore (invoking **DosSemWait** with **Timeout** set to zero) until APPC clears the semaphore.

5. The TP checks the new value of **primary_rc**.

   If **primary_rc** is AP_OK, the local TP can examine the other returned parameters and manipulate the asynchronously received data.

   If **primary_rc** is not AP_OK, only **secondary_rc** and **rts_rcvd** (request-to-send received) are meaningful.

Conversation State Effects

The conversation must be in RECEIVE or SEND state when the TP issues this verb.

Issuing **MC_RECEIVE_AND_POST** while the conversation is in SEND state has the following effects:

- The local LU sends the information in its send buffer and a SEND indicator to the partner TP.
- The conversation changes to PENDING_POST state; the local TP is ready to receive information from the partner TP asynchronously.

The conversation changes states twice:

- Upon initial return of the verb, if **primary_rc** contains AP_OK, the conversation changes to PENDING_POST state.
- After completion of the verb, the state changes depending on the value of the following:

  The **primary_rc** parameter

  The **what_rcvd** parameter if **primary_rc** is AP_OK

The following table shows the new state associated with each value of **what_rcvd** when **primary_rc** is AP_OK.

what_rcvd	New state
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE

AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	RECEIVE
AP_DATA_COMPLETE	RECEIVE
AP_DATA_INCOMPLETE	RECEIVE
AP_SEND	SEND
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table shows the new state associated with each value of **primary_rc** other than AP_OK.

primary_rc	**New state**
AP_CANCELED	No change
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_PROG_ERROR_NO_TRUNC	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_NO_TRUNC	RECEIVE
AP_PROG_ERROR_TRUNC	RECEIVE
AP_SVC_ERROR_TRUNC	RECEIVE

MC_RECEIVE_AND_WAIT

The **MC_RECEIVE_AND_WAIT** verb receives any data that is currently available from the partner transaction program (TP). If no data is currently available, the local TP waits for data to arrive.

To allow full use to be made of the asynchronous support, asynchronously issued **MC_RECEIVE_AND_WAIT** verbs have been altered to act like MC_RECEIVE_AND_POST verbs. Specifically, while an asynchronous **MC_RECEIVE_AND_WAIT** is outstanding, the following verbs can be issued on the same conversation:

- GET_TYPE
- MC_GET_ATTRIBUTES
- MC_REQUEST_TO_SEND
- MC_SEND_ERROR
- MC_TEST_RTS
- TP_ENDED

This allows an application, and in particular, a 5250 emulator, to use an asynchronous **MC_RECEIVE_AND_WAIT** to receive data. While the **MC_RECEIVE_AND_WAIT** is outstanding, it can still use **MC_SEND_ERROR** and **MC_REQUEST_TO_SEND**. It is recommended that you use this feature for full asynchronous support.

The following structure describes the verb control block (VCB) used by the **MC_RECEIVE_AND_WAIT** verb.

Syntax

```
struct mc_receive_and_wait {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      what_rcvd;
    unsigned char       rtn_status;
    unsigned char       reserv4;
    unsigned char       rts_rcvd;
    unsigned char       reserv5;
    unsigned short      max_len;
    unsigned short      dlen;
    unsigned char FAR * dptr;
    unsigned char       reserv6[5];
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_RECEIVE_AND_WAIT.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Specifies the conversation identifier.

The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

what_rcvd

Returned parameter. Indicates whether data or conversation status was received.

- AP_CONFIRM_DEALLOCATE indicates that the partner TP has issued MC_DEALLOCATE with **dealloc_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **MC_ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues MC_CONFIRMED.

- AP_CONFIRM_SEND indicates that the partner TP has issued MC_PREPARE_TO_RECEIVE with **ptr_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **MC_ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues **MC_CONFIRMED** and begins to send data.

- AP_CONFIRM_WHAT_RECEIVED indicates that the partner TP has issued MC_CONFIRM. Upon receiving this value, the local TP normally issues **MC_CONFIRMED**.

- AP_DATA_COMPLETE indicates, for **MC_RECEIVE_AND_WAIT**, that the local TP has received a complete data record or the last part of a data record. Upon receiving this value, the local TP normally reissues **MC_RECEIVE_AND_WAIT** or issues another receive verb. If the partner TP has sent more data, the local TP begins to receive a new unit of data.

  Otherwise, the local TP examines status information, if **primary_rc** contains AP_OK and **what_rcvd** contains AP_SEND, AP_CONFIRM_SEND, AP_CONFIRM_DEALLOCATE, or AP_CONFIRM_WHAT_RECEIVED.

  See Return Codes in this topic for the next action the local TP normally takes.

  If primary_rc contains AP_DEALLOC_NORMAL, the conversation has been deallocated in response to MC_DEALLOCATE issued by the partner TP.

- AP_DATA_INCOMPLETE indicates that the local TP has received an incomplete data record. The **max_len** parameter specified a value less than the length of the data record (or less than the remainder of the data record if this is not the first receive verb to read the record). Upon receiving this value, the local TP normally reissues **MC_RECEIVE_AND_WAIT** (or issues another receive verb) to receive the next part of the record.

- AP_NONE indicates that the TP did not receive data or conversation status indicators.

- AP_SEND indicates, for the partner TP, that the conversation has entered RECEIVE state. For the local TP, the conversation is now in SEND state. Upon receiving this value, the local TP normally uses MC_SEND_DATA to begin sending data.

rtn_status

Supplied parameter. Indicates whether both data and conversation status indicators should be returned within one API call.

- AP_NO specifies that indicators should be returned individually on separate invocations of the verb.

- AP_YES specifies that indicators should be returned together, provided both are available. Both can be returned when:

  The receive buffer is large enough to hold all of the data that precedes the status indicator.

  The data is the last data record before the status indicator.

rts_rcvd

Returned parameter. Contains the request-to-send indicator.

- AP_YES indicates that the partner TP has issued MC_REQUEST_TO_SEND, which requests that the local TP change the conversation to RECEIVE state.

- AP_NO indicates that the partner TP has not issued **MC_REQUEST_TO_SEND**.

max_len

Supplied parameter. Indicates the maximum number of bytes of data the local TP can receive. The range is from 0 through 65535.

For the Microsoft® Windows® 2000 operating system and the Windows graphical environment, this value must not exceed the length of the buffer to contain the received data.

For the OS/2 operating system, the offset of **dptr** plus the value of **max_len** must not exceed the size of the data segment.

By issuing **MC_RECEIVE_AND_WAIT** with **max_len** set to zero, the local TP can determine whether the partner TP has data to send, seeks confirmation, or has changed the conversation state.

dlen

Returned parameter. Indicates the number of bytes of data received. Data is stored in the buffer specified by **dptr**. A length of zero indicates that no data was received.

dptr

Supplied parameter. Provides the address of the buffer to contain the data received by the local TP.

For the Windows 2000 operating system and the Windows graphical environment, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For the OS/2 operating system, the data buffer must reside on an unnamed, shared segment, which is allocated by the **DosAllocSeg** function with Flags equal to 1. The data buffer must fit entirely on the data segment.

For the Windows environment, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

Return Codes
AP_OK

Primary return code; the verb executed successfully.

When **rtn_status** is AP_YES, the preceding return code or one of the following return codes can be returned.

AP_DATA_COMPLETE_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_SEND.

AP_DATA_COMPLETE_CONFIRM_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_SEND.

AP_DATA_COMPLETE_CONFIRM

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_WHAT_RECEIVED.

AP_DATA_COMPLETE_CONFIRM_DEALL

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_DEALLOCATE.

AP_DEALLOC_NORMAL

Primary return code; the partner TP has deallocated the conversation without requesting confirmation and issued MC_DEALLOCATE with **dealloc_type** set to one of the following:

- AP_CONFIRM_SYNC_LEVEL
- AP_FLUSH
- AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

If **rtn_status** is AP_YES, examine **what_rcvd** also.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_RETURN_STATUS_WITH_DATA

Secondary return code; the specified **rtn_status** value was not recognized by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_RCV_AND_WAIT_BAD_STATE

Secondary return code; the conversation was not in RECEIVE or SEND state when the TP issued this verb.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner logical unit (LU) or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_NO_TRUNC

Primary return code; the partner TP has issued MC_SEND_ERROR while the conversation was in SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **MC_SEND_ERROR**. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

Remarks

The local TP receives data through the following process:

1. The local TP issues a receive verb until it finishes receiving a complete unit of data. The data received is one data record.

   The local TP may need to issue the receive verb several times in order to receive a complete unit of data. After a complete unit of data has been received, the local TP can manipulate it.

   The receive verbs are MC_RECEIVE_AND_POST, **MC_RECEIVE_AND_WAIT**, and MC_RECEIVE_IMMEDIATE.

2. The local TP issues the receive verb again. This has one of the following effects:

   - If the partner TP has sent more data, the local TP begins to receive a new unit of data.
   - If the partner TP has finished sending data or is waiting for confirmation, status information (available through the **what_rcvd** parameter) indicates the next action the local TP normally takes.

The conversation must be in RECEIVE or SEND state when the TP issues this verb.

Issuing the Verb in SEND State

Issuing **MC_RECEIVE_AND_WAIT** while the conversation is in SEND state has the following effects:

- The local LU sends the information in its send buffer and a SEND indicator to the partner TP.
- The conversation changes to RECEIVE state; the local TP waits for the partner TP to send data.

State Change

The new conversation state is determined by the following factors:

- The state the conversation is in when the TP issues the verb.
- The **primary_rc** parameter.
- The **what_rcvd** parameter if **primary_rc** contains AP_OK.

Verb Issued in SEND State

The following table details the state changes when **MC_RECEIVE_AND_WAIT** is issued in SEND state and **primary_rc** is AP_OK.

what_rcvd	**New state**
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	RECEIVE
AP_DATA_COMPLETE	RECEIVE
AP_DATA_INCOMPLETE	RECEIVE
AP_SEND	No change
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table details the state changes when **MC_RECEIVE_AND_WAIT** is issued in SEND state and **primary_rc** is not AP_OK.

primary_rc	**New state**
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	RECEIVE

AP_PROG_ERROR_NO_TRUNC	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_NO_TRUNC	RECEIVE

Verb Issued in RECEIVE State

The following table details the state changes when **MC_RECEIVE_AND_WAIT** is issued in RECEIVE state and **primary_rc** is AP_OK.

what_rcvd	**New state**
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	No change
AP_DATA_COMPLETE	No change
AP_DATA_INCOMPLETE	No change
AP_SEND	SEND
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table details the state changes when **MC_RECEIVE_AND_WAIT** is issued in RECEIVE state and **primary_rc** is not AP_OK.

AP_SVC_ERROR_TRUNC	No change

MC_RECEIVE_IMMEDIATE

The **MC_RECEIVE_IMMEDIATE** verb receives any data currently available from the partner transaction program (TP). If no data is available, the local TP does not wait. To avoid blocking the conversation, issue MC_RECEIVE_AND_WAIT in conjunction with WinAsyncAPPC. The following structure describes the verb control block (VCB) used by the **MC_RECEIVE_IMMEDIATE** verb.

Syntax

```
struct mc_receive_immediate {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      what_rcvd;
    unsigned char       rtn_status;
    unsigned char       reserv4;
    unsigned char       rts_rcvd;
    unsigned char       reserv5;
    unsigned short      max_len;
    unsigned short      dlen;
    unsigned char FAR * dptr;
    unsigned char       reserv6[5];
};
```

Members

Opcode

Supplied parameter. Specifies the verb operation code, AP_M_RECEIVE_IMMEDIATE.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

Reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

what_rcvd

Returned parameter. Contains information received with the incoming data:

- AP_CONFIRM_DEALLOCATE indicates that the partner TP has issued MC_DEALLOCATE with **dealloc_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **MC_ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues MC_CONFIRMED.

- AP_CONFIRM_SEND indicates that the partner TP has issued MC_PREPARE_TO_RECEIVE with **ptr_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **MC_ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues **MC_CONFIRMED**, and begins to send data.

- AP_CONFIRM_WHAT_RECEIVED indicates that the partner TP has issued MC_CONFIRM. Upon receiving this value, the local TP normally issues **MC_CONFIRMED**.

- AP_DATA_COMPLETE indicates, for **MC_RECEIVE_IMMEDIATE** in mapped conversations, that the local TP has received a complete data record or the last part of a data record. Upon receiving this value, the local TP normally reissues **MC_RECEIVE_IMMEDIATE** or issues another receive verb. If the partner TP has sent more data, the local TP begins to receive a new unit of data.

  Otherwise, the local TP examines status information if **primary_rc** contains AP_OK and **what_rcvd** contains any of these values:

  AP_SEND

  AP_CONFIRM_SEND

  AP_CONFIRM_DEALLOCATE

  AP_CONFIRM_WHAT_RECEIVED

  See the description of the value in Return Codes in this topic for the next action the local TP normally takes.

  If **primary_rc** contains AP_DEALLOC_NORMAL, the conversation has been deallocated in response to MC_DEALLOCATE issued by the partner TP.

- AP_DATA_INCOMPLETE indicates for **MC_RECEIVE_IMMEDIATE** in mapped conversations that the local TP has received an incomplete data record. The **max_len** parameter specified a value less than the length of the data record (or less than the remainder of the data record if this is not the first receive verb to read the record). Upon receiving this value, the local TP normally reissues **MC_RECEIVE_IMMEDIATE** (or issues another receive verb) to receive the next part of the record.

- AP_NONE indicates that the TP did not receive data or conversation status indicators.

- AP_SEND indicates, for the partner TP, the conversation has entered RECEIVE state. For the local TP, the conversation is now in SEND state. Upon receiving this value, the local TP normally uses MC_SEND_DATA to begin sending data.

rtn_status

Supplied parameter. Indicates whether both data and conversation status indicators should be returned within one API call.

- AP_NO specifies that indicators should be returned individually on separate invocations of the verb.

- AP_YES specifies that indicators should be returned together, provided both are available. Both can be returned when:

  The receive buffer is large enough to hold all of the data that precedes the status indicator.

  The data is the last data record before the status indicator.

rts_rcvd

Returned parameter. Contains the request-to-send indicator. Possible values are:

- AP_YES indicates that the partner TP has issued MC_REQUEST_TO_SEND, which requests that the local TP change the

conversation to RECEIVE state.

- AP_NO indicates that the partner TP has not issued **MC_REQUEST_TO_SEND**.

max_len

Supplied parameter. Indicates the maximum number of bytes of data the local TP can receive. The range is from 0 through 65535.

For the Microsoft® Windows® 2000 operating system and the Windows graphical environment, this value must not exceed the length of the buffer to contain the received data.

For the OS/2 operating system, the offset of **dptr** plus the value of **max_len** must not exceed the size of the data segment.

By issuing **MC_RECEIVE_IMMEDIATE** with **max_len** set to zero, the local TP can determine whether the partner TP has data to send, seeks confirmation, or has changed the conversation state.

dlen

Returned parameter. Provides the number of bytes of data received. Data is stored in a buffer specified by **dptr**. A length of zero indicates that no data was received.

dptr

Supplied parameter. Address of the buffer to contain the data received by the local TP.

For the Windows 2000 operating system and the Windows graphical environment, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

For the OS/2 operating system, the data buffer must reside on an unnamed, shared segment, which is allocated by the function **DosAllocSeg** with Flags equal to 1. The data buffer must fit entirely on the data segment.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

When **rtn_status** is AP_YES, the preceding return code or one of the following return codes can be returned.

AP_DATA_COMPLETE_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_SEND.

AP_DATA_COMPLETE_CONFIRM_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_SEND.

AP_DATA_COMPLETE_CONFIRM

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_WHAT_RECEIVED.

AP_DATA_COMPLETE_CONFIRM_DEALL

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_DEALLOCATE.

AP_UNSUCCESSFUL

Primary return code; no data is immediately available from the partner TP.

AP_DEALLOC_NORMAL

Primary return code; the partner TP has deallocated the conversation without requesting confirmation. The partner TP issued MC_DEALLOCATE with **dealloc_type** set to one of the following:

- AP_FLUSH
- AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

If **rtn_status** is AP_YES, examine **what_rcvd** also.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_RETURN_STATUS_WITH_DATA

Secondary return code; the specified **rtn_status** value was not recognized by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_RCV_IMMD_BAD_STATE

Secondary return code; the conversation was not in RECEIVE state.

AP_ALLOCATION_ERROR

Secondary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner logical unit (LU) or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_NO_TRUNC

Primary return code; the partner TP has issued MC_SEND_ERROR while the conversation was in SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **MC_SEND_ERROR**. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

Remarks

The local TP receives data through the following process:

1. The local TP issues a receive verb until it finishes receiving a complete unit of data. The data received is one data record.

   The local TP may need to issue the receive verb several times in order to receive a complete unit of data. After a complete unit of data has been received, the local TP can manipulate it.

   The receive verbs are MC_RECEIVE_AND_POST, MC_RECEIVE_AND_WAIT, and **MC_RECEIVE_IMMEDIATE**.

2. The local TP issues the receive verb again. This has one of the following effects:

   - If the partner TP has sent more data, the local TP begins to receive a new unit of data.
   - If the partner TP has finished sending data or is waiting for confirmation, status information (available through **what_rcvd**) indicates the next action the local TP normally takes.

The conversation must be in RECEIVE state when the TP issues this verb.

The new state is determined by **primary_rc**. If **primary_rc** is AP_OK, the new state is determined by **what_rcvd**.

The following table details the state changes when the **primary_rc** is AP_OK.

what_rcvd	**New state**
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	No change
AP_DATA_COMPLETE	No change
AP_DATA_INCOMPLETE	No change
AP_SEND	SEND
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table details the state changes when the **primary_rc** is not AP_OK.

primary_rc	New state
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET

AP_SVC_ERROR_PURGING	No change
AP_SVC_ERROR_NO_TRUNC	No change
AP_PROG_ERROR_TRUNC	No change
AP_SVC_ERROR_TRUNC	No change
AP_UNSUCCESSFUL	No change

MC_RECEIVE_LOG_DATA

The **MC_RECEIVE_LOG_DATA** verb allows the user to register to receive the log data associated with an inbound Function Management Header 7 (FMH7) error report. The verb passes a buffer to APPC, and any log data received is placed in that buffer. APPC continues to use this buffer as successive FMH7s arrive until it is provided with another buffer (that is, until the transaction program (TP) issues another **MC_RECEIVE_LOG_DATA** specifying a different buffer or no buffer at all).

Note that the TP itself is responsible for allocating and freeing the buffer. After the buffer has been passed to APPC, the TP should either issue another **MC_RECEIVE_LOG_DATA** specifying a new buffer or a zero-length buffer, or wait until the conversation has finished before freeing the original buffer.

When an FMH7 is received, APPC copies any associated error log general data stream (GDS) into the buffer. If there is no associated error log variable, the buffer is zeroed out. It is up to the TP to check the buffer whenever a return code from a receive verb indicates that an error has been received.

The following structure describes the verb control block (VCB) used by the **MC_RECEIVE_LOG_DATA** verb.

Syntax

```
struct mc_receive_log_data {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv1;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      log_dlen;
    unsigned char FAR * log_dptr;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_RECEIVE_LOG_DATA.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv1

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

log_dlen

Supplied parameter. Specifies the maximum length of log data that APPC can place in the buffer (that is, the buffer size). The range is from 0 through 65535. Note that a length of zero here indicates that any previous **MC_RECEIVE_LOG_DATA** verb

should be cancelled.

log_dptr

Supplied parameter. Specifies the address of the buffer that APPC will use to store the log data.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

MC_REQUEST_TO_SEND

The **MC_REQUEST_TO_SEND** verb notifies the partner transaction program (TP) that the local TP wants to send data.

The following structure describes the verb control block (VCB) used by the **MC_REQUEST_TO_SEND** verb.

Syntax

```
struct mc_request_to_send {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_REQUEST_TO_SEND.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier.

The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_R_T_S_BAD_STATE

Secondary return code; the conversation is not in an allowed state when the TP issued this verb.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with MC_ALLOCATE, it may indicate that no communications system could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Microsoft Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any of the following states when the TP issues this verb:

CONFIRM

PENDING_POST (OS/2)

RECEIVE

There is no state change.

The request-to-send notification is received by the partner program through the **rts_rcvd** parameter of the following verbs:

- MC_CONFIRM
- MC_RECEIVE_AND_POST
- MC_RECEIVE_AND_WAIT
- MC_RECEIVE_IMMEDIATE
- MC_SEND_DATA
- MC_SEND_ERROR

It is also indicated by a **primary_rc** of AP_OK on MC_TEST_RTS.

Request-to-send notification is sent to the partner TP immediately; APPC does not wait until the send buffer fills up or is flushed. Consequently, the request-to-send notification may arrive out of sequence. For example, if the local TP is in SEND state and issues MC_PREPARE_TO_RECEIVE followed by **MC_REQUEST_TO_SEND**, the partner TP, in RECEIVE state, may receive the request-to-send notification before it receives the send notification. For this reason, request-to-send can be reported to a TP through a receive verb.

In response to this request, the partner TP can change the conversation to:

- RECEIVE state by issuing **MC_PREPARE_TO_RECEIVE** or MC_RECEIVE_AND_WAIT.
- PENDING_POST state by issuing MC_RECEIVE_AND_POST.

The partner TP can also ignore the request-to-send.

The conversation state changes to SEND for the local TP when the local TP receives one of the following values through the **what_rcvd** parameter of a subsequent receive verb:

- AP_CONFIRM_SEND and replies with MC_CONFIRMED
- AP_DATA_COMPLETE_CONFIRM_SEND and replies with **MC_CONFIRMED**
- AP_SEND

The receive verbs are MC_RECEIVE_AND_POST, MC_RECEIVE_IMMEDIATE, and MC_RECEIVE_AND_WAIT.

MC_SEND_CONVERSATION

The **MC_SEND_CONVERSATION** verb allocates a session between the local logical unit (LU) and partner LU, sends data on the session, and then deallocates the session.

The following structure describes the verb control block (VCB) used by the **MC_SEND_CONVERSATION** verb.

Syntax

```
struct mc_send_conversation {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       reserv3[8];
    unsigned char       rtn_ctl;
    unsigned char       reserv4;
    unsigned long       conv_group_id;
    unsigned long       sense_data;
    unsigned char       plu_alias[8];
    unsigned char       mode_name[8];
    unsigned char       tp_name[64];
    unsigned char       security;
    unsigned char       reserv6[11];
    unsigned char       pwd[10];
    unsigned char       user_id[10];
    unsigned short      pip_dlen;
    unsigned char FAR * pip_dptr;
    unsigned char       reserv6;
    unsigned char       fqplu_name[17];
    unsigned char       reserv7[8];
    unsigned short      dlen;
    unsigned char FAR * dptr;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_SEND_CONVERSATION.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local transaction program (TP). The value of this parameter was returned by TP_STARTED.

conv_id

Supplied parameter. Provides the conversation identifier.

The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

rtn_ctl

Supplied parameter. Specifies how APPC should select a session to allocate for the conversation and when the local LU should return control to the local TP. The allowed values are:

- AP_IMMEDIATE specifies that the LU allocates a contention-winner session, if one is immediately available, and returns control to the TP.
- AP_WHEN_SESSION_ALLOCATED specifies that the LU does not return control to the TP until it allocates a session or encounters one of the errors described in Return Codes in this topic. If the session limit is zero, the LU returns control immediately. Note that if a session is not available, the TP waits for one.
- AP_WHEN_SESSION_FREE specifies that the LU allocates a contention-winner or contention-loser session, if one is available or able to be activated, and returns control to the TP. If an error occurs (as described in Return Codes in this topic) the call will return immediately with the error in the **primary_rc** and **secondary_rc** fields.
- AP_WHEN_CONWINNER_ALLOC specifies that the LU does not return control until it allocates a contention-winner session or encounters one of the errors described in Return Codes in this topic. If the session limit is zero, the LU returns control immediately. Note that if a session is not available, the TP waits for one.
- AP_WHEN_CONV_GROUP_ALLOC specifies that the LU does not return control to the TP until it allocates the session specified by **conv_group_id** or encounters one of the errors described in Return Codes in this topic. If the session is not available, the TP waits for it to become free.

conv_group_id

Supplied/returned parameter. Used as a supplied parameter when **rtn_ctl** is WHEN_CONV_GROUP_ALLOC to specify the identity of the conversation group from which the session should be allocated. When **rtn_ctl** specifies a different value, and the **primary_rc** is AP_OK, this is a returned value. The purpose of this parameter is to provide a TP with the assurance that the same session will be reallocated and therefore the conversations conducted over the session will occur in the same sequence that they were initiated.

sense_data

Returned parameter. If the primary and secondary return codes indicate an allocation error (retry or no-retry), an SNA-defined sense code is returned.

plu_alias

Supplied parameter. Specifies the alias by which the partner LU is known to the local TP. This parameter must match the name of a partner LU established during configuration. The parameter is an 8-byte, type G ASCII character set that includes:

- Uppercase letters
- Numerals 0 to 9
- Spaces
- Special characters $, #, %, and @

If the value of this parameter is fewer than eight bytes, pad it on the right with ASCII spaces (0x20).

mode_name

Supplied parameter. Specifies the name of a set of networking characteristics defined during configuration. This parameter must match the name of a mode associated with the partner LU during configuration.

The parameter is an 8-byte EBCDIC character string. It can consist of characters from the type A EBCDIC character set, including all EBCDIC spaces. These characters are:

- Uppercase letters

- Numerals 0 to 9
- Special characters $, #, and @

The first character in the string must be an uppercase letter or special character.

In a mapped conversation, the name cannot be SNASVCMG (a reserved mode name used internally by APPC).

tp_name

Supplied parameter. Specifies the name of the invoked TP. The value of **tp_name** specified by MC_ALLOCATE in the invoking TP must match the value of **tp_name** specified by RECEIVE_ALLOCATE in the invoked TP.

The parameter is a 64-byte, case-sensitive, EBCDIC character string. This parameter can consist of characters from the type AE EBCDIC character set. These characters are:

- Uppercase and lowercase letters
- Numerals 0 to 9
- Special characters $, #, @, and period (.)

If the TP name is fewer than 64 bytes, use EBCDIC spaces (0x40) to pad it on the right.

The SNA convention is that a service TP name can have up to four characters. The first character is a hexadecimal byte between 0x00 and 0x3F. The other characters are from the EBCDIC AE character set.

security

Supplied parameter. Specifies the information the partner LU requires in order to validate access to the invoked TP.

- AP_NONE specifies that the invoked TP uses no conversation security.
- AP_PGM specifies that the invoked TP uses conversation security and requires a user identifier and password. Use **user_id** and **pwd** to supply this information.
- AP_SAME specifies that the invoked TP, invoked with a valid user identifier and password, in turn invokes another TP.

For example, assume that TP A invokes TP B with a valid user identifier and password, and TP B in turn invokes TP C. If TP B specifies the value AP_SAME, APPC will send the LU for TP C the user identifier from TP A and an already-verified indicator. This indicator indicates to TP C not to require the password (if TP C is configured to accept an already-verified indicator).

pwd

Supplied parameter. Specifies the password associated with **user_id**. This parameter is required only if the security parameter is set to AP_PGM and must match the password for **user_id** that was established during configuration.

This parameter is a 10-byte, case-sensitive, EBCDIC character string. It can consist of characters from the type AE EBCDIC character set. These characters are:

- Uppercase and lowercase letters
- Numerals 0 to 9
- Special characters $, #, @, and period (.)

If the password is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

user_id

Supplied parameter. Specifies the user identifier required to access the partner TP. This parameter is required only if the security parameter is set to AP_PGM and must match one of the user identifiers configured for the partner TP.

The parameter can consist of characters from the type AE EBCDIC character set. These characters are:

- Uppercase and lowercase letters
- Numerals 0 to 9
- Special characters $, #, @, and period (.)

If the user identifier is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

pip_dlen

Supplied parameter. Specifies the length of the PIP to be passed to the partner TP. The range for this parameter is from 0 through 32767.

pip_dptr

Supplied parameter. Specifies the address of the buffer containing PIP data. Use this parameter only if **pip_dlen** is greater than zero.

PIP data can consist of initialization parameters or environmental setup information required by a partner TP or remote operating system. The PIP data must follow the GDS format. For more information, see your IBM SNA manual(s).

For the Microsoft® Windows® 2000 operating system, the data buffer can reside in a static data area or in a globally allocated area.

fqplu_name

Supplied parameter. Specifies the fully qualified name of the local LU. This parameter must match the fully qualified name of the local LU defined in the remote node. The parameter is made up of two type A EBCDIC character strings (each of up to eight characters), which are the network name (NETID) and the LU name of the partner LU. The names are separated by an EBCDIC period (.). The NETID can be omitted, and if this is the case, the period should also be omitted.

This name must be provided if no **plu_alias** is provided.

Type A EBCDIC characters contain:

- Uppercase letters
- Numerals 0 to 9
- Special characters $, #, and @

If the value of this parameter is fewer than 17 bytes, pad it on the right with EBCDIC spaces (0x40).

dlen

Supplied parameter. Specifies the number of bytes of data to be put in the local LU's send buffer. The range for this parameter is from 0 through 65535.

dptr

Supplied parameter. Specifies the address of the buffer containing the data to be put in the local LU's send buffer.

For the Windows 2000 operating system, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_UNSUCCESSFUL

Primary return code; the supplied parameter **rtn_ctl** specified immediate return of the control to the TP (AP_IMMEDIATE), and the local LU did not have an available contention-winner session.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_RETURN_CONTROL

Secondary return code; the value specified for **rtn_ctl** was invalid.

AP_BAD_SECURITY

Secondary return code; the value specified for **security** was invalid.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_PIP_LEN_INCORRECT

Secondary return code; the value of **pip_dlen** was greater than 32767.

AP_UNKNOWN_PARTNER_MODE

Secondary return code; the value specified for **mode_name** was invalid.

AP_BAD_PARTNER_LU_ALIAS

Secondary return code, APPC did not recognize the supplied **partner_lu_alias**.

AP_NO_USE_OF_SNASVCMG

Secondary return code; SNASVCMG is not a valid value for **mode_name**.

AP_INVALID_DATA_SEGMENT

Secondary return code; the PIP data or application data was longer than the allocated data segment, or the address of a data buffer was wrong.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with MC_ALLOCATE, it may indicate that no communications system could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can

satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

This verb is issued by the invoking TP to conduct an entire conversation with the remote TP. If the remote TP rejects either the conversation initiation or the data, the invoking TP will not receive notification of the rejection.

The conversation state is RESET when the TP issues this verb. There is no state change.

Several parameters of **MC_SEND_CONVERSATION** are EBCDIC or ASCII strings. A TP can use the common service verb (CSV) CONVERT to translate a string from one character set to the other.

Normally, the value of **mode_name** must match the name of a mode configured for the invoked TP's node and associated during configuration with the partner LU. If one of the modes associated with the partner LU on the invoked TP's node is an implicit mode, the session established between the two LUs will be of the implicit mode when no mode name associated with the partner LU matches the value of **mode_name**.

MC_SEND_DATA

The **MC_SEND_DATA** verb places data in the local logical unit's (LU) send buffer for transmission to the partner transaction program (TP).

The following structure describes the verb control block (VCB) used by the **MC_SEND_DATA** verb.

Syntax

```
struct mc_send_data {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       rts_rcvd;
    unsigned char       data_type;
    unsigned short int  dlen;
    unsigned char FAR * dptr ;
    unsigned char       type;
    unsigned char       reserv4;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_SEND_DATA.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier.

The value of this parameter is returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

rts_rcvd

Returned parameter. Provides the request-to-send-received indicator.

- AP_YES indicates that the partner TP has issued MC_REQUEST_TO_SEND, which requests that the local TP change the conversation to RECEIVE state. To change to RECEIVE state, the local TP can use MC_PREPARE_TO_RECEIVE, MC_RECEIVE_AND_WAIT, or MC_RECEIVE_AND_POST.

- AP_NO indicates that the partner TP has not issued **MC_REQUEST_TO_SEND**.

data_type

Supplied parameter. Specifies the type of data to be sent if Sync Point is supported. Valid parameters are:

AP_APPLICATION

AP_USER_CONTROL_DATA

AP_PS_HEADER

dlen

Supplied parameter. Specifies the number of bytes of data to be put in the local LU's send buffer. The range is from 0 through 65535.

dptr

Supplied parameter. Specifies the address of the buffer containing the data to be put in the local LU's send buffer.

For the Windows 2000 operating system, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

type

Supplied parameter. Allows a TP to send data and perform other functions within one API call. For example, you can combine **MC_SEND_DATA** with **type** set to CONFIRM to accomplish the same objective as issuing **MC_SEND_DATA** followed by MC_CONFIRM.

- AP_SEND_DATA_CONFIRM corresponds to **MC_SEND_DATA** followed by **MC_CONFIRM**.
- AP_SEND_DATA_FLUSH corresponds to **MC_SEND_DATA** followed by MC_FLUSH.
- AP_SEND_DATA_DEALLOC_ABEND corresponds to **MC_SEND_DATA** followed by MC_DEALLOCATE with a **dealloc_type** of AP_ABEND.
- AP_SEND_DATA_DEALLOC_FLUSH corresponds to **MC_SEND_DATA** followed by **MC_DEALLOCATE** with a **dealloc_type** of AP_FLUSH.
- AP_SEND_DATA_DEALLOC_SYNC_LEVEL corresponds to **MC_SEND_DATA** followed by **MC_DEALLOCATE** with a **dealloc_type** of AP_SYNC_LEVEL.
- AP_SEND_DATA_P_TO_R_FLUSH corresponds to **MC_SEND_DATA** followed by MC_PREPARE_TO_RECEIVE with a **ptr_type** of AP_FLUSH.
- AP_SEND_DATA_P_TO_R_SYNC_LEVEL corresponds to **MC_SEND_DATA** followed by **MC_PREPARE_TO_RECEIVE** with a **ptr_type** of AP_SYNC_LEVEL and **locks** set to AP_SHORT.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_SEND_DATA_INVALID_TYPE

Secondary return code; the specified type was not recognized by APPC.

AP_SEND_DATA_CONFIRM_SYNC_NONE

Secondary return code; the **type** CONFIRM is not permitted for a conversation that was allocated with a **sync_level** of NONE.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_SEND_DATA_NOT_SEND_STATE

Secondary return code; the local TP issued **MC_SEND_DATA**, but the conversation was not in SEND state.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with MC_ALLOCATE, it may indicate that no communications system could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Microsoft Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **MC_SEND_ERROR**. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

Remarks

The conversation must be in SEND state when the TP issues this verb. State changes, based on **primary_rc**, are summarized in the following table.

primary_rc	**New state**
AP_OK	No change
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE

MC_SEND_DATA may wait indefinitely because the partner TP has not issued a receive verb. If this occurs, the send buffer may fill up.

The data collected in the local LU's send buffer is transmitted to the partner LU (and partner TP) when one of the following occurs:

- The send buffer fills up.
- The local TP issues MC_FLUSH, MC_CONFIRM, or MC_DEALLOCATE (or other verb that flushes the LU's send buffer).

MC_SEND_ERROR

The **MC_SEND_ERROR** verb notifies the partner transaction program (TP) that the local TP has encountered an application-level error.

The following structure describes the verb control block (VCB) used by the **MC_SEND_ERROR** verb.

Syntax

```
struct mc_send_error {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       rts_rcvd;
      unsigned char       err_type;
    unsigned char       err_dir;
    unsigned char       reserv4;
    unsigned char       reserv5[2];
    unsigned char       reserv6[4];
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_SEND_ERROR.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by MC_ALLOCATEin the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

rts_rcvd

Returned parameter. Indicates whether the partner TP issued MC_REQUEST_TO_SEND.Possible values include:

- AP_YES indicates that the partner TP has issued **MC_REQUEST_TO_SEND**, which requests that the local TP change the conversation to RECEIVE state. To change to RECEIVE state, the local TP can use MC_PREPARE_TO_RECEIVE, MC_RECEIVE_AND_WAIT, or MC_RECEIVE_AND_POST.

- AP_NO indicates that the partner TP has not issued **MC_REQUEST_TO_SEND**.

err_type

For a mapped conversation, this parameter is supplied if Sync Point is supported. Valid values are:

AP_PROG

AP_BACKOUT_NO_RESYNC

AP_BACKOUT_RESYNC

err_dir

Supplied parameter. Indicates whether the error is with data just received or with data that is about to be sent. Use this parameter only when the conversation is in SEND_PENDING state. The parameter is ignored otherwise. The following are allowed values:

- AP_RCV_DIR_ERROR indicates that the TP issued **MC_SEND_ERROR** after detecting an error associated with the data just received.
- AP_SEND_DIR_ERROR indicates that the TP issued **MC_SEND_ERROR** after detecting an error associated with data it was going to send. For example, the TP encountered an error while reading data from the disk drive.

reserv3

A reserved field.

Return Codes
AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_ERROR_DIRECTION

Secondary return code; the specified **err_dir** was not recognized by APPC.

AP_SEND_ERROR_BAD_TYPE

Secondary return code; the value of **err_type** was invalid.

AP_SEND_ERROR_LOG_LL_WRONG

Secondary return code; the LL field of the error log GDS variable did not match the actual length of the data.

The following return codes can be generated when **MC_SEND_ERROR** is issued in any allowed state:

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with MC_ALLOCATE, it may indicate that no communications system could be found to support the local logical unit (LU). (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Microsoft Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This may occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

The following return codes can be generated only if **MC_SEND_ERROR** is issued in SEND state:

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after MC_ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **MC_SEND_ERROR**. Data sent but not yet received is purged.

AP_DEALLOC_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued MC_DEALLOCATE with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner LU to send an **MC_DEALLOCATE** request.

The following return code can be generated only if **MC_SEND_ERROR** is issued in RECEIVE state:

AP_DEALLOC_NORMAL

Primary return code; this return code does not indicate an error.

The partner TP issued MC_DEALLOCATE with **dealloc_type** set to one of the following:

- AP_FLUSH
- AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

Remarks

The conversation can be in any state except RESET when the TP issues this verb. The conversation state must be SEND_PENDING if **err_dir** is used.

The local TP sends the error notification immediately to the partner TP; it does not hold the information in the local LU's send buffer.

Upon successful execution of this verb, the conversation is in SEND state for the local TP and in RECEIVE state for the partner TP.

The new state is determined by **primary_rc**. Possible state changes are summarized in the following table.

primary_rc	**New state**
AP_OK	SEND
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE

If the conversation is in RECEIVE state when the TP issues **MC_SEND_ERROR**, incoming data is purged by APPC. This data includes:

- Data sent by MC_SEND_DATA.
- Return code indicators.
- Confirmation requests.
- Deallocation requests.

APPC does not purge an incoming request-to-send indicator. APPC replaces purged incoming return code indicators with other return codes. The primary return code AP_OK replaces the following purged return code indicators:

AP_PROG_ERROR_NO_TRUNC

AP_PROG_ERROR_PURGING

AP_PROG_ERROR_TRUNC

AP_SVC_ERROR_NO_TRUNC

AP_SVC_ERROR_PURGING

AP_SVC_ERROR_TRUNC

The primary return code AP_DEALLOC_NORMAL replaces the following purged return code indicators:

AP_ALLOCATION_ERROR

AP_ALLOCATION_FAILURE_NO_RETRY

AP_ALLOCATION_FAILURE_RETRY

AP_CONVERSATION_TYPE_MISMATCH

AP_DEALLOC_ABEND

AP_DEALLOC_ABEND_PROG

AP_DEALLOC_ABEND_SVC

AP_DEALLOC_ABEND_TIMER

AP_PIP_NOT_ALLOWED

AP_PIP_NOT_SPECIFIED_CORRECTLY

AP_SECURITY_NOT_VALID

AP_SYNC_LEVEL_NOT_SUPPORTED

AP_TP_NAME_NOT_RECOGNIZED

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

AP_TRANS_PGM_NOT_AVAIL_RETRY

When the conversation is in SEND_PENDING state, APPC reports the following return codes to the partner TP based on the value in **err_dir**:

AP_PROG_ERROR_PURGING

The local TP issued **MC_SEND_ERROR** with RECEIVE as the **err_dir**.

AP_PROG_ERROR_NO_TRUNC

The local TP issued **MC_SEND_ERROR** with SEND as the **err_dir**.

MC_TEST_RTS

The **MC_TEST_RTS** verb determines whether a request-to-send notification has been received from the partner transaction program (TP).

The following structure describes the verb control block (VCB) used by the **MC_TEST_RTS** verb.

Syntax

```
struct mc_test_rts {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       reserv3;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_TEST_RTS.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter was returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv3

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_UNSUCCESSFUL

Primary return code; request-to-send notification has not been received.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with MC_ALLOCATE, it may indicate that no communications system could be found to support the local logical unit (LU). (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any state except RESET when the TP issues this verb.

There is no state change.

MC_TEST_RTS_AND_POST

The **MC_TEST_RTS_AND_POST** verb allows an application, typically a 5250 emulator, to request asynchronous notification when a partner transaction program (TP) requests send direction.

The following structure describes the verb control block (VCB) used by the **MC_TEST_RTS_AND_POST** verb.

Syntax

```
struct mc_test_rts_and_post {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       reserv3;
    unsigned long       handle;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_M_TEST_RTS_AND_POST.

opext

Supplied parameter. Specifies the verb operation extension, AP_MAPPED_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter was returned by MC_ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv3

A reserved field.

handle

Supplied parameter. On Microsoft® Windows® 2000, this field provides the event handle to set.

Return Codes from Initial Verb

AP_OK

Primary return code; the verb executed successfully. Note particularly that a return code of AP_OK from the initial verb does not indicate that **MC_REQUEST_TO_SEND** verb received from the partner TP. It simply indicates that the facility to receive asynchronous notification has been registered.

AP_UNSUCCESSFUL

Primary return code; request-to-send notification has not been received.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with MC_ALLOCATE, it may indicate that no communications system could be found to support the local logical unit (LU). (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **MC_ALLOCATE** request.

When **MC_ALLOCATE** produces this return code for a Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Return Codes from Asynchronous Completion
AP_OK

Primary return code; the request-to-send notification has been received from the partner TP.

AP_CANCELLED

The outstanding **TEST_RTS_AND_POST** verb has been terminated. This will occur if the underlying conversation has been deallocated or an AP_TP_ENDED has been issued. Note that as with **RECEIVE_AND_POST**, the TP is still responsible for correctly terminating the conversation and possibly terminating the TP. Issuing another verb, such as **RECEIVE_IMMEDIATE,** at this point will indicate the reason for the conversation failure.

Remarks

The conversation can be in any state except RESET when the TP issues this verb. There is no state change.

A common feature of many APPC applications, such as 5250 emulators, is a requirement to detect a partner's request to send. Currently, this can be done by polling the APPC interface to detect the partner's request. For example, an application can occasionally issue one of the following verbs:

- **MC_TEST_RTS**
- **MC_RECEIVE_IMMEDIATE** and check the **rts_rcvd** field
- **MC_SEND_DATA** of zero bytes, again checking the **rts_rcvd** field.

Some of the problems associated with this polling approach are:

- The application must continually interrupt its main work to poll APPC.
- The partner's request is not detected as soon as it becomes available.
- These approaches are processor-intensive.

The **MC_TEST_RTS_AND_POST** verb allows an application running on Windows 2000, typically a 5250 emulator, to request asynchronous notification when the partner TP requests send direction.

An APPC application typically issues the **MC_TEST_RTS_AND_POST** verb while in SEND state and then continues with its main processing. A request for send direction from the partner TP is indicated asynchronously to the application. After dealing with the partner's request, the application typically returns to SEND state, reissues **MC_TEST_RTS_AND_POST**, and continues.

The **MC_TEST_RTS_AND_POST** verb completes synchronously and the return code AP_OK indicates that a request for asynchronous notification has been registered. It is important to emphasize that this does not indicate that request-to-send was received from the partner TP.

When the partner's request to send is received, the asynchronous event completion occurs. It is important to note that this may be before the completion of the local TP's original **MC_TEST_RTS_AND_POST** verb. This will be the case if the partner's request to send was received before the local TP's **MC_TEST_RTS_AND_POST** verb was issued, or while the local TP's **MC_TEST_RTS_AND_POST** verb was being processed.

POST_ON_RECEIPT

The **POST_ON_RECEIPT** verb allows the application to register to receive a notification when data or status arrives at the local logical unit (LU) without actually receiving it at the same time. This verb can only be issued while in RECEIVE state and it never causes a change in conversation state. This verb is only supported on Microsoft® Windows® 2000.

When the transaction program (TP) issues this verb, APPC returns control to the TP immediately. When the specified conditions are satisfied the Win32® event specified by the **sema** parameter is signaled and the verb completes. Then the TP looks at the return code in the verb control block to determine whether or not any data or status notification has arrived at the local LU and issues a RECEIVE_IMMEDIATE or RECEIVE_AND_WAIT verb to actually receive the data or status notification.

The **POST_ON_RECEIPT** verb implements both the **POST_ON_RECEIPT** and **TEST** verbs as described in the IBM Transaction Programmer's manual for LU Type 6.2.

The following structure describes the verb control block (VCB) used by the **POST_ON_RECEIPT** verb.

Syntax

```
struct post_on_receipt {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv1;
    unsigned char    primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned short   reserv2;
    unsigned char    fill;
    unsigned char    reserv4;
    unsigned short   max_len;
    unsigned short   reserv5;
    unsigned char *  reserv6;
    unsigned char    reserv7[5];
    unsigned long    sema;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_POST_ON_RECEIPT.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv1

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or byRECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATEin the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv2

A reserved field.

fill

Supplied parameter. Specifies how the local TP receives data. The following values are allowed:

AP_BUFFER

Specifies that APPC should post a notification when the number of data bytes specified by **max_len** have arrived at the local LU, the end of the data has been reached, or information other than data is received (such as a conversation status, a confirmation, or a syncpoint request).

AP_LL

Specifies that APPC should post a notification when a complete or truncated logical record is received, when a portion of a logical record is received which is at least equal in length to the length specified by **max_len**, or when information other than data is received.

reserv4

A reserved field.

max_len

Supplied parameter. Specifies the length of data that triggers APPC to post a notification to the TP.

reserv5

A reserved field.

reserv6

A reserved field.

reserv7

A reserved field.

sema

Supplied parameter. Specifies the handle of a Win32 event. The event should have been created by the TP and the TP is responsible for ensuring that it is reset before a call is made and after the verb completes.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_DATA

Secondary return code; data is available for the program to receive.

AP_NOT_DATA

Secondary return code; information other than data is available for the program to receive.

AP_CANCELLED

Primary return code; the verb was canceled.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_INVALID_SEMAPHORE_HANDLE

Secondary return code; the **sema** parameter was not set to a valid value.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_DEALLOC_ABEND_PROG

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued DEALLOCATE with **dealloc_type**set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_DEALLOC_NORMAL

Primary return code; the partner TP has deallocated the conversation without requesting confirmation and issued DEALLOCATE with **dealloc_type** set to one of the following:

- AP_CONFIRM_SYNC_LEVEL
- AP_FLUSH
- AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

AP_PROG_ERROR_NO_TRUNC

Primary return code; the partner TP has issued SEND_ERROR while the conversation was in SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued SEND_ERROR. Data sent but not yet received is purged.

AP_PROG_ERROR_TRUNC

Primary return code; the partner TP has issued SEND_ERROR while the conversation was in SEND state. Data was truncated.

AP_SVC_ERROR_NO_TRUNC

Primary return code; the partner TP (or partner LU) issued SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP was not truncated.

AP_SVC_ERROR_PURGING

Primary return code; the partner TP (or partner LU) issued SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

AP_SVC_ERROR_TRUNC

Primary return code; the partner TP (or partner LU) issued SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been truncated.

Remarks

While a **POST_ON_RECEIPT** verb is outstanding, the following verbs can be issued on the same conversation:

GET_ATTRIBUTES

GET_TYPE

DEALLOCATE

RECEIVE_AND_WAIT

RECEIVE_IMMEDIATE

REQUEST_TO_SEND

SEND_ERROR

TEST_RTS

TP_ENDED

Issuing any of the following verbs prior to completion of the asynchronous **POST_ON_RECEIPT** verb causes the **POST_ON_RECEIPT** verb to be canceled (the Win32 event is signaled and the primary return code in the verb control block is set to AP_CANCELLED).

DEALLOCATE

RECEIVE_AND_WAIT

RECEIVE_IMMEDIATE

SEND_ERROR

TP_ENDED

PREPARE_TO_RECEIVE

The **PREPARE_TO_RECEIVE** verb changes the state of the conversation for the local transaction program (TP) from SEND to RECEIVE.

The following structure describes the verb control block (VCB) used by the **PREPARE_TO_RECEIVE** verb.

Syntax

```
struct prepare_to_receive {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    primary_rc;
    unsigned short   reserv2;
    unsigned long    secondary_rc;
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    ptr_type;
    unsigned char    locks;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_PREPARE_TO_RECEIVE.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or byRECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATEin the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

ptr_type

Supplied parameter. Specifies how to perform the state change.

Use AP_FLUSH to send the contents of the local logical unit's (LU) send buffer to the partner LU (and TP) before changing the conversation's state to RECEIVE.

The AP_SYNC_LEVEL value uses the conversation's synchronization level (established by **ALLOCATE**) to determine how to perform the state change.

If the synchronization level of the conversation is AP_NONE, APPC sends the contents of the local LU's send buffer to the partner TP before changing the conversation's state to RECEIVE. If the synchronization level is AP_CONFIRM_SYNC_LEVEL, APPC sends the contents of the local LU's send buffer and a confirmation request to the partner TP. Upon receiving confirmation from the partner TP, APPC changes the conversation's state to RECEIVE. If, however, the partner TP reports an error, the state changes to RECEIVE or RESET. See the Remarks in this topic.

locks

Supplied parameter. Specifies when APPC should return control to the local TP.

Use this parameter only if **ptr_type** is set to AP_SYNC_LEVEL and the synchronization level of the conversation, established by ALLOCATE, is AP_CONFIRM_SYNC_LEVEL. (Otherwise, the parameter is ignored.)

Use AP_LONG to indicate that APPC returns control to the local TP when the confirmation and subsequent data from the partner TP arrive at the local LU. (This method results in more efficient use of the network but requires a longer time to return control to the local TP.)

Use AP_SHORT to indicate that APPC returns control to the local TP when the confirmation from the partner TP arrives at the local LU.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_P_TO_R_INVALID_TYPE

Secondary return code; the **ptr_type** parameter was not set to a valid value.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_P_TO_R_NOT_SEND_STATE

Secondary return code; the conversation was not in SEND state.

AP_P_TO_R_NOT_LL_BDY

Secondary return code; the local TP did not finish sending a logical record.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE, it can indicate that no communications system could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued SEND_ERROR with **err_type** set to AP_PROG. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND_PROG

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_PURGING

Primary return code; the partner TP (or partner LU) issued a SEND_ERROR verb with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

Remarks

Before changing the conversation state, this verb performs the equivalent of one of the following:

- FLUSH, by sending the contents of the local LU's send buffer to the partner LU (and TP).

- CONFIRM, by sending the contents of the local LU's send buffer and a confirmation request to the partner TP.

After this verb has successfully executed, the local TP can receive data.

The conversation must be in SEND state when the TP issues this verb.

State changes, summarized in the following table, are based on the value of **primary_rc**.

primary_rc	**New state**
AP_OK	RECEIVE
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE

The conversation does not change to SEND state for the partner TP until the partner TP receives one of the following values through the **what_rcvd** parameter of a subsequent receive verb:

- AP_SEND
- AP_CONFIRM_SEND and replies with CONFIRMED
- AP_DATA_COMPLETE_CONFIRM_SEND and replies with **CONFIRMED**
- AP_DATA_CONFIRM_SEND and replies with **CONFIRMED**

The receive verbs are RECEIVE_AND_POST, RECEIVE_IMMEDIATE, and RECEIVE_AND_WAIT.

RECEIVE_ALLOCATE

The **RECEIVE_ALLOCATE** verb is issued by the invoked transaction program (TP) to confirm that the invoked TP is ready to begin a conversation with the invoking TP that issued ALLOCATE or MC_ALLOCATE.

The following structure describes the verb control block (VCB) used by the **RECEIVE_ALLOCATE** verb.

Syntax

```
struct receive_allocate {
    unsigned short   opcode;
    unsigned char    opext;
    unsigned char    reserv2;
    unsigned short   primary_rc;
    unsigned long    secondary_rc;
    unsigned char    tp_name[64];
    unsigned char    tp_id[8];
    unsigned long    conv_id;
    unsigned char    sync_level;
    unsigned char    conv_type;
    unsigned char    user_id[10];
    unsigned char    lu_alias[8];
    unsigned char    plu_alias[8];
    unsigned char    mode_name[8];
    unsigned char    reserv3[2];
    unsigned long    conv_group_id;
    unsigned char    fqplu_name[17];
    unsigned char    pip_incoming;
    unsigned char    syncpoint_rqd;
    unsigned char    reserv4[3];
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_RECEIVE_ALLOCATE.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_name

Supplied parameter. Provides the name of the local TP. The value of **tp_name** must match the TP name configured through registry or environment variables. APPC matches the **RECEIVE_ALLOCATE** verb's **tp_name** parameter with the TP name specified by the incoming allocate, which is generated by MC_ALLOCATE or ALLOCATE in the invoking TP.

This parameter is a 64-byte EBCDIC character string and is case-sensitive. The **tp_name** parameter can consist of characters from the type AE EBCDIC character set:

- Uppercase and lowercase letters
- Numerals 0 through 9

- Special characters $, #, and period (.)

If **tp_name** is fewer than 64 bytes, use EBCDIC spaces (0x40) to pad it on the right.

The SNA convention is that a service TP name can have up to four characters. The first character is a hexadecimal byte between 0x00 and 0x3F. The other characters are from the type AE EBCDIC character set.

tp_id

Returned parameter. Identifies the local TP.

conv_id

Returned parameter. Provides the conversation identifier. It identifies the conversation APPC has established between the two partner TPs.

sync_level

Returned parameter. Specifies the synchronization level of the conversation. It determines whether the TPs can request confirmation of receipt of data and confirm receipt of data.

- AP_NONE specifies that confirmation processing will not be used in this conversation.
- AP_CONFIRM_SYNC_LEVEL specifies that the TPs can use confirmation processing in this conversation.
- AP_SYNCPT specifies that TPs can use Sync Point Level 2 confirmation processing in this conversation.

conv_type

Returned parameter. Specifies the type of conversation chosen by the partner TP, using MC_ALLOCATE or ALLOCATE. The following are possible values:

AP_BASIC_CONVERSATION

AP_MAPPED_CONVERSATION

user_id

Returned parameter. Provides the user identifier specified by the partner TP, using **MC_ALLOCATE** or **ALLOCATE** (if the partner TP set the **MC_ALLOCATE** or **ALLOCATE** verb's security parameter to AP_PGM or AP_SAME). It is a type AE EBCDIC character string.

lu_alias

Returned parameter. Provides the alias by which the local logical unit (LU) is known to the local TP. It is an ASCII character string.

plu_alias

Returned parameter. Provides the alias by which the partner LU (which initiated the incoming allocate) is known to the local TP. It is an ASCII character string.

mode_name

Returned parameter. Provides the mode name specified by **MC_ALLOCATE** or **ALLOCATE** in the partner TP. It is the name of a set of networking characteristics defined during configuration. The **mode_name** is a type A EBCDIC character string.

reserv3

A reserved field.

conv_group_id

Conversation group identifier.

fqplu_name

This returned parameter provides the fully qualified LU name.

pip_incoming

This optional supplied and returned parameter is applicable only if Sync Point services are required.

For the supplied parameter:

AP_YES if TP does accept PIP data.

AP_NO if TP does not accept PIP data.

For the returned parameter:

AP_YES if PIP data is available.

AP_NO if PIP data is not available.

syncpoint_rqd

This parameter indicates if Sync Point services are required.

AP_YES if Sync Point is required.

AP_NO if Sync Point is not required.

reserv4

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_UNDEFINED_TP_NAME

Secondary return code; the TP name was not configured correctly.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_ALLOCATE_NOT_PENDING

Secondary return code; APPC did not find an incoming allocate (from the invoking TP) to match the value of **tp_name**, supplied by **RECEIVE_ALLOCATE**. **RECEIVE_ALLOCATE** waited for the incoming allocate and eventually timed out.

AP_INVALID_PROCESS

Secondary return code; the process issuing **RECEIVE_ALLOCATE** was different from the one started by APPC.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

This must be the first APPC verb issued by the invoked TP. The initial state is RESET. If the verb executes successfully (**primary_rc** is AP_OK), the state changes to RECEIVE.

In response to this verb, APPC establishes a conversation between the two TPs and generates a TP identifier for the invoked TP and a conversation identifier. These identifiers are required parameters for subsequent APPC verbs.

If the invoked TP issues **RECEIVE_ALLOCATE** and a corresponding incoming allocate (resulting from MC_ALLOCATE or ALLOCATE issued by the invoking TP) is not present, the invoked TP waits until the incoming allocate arrives or the verb times out. The time-out value is set by the system administrator.

Host Integration Server also supports APPC RECEIVE_ALLOCATE_EX and RECEIVE_ALLOCATE_EX_END functions, to simplify the design and implementation of some invokable transaction programs. This function allows an APPC application to receive all incoming FMH-5 Attach requests received by Host Integration Server over a specific Local APPC LU, allowing an application to act as an "attach manager." An attach manager is a program that handles an incoming FMH-5 Attach request to start an LU6.2 conversation. When an APPC application calls RECEIVE_ALLOCATE (as opposed to RECEIVE_ALLOCATE_EX), Host Integration Server handles the attach manager functionality.

For more information on attach manager, see RECEIVE_ALLOCATE_EX.

RECEIVE_ALLOCATE_EX

The RECEIVE_ALLOCATE_EX verb accepts a new VCB structure to allow registration of an attach manager.

Syntax

```
typedef struct receive_allocate_ex {
    unsigned short    opcode;
        unsigned char     opext;
        unsigned char     format;
        unsigned short    primary_rc;
        unsigned long    secondary_rc;
       unsigned char     tp_name[64];
       unsigned char     tp_id[8];
       unsigned long     conv_id;
       unsigned char     sync_level;
        unsigned char    conv_type;
        unsigned char     user_id[10];
       unsigned char     lu_alias[8];
       unsigned char     plu_alias[8];
       unsigned char     mode_name[8];
       unsigned char     reserv3[2];
       unsigned long     conv_group_id;
       unsigned char     fqplu_name[17];
       unsigned char     pip_incoming;
       unsigned long     timeout;
       unsigned char     password[10];
       unsigned char     reserv5[2];
       unsigned char     attach_id[8];
 }
```

Members

opcode

Supplied parameter: RECEIVE_ALLOCATE_EX

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

format

Reserved parameter.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued.

tp_name

Supplied parameter. The **tp_name** is a returned parameter only. However, the application must allocate sufficient buffer space to hold the **tp_name** (that is, 64 characters) and initialize the name to EBCDIC spaces (hexadecimal X'40')

The returned verb will contain the actual TP name sent by the remote system.

tp_id

Returned parameter. Identifies the local TP.

conv_id

Returned parameter. Provides the conversation identifier. It identifies the conversation APPC has established between the two partner TPs.

sync_level

Returned parameter. Specifies the synchronization level of the conversation. It determines whether the TPs can request confirmation of receipt of data and confirm receipt of data.

- **AP_NONE** specifies that confirmation processing will not be used in this conversation.
- **AP_CONFIRM_SYNC_LEVEL** specifies that the TPs can use confirmation processing in this conversation.

AP_SYNCPT specifies that TPs can use Sync Point Level 2 confirmation processing in this conversation.

conv_type

Returned parameter. Specifies the type of conversation chosen by the partner TP, using **MC_ALLOCATE** or **ALLOCATE**. The following are possible values:

AP_BASIC_CONVERSATION

AP_MAPPED_CONVERSATION

user_id

This is the EBCDIC user_id sent by the remote system

lu_alias

Supplied parameter. Local LU alias. Must be supplied to register an attach manager. Only one attach manager may be registered for a given Local LU alias within the Host Integration Server subdomain. If another attach manager process is already registered for this lu_alias, the following error will be returned:

primary_rc = AP_STATE_CHECK (0x0002) secondary_rc = AP_LU_ALREADY_REGISTERED (0x0000050A)

This indicates that Host Integration Server was unable to register this attach manager.

plu_alias

Returned parameter. Provides the alias by which the partner LU (which initiated the incoming allocate) is known to the local TP. It is an ASCII character string.

mode_name

Returned parameter. Provides the mode name specified by **MC_ALLOCATE** or **ALLOCATE** in the partner TP. It is the name of a set of networking characteristics defined during configuration. The mode_name is a type A EBCDIC character string.

reserv3

Reserved parameter.

conv_group_id

Conversation group identifier.

fqplu_name

This returned parameter provides the fully qualified LU name.

pip_incoming

Supplied parameter. If this attach manager will accept incoming FMH-5 Attaches which include PIP data, then set this to **AP_YES**. Otherwise, set this to **AP_NO**.

Returned parameter: If PIP data is present in the incoming Attach, this is set to **AP_YES**. If no PIP data is present, this will be set to **AP_NO**.

timeout

Timeout, in seconds. A value of 0xFFFFFFFF can be used to wait forever.

password

Returned parameter: This is the EBCDIC password sent by the remote system. If the remote system supports "Password substitution" (password encryption), the encrypted password will be received in **RECEIVE_ALLOCATE_EX**. There is no facility to decrypt this password, so the application will not be able to verify the user credentials.

reserv5

Reserved parameter.

attach_id

Returned parameter. Always set to 0. This field is defined for source compatibility with non-Microsoft SNA products.

Remarks

Host Integration Server supports APPC **RECEIVE_ALLOCATE_EX** and **RECEIVE_ALLOCATE_EX_END** to simplify the design and implementation of some invokable transaction programs. This function allows an APPC application to receive all incoming FMH-5 Attach requests received by Host Integration Server over a specific Local APPC LU, allowing an application to act as an "attach manager." An attach manager is a program that handles an incoming FMH-5 Attach request to start an LU6.2 conversation. When an APPC application calls **RECEIVE_ALLOCATE** (as opposed to **RECEIVE_ALLOCATE_EX**), Host Integration Server handles the attach manager functionality. To implement the attach manager functionality within an APPC application, the following occurs:

- The application supplies a Local APPC LU alias to the **RECEIVE_ALLOCATE_EX** function, with a tp_name of EBCDIC spaces (hexadecimal X'40').
- When Host Integration Server receives an incoming FMH-5 Attach request over an LU6.2 session using that Local APPC LU, Host Integration Server will route the request to the application.
- When the **RECEIVE_ALLOCATE_EX** completes, the application is responsible for the following:
    1. Accepting or rejecting the FMH-5 Attach
    2. Verifying any conversation level security, and
    3. If accepting the attach request, completely handling the request within its Win32 process context.
- To stop listening for new incoming attach requests, the application calls **RECEIVE_ALLOCATE_EX_END**.
- After a process issues **RECEIVE_ALLOCATE_EX**, the process should not call **RECEIVE_ALLOCATE** with a specific TP name. Likewise, if a process calls **RECEIVE_ALLOCATE**, that process should not later call **RECEIVE_ALLOCATE_EX**. In other words, for the duration of a process supporting an invokable TP, the process should exclusively call **RECEIVE_ALLOCATE**, or **RECEIVE_ALLOCATE_EX**, but not both.

It is not possible for the application to dispatch the incoming attach request to another process, as the conversation ID is only valid within its own application context.

Note
: Host Integration Server does not support auto starting an attach manager application. In other words, if an application calls **RECEIVE_ALLOCATE_EX**, the application must be started before any incoming Attach requests arrive over the Local LU.

The current specification does not return the Security Indicator (Byte 4 of the FMH-5 Attach). So, the application will need to accommodate incoming attach requests that contain the following:

1. Neither a user_id or password (when no security is sent in the attach),
2. A user_id only (such as for "already verified" attaches), or
3. Both a user_id and password (if user authorization is required).

In the LU6.2 BIND request, Host Integration Server indicates support for incoming FMH-5 Attach requests that contain user security, already verified, and password substitution. Host Integration Server does not support incoming attaches which request persistent verification.

The **RECEIVE_ALLOCATE_EX** function allows an application to register as an attach manager if the tp_name is set to all EBCDIC spaces (X'40') and a Local LU alias is supplied in the lu_alias field. When registered as an attach manager for a given lu_alias, Host Integration Server will route all incoming attaches received over the lu_alias to the application. See below for more information on how Host Integration Server routes incoming FMH-5 attach requests.

The application may call **RECEIVE_ALLOCATE_EX** more than once to register as the attach manager for one or more Local LU. However, only one attach manager may be registered on a given lu_alias within the SNA subdomain (that is, across all Host Integration Servers and attached Host Integration Server clients). The application cannot supply a blank tp_name and blank lu_alias. In other words, an application cannot register as the default attach manager to receive all incoming attach requests for an SNA subdomain.

When **RECEIVE_ALLOCATE_EX** completes, the application is responsible for the following:

- Deciding whether the attach will be accepted or not. Host Integration Server provides no mechanism for configuring transaction programs (TPs). The application must have its own means of defining which tp names it will support.

- If accepted, the application must verify conversation security attributes (user_id, password) and for handling the processing of the new conversation.

- The tp_id and conv_id cannot be passed to a separate process for handling. All TP processing must be provided by the application.

If the application chooses to reject the attach request, **[MC_]DEALLOCATE** must be called, specifying the conv_id received in the completed **RECEIVE_ALLOCATE_EX**, along with an appropriate reason code in the dealloc_type parameter, using these new extended codes:

```
#define AP_DEALLOC_SECURITY_NOT_VALID_PASSWORD_EXPIRED 0x10
#define AP_DEALLOC_SECURITY_NOT_VALID_PASSWORD_INVALID 0x11
#define AP_DEALLOC_SECURITY_NOT_VALID_USERID_REVOKED 0x12
#define AP_DEALLOC_SECURITY_NOT_VALID_USERID_INVALID 0x13
#define AP_DEALLOC_SECURITY_NOT_VALID_USERID_MISSING 0x14
#define AP_DEALLOC_SECURITY_NOT_VALID_PASSWORD_MISSING 0x15
#define AP_DEALLOC_SECURITY_NOT_VALID_GROUP_INVALID 0x16
#define AP_DEALLOC_SECURITY_NOT_VALID_USERID_REVOKED_IN_GROUP 0x17
#define AP_DEALLOC_SECURITY_NOT_VALID_USERID_NOT_DEFD_TO_GROUP 0x18
#define AP_DEALLOC_SECURITY_NOT_VALID_NOT_AUTHORIZED_AT_REMOTE_LU 0x19
#define AP_DEALLOC_SECURITY_NOT_VALID_NOT_AUTHORIZED_FROM_LOCAL_LU 0x1A
#define AP_DEALLOC_SECURITY_NOT_VALID_NOT_AUTHORIZED_TO_TRANSACTION_PROGRAM 0x1B
#define AP_DEALLOC_SECURITY_NOT_VALID_INSTALLATION_EXIT_FAILED 0x1C
#define AP_DEALLOC_SECURITY_NOT_VALID_PROCESSING_FAILURE 0x1D
#define AP_DEALLOC_SECURITY_NOT_VALID_PROTOCOL_VIOLATION 0x1E
```

When the application sets the above dealloc_type, the Host Integration Server then sends the corresponding sense code within the FMH-7 error sent to the remote system when rejecting the FMH-5 Attach request:

```
#define AP_SECURITY_NOT_VALID_PASSWORD_EXPIRED APPC_FLIPL(x080fff00)
#define AP_SECURITY_NOT_VALID_PASSWORD_INVALID APPC_FLIPL(x080fff01)
#define AP_SECURITY_NOT_VALID_USERID_REVOKED APPC_FLIPL(x080fff02)
#define AP_SECURITY_NOT_VALID_USERID_INVALID APPC_FLIPL(x080fff03)
#define AP_SECURITY_NOT_VALID_USERID_MISSING APPC_FLIPL(x080fff04)
#define AP_SECURITY_NOT_VALID_PASSWORD_MISSING APPC_FLIPL(x080fff05)
#define AP_SECURITY_NOT_VALID_GROUP_INVALID APPC_FLIPL(x080fff06)
#define AP_SECURITY_NOT_VALID_USERID_REVOKED_IN_GROUP APPC_FLIPL(x080fff07)
#define AP_SECURITY_NOT_VALID_USERID_NOT_DEFD_TO_GROUP APPC_FLIPL(x080fff08)
#define AP_SECURITY_NOT_VALID_NOT_AUTHORIZED_AT_REMOTE_LU APPC_FLIPL(x080fff09)
```

```
#define AP_SECURITY_NOT_VALID_NOT_AUTHORIZED_FROM_LOCAL_LU APPC_FLIPL(x080fff0A)

#define AP_SECURITY_NOT_VALID_NOT_AUTHORIZED_TO_TRANSACTION_PROGRAM APPC_FLIPL(x080fff0B)

#define AP_SECURITY_NOT_VALID_INSTALLATION_EXIT_FAILED APPC_FLIPL(x080fff0C)

#define AP_SECURITY_NOT_VALID_PROCESSING_FAILURE APPC_FLIPL(x080fff0D)

#define AP_SECURITY_NOT_VALID_PROTOCOL_VIOLATION APPC_FLIPL(x080fff0E)
```

Before calling **RECEIVE_ALLOCATE_EX**, the application may want to verify the configuration settings for the Local APPC LU to determine if the LU supports sync level 2, or is a member of the default LU pool. To do this, use the enhanced **GET_LU_STATUS** API.

To deregister as the attach manager for a given Local APPC LU, the application must call **RECEIVE_ALLOCATE_EX_END**, documented below. If an application has registered as the attach manager for more than one lu_alias, **RECEIVE_ALLOCATE_EX_END** must be called for each lu_alias.

The application should try to have a **RECEIVE_ALLOCATE_EX** pending at all times, in order to handle incoming attach requests in a timely manner. If the application fails to post new **RECEIVE_ALLOCATE_EX**, Host Integration Server queues up to 2,048 incoming attaches against the application, if the application is running on the Host Integration Server, or 256 if running on an SNA Windows NT client. If the limit is exceeded, Host Integration Server rejects the attach request with sense code X'084B6031', or **AP_TRANS_PGM_NOT_AVAIL_RETRY**.

RECEIVE_ALLOCATE_EX_END

The RECEIVE_ALLOCATE_EX_END verb allows an application to deregister as the attach manager for a given Local APPC LU (lu_alias). This verb must be called for each lu_alias previously passed to the RECEIVE_ALLOCATE_EX request.

Syntax

```
typedef struct receive_allocate_ex_end {
       unsigned short opcode;
       unsigned char reserv2[2];
       unsigned short primary_rc;
       unsigned long secondary_rc;
       unsigned char tp_name[64];
       unsigned char lu_alias[8];
       unsigned char reserved3[20];
 };
```

Members

Opcode

A supplied parameter. Specifies the verb operation code, RECEIVE_ALLOCATE_EX_END.

reserv2

A reserved field.

primary_rc

If the lu_alias has not been previously registered by the application, the following error is returned:

AP_STATE_CHECK (0x0002)

secondary_rc

If the lu_alias has not been previously registered by the application, the following error is returned:

AP_ATTACH_MANAGER_INACTIVE (0x00000508)

tp_name

Must be all EBCDIC spaces (X'40')

lu_alias

Must be supplied and must match the lu_alias provided in a previous RECEIVE_ALLOCATE_EX request from the same process

reserved3

A reserved field.

Remarks

If the application is providing sync point support, the application needs to know when the LU-LU session limits have dropped to zero. This can be done by polling the **GET_LU_STATUS** API.

After calling **RECEIVE_ALLOCATE_EX_END** to deregister an attach manager, Host Integration Server does not tear down any existing LU6.2 sessions. To tear down an existing session, call the **DEACTIVATE_SESSION** function, supplying the appropriate lu_alias and plu_alias. If you are using Sync Level 2, deactivating the LU6.2 sessions notifies the Remote LU that the syncpoint manager has gone away and thus, a new ExchangeLogNames is required for the next connection.

RECEIVE_AND_POST

The **RECEIVE_AND_POST** verb receives application data and status information asynchronously. This allows the local transaction program (TP) to proceed with processing while data is still arriving at the local logical unit (LU).

While an asynchronous **RECEIVE_AND_POST** is outstanding, the following verbs can be issued on the same conversation:

- DEALLOCATE (AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER)
- GET_ATTRIBUTES
- GET_TYPE
- REQUEST_TO_SEND
- SEND_ERROR
- TEST_RTS
- TP_ENDED

This allows an application to use an asynchronous **RECEIVE_AND_POST** to receive data. While the **RECEIVE_AND_POST** is outstanding, it can still use **SEND_ERROR** and **REQUEST_TO_SEND**. It is recommended that you use this feature for full asynchronous support. For information on how a TP receives data and how to use this verb, see Remarks in this topic.

The following structure describes the verb control block (VCB) used by the **RECEIVE_AND_POST** verb.

Syntax

```
struct receive_and_post {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      what_rcvd;
    unsigned char       rtn_status;
    unsigned char       fill;
    unsigned char       rts_rcvd;
    unsigned char       reserv4;
    unsigned short      max_len;
    unsigned short      dlen;
    unsigned char FAR * dptr;
    unsigned char FAR * sema;
    unsigned char       reserv5;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_RECEIVE_AND_POST.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or byRECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATEin the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

what_rcvd

Returned parameter. Indicates whether data or conversation status was received. Possible values are listed following the Members section

rtn_status

Supplied parameter. Indicates whether both data and conversation status indicators should be returned within one API call.

- AP_NO specifies that indicators should be returned individually on separate invocations of the verb.
- AP_YES specifies that indicators should be returned together, provided both are available. Both can be returned when:

  The receive buffer is large enough to hold all of the data that precedes the status indicator.

  The **fill** parameter specifies BUFFER or LL, and the data is the last logical record before the status indicator.

fill

Supplied parameter. Specifies how the local TP receives data.

Use AP_BUFFER to indicate that the local TP receives data until the number of bytes specified by **max_len** is reached or until end of data. Data is received without regard for the logical-record format.

Use AP_LL to indicate that data is received in logical-record format. The data received can be:

- A complete logical record.
- A **max_len** byte portion of a logical record.
- The end of a logical record**.**

rts_rcvd

Returned parameter. Indicates whether the partner TP issued REQUEST_TO_SEND. Possible values are:

- AP_YES indicates that the partner TP issued **REQUEST_TO_SEND**, which requests that the local TP change the conversation to RECEIVE state.
- AP_NO indicates that the partner TP has not issued **REQUEST_TO_SEND**.

max_len

Supplied parameter. Specifies the maximum number of bytes of data the local TP can receive. The range is from 0 through 65535.

The value must not exceed the length of the buffer to contain the received data. The offset of **dptr** plus the value of **max_len** must not exceed the size of the data segment.

Dlen

Returned parameter. Specifies the number of bytes of data received. Data is stored in the buffer specified by **dptr**. A length of zero indicates that no data was received.

dptr

Supplied parameter. Provides the address of the buffer to contain the data received by the local LU.

For Microsoft® Windows® 2000, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

sema

Supplied parameter. Provides the address of the semaphore that APPC is to clear when the asynchronous receiving operation is finished. The **sema** parameter is an event handle obtained by calling either the **CreateEvent** or **OpenEvent** Win32 function.

Values Returned by the what_rcvd Parameter

- AP_CONFIRM_DEALLOCATE indicates that the partner TP issued DEALLOCATE with **dealloc_type** set to AP_SYNC_LEVEL. The conversation's synchronization level, established by ALLOCATE, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues CONFIRMED.

- AP_CONFIRM_SEND indicates that the partner TP issued PREPARE_TO_RECEIVE with **ptr_type** set to AP_SYNC_LEVEL. The conversation's synchronization level, established by **ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues **CONFIRMED**, and begins to send data.

- AP_CONFIRM_WHAT_RECEIVED indicates that the partner TP issued CONFIRM. Upon receiving this value, the local TP normally issues **CONFIRMED**.

- AP_DATA indicates that this value can be returned by **RECEIVE_AND_POST** if **fill** is set to AP_BUFFER. The local TP received data until **max_len** or the end of the data was reached. For more information, see Remarks in this topic.

- AP_DATA_COMPLETE indicates, for **RECEIVE_AND_POST**, that the local TP has received a complete data record or the last part of a data record.

  For **RECEIVE_AND_POST** with **fill** set to AP_LL, this value indicates that the local TP has received a complete logical record or the end of a logical record.

  Upon receiving this value, the local TP normally reissues **RECEIVE_AND_POST** or issues another receive verb. If the partner TP has sent more data, the local TP begins to receive a new unit of data.

  Otherwise, the local TP examines status information.

  If **primary_rc** contains AP_OK and **what_rcvd** contains AP_SEND, AP_CONFIRM_SEND, AP_CONFIRM_DEALLOCATE, or AP_CONFIRM_WHAT_RECEIVED, see the description of the value (in this section) for the next action the local TP normally takes.

  If **primary_rc** contains AP_DEALLOC_NORMAL, the conversation has been deallocated in response to the DEALLOCATE issued by the partner TP.

- AP_DATA_INCOMPLETE indicates, for **RECEIVE_AND_POST**, that the local TP has received an incomplete data record. The **max_len** parameter specified a value less than the length of the data record (or less than the remainder of the data record if this is not the first receive verb to read the record).

  For **RECEIVE_AND_POST** with **fill** set to AP_LL, this value indicates that the local TP has received an incomplete logical record.

  Upon receiving this value, the local TP normally reissues **RECEIVE_AND_POST** (or issues another receive verb) to receive the next part of the record.

- AP_NONE indicates that the TP did not receive data or conversation status indicators.
- AP_SEND indicates, for the partner TP, that the conversation has entered RECEIVE state. For the local TP, the conversation is now in SEND state. Upon receiving this value, the local TP normally uses SEND_DATA to begin sending data.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

When **rtn_status** is AP_YES, the preceding return code or one of the following return codes can be returned.

AP_DATA_COMPLETE_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_SEND.

AP_DATA_COMPLETE_CONFIRM_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_SEND.

AP_DATA_COMPLETE_CONFIRM

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_WHAT_RECEIVED.

AP_DATA_COMPLETE_CONFIRM_DEALL

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_DEALLOCATE.

AP_DATA_SEND

Primary return code; this is a combination of AP_DATA and AP_SEND.

AP_DATA_CONFIRM_SEND

Primary return code; this is a combination of AP_DATA and AP_CONFIRM_SEND.

AP_DATA_CONFIRM

Primary return code; this is a combination of AP_DATA and AP_CONFIRM.

AP_DATA_CONFIRM_DEALLOCATE

Primary return code; this is a combination of AP_DATA and AP_CONFIRM_DEALLOCATE.

AP_DEALLOC_NORMAL

Primary return code; the partner TP issued DEALLOCATE with **dealloc_type** set to AP_FLUSH or AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE.

If **rtn_status** is AP_YES, examine **what_rcvd** also.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_RETURN_STATUS_WITH_DATA

Secondary return code; the specified **rtn_status** value was not recognized by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_INVALID_SEMAPHORE_HANDLE

Secondary return code; the address of the RAM semaphore or system semaphore handle was invalid.

APPC cannot trap all invalid semaphore handles. If the TP passes a bad RAM semaphore handle, a protection violation results.

AP_RCV_AND_POST_BAD_FILL

Secondary return code; the **fill** parameter was set to an invalid value.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_RCV_AND_POST_BAD_STATE

Secondary return code; the conversation was not in RECEIVE or SEND state when the TP issued this verb.

AP_RCV_AND_POST_NOT_LL_BDY

Secondary return code; the conversation was in SEND state; the TP began but did not finish sending a logical record.

AP_CANCELED

Primary return code; the local TP issued one of the following verbs, which canceled **RECEIVE_AND_POST**:

DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER

SEND_ERROR

TP_ENDED

Issuing one of these verbs causes the semaphore to be cleared.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE, it can indicate that no communications system could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_NO_TRUNC

Primary return code; the partner TP issued SEND_ERROR with **err_type** set to AP_PROG while the conversation was in SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. Data sent but not yet received is purged.

AP_PROG_ERROR_TRUNC

Primary return code; in SEND state, after sending an incomplete logical record, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. The local TP may have received the first part of the logical record through a receive verb.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND_PROG

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_NO_TRUNC

Primary return code; while in SEND state, the partner TP (or partner LU) issued SEND_ERROR with **err_type** set to AP_SVC. Data was not truncated.

AP_SVC_ERROR_PURGING

Primary return code; the partner TP (or partner LU) issued **SEND_ERROR** with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

AP_SVC_ERROR_TRUNC

Primary return code; in SEND state, after sending an incomplete logical record, the partner TP (or partner LU) issued **SEND_ERROR**. The local TP may have received the first part of the logical record.

Remarks

The local TP receives data through the following process:

1. The local TP issues a receive verb until it finishes receiving a complete unit of data. The data received can be:

- One logical record.
- A buffer of data received independent of its logical-record format.

The local TP may need to issue the receive verb several times in order to receive a complete unit of data. After a complete unit of data has been received, the local TP can manipulate it. The receive verbs are **RECEIVE_AND_POST**, RECEIVE_AND_WAIT, and RECEIVE_IMMEDIATE.

2. The local TP issues the receive verb again. This has one of the following effects:

   - If the partner TP has sent more data, the local TP begins to receive a new unit of data.
   - If the partner TP has finished sending data or is waiting for confirmation, status information (available through **what_rcvd**) indicates the next action the local TP normally takes.

The following procedure shows tasks performed by the local TP in using **RECEIVE_AND_POST**.

To use RECEIVE_AND_POST

1. For the Microsoft Windows® 2000 operating system, the TP retrieves the WinAsyncAPPC message number by calling the **RegisterWindowMessage** API or allocating a semaphore. The **sema** field should be set to NULL if the application expects to be notified through the Windows message mechanism.

   APPC sends the Windows message or clears the semaphore when the local TP finishes receiving data.

   The semaphore will remain set while the local TP receives data asynchronously. APPC will clear the semaphore when the local TP finishes receiving data.

2. The TP issues **RECEIVE_AND_POST**.
3. The TP checks the value of **primary_rc**.

   If **primary_rc** is AP_OK, the receive buffer (pointed to by **dptr**) is asynchronously receiving data from the partner TP. While receiving data asynchronously, the local TP can:

   - Perform tasks not related to this conversation.
   - Issue REQUEST_TO_SEND.
   - Gather information about this conversation by issuing GET_TYPE, GET_ATTRIBUTES, or TEST_RTS.
   - Prematurely cancel **RECEIVE_AND_POST** by issuing DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER; SEND_ERROR;or TP_ENDED.

   If, however, **primary_rc** is not AP_OK, **RECEIVE_AND_POST** has failed. In this case, the local TP does not perform the next two tasks.

4. For the Windows 2000 operating system, when the TP finishes receiving data asynchronously, APPC issues the WinAsyncAPPC Windows message or clears the semaphore.
5. The TP checks the new value of **primary_rc**.

   If **primary_rc** is AP_OK, the local TP can examine the other returned parameters and manipulate the asynchronously received data.

   If **primary_rc** is not AP_OK, only **secondary_rc** and **rts_rcvd** (request-to-send received) are meaningful.

Conversation State Effects

The conversation must be in RECEIVE or SEND state when the TP issues this verb.

Issuing **RECEIVE_AND_POST** while the conversation is in SEND state has the following effects:

- The local LU sends the information in its send buffer and a SEND indicator to the partner TP.
- The conversation changes to PENDING_POST state; the local TP is ready to receive information from the partner TP asynchronously.

The conversation changes states twice:

- Upon initial return of the verb, if **primary_rc** contains AP_OK, the conversation changes to PENDING_POST state.
- After completion of the verb, the state changes depending on the value of the following:

  The **primary_rc** parameter

  The **what_rcvd** parameter if **primary_rc** is AP_OK

The following table shows the new state associated with each value of **what_rcvd** when **primary_rc** is AP_OK.

what_rcvd	**New state**
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	RECEIVE
AP_DATA_COMPLETE	RECEIVE
AP_DATA_INCOMPLETE	RECEIVE
AP_SEND	SEND
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table shows the new state associated with each value of **primary_rc** other than AP_OK.

primary_rc	**New state**
AP_CANCELED	No change
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET

AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_PROG_ERROR_NO_TRUNC	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_NO_TRUNC	RECEIVE
AP_PROG_ERROR_TRUNC	RECEIVE
AP_SVC_ERROR_TRUNC	RECEIVE

End of Data for a Basic Conversation

If the local TP issues **RECEIVE_AND_POST** and sets **fill** to AP_BUFFER, the receipt of data ends when **max_len** or the end of the data is reached. The end of the data is indicated by either **primary_rc** with a value other than AP_OK (for example, AP_DEALLOC_NORMAL), or by **what_rcvd** with one of the following values:

AP_SEND

AP_CONFIRM_SEND

AP_CONFIRM_DEALLOCATE

AP_CONFIRM_WHAT_RECEIVED

AP_DATA_CONFIRM_SEND

AP_DATA_CONFIRM_DEALLOCATE

AP_DATA_CONFIRM

To determine if the end of the data has been reached, the local TP reissues **RECEIVE_AND_POST**. If the new **primary_rc** contains AP_OK and **what_rcvd** contains AP_DATA, the end of the data has not been reached. If, however, the end of the data has been reached, **primary_rc** or **what_rcvd** will indicate the cause of the end of the data.

Troubleshooting

The local TP can wait indefinitely if one of the following situations occurs:

- For the Windows 2000 operating system, the local TP issues a **RECEIVE_AND_POST** request, but either the partner TP has not sent data or the initial **primary_rc** is not AP_OK.

- For the OS/2 operating system, the local TP issues a **DosSemWait** function call, but either the partner TP has not sent data or the initial **primary_rc** is not AP_OK.

This is because APPC will not issue the Windows message or clear the semaphore.

When a condition resulting in one of the following **primary_rc** parameters occurs, APPC does not clear the semaphore:

AP_INVALID_SEMAPHORE_HANDLE

AP_INVALID_VERB_SEGMENT

AP_STACK_TOO_SMALL

To test **what_rcvd**, issue **RECEIVE_AND_POST** with **max_len** set to zero, so that the local TP can determine whether the partner TP has data to send, seeks confirmation, or has changed the conversation state.

RECEIVE_AND_WAIT

The **RECEIVE_AND_WAIT** verb receives any data that is currently available from the partner transaction program (TP). If no data is currently available, the local TP waits for data to arrive.

To allow full use to be made of the asynchronous support, asynchronously issued **RECEIVE_AND_WAIT** verbs have been altered to act like RECEIVE_AND_POST verbs. Specifically, while an asynchronous **RECEIVE_AND_WAIT** is outstanding, the following verbs can be issued on the same conversation:

- DEALLOCATE(AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER)
- GET_ATTRIBUTES
- GET_TYPE
- REQUEST_TO_SEND
- SEND_ERROR
- TEST_RTS
- TP_ENDED

This allows an application, and in particular, a 5250 emulator, to use an asynchronous **RECEIVE_AND_WAIT** to receive data. While the **RECEIVE_AND_WAIT** is outstanding, it can still use **SEND_ERROR** and **REQUEST_TO_SEND**. It is recommended that you use this feature for full asynchronous support.

The following structure describes the verb control block (VCB) used by the **RECEIVE_AND_WAIT** verb.

Syntax

```
struct receive_and_wait {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      what_rcvd;
    unsigned char       rtn_status;
    unsigned char       fill;
    unsigned char       rts_rcvd;
    unsigned char       reserv4;
    unsigned short      max_len;
    unsigned short      dlen;
    unsigned char FAR * dptr;
    unsigned char       reserv5[5];
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_RECEIVE_AND_WAIT.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Specifies the conversation identifier.

The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

what_rcvd

Returned parameter. Indicates whether data or conversation status was received. Possible values are listed in the table following the Members section.

rtn_status

Supplied parameter. Indicates whether both data and conversation status indicators should be returned within one API call.

- AP_NO specifies that indicators should be returned individually on separate invocations of the verb.
- AP_YES specifies that indicators should be returned together, provided both are available. Both can be returned when:

  The receive buffer is large enough to hold all of the data that precedes the status indicator.

  The **fill** parameter specifies BUFFER or LL, and the data is the last logical record before the status indicator.

fill

Supplied parameter. Used in a basic conversation to specify how the local TP receives data. The following are allowed values:

- AP_BUFFER specifies that the local TP receives data until the number of bytes specified by **max_len** is reached or until the end of the data. Data is received without regard for the logical-record format.
- AP_LL specifies that data is received in logical-record format. The data received can be a complete logical record, a **max_len** byte portion of a logical record, or the end of a logical record.

rts_rcvd

Returned parameter. Contains the request-to-send indicator. Possible values are:

- AP_YES indicates that the partner TP has issued REQUEST_TO_SEND, which requests that the local TP change the conversation to RECEIVE state.
- AP_NO indicates that the partner TP has not issued **REQUEST_TO_SEND**.

max_len

Supplied parameter. Indicates the maximum number of bytes of data the local TP can receive. The range is from 0 through 65535.

For the Microsoft Windows 2000 operating system, this value must not exceed the length of the buffer to contain the received data.

By issuing **RECEIVE_AND_WAIT** with **max_len** set to zero, the local TP can determine whether the partner TP has data to

send, seeks confirmation, or has changed the conversation state.

dlen

Returned parameter. Indicates the number of bytes of data received. Data is stored in the buffer specified by **dptr**. A length of zero indicates that no data was received.

dptr

Supplied parameter. Provides the address of the buffer to contain the data received by the local TP.

For the Windows 2000 operating system, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

Values Returned by the what_rcvd Parameter

- AP_CONFIRM_DEALLOCATE indicates that the partner TP has issued DEALLOCATE with **dealloc_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues CONFIRMED.

- AP_CONFIRM_SEND indicates that the partner TP has issued PREPARE_TO_RECEIVE with **ptr_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues **CONFIRMED** and begins to send data.

- AP_CONFIRM_WHAT_RECEIVED indicates that the partner TP has issued CONFIRM. Upon receiving this value, the local TP normally issues **CONFIRMED**.

- AP_DATA can be returned in a basic conversation by **RECEIVE_AND_WAIT** if **fill** is set to AP_BUFFER. The local TP received data until **max_len** or end of data was reached. For more information, see "**RECEIVE_AND_WAIT** End of Data" at the end of this topic.

- AP_DATA_COMPLETE indicates, for **RECEIVE_AND_WAIT**, that the local TP has received a complete data record or the last part of a data record.

  For **RECEIVE_AND_WAIT** with **fill** set to AP_LL, this value indicates that the local TP has received a complete logical record or the end of a logical record.

  Upon receiving this value, the local TP normally reissues **RECEIVE_AND_WAIT** or issues another receive verb. If the partner TP has sent more data, the local TP begins to receive a new unit of data.

  Otherwise, the local TP examines status information, if **primary_rc** contains AP_OK and **what_rcvd** contains AP_SEND, AP_CONFIRM_SEND, AP_CONFIRM_DEALLOCATE, or AP_CONFIRM_WHAT_RECEIVED.

  See Return Codes in this topic for the next action the local TP normally takes.

  If **primary_rc** contains AP_DEALLOC_NORMAL, the conversation has been deallocated in response to DEALLOCATE issued by the partner TP.

- AP_DATA_INCOMPLETE indicates, for **RECEIVE_AND_WAIT**, that the local TP has received an incomplete data record. The **max_len** parameter specified a value less than the length of the data record (or less than the remainder of the data record if this is not the first receive verb to read the record).

  For **RECEIVE_AND_WAIT** with **fill** set to AP_LL, this value indicates that the local TP has received an incomplete logical record.

  Upon receiving this value, the local TP normally reissues **RECEIVE_AND_WAIT** (or issues another receive verb) to receive the next part of the record.

- AP_NONE indicates that the TP did not receive data or conversation status indicators.

- AP_SEND indicates, for the partner TP, that the conversation has entered RECEIVE state. For the local TP, the conversation

is now in SEND state. Upon receiving this value, the local TP normally uses SEND_DATA to begin sending data.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

When **rtn_status** is AP_YES, the preceding return code or one of the following return codes can be returned.

AP_DATA_COMPLETE_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_SEND.

AP_DATA_COMPLETE_CONFIRM_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_SEND.

AP_DATA_COMPLETE_CONFIRM

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_WHAT_RECEIVED.

AP_DATA_COMPLETE_CONFIRM_DEALL

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_DEALLOCATE.

AP_DATA_SEND

Primary return code; this is a combination of AP_DATA and AP_SEND.

AP_DATA_CONFIRM_SEND

Primary return code; this is a combination of AP_DATA and AP_CONFIRM_SEND.

AP_DATA_CONFIRM

Primary return code; this is a combination of AP_DATA and AP_CONFIRM_WHAT_RECEIVED.

AP_DATA_CONFIRM_DEALLOCATE

Primary return code; this is a combination of AP_DATA and AP_CONFIRM_DEALLOCATE.

AP_DEALLOC_NORMAL

Primary return code; the partner TP has deallocated the conversation without requesting confirmation and issued DEALLOCATE with **dealloc_type** set to one of the following:

AP_CONFIRM_SYNC_LEVEL

AP_FLUSH

AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

If **rtn_status** is AP_YES, examine **what_rcvd** also.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_RETURN_STATUS_WITH_DATA

Secondary return code; the specified **rtn_status** value was not recognized by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_RCV_AND_WAIT_BAD_FILL

Secondary return code; for basic conversations, **fill** was set to an invalid value.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_RCV_AND_WAIT_BAD_STATE

Secondary return code; the conversation was not in RECEIVE or SEND state when the TP issued this verb.

AP_RCV_AND_WAIT_NOT_LL_BDY

Secondary return code; for basic conversations, the conversation was in SEND state; the TP began but did not finish sending a logical record.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner logical unit (LU) or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE, it may indicate that no communications system could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_NO_TRUNC

Primary return code; the partner TP has issued SEND_ERROR with **err_type** set to AP_PROG while the conversation was in SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. Data sent but not yet received is purged.

AP_PROG_ERROR_TRUNC

Primary return code; in SEND state, after sending an incomplete logical record, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. The local TP may have received the first part of the logical record through a receive verb.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND_PROG

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP has issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_NO_TRUNC

Primary return code; while in SEND state, the partner TP (or partner LU) issued SEND_ERROR with **err_type** set to AP_SVC. Data was not truncated.

AP_SVC_ERROR_PURGING

Primary return code; the partner TP (or partner LU) issued **SEND_ERROR** with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

AP_SVC_ERROR_NO_TRUNC

Primary return code; while in SEND state, after sending an incomplete logical record, the partner TP (or partner LU) issued **SEND_ERROR**. The local TP may have received the first part of the logical record.

Remarks

The local TP receives data through the following process:

1. The local TP issues a receive verb until it finishes receiving a complete unit of data. The data received can be:
   - One logical record.
   - A buffer of data received independent of its logical-record format.

   The local TP may need to issue the receive verb several times in order to receive a complete unit of data. After a complete unit of data has been received, the local TP can manipulate it.

   The receive verbs are RECEIVE_AND_POST, **RECEIVE_AND_WAIT**, and RECEIVE_IMMEDIATE.

2. The local TP issues the receive verb again. This has one of the following effects:

    - If the partner TP has sent more data, the local TP begins to receive a new unit of data.
    - If the partner TP has finished sending data or is waiting for confirmation, status information (available through the **what_rcvd** parameter) indicates the next action the local TP normally takes.

The conversation must be in RECEIVE or SEND state when the TP issues this verb.

Issuing the Verb in SEND State

Issuing **RECEIVE_AND_WAIT** while the conversation is in SEND state has the following effects:

- The local LU sends the information in its send buffer and a SEND indicator to the partner TP.
- The conversation changes to RECEIVE state; the local TP waits for the partner TP to send data.

State Change

The new conversation state is determined by the following factors:

- The state the conversation is in when the TP issues the verb.
- The **primary_rc** parameter.
- The **what_rcvd** parameter if **primary_rc** contains AP_OK.

Verb Issued in SEND State

The following table details the state changes when **RECEIVE_AND_WAIT** is issued in SEND state and **primary_rc** is AP_OK.

what_rcvd	**New state**
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	RECEIVE
AP_DATA_COMPLETE	RECEIVE

AP_DATA_INCOMPLETE	RECEIVE
AP_SEND	No change
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table details the state changes when **RECEIVE_AND_WAIT** is issued in SEND state and **primary_rc** is not AP_OK.

primary_rc	**New state**
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_PROG_ERROR_NO_TRUNC	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_NO_TRUNC	RECEIVE

Verb Issued in RECEIVE State

The following table details the state changes when **RECEIVE_AND_WAIT** is issued in RECEIVE state and **primary_rc** is AP_OK.

what_rcvd	**New state**
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM

AP_DATA_CONFIRM	CONFIRM
AP_DATA	No change
AP_DATA_COMPLETE	No change
AP_DATA_INCOMPLETE	No change
AP_SEND	SEND
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table details the state changes when **RECEIVE_AND_WAIT** is issued in RECEIVE state and **primary_rc** is not AP_OK.

primary_rc	**New state**
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	No change
AP_PROG_ERROR_NO_TRUNC	No change
AP_SVC_ERROR_PURGING	No change
AP_SVC_ERROR_NO_TRUNC	No change
AP_PROG_ERROR_TRUNC	No change
AP_SVC_ERROR_TRUNC	No change

RECEIVE_AND_WAIT End of Data

In basic conversations, if the local TP issues **RECEIVE_AND_WAIT** and sets **fill** to AP_BUFFER, the receipt of the data ends when **max_len** or the end of the data is reached. The end of the data is indicated by either:

- A **primary_rc** parameter with a value other than AP_OK (for example, AP_DEALLOC_NORMAL).
- A **what_rcvd** parameter with one of the following values:

  AP_SEND

  AP_CONFIRM_SEND

AP_CONFIRM_DEALLOCATE

AP_CONFIRM_WHAT_RECEIVED

AP_DATA_CONFIRM_SEND

AP_DATA_CONFIRM_DEALLOCATE

AP_DATA_CONFIRM

To determine if the end of the data has been reached, the local TP reissues **RECEIVE_AND_WAIT**. If the new **primary_rc** contains AP_OK and **what_rcvd** contains AP_DATA, the end of the data has not been reached. If, however, the end of the data has been reached, **primary_rc** or **what_rcvd** will indicate the cause of the end of the data.

RECEIVE_AND_WAIT waits for data or an indicator to be sent by the partner TP. If you need the local TP to operate continuously, use RECEIVE_IMMEDIATE instead.

RECEIVE_IMMEDIATE

The **RECEIVE_IMMEDIATE** verb receives any data currently available from the partner transaction program (TP). If no data is available, the local TP does not wait. To avoid blocking the conversation, the Microsoft Windows 2000 system can issue RECEIVE_AND_WAIT in conjunction with WinAsyncAPPC.

The following structure describes the verb control block used by the **RECEIVE_IMMEDIATE** verb.

Syntax

```
struct receive_immediate {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      what_rcvd;
    unsigned char       rtn_status;
    unsigned char       fill;
    unsigned char       rts_rcvd;
    unsigned char       reserv4;
    unsigned short      max_len;
    unsigned short      dlen;
    unsigned char FAR * dptr;
    unsigned char       reserv5[5];
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_RECEIVE_IMMEDIATE.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

what_rcvd

Returned parameter. Contains information received with the incoming data. Possible values are listed following the Members section.

rtn_status

Supplied parameter. Indicates whether both data and conversation status indicators should be returned within one API call.

Use AP_NO to specify that indicators should be returned individually on separate invocations of the verb.

Use AP_YES to specify that indicators should be returned together, provided both are available. Both can be returned when:

- The receive buffer is large enough to hold all of the data that precedes the status indicator.
- The **fill** parameter specifies either BUFFER or LL, and the data is the last logical record before the status indicator.

fill

Supplied parameter. Specifies the manner in which the local TP receives data. It is used only for **RECEIVE_IMMEDIATE**.

Use AP_BUFFER to indicate that the local TP receives data until the number of bytes specified by **max_len** is reached or until end of data. Data is received without regard for the logical-record format.

Use AP_LL to indicate that data is received in logical-record format. The data received can be a complete logical record, a **max_len** byte portion of a logical record, or the end of a logical record.

rts_rcvd

Returned parameter. Contains the request-to-send indicator. Possible values are:

- AP_YES indicates that the partner TP has issued REQUEST_TO_SEND, which requests that the local TP change the conversation to RECEIVE state.
- AP_NO indicates that the partner TP has not issued **REQUEST_TO_SEND**.

max_len

Supplied parameter. Indicates the maximum number of bytes of data the local TP can receive. The range is from 0 through 65535.

For the Windows 2000 operating system, this value must not exceed the length of the buffer to contain the received data.

By issuing **RECEIVE_IMMEDIATE** with **max_len** set to zero, the local TP can determine whether the partner TP has data to send, seeks confirmation, or has changed the conversation state.

dlen

Returned parameter. Provides the number of bytes of data received. Data is stored in a buffer specified by **dptr**. A length of zero indicates that no data was received.

dptr

Supplied parameter. Address of the buffer to contain the data received by the local TP.

For the Windows 2000 operating system, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

Values Returned by the what_rcvd Parameter

- AP_CONFIRM_DEALLOCATE indicates that the partner TP has issued DEALLOCATE with **dealloc_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues CONFIRMED.
- AP_CONFIRM_SEND indicates that the partner TP has issued PREPARE_TO_RECEIVE with **ptr_type** set to AP_SYNC_LEVEL, and the conversation's synchronization level, established by **ALLOCATE**, is AP_CONFIRM_SYNC_LEVEL. Upon receiving this value, the local TP normally issues **CONFIRMED**, and begins to send data.
- AP_CONFIRM_WHAT_RECEIVED indicates that the partner TP has issued CONFIRM. Upon receiving this value, the local TP normally issues **CONFIRMED**.
- AP_DATA is returned for basic conversations by **RECEIVE_IMMEDIATE** if **fill** is set to AP_BUFFER. The local TP received data until **max_len** or end of data was reached. For more information, see "RECEIVE_IMMEDIATE End of Data" at the end

of this topic.

- AP_DATA_COMPLETE indicates, for **RECEIVE_IMMEDIATE** with **fill** set to AP_LL in basic conversations, that the local TP has received a complete logical record or the end of a logical record.

  Upon receiving this value, the local TP normally reissues **RECEIVE_IMMEDIATE** or issues another receive verb. If the partner TP has sent more data, the local TP begins to receive a new unit of data.

  Otherwise, the local TP examines status information if **primary_rc** contains AP_OK and **what_rcvd** contains any of these values:

  AP_SEND

  AP_CONFIRM_SEND

  AP_CONFIRM_DEALLOCATE

  AP_CONFIRM_WHAT_RECEIVED

  See the description of the value in Return Codes in this topic for the next action the local TP normally takes.

  If **primary_rc** contains AP_DEALLOC_NORMAL, the conversation has been deallocated in response to DEALLOCATE issued by the partner TP.

- AP_DATA_INCOMPLETE indicates for **RECEIVE_IMMEDIATE** in mapped conversations that the local TP has received an incomplete data record. The **max_len** parameter specified a value less than the length of the data record (or less than the remainder of the data record if this is not the first receive verb to read the record).

  For **RECEIVE_IMMEDIATE** with **fill** set to AP_LL in basic conversations, this value indicates that the local TP has received an incomplete logical record.

  Upon receiving this value, the local TP normally reissues RECEIVE_IMMEDIATE (or issues another receive verb) to receive the next part of the record.

- AP_NONE indicates that the TP did not receive data or conversation status indicators.

- AP_SEND indicates, for the partner TP, the conversation has entered RECEIVE state. For the local TP, the conversation is now in SEND state. Upon receiving this value, the local TP normally uses SEND_DATAto begin sending data.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

When **rtn_status** is AP_YES, the preceding return code or one of the following return codes can be returned.

AP_DATA_COMPLETE_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_SEND.

AP_DATA_COMPLETE_CONFIRM_SEND

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_SEND.

AP_DATA_COMPLETE_CONFIRM

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_WHAT_RECEIVED.

AP_DATA_COMPLETE_CONFIRM_DEALL

Primary return code; this is a combination of AP_DATA_COMPLETE and AP_CONFIRM_DEALLOCATE.

AP_DATA_SEND

Primary return code; this is a combination of AP_DATA and AP_SEND.

AP_DATA_CONFIRM_SEND

Primary return code; this is a combination of AP_DATA and AP_CONFIRM_SEND.

AP_DATA_CONFIRM

Primary return code; this is a combination of AP_DATA and AP_CONFIRM_WHAT_RECEIVED.

AP_DATA_CONFIRM_DEALLOCATE

Primary return code; this is a combination of AP_DATA and AP_CONFIRM_DEALLOCATE.

AP_UNSUCCESSFUL

Primary return code; no data is immediately available from the partner TP.

AP_DEALLOC_NORMAL

Primary return code; the partner TP has deallocated the conversation without requesting confirmation. The partner TP issued DEALLOCATE with **dealloc_type** set to one of the following:

- AP_FLUSH
- AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

If **rtn_status** is AP_YES, examine **what_rcvd** also.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_RETURN_STATUS_WITH_DATA

Secondary return code; the specified **rtn_status** value was not recognized by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_RCV_IMMD_BAD_FILL

Secondary return code for a basic conversation; the **fill** parameter was set to an invalid value.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_RCV_IMMD_BAD_STATE

Secondary return code; the conversation was not in RECEIVE state.

AP_ALLOCATION_ERROR

Secondary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner logical unit (LU) or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE, it can indicate that no communications system could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_NO_TRUNC

Primary return code; the partner TP has issued SEND_ERROR with **err_type** set to AP_PROG while the conversation was in SEND state. Data was not truncated.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. Data sent but not yet received is purged.

AP_PROG_ERROR_TRUNC

Primary return code; in SEND state, after sending an incomplete logical record, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. The local TP may have received the first part of the logical record through a receive verb.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND_PROG

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP has issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_NO_TRUNC

Primary return code; while in SEND state, the partner TP (or partner LU) issued **SEND_ERROR** with **err_type** set to AP_SVC. Data was not truncated.

AP_SVC_ERROR_PURGING

Primary return code; the partner TP (or partner LU) issued **SEND_ERROR** with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

AP_SVC_ERROR_TRUNC

Primary return code; in SEND state, after sending an incomplete logical record, the partner TP (or partner LU) issued **SEND_ERROR**. The local TP may have received the first part of the logical record.

Remarks

The local TP receives data through the following process:

1. The local TP issues a receive verb until it finishes receiving a complete unit of data. The data received can be:

   - One logical record.
   - A buffer of data received independent of its logical-record format.

   The local TP may need to issue the receive verb several times in order to receive a complete unit of data. After a complete unit of data has been received, the local TP can manipulate it.

   The receive verbs are RECEIVE_AND_POST, RECEIVE_AND_WAIT, and **RECEIVE_IMMEDIATE**.

2. The local TP issues the receive verb again. This has one of the following effects:

   - If the partner TP has sent more data, the local TP begins to receive a new unit of data.
   - If the partner TP has finished sending data or is waiting for confirmation, status information (available through **what_rcvd**) indicates the next action the local TP normally takes.

The conversation must be in RECEIVE state when the TP issues this verb.

The new state is determined by **primary_rc**. If **primary_rc** is AP_OK, the new state is determined by **what_rcvd**.

The following table details the state changes when the **primary_rc** is AP_OK.

what_rcvd	**New state**
AP_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_DATA_COMPLETE_CONFIRM_DEALL	CONFIRM_DEALLOCATE
AP_DATA_CONFIRM_DEALLOCATE	CONFIRM_DEALLOCATE
AP_CONFIRM_SEND	CONFIRM_SEND

AP_DATA_COMPLETE_CONFIRM_SEND	CONFIRM_SEND
AP_DATA_CONFIRM_SEND	CONFIRM_SEND
AP_CONFIRM_WHAT_RECEIVED	CONFIRM
AP_DATA_COMPLETE_CONFIRM	CONFIRM
AP_DATA_CONFIRM	CONFIRM
AP_DATA	No change
AP_DATA_COMPLETE	No change
AP_DATA_INCOMPLETE	No change
AP_SEND	SEND
AP_DATA_COMPLETE_SEND	SEND_PENDING

The following table details the state changes when the **primary_rc** is not AP_OK.

primary_rc	**New state**
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	No change
AP_PROG_ERROR_NO_TRUNC	No change
AP_SVC_ERROR_PURGING	No change
AP_SVC_ERROR_NO_TRUNC	No change
AP_PROG_ERROR_TRUNC	No change
AP_SVC_ERROR_TRUNC	No change
AP_UNSUCCESSFUL	No change

RECEIVE IMMEDIATE End of Data

In basic conversations, if the local TP issues **RECEIVE_IMMEDIATE** and sets **fill** to AP_BUFFER, the receipt of the data ends when **max_len** or the end of the data is reached. The end of the data is indicated by either:

- A **primary_rc** parameter with a value other than AP_OK (for example, AP_DEALLOC_NORMAL).
- A **what_rcvd** parameter with one of the following values:

  AP_SEND

  AP_CONFIRM_SEND

  AP_CONFIRM_DEALLOCATE

  AP_CONFIRM_WHAT_RECEIVED

  AP_DATA_CONFIRM_SEND

  AP_DATA_CONFIRM_DEALLOCATE

  AP_DATA_CONFIRM

To determine if the end of the data has been reached, the local TP reissues **RECEIVE_IMMEDIATE**. If the new **primary_rc** parameter contains AP_OK and **what_rcvd** contains AP_DATA, the end of the data has not been reached. If, however, the end of the data has been reached, **primary_rc** or **what_rcvd** will indicate the cause of the end of the data.

RECEIVE_LOG_DATA

The **RECEIVE_LOG_DATA** verb allows the user to register to receive the log data associated with an inbound Function Management Header 7 (FMH7) error report. The verb passes a buffer to APPC, and any log data received is placed in that buffer. APPC continues to use this buffer as successive FMH7s arrive until it is provided with another one (that is, until the transaction program (TP) issues another **RECEIVE_LOG_DATA** specifying a different buffer or no buffer at all).

Note that the TP itself is responsible for allocating and freeing the buffer. After the buffer has been passed to APPC, the TP should either issue another **RECEIVE_LOG_DATA** specifying a new buffer or a zero-length buffer, or wait until the conversation has finished before freeing the original buffer.

When an FMH7 is received, APPC copies any associated error log general data stream (GDS) into the buffer. If there is no associated error log variable, the buffer is zeroed out. It is up to the TP to check the buffer whenever a return code from a receive verb indicates that an error has been received.

The following structure describes the verb control block (VCB) used by the **RECEIVE_LOG_DATA** verb.

Syntax

```
struct receive_log_data {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv1;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned short      log_dlen;
    unsigned char FAR * log_dptr;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_RECEIVE_LOG_DATA.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv1

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

log_dlen

Supplied parameter. Specifies the maximum length of log data that APPC can place in the buffer (that is, the buffer size). The range is from 0 through 65535. Note that a length of zero here indicates that any previous **RECEIVE_LOG_DATA** verb

should be cancelled.

log_dptr

Supplied parameter. Specifies the address of the buffer that APPC will use to store the log data.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

REQUEST_TO_SEND

The **REQUEST_TO_SEND** verb notifies the partner transaction program (TP) that the local TP wants to send data.

The following structure describes the verb control block (VCB) used by the **REQUEST_TO_SEND** verb.

Syntax

```
struct request_to_send {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_REQUEST_TO_SEND.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier.

The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_R_T_S_BAD_STATE

Secondary return code; the conversation is not in an allowed state when the TP issued this verb.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE, it may indicate that no communications system could be found to support the local logical unit (LU). (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Microsoft Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any of the following states when the TP issues this verb:

CONFIRM

PENDING_POST (OS/2)

RECEIVE

There is no state change.

The request-to-send notification is received by the partner program through the **rts_rcvd** parameter of the following verbs:

- CONFIRM
- RECEIVE_AND_POST
- RECEIVE_AND_WAIT
- RECEIVE_IMMEDIATE
- SEND_DATA
- SEND_ERROR

It is also indicated by a **primary_rc** of AP_OK on TEST_RTS.

Request-to-send notification is sent to the partner TP immediately; APPC does not wait until the send buffer fills up or is flushed. Consequently, the request-to-send notification may arrive out of sequence. For example, if the local TP is in SEND state and issues PREPARE_TO_RECEIVE followed by **REQUEST_TO_SEND**, the partner TP, in RECEIVE state, may receive the request-to-send notification before it receives the send notification. For this reason, request-to-send can be reported to a TP through a receive verb.

In response to this request, the partner TP can change the conversation to:

- RECEIVE state by issuing **PREPARE_TO_RECEIVE** or **RECEIVE_AND_WAIT**.
- PENDING_POST state by issuing **RECEIVE_AND_POST**.

The partner TP can also ignore the request-to-send.

The conversation state changes to SEND for the local TP when the local TP receives one of the following values through the **what_rcvd** parameter of a subsequent receive verb:

- AP_CONFIRM_SEND and replies with CONFIRMED
- AP_DATA_COMPLETE_CONFIRM_SEND and replies with **CONFIRMED**
- AP_DATA_CONFIRM_SEND and replies with **CONFIRMED**
- AP_SEND

The receive verbs are RECEIVE_AND_POST, RECEIVE_IMMEDIATE, and RECEIVE_AND_WAIT.

SEND_CONVERSATION

The **SEND_CONVERSATION** verb allocates a session between the local logical unit (LU) and partner LU, sends data on the session, and then deallocates the session.

The following structure describes the verb control block (VCB) used by the **SEND_CONVERSATION** verb.

Syntax

```
struct send_conversation {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
       unsigned char       reserv3[8];
    unsigned char       rtn_ctl;
    unsigned char       reserv4;
    unsigned long       conv_group_id;
    unsigned long       sense_data;
    unsigned char       plu_alias[8];
    unsigned char       mode_name[8];
    unsigned char       tp_name[64];
    unsigned char       security;
    unsigned char       reserv6[11];
    unsigned char       pwd[10];
    unsigned char       user_id[10];
    unsigned short      pip_dlen;
    unsigned char FAR * pip_dptr;
    unsigned char       reserv6;
    unsigned char       fqplu_name[17];
    unsigned char       reserv7[8];
    unsigned short      dlen;
    unsigned char FAR * dptr;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_SEND_CONVERSATION.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local transaction program (TP). The value of this parameter was returned by TP_STARTED.

conv_id

Supplied parameter. Provides the conversation identifier.

The value of this parameter is returned by ALLOCATE in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

rtn_ctl

Supplied parameter. Specifies how APPC should select a session to allocate for the conversation and when the local LU should return control to the local TP. The allowed values are:

- AP_IMMEDIATE specifies that the LU allocates a contention-winner session, if one is immediately available, and returns control to the TP.
- AP_WHEN_SESSION_ALLOCATED specifies that the LU does not return control to the TP until it allocates a session or encounters one of the errors described in Return Codes in this topic. If the session limit is zero, the LU returns control immediately. Note that if a session is not available, the TP waits for one.
- AP_WHEN_SESSION_FREE specifies that the LU allocates a contention-winner or contention-loser session, if one is available or able to be activated, and returns control to the TP. If an error occurs (as described in Return Codes in this topic) the call will return immediately with the error in the **primary_rc** and **secondary_rc** fields.
- AP_WHEN_CONWINNER_ALLOC specifies that the LU does not return control until it allocates a contention-winner session or encounters one of the errors described in Return Codes in this topic. If the session limit is zero, the LU returns control immediately. Note that if a session is not available, the TP waits for one.
- AP_WHEN_CONV_GROUP_ALLOC specifies that the LU does not return control to the TP until it allocates the session specified by **conv_group_id** or encounters one of the errors described in Return Codes in this topic. If the session is not available, the TP waits for it to become free.

conv_group_id

Supplied/returned parameter. Used as a supplied parameter when **rtn_ctl** is WHEN_CONV_GROUP_ALLOC to specify the identity of the conversation group from which the session should be allocated. When **rtn_ctl** specifies a different value, and the **primary_rc** is AP_OK, this is a returned value. The purpose of this parameter is to provide a TP with the assurance that the same session will be reallocated and therefore the conversations conducted over the session will occur in the same sequence that they were initiated.

sense_data

Returned parameter. If the primary and secondary return codes indicate an allocation error (retry or no-retry), an SNA-defined sense code is returned.

plu_alias

Supplied parameter. Specifies the alias by which the partner LU is known to the local TP. This parameter must match the name of a partner LU established during configuration. The parameter is an 8-byte, type G ASCII character set that includes:

- Uppercase letters
- Numerals 0 to 9
- Spaces
- Special characters $, #, %, and @

If the value of this parameter is fewer than eight bytes, pad it on the right with ASCII spaces (0x20).

mode_name

Supplied parameter. Specifies the name of a set of networking characteristics defined during configuration. This parameter must match the name of a mode associated with the partner LU during configuration.

The parameter is an 8-byte EBCDIC character string. It can consist of characters from the type A EBCDIC character set, including all EBCDIC spaces. These characters are:

- Uppercase letters

- Numerals 0 to 9
- Special characters $, #, and @

The first character in the string must be an uppercase letter or special character.

Using the name SNASVCMG (a reserved mode name used internally by APPC) in a basic conversation is not recommended.

tp_name

Supplied parameter. Specifies the name of the invoked TP. The value of **tp_name** specified by ALLOCATE in the invoking TP must match the value of **tp_name** specified by RECEIVE_ALLOCATE in the invoked TP.

The parameter is a 64-byte, case-sensitive, EBCDIC character string. This parameter can consist of characters from the type AE EBCDIC character set. These characters are:

- Uppercase and lowercase letters
- Numerals 0 to 9
- Special characters $, #, @, and period (.)

If the TP name is fewer than 64 bytes, use EBCDIC spaces (0x40) to pad it on the right.

The SNA convention for naming a service TP is up to four characters. The first character is a hexadecimal byte between 0x00 and 0x3F. The other characters are from the EBCDIC AE character set.

security

Supplied parameter. Specifies the information the partner LU requires in order to validate access to the invoked TP.

- AP_NONE specifies that the invoked TP uses no conversation security.
- AP_PGM specifies that the invoked TP uses conversation security and requires a user identifier and password. Use **user_id** and **pwd** to supply this information.
- AP_SAME specifies that the invoked TP, invoked with a valid user identifier and password, in turn invokes another TP.

For example, assume that TP A invokes TP B with a valid user identifier and password, and TP B in turn invokes TP C. If TP B specifies the value AP_SAME, APPC will send the LU for TP C the user identifier from TP A and an already-verified indicator. This indicator indicates to TP C not to require the password (if TP C is configured to accept an already-verified indicator).

pwd

Supplied parameter. Specifies the password associated with **user_id**. This parameter is required only if the security parameter is set to AP_PGM and must match the password for **user_id** that was established during configuration.

This parameter is a 10-byte, case-sensitive, EBCDIC character string. It can consist of characters from the type AE EBCDIC character set. These characters are:

- Uppercase and lowercase letters
- Numerals 0 to 9
- Special characters $, #, @, and period (.)

If the password is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

user_id

Supplied parameter. Specifies the user identifier required to access the partner TP. This parameter is required only if the security parameter is set to AP_PGM and must match one of the user identifiers configured for the partner TP.

The parameter can consist of characters from the type AE EBCDIC character set. These characters are:

- Uppercase and lowercase letters
- Numerals 0 to 9
- Special characters $, #, @, and period (.)

If the user identifier is fewer than 10 bytes, use EBCDIC spaces (0x40) to pad it on the right.

pip_dlen

Supplied parameter. Specifies the length of the PIP to be passed to the partner TP. The range for this parameter is from 0 through 32767.

pip_dptr

Supplied parameter. Specifies the address of the buffer containing PIP data. Use this parameter only if **pip_dlen** is greater than zero.

PIP data can consist of initialization parameters or environmental setup information required by a partner TP or remote operating system. The PIP data must follow the GDS format. For more information, see your IBM SNA manual(s).

For the Microsoft Windows 2000 operating system, the data buffer can reside in a static data area or in a globally allocated area.

fqplu_name

Supplied parameter. Specifies the fully qualified name of the local LU. This parameter must match the fully qualified name of the local LU defined in the remote node. The parameter is made up of two type A EBCDIC character strings (each of up to eight characters), which are the network name (NETID) and the LU name of the partner LU. The names are separated by an EBCDIC period (.). The NETID can be omitted, and if this is the case, the period should also be omitted.

This name must be provided if no **plu_alias** is provided.

Type A EBCDIC characters contain:

- Uppercase letters
- Numerals 0 to 9
- Special characters $, #, and @

If the value of this parameter is fewer than 17 bytes, pad it on the right with EBCDIC spaces (0x40).

dlen

Supplied parameter. Specifies the number of bytes of data to be put in the local LU's send buffer. The range for this parameter is from 0 through 65535.

dptr

Supplied parameter. Specifies the address of the buffer containing the data to be put in the local LU's send buffer.

For the Windows 2000 operating system, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_UNSUCCESSFUL

Primary return code; the supplied parameter **rtn_ctl** specified immediate return of the control to the TP (AP_IMMEDIATE), and the local LU did not have an available contention-winner session.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_RETURN_CONTROL

Secondary return code; the value specified for **rtn_ctl** was invalid.

AP_BAD_SECURITY

Secondary return code; the value specified for **security** was invalid.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_PIP_LEN_INCORRECT

Secondary return code; the value of **pip_dlen** was greater than 32767.

AP_UNKNOWN_PARTNER_MODE

Secondary return code; the value specified for **mode_name** was invalid.

AP_BAD_PARTNER_LU_ALIAS

Secondary return code; APPC did not recognize the supplied **partner_lu_alias**.

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with ALLOCATE, it may indicate that no communications system could be found to support the local LU. (For example, the local LU alias specified with TP_STARTED is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

This verb is issued by the invoking TP to conduct an entire conversation with the remote TP. If the remote TP rejects either the conversation initiation or the data, the invoking TP will not receive notification of the rejection.

The conversation state is RESET when the TP issues this verb. There is no state change.

Several parameters of **SEND_CONVERSATION** are EBCDIC or ASCII strings. A TP can use the CSV CONVERT to translate a string from one character set to the other.

Normally, the value of **mode_name** must match the name of a mode configured for the invoked TP's node and associated during configuration with the partner LU. If one of the modes associated with the partner LU on the invoked TP's node is an implicit mode, the session established between the two LUs will be of the implicit mode when no mode name associated with the partner LU matches the value of **mode_name**.

SEND_DATA

The **SEND_DATA** verb places data in the local logical unit's (LU) send buffer for transmission to the partner transaction program (TP).

The following structure describes the verb control block (VCB) used by the **SEND_DATA** verb.

Syntax

```
struct send_data {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       rts_rcvd;
       unsigned char       data_type;
    unsigned short int  dlen;
    unsigned char FAR * dptr ;
    unsigned char       type;
    unsigned char       reserv4;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_SEND_DATA.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier.

The value of this parameter is returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

rts_rcvd

Returned parameter. Provides the request-to-send-received indicator.

- AP_YES indicates that the partner TP has issued REQUEST_TO_SEND, which requests that the local TP change the conversation to RECEIVE state. To change to RECEIVE state, the local TP can use PREPARE_TO_RECEIVE, RECEIVE_AND_WAIT, or RECEIVE_AND_POST.

- AP_NO indicates that the partner TP has not issued **REQUEST_TO_SEND**.

data_type

Supplied parameter. Specifies the type of data to be sent if Sync Point is supported. Valid parameters are:

AP_APPLICATION

AP_USER_CONTROL_DATA

AP_PS_HEADER

dlen

Supplied parameter. Specifies the number of bytes of data to be put in the local LU's send buffer. The range is from 0 through 65535.

dptr

Supplied parameter. Specifies the address of the buffer containing the data to be put in the local LU's send buffer.

For the Microsoft Windows 2000 operating system, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

type

Supplied parameter. Allows a TP to send data and perform other functions within one API call. For example, you can combine **SEND_DATA** with **type** set to CONFIRM to accomplish the same objective as issuing **SEND_DATA** followed by CONFIRM.

- AP_SEND_DATA_CONFIRM corresponds to **SEND_DATA** followed by **CONFIRM**.
- AP_SEND_DATA_FLUSH corresponds to **SEND_DATA** followed by FLUSH.
- AP_SEND_DATA_DEALLOC_ABEND corresponds to **SEND_DATA** followed by DEALLOCATE with a **dealloc_type** of AP_ABEND_PROG.
- AP_SEND_DATA_DEALLOC_FLUSH corresponds to **SEND_DATA** followed by **DEALLOCATE** with a **dealloc_type** of AP_FLUSH.
- AP_SEND_DATA_DEALLOC_SYNC_LEVEL corresponds to **SEND_DATA** followed by **DEALLOCATE** with a **dealloc_type** of AP_SYNC_LEVEL.
- AP_SEND_DATA_P_TO_R_FLUSH corresponds to **SEND_DATA** followed by PREPARE_TO_RECEIVE with a **ptr_type** of AP_FLUSH.
- AP_SEND_DATA_P_TO_R_SYNC_LEVEL corresponds to **SEND_DATA** followed by **PREPARE_TO_RECEIVE** with a **ptr_type** of AP_SYNC_LEVEL and **locks** set to AP_SHORT.

reserv4

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_LL

Secondary return code; the logical record length field of a logical record contained an invalid value—0x0000, 0x0001,

0x8000, or 0x8001. See About Transaction Programs for information on logical records.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the length specified for the data buffer was longer than the segment allocated to contain the buffer.

AP_SEND_DATA_INVALID_TYPE

Secondary return code; the specified type was not recognized by APPC.

AP_SEND_DATA_CONFIRM_SYNC_NONE

Secondary return code; the **type** CONFIRM is not permitted for a conversation that was allocated with a **sync_level** of NONE.

AP_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

AP_SEND_DATA_NOT_SEND_STATE

Secondary return code; the local TP issued **SEND_DATA**, but the conversation was not in SEND state.

AP_SEND_DATA_NOT_LL_BDY

Secondary return code; the TP started but did not finish sending a logical record. This occurs only when the **type** parameter is one of the following:

AP_SEND_DATA_CONFIRM

AP_SEND_DATA_DEALLOC_FLUSH

AP_SEND_DATA_DEALLOC_SYNC_LEVEL

AP_SEND_DATA_P_TO_R_FLUSH

AP_SEND_DATA_P_TO_R_SYNC_LEVEL

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with **ALLOCATE**, it may indicate that no communications system could be found to support the local LU. (For example, the local LU alias specified with **TP_STARTED** is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. Data sent but not yet received is purged.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

AP_DEALLOC_ABEND_PROG

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP has issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_PURGING

Primary return code; the partner TP (or partner LU) issued a **SEND_ERROR** verb with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

Remarks

The conversation must be in SEND state when the TP issues this verb. State changes, based on **primary_rc**, are summarized in the following table.

primary_rc	**New state**
AP_OK	No change
AP_ALLOCATION_ERROR	RESET

AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE

SEND_DATA may wait indefinitely because the partner TP has not issued a receive verb. If this occurs, the send buffer may fill up.

The data collected in the local LU's send buffer is transmitted to the partner LU (and partner TP) when one of the following occurs:

- The send buffer fills up.
- The local TP issues FLUSH, CONFIRM, or DEALLOCATE (or other verb that flushes the LU's send buffer).

SEND_ERROR

The **SEND_ERROR** verb notifies the partner transaction program (TP) that the local TP has encountered an application-level error.

The following structure describes the verb control block (VCB) used by the **SEND_ERROR** verb.

Syntax

```
struct send_error {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       rts_rcvd;
    unsigned char       err_type;
    unsigned char       err_dir;
    unsigned char       reserv3;
    unsigned short      log_dlen;
    unsigned char FAR * log_dptr;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_SEND_ERROR.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP.

The value of this parameter is returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter is returned by ALLOCATEin the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

rts_rcvd

Returned parameter. Indicates whether the partner TP issued REQUEST_TO_SEND.Possible values include:

- AP_YES indicates that the partner TP has issued **REQUEST_TO_SEND**, which requests that the local TP change the conversation to RECEIVE state. To change to RECEIVE state, the local TP can use PREPARE_TO_RECEIVE, RECEIVE_AND_WAIT, or RECEIVE_AND_POST.

- AP_NO indicates that the partner TP has not issued **REQUEST_TO_SEND**.

err_type

Supplied parameter. Indicates the type of the error being reported—application program or service program.

AP_PROG indicates that the error is to be reported to an end-user application program. This value causes APPC to send one of the following return codes to the partner TP:

AP_PROG_ERROR_NO_TRUNC

AP_PROG_ERROR_PURGING

AP_PROG_ERROR_TRUNC

AP_SVC indicates that the error is to be reported to a service program. This value causes APPC to send one of the following return codes to the partner TP:

AP_SVC_ERROR_NO_TRUNC

AP_SVC_ERROR_PURGING

AP_SVC_ERROR_TRUNC

err_dir

Supplied parameter. Indicates whether the error is with data just received or with data that is about to be sent. Use this parameter only when the conversation is in SEND_PENDING state. The parameter is ignored otherwise. The following are allowed values:

- AP_RCV_DIR_ERROR indicates that the TP issued **SEND_ERROR** after detecting an error associated with the data just received.
- AP_SEND_DIR_ERROR indicates that the TP issued **SEND_ERROR** after detecting an error associated with data it was going to send. For example, the TP encountered an error while reading data from the disk drive.

reserv3

A reserved field.

log_dlen

Supplied parameter for basic conversations; specifies the number of bytes of data to be sent to the error log file. The range is from 0 through 32767.

A length of zero indicates that there is no error log data.

log_dptr

Supplied parameter for basic conversations; specifies the address of the data buffer containing error information. The data is sent to the local error log and to the partner logical unit (LU).

This parameter is used by **SEND_ERROR** if **log_dlen** is greater than zero.

For Microsoft Windows 2000, the data buffer can reside in a static data area or in a globally allocated area. The data buffer must fit entirely within this area.

The TP must format the error data as a GDS error log variable. For more information, see your IBM SNA manual(s).

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_BAD_ERROR_DIRECTION

Secondary return code; the specified **err_dir** was not recognized by APPC.

AP_INVALID_DATA_SEGMENT

Secondary return code; the error data for the log file was longer than the segment allocated to contain the error data, or the address of the error data buffer was wrong.

AP_SEND_ERROR_BAD_TYPE

Secondary return code; the value of **err_type** was invalid.

AP_SEND_ERROR_LOG_LL_WRONG

Secondary return code; the LL field of the error log GDS variable did not match the actual length of the data.

The following return codes can be generated when **SEND_ERROR** is issued in any allowed state:

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with **ALLOCATE**, it may indicate that no communications system could be found to support the local LU. (For example, the local LU alias specified with **TP_STARTED** is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONV_FAILURE_NO_RETRY

Primary return code; the conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

AP_CONV_FAILURE_RETRY

Primary return code; the conversation was terminated because of a temporary error. Restart the TP to see if the problem

occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This may occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

The following return codes can be generated only if **SEND_ERROR** is issued in SEND state:

AP_ALLOCATION_ERROR

Primary return code; APPC has failed to allocate a conversation. The conversation state is set to RESET.

This code may be returned through a verb issued after ALLOCATE.

AP_ALLOCATION_FAILURE_NO_RETRY

Secondary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

AP_ALLOCATION_FAILURE_RETRY

Secondary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

AP_CONVERSATION_TYPE_MISMATCH

Secondary return code; the partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

AP_PIP_NOT_ALLOWED

Secondary return code; the allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

AP_PIP_NOT_SPECIFIED_CORRECTLY

Secondary return code; the partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

AP_SECURITY_NOT_VALID

Secondary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

AP_SYNC_LEVEL_NOT_SUPPORTED

Secondary return code; the partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

AP_TP_NAME_NOT_RECOGNIZED

Secondary return code; the partner LU does not recognize the TP name specified in the allocation request.

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

AP_TRANS_PGM_NOT_AVAIL_RETRY

Secondary return code; the remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

AP_PROG_ERROR_PURGING

Primary return code; while in RECEIVE, PENDING, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the partner TP issued **SEND_ERROR** with **err_type** set to AP_PROG. Data sent but not yet received is purged.

The following return codes can be generated only if **SEND_ERROR** is issued in SEND state:

AP_DEALLOC_ABEND_PROG

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner TP has issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP has encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

AP_DEALLOC_ABEND_SVC

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_SVC.

AP_DEALLOC_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner TP issued **DEALLOCATE** with **dealloc_type** set to AP_ABEND_TIMER.

AP_SVC_ERROR_PURGING

Primary return code; the partner TP (or partner LU) issued **SEND_ERROR** with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

The following return code can be generated only if **SEND_ERROR** is issued in RECEIVE state:

AP_DEALLOC_NORMAL

Primary return code; this return code does not indicate an error.

The partner TP issued DEALLOCATE with **dealloc_type** set to one of the following:

- AP_FLUSH
- AP_SYNC_LEVEL with the synchronization level of the conversation specified as AP_NONE

Remarks

The conversation can be in any state except RESET when the TP issues this verb. The conversation state must be SEND_PENDING if **err_dir** is used.

The local TP sends the error notification immediately to the partner TP; it does not hold the information in the local LU's send buffer.

Upon successful execution of this verb, the conversation is in SEND state for the local TP and in RECEIVE state for the partner TP.

The new state is determined by **primary_rc**. Possible state changes are summarized in the following table.

primary_rc	New state
AP_OK	SEND
AP_ALLOCATION_ERROR	RESET
AP_CONV_FAILURE_RETRY	RESET
AP_CONV_FAILURE_NO_RETRY	RESET
AP_DEALLOC_ABEND	RESET
AP_DEALLOC_ABEND_PROG	RESET
AP_DEALLOC_ABEND_SVC	RESET
AP_DEALLOC_ABEND_TIMER	RESET
AP_DEALLOC_NORMAL	RESET
AP_PROG_ERROR_PURGING	RECEIVE
AP_SVC_ERROR_PURGING	RECEIVE

If the conversation is in RECEIVE state when the TP issues **SEND_ERROR**, incoming data is purged by APPC. This data includes:

- Data sent by SEND_DATA.
- Return code indicators.
- Confirmation requests.
- Deallocation requests.

APPC does not purge an incoming request-to-send indicator. APPC replaces purged incoming return code indicators with other return codes. The primary return code AP_OK replaces the following purged return code indicators:

AP_PROG_ERROR_NO_TRUNC

AP_PROG_ERROR_PURGING

AP_PROG_ERROR_TRUNC

AP_SVC_ERROR_NO_TRUNC

AP_SVC_ERROR_PURGING

AP_SVC_ERROR_TRUNC

The primary return code AP_DEALLOC_NORMAL replaces the following purged return code indicators:

AP_ALLOCATION_ERROR

AP_ALLOCATION_FAILURE_NO_RETRY

AP_ALLOCATION_FAILURE_RETRY

AP_CONVERSATION_TYPE_MISMATCH

AP_DEALLOC_ABEND

AP_DEALLOC_ABEND_PROG

AP_DEALLOC_ABEND_SVC

AP_DEALLOC_ABEND_TIMER

AP_PIP_NOT_ALLOWED

AP_PIP_NOT_SPECIFIED_CORRECTLY

AP_SECURITY_NOT_VALID

AP_SYNC_LEVEL_NOT_SUPPORTED

AP_TP_NAME_NOT_RECOGNIZED

AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

AP_TRANS_PGM_NOT_AVAIL_RETRY

When the conversation is in SEND_PENDING state, APPC reports the following return codes to the partner TP based on the value in **err_dir**:

AP_PROG_ERROR_PURGING

The local TP issued **SEND_ERROR** with RECEIVE as the **err_dir**.

AP_PROG_ERROR_NO_TRUNC

The local TP issued **SEND_ERROR** with SEND as the **err_dir**.

AP_SVC_ERROR_PURGING

The local TP issued **SEND_ERROR** with RECEIVE as the **err_dir.**

AP_SVC_ERROR_NO_TRUNC

The local TP issued **SEND_ERROR** with SEND as the **err_dir**.

TEST_RTS

The **TEST_RTS** verb determines whether a request-to-send notification has been received from the partner transaction program (TP).

The following structure describes the verb control block (VCB) used by the **TEST_RTS** verb.

Syntax

```
struct test_rts {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       reserv3;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_TEST_RTS.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter was returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv3

A reserved field.

Return Codes

AP_OK

Primary return code; the verb executed successfully.

AP_UNSUCCESSFUL

Primary return code; request-to-send notification has not been received.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with **ALLOCATE**, it may indicate that no communications system could be found to support the local logical unit (LU). (For example, the local LU alias specified with **TP_STARTED** is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Remarks

The conversation can be in any state except RESET when the TP issues this verb.

There is no state change.

TEST_RTS_AND_POST

The **TEST_RTS_AND_POST** verb allows an application, typically a 5250 emulator, to request asynchronous notification when a partner transaction program (TP) requests send direction.

The following structure describes the verb control block (VCB) used by the **TEST_RTS_AND_POST** verb.

Syntax

```
struct test_rts {
    unsigned short      opcode;
    unsigned char       opext;
    unsigned char       reserv2;
    unsigned short      primary_rc;
    unsigned long       secondary_rc;
    unsigned char       tp_id[8];
    unsigned long       conv_id;
    unsigned char       reserv3;
    unsigned long       handle;
};
```

Members

opcode

Supplied parameter. Specifies the verb operation code, AP_B_TEST_RTS_AND_POST.

opext

Supplied parameter. Specifies the verb operation extension, AP_BASIC_CONVERSATION.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

tp_id

Supplied parameter. Identifies the local TP. The value of this parameter was returned by TP_STARTED in the invoking TP or by RECEIVE_ALLOCATE in the invoked TP.

conv_id

Supplied parameter. Provides the conversation identifier. The value of this parameter was returned by ALLOCATE in the invoking TP or by **RECEIVE_ALLOCATE** in the invoked TP.

reserv3

A reserved field.

handle

Supplied parameter. On Microsoft® Windows® 2000, this field provides the event handle to set.

Return Codes from Initial Verb

AP_OK

Primary return code; the verb executed successfully. Note particularly that a return code of AP_OK from the initial verb does not indicate that **REQUEST_TO_SEND** verb received from the partner TP. It simply indicates that the facility to receive asynchronous notification has been registered.

AP_UNSUCCESSFUL

Primary return code; request-to-send notification has not been received.

AP_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

AP_BAD_CONV_ID

Secondary return code; the value of **conv_id** did not match a conversation identifier assigned by APPC.

AP_BAD_TP_ID

Secondary return code; the value of **tp_id** did not match a TP identifier assigned by APPC.

AP_INVALID_SEMAPHORE_HANDLE

Secondary return code, the value of **handle** was invalid.

AP_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

AP_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

When this return code is used with **ALLOCATE**, it may indicate that no communications system could be found to support the local logical unit (LU). (For example, the local LU alias specified with **TP_STARTED** is incorrect or has not been configured.) Note that if **lu_alias** or **mode_name** is fewer than eight characters, you must ensure that these fields are filled with spaces to the right. This error is returned if these parameters are not filled with spaces, since there is no node available that can satisfy the **ALLOCATE** request.

When **ALLOCATE** produces this return code for a Host Integration Server 2009 Client system configured with multiple nodes, there are two secondary return codes as follows:

0xF0000001

Secondary return code; no nodes have been started.

0xF0000002

Secondary return code; at least one node has been started, but the local LU (when **TP_STARTED** is issued) is not configured on any active nodes. The problem could be either of the following:

- The node with the local LU is not started.
- The local LU is not configured.

AP_CONVERSATION_TYPE_MIXED

Primary return code; the TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

AP_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

AP_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

AP_CONV_BUSY

Primary return code; there can only be one outstanding conversation verb at a time on any conversation. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **conv_id**.

AP_THREAD_BLOCKING

Primary return code; the calling thread is already in a blocking call.

AP_UNEXPECTED_DOS_ERROR

Primary return code; the operating system has returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

Return Codes from Asynchronous Completion
AP_OK

Primary return code; the request-to-send notification has been received from the partner TP.

AP_CANCELLED

The outstanding **TEST_RTS_AND_POST** verb has been terminated. This will occur if the underlying conversation has been deallocated or an AP_TP_ENDED has been issued. Note that as with **RECEIVE_AND_POST**, the TP is still responsible for correctly terminating the conversation and possibly terminating the TP. Issuing another verb, such as **RECEIVE_IMMEDIATE,** at this point will indicate the reason for the conversation failure.

The conversation can be in any state except RESET when the TP issues this verb. There is no state change.

A common feature of many APPC applications, such as 5250 emulators, is a requirement to detect a partner's request to send. Currently, this can be done by polling the APPC interface to detect the partner's request. For example, an application can occasionally issue one of the following verbs:

- **TEST_RTS**

Remarks

- **RECEIVE_IMMEDIATE** and check the **rts_rcvd** field
- **SEND_DATA** of zero bytes, again checking the **rts_rcvd** field.

Some of the problems associated with this polling approach are:

- The application must continually interrupt its main work to poll APPC.
- The partner's request is not detected as soon as it becomes available.
- These approaches are processor-intensive.

The **TEST_RTS_AND_POST** verb allows an application running on Windows 2000, typically a 5250 emulator, to request asynchronous notification when the partner TP requests send direction.

An APPC application typically issues the **TEST_RTS_AND_POST** verb while in SEND state and then continues with its main processing. A request for send direction from the partner TP is indicated asynchronously to the application. After dealing with the partner's request, the application typically returns to SEND state, reissues **TEST_RTS_AND_POST**, and continues.

The **TEST_RTS_AND_POST** verb completes synchronously and the return code AP_OK indicates that a request for asynchronous notification has been registered. It is important to emphasize that this does not indicate that request-to-send was received from the partner TP.

When the partner's request to send is received, the asynchronous event completion occurs. It is important to note that this may be before the completion of the local TP's original **TEST_RTS_AND_POST** verb. This will be the case if the partner's request to send was received before the local TP's **TEST_RTS_AND_POST** verb was issued, or while the local TP's **TEST_RTS_AND_POST** verb was being processed.

APPC Extensions for the Windows Environment

This section describes API extensions to Windows Advanced Program-to-Program Communications (APPC) that allow asynchronous communication. Asynchronous communication occurs when a function returns before the request completes. The application is notified later when the request is completed.

Under Microsoft® Windows® 2000, three methods are available for asynchronous communication using the APPC API:

- Message posting using window handles.
- Waiting on Win32® events.
- Using Win32 I/O completion ports.

The first method uses messages posted to a window handle to notify an application of verb completion. This method using window handles and messages was supported on Microsoft Windows 3.x. There is one such window for each APPC application, independent of the number of conversations. Each APPC conversation can have one asynchronous verb outstanding at any time. When a verb completes, the posting to the window takes as parameters the asynchronous task handle returned by the original call and a pointer to the verb control block which has completed, containing the return codes of the verb.

The extensions using window handles and message posting described in this section (WinAsyncAPPC) were designed for all implementations and versions of Microsoft Windows from version 3.0 through the latest versions of Windows 2000. They provided compatibility for Windows programming and optimum application performance in the 16-bit Windows operating environment.

A second method using Win32 events for notification is supported. The extensions using Win32 events described in this section (WinAsyncAPPCEx) operate only on Windows 2000, and offer optimum application performance in the 32-bit Windows operating environment. If an event has been registered with the conversation, then an application can call the Win32 **WaitForSingleObject** or **WaitForMultipleObjects** function to wait to be notified of the completion of the verb.

A third method using Win32 I/O completion ports for notification is supported on Windows 2000. The extensions using I/O completion ports described in this section (WinAsyncAPPCIOCP) operate only on Windows 2000, and offer optimum application performance in the 32-bit Windows operating environment. If an I/O completion port has been created using **CreateIoCompletionPort**, then an application can call the Win32 **GetQueuedCompletionStatus** function to wait to be notified of the completion of the verb.

Windows APPC allows multithreaded Windows-based processes. A process contains one or more threads of execution. All references to threads in this document refer to actual threads in multithreaded Windows environments.

This section provides, for each extension, a definition of the function, syntax, returns, and remarks for using the function.

In This Section

- WinAPPCUnhookBlockingHook

WinAsyncAPPC

The **WinAsyncAPPC** function provides an asynchronous entry point for all of the APPC verbs. Use this function instead of the blocking versions of the verbs if you run your application and want to use message posting using Windows handles for asynchronous verb completion.

Syntax

```
HANDLE WINAPI WinAsyncAPPC(
HANDLE hWnd,
Long lpVcb
);
```

Parameters

hWnd

A window handle that will be used for message posting to notify an application when an APPC verb completes.

lpVcb

Pointer to the verb control block.

Return Value

The return value specifies whether the asynchronous request was successful. If the function was successful, the return value is an asynchronous task handle. If the function was not successful, a zero is returned.

When this function returns with a successful value, this does not indicate that the APPC call will ultimately return successfully. It only indicates that it was possible for the APPC library to attempt the APPC call asynchronously using message posting for notification.

Remarks

For an example of how to use this verb in transaction programs (TPs), see the send and receive sample TP (SENDRECV.C located in the APPC folder) included in the SDK.

APPC verbs used in basic conversations that can block are as follows:

- ALLOCATE
- CONFIRM
- CONFIRMED
- DEALLOCATE
- FLUSH
- PREPARE_TO_RECEIVE
- RECEIVE_ALLOCATE
- RECEIVE_AND_WAIT
- REQUEST_TO_SEND
- SEND_CONVERSATION
- SEND_DATA
- SEND_ERROR

- TP_ENDED
- TP_STARTED

APPC verbs used in mapped conversations that can block are as follows:

- MC_ALLOCATE
- MC_CONFIRM
- MC_CONFIRMED
- MC_DEALLOCATE
- MC_FLUSH
- MC_PREPARE_TO_RECEIVE
- MC_RECEIVE_AND_WAIT
- MC_REQUEST_TO_SEND
- MC_SEND_CONVERSATION
- MC_SEND_DATA
- MC_SEND_ERROR

When using the synchronous or asynchronous versions of a verb, an application can only have one outstanding function in progress on a conversation at a time. An attempt to initiate a second function results in the error code AP_CONV_BUSY.

The exceptions to the preceding paragraph are:

- RECEIVE_AND_POST
- MC_RECEIVE_AND_POST
- RECEIVE_AND_WAIT
- MC_RECEIVE_AND_WAIT

To allow full use of the asynchronous support, asynchronously issued **RECEIVE_AND_WAIT** and **MC_RECEIVE_AND_WAIT** verbs have been altered to act like the **RECEIVE_AND_POST** and **MC_RECEIVE_AND_POST** verbs. Specifically, while an asynchronous version of one of these verbs is outstanding, the following verbs can be issued on the same conversation:

- DEALLOCATE (AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER)
- GET_ATTRIBUTES or MC_GET_ATTRIBUTES
- GET_TYPE
- REQUEST_TO_SEND or MC_REQUEST_TO_SEND
- SEND_ERROR or MC_SEND_ERROR

- TEST_RTS or MC_TEST_RTS
- TP_ENDED

This allows an application, in particular, a 5250 emulator, to use an asynchronous **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** to receive data. While the **RECEIVE_AND_POST**, **MC_RECEIVE_AND_POST**, **RECEIVE_AND_WAIT**, or **MC_RECEIVE_AND_WAIT** is outstanding, it can still use **SEND_ERROR** or **MC_SEND_ERROR** and **REQUEST_TO_SEND** or **MC_REQUEST_TO_SEND**. It is recommended that you use this feature for full asynchronous support.

When the asynchronous operation is complete, the application's window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinAsyncAPPC" as the input string. The *wParam* argument contains the asynchronous task handle returned by the original function call. The *lParam* argument contains the original VCB pointer and can be dereferenced to determine the final return code.

As part of the Windows APPC definition, WinAPPCCancelAsyncRequest allows an application to cancel any asynchronous APPC action; but terminates the related conversation or TP as appropriate. Any outstanding operations return with AP_CANCELED as the return code.

If the function returns successfully, a **WinAsyncAPPC** message is posted to the application when the operation completes or the conversation is canceled.

WinAsyncAPPCEx

The **WinAsyncAPPCEx** function provides an asynchronous entry point for all of the APPC verbs. Use this function instead of the blocking versions of the verbs to allow multiple sessions to be handled on the same thread using events. This verb is only supported on Microsoft® Windows® 2000 and uses Win32® events.

Syntax

```
    HANDLE WINAPI WinAsyncAPPCEx(
HANDLEevent_handle,
longlpVcb);
```

Parameters

event_handle

Handle used for event notification using Win32 events.

lpVcb

Pointer to the verb control block.

Return Value

The return value specifies whether the asynchronous resolution request was successful. If the function was successful, the return value is an asynchronous task handle. If the function was not successful, a zero is returned.

When this function returns with a successful value, this does not indicate that the APPC call will ultimately return successfully. It only indicates that it was possible for the APPC library to attempt the APPC call asynchronously using events for notification.

Remarks

This function is intended for use with **WaitForSingleObject** or **WaitForMultipleObjects** in the Win32 API. These functions are described in the "Reference" section of the Microsoft Platform SDK documentation.

For an example of how to use this verb in multithreaded TPs, see the multithreaded send and receive sample TPs (MRCV.C, MSEND.C, and MSENDRCV.C located in the MSENDRCV folder) included in the SDK.

APPC verbs used in basic conversations that can block are as follows:

- ALLOCATE
- CONFIRM
- CONFIRMED
- DEALLOCATE
- FLUSH
- PREPARE_TO_RECEIVE
- RECEIVE_ALLOCATE
- RECEIVE_AND_WAIT
- REQUEST_TO_SEND
- SEND_CONVERSATION
- SEND_DATA

- SEND_ERROR
- TP_ENDED
- TP_STARTED

APPC verbs used in mapped conversations that can block are as follows:

- MC_ALLOCATE
- MC_CONFIRM
- MC_CONFIRMED
- MC_DEALLOCATE
- MC_FLUSH
- MC_PREPARE_TO_RECEIVE
- MC_RECEIVE_AND_WAIT
- MC_REQUEST_TO_SEND
- MC_SEND_CONVERSATION
- MC_SEND_DATA
- MC_SEND_ERROR
- RECEIVE_ALLOCATE
- TP_ENDED
- TP_STARTED

When using the synchronous or asynchronous versions of a verb, an application can only have one outstanding function in progress on a conversation at a time. An attempt to initiate a second function results in the error code AP_CONV_BUSY.

Note
The exceptions to the preceding paragraph are RECEIVE_AND_POST, MC_RECEIVE_AND_POST, RECEIVE_AND_WAIT, and MC_RECEIVE_AND_WAIT.

Note
To allow full use of the asynchronous support, asynchronously issued **RECEIVE_AND_WAIT** and **MC_RECEIVE_AND_WAIT** verbs have been altered to act like the **RECEIVE_AND_POST** and **MC_RECEIVE_AND_POST** verbs. Specifically, while an asynchronous version of one of these verbs is outstanding, the following verbs can be issued on the same conversation:

- DEALLOCATE (AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER)
- GET_ATTRIBUTES or MC_GET_ATTRIBUTES
- GET_TYPE

- REQUEST_TO_SEND or MC_REQUEST_TO_SEND
- SEND_ERROR or MC_SEND_ERROR
- TEST_RTS or MC_TEST_RTS
- TP_ENDED

Note
This allows an application, in particular, a server application, to use an asynchronous **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** to receive data. While the **RECEIVE_AND_POST**, **MC_RECEIVE_AND_POST**, **RECEIVE_AND_WAIT**, or **MC_RECEIVE_AND_WAIT** is outstanding, it can still use **SEND_ERROR** or **MC_SEND_ERROR** and **REQUEST_TO_SEND** or **MC_REQUEST_TO_SEND**. It is recommended that you use this feature for full asynchronous support, and in particular, for support of multiple conversations on the same thread.

When the asynchronous operation is complete, the application is notified through the signaling of the event. Upon signaling of the event, examine the APPC primary return code and secondary return code in the verb control block for any error conditions.

WinAsyncAPPCIOCP

The **WinAsyncAPPCIOCP** function provides an asynchronous entry point for all of the APPC verbs. Use this function instead of the blocking versions of the verbs to allow multiple sessions to be handled on the same thread using I/O completion ports. This verb is only supported on Microsoft Windows 2000, and uses Win32 I/O completion ports.

Syntax

```
    HANDLE WINAPI WinAsyncAPPCIOCP(
APPC_IOCP_INFO *iocp_handle,
longlpVcb);
```

Parameters

iocp_handle

A pointer to an **APPC_IOCP_INFO** structure used for passing I/O completion port information.

lpVcb

Pointer to the verb control block

The **APPC_IOCP_INFO** structure has the following prototype:

```
APPC_CompletionPort;APPC_NumberOfBytesTransferred;
    APPC_CompletionKey;
    APPC_pOverlapped;
```

APPC_CompletionPort

This supplied parameter is the HANDLE returned by the call to the **CreateIoCompletionPort** function when the I/O completion port is created. The I/O completion port must be created before calling the **WinAsyncAPPCIOCP** function. When the verb completes, the APPC Library calls the **PostQueuedCompletionStatus** function with the remaining fields in the structure as inputs, and these fields are simply passed through to the **GetQueuedCompletionStatus** function issued by the application.

APPC_NumberOfBytesTransferred

This supplied parameter is ignored. When the APPC verb completes, the APPC Library calls the **PostQueuedCompletionStatus** function with this field as an input, and the value returned for the *dwNumberOfBytesTransferred* is simply passed through to the **GetQueuedCompletionStatus** function issued by the application.

APPC_CompletionKey

This supplied parameter is ignored. When the APPC verb completes, the APPC Library calls the **PostQueuedCompletionStatus** function with this field as an input, and the value returned for the *dwCompletionKey* is simply passed through to the **GetQueuedCompletionStatus** function issued by the application.

APPC_pOverlapped

This supplied parameter is ignored. When the APPC verb completes, the APPC Library calls the **PostQueuedCompletionStatus** function with this field as an input, and the value returned for the *lpOverlapped* is simply passed through to the **GetQueuedCompletionStatus** function issued by the application.

Return Value

The return value specifies whether the asynchronous resolution request was successful. If the function was successful, the return value is an asynchronous task handle. If the function was not successful, a zero is returned.

When this function returns with a successful value, this does not indicate that the APPC call will ultimately return successfully. It only indicates that it was possible for the APPC library to attempt the APPC call asynchronously using an I/O completion port for notification.

Remarks

This function is intended for use with **CreateIoCompletionPort** and **GetQueuedCompletionStatus** in the Win32 API. These functions are described in the "Reference" section of the Microsoft Platform SDK documentation.

For an example of how to use this verb in multithreaded TPs, see the multithreaded receive sample TP (MRCVIO located in the SNA\MSENDRCV folder) using I/O completion ports included in the Host Integration Server 2009 SDK.

APPC verbs used in basic conversations that can block are as follows:

- ALLOCATE
- CONFIRM
- CONFIRMED
- DEALLOCATE
- FLUSH
- PREPARE_TO_RECEIVE
- RECEIVE_ALLOCATE
- RECEIVE_AND_WAIT
- REQUEST_TO_SEND
- SEND_CONVERSATION
- SEND_DATA
- SEND_ERROR
- TP_ENDED
- TP_STARTED

APPC verbs used in mapped conversations that can block are as follows:

- MC_ALLOCATE
- MC_CONFIRM
- MC_CONFIRMED
- MC_DEALLOCATE
- MC_FLUSH
- MC_PREPARE_TO_RECEIVE
- MC_RECEIVE_AND_WAIT
- MC_REQUEST_TO_SEND
- MC_SEND_CONVERSATION

- MC_SEND_DATA
- MC_SEND_ERROR
- RECEIVE_ALLOCATE
- TP_ENDED
- TP_STARTED

When using the synchronous or asynchronous versions of a verb, an application can only have one outstanding function in progress on a conversation at a time. An attempt to initiate a second function results in the error code AP_CONV_BUSY.

The exceptions to the preceding paragraph are RECEIVE_AND_POST, MC_RECEIVE_AND_POST, RECEIVE_AND_WAIT, and MC_RECEIVE_AND_WAIT.

To allow full use of the asynchronous support, asynchronously issued **RECEIVE_AND_WAIT** and **MC_RECEIVE_AND_WAIT** verbs have been altered to act like the **RECEIVE_AND_POST** and **MC_RECEIVE_AND_POST** verbs. Specifically, while an asynchronous version of one of these verbs is outstanding, the following verbs can be issued on the same conversation:

- DEALLOCATE (AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER)
- GET_ATTRIBUTES or MC_GET_ATTRIBUTES
- GET_TYPE
- REQUEST_TO_SEND or MC_REQUEST_TO_SEND
- SEND_ERROR or MC_SEND_ERROR
- TEST_RTS or MC_TEST_RTS
- TP_ENDED

This allows an application, in particular, a server application, to use an asynchronous **RECEIVE_AND_WAIT** or **MC_RECEIVE_AND_WAIT** to receive data. While the **RECEIVE_AND_POST**, **MC_RECEIVE_AND_POST**, **RECEIVE_AND_WAIT**, or **MC_RECEIVE_AND_WAIT** is outstanding, it can still use **SEND_ERROR** or **MC_SEND_ERROR** and **REQUEST_TO_SEND** or **MC_REQUEST_TO_SEND**. It is recommended that you use this feature for full asynchronous support, and in particular, for support of multiple conversations on the same thread.

When the asynchronous operation is complete, the application is notified through the **GetQueuedCompletionStatus** function. Upon I/O completion, examine the APPC primary return code and secondary return code in the verb control block for any error conditions.

WinAPPCCancelAsyncRequest

The **WinAPPCCancelAsyncRequest** function cancels an outstanding WinAsyncAPPC-based request.

Syntax

```
    int WINAPI WinAPPCCancelAsyncRequest(
HANDLE hAsyncTaskID);
```

Parameters

hAsyncTaskID

Supplied parameter. Specifies the asynchronous task to be canceled.

Return Value

The return value specifies whether the asynchronous request was canceled. If the value is zero, the request was canceled. Otherwise, the value is one of the following:

WAPPCINVALID

An error code indicating that the specified asynchronous task identifier was invalid.

WAPPCALREADY

An error code indicating that the asynchronous routine being canceled has already completed.

Remarks

An asynchronous task previously initiated by issuing one of the **WinAsyncAPPC**, **WinAsyncAPPCEx**, or **WinAsyncAPPCIOCP** functions can be canceled prior to completion by issuing the **WinAPPCCancelAsyncRequest** function, specifying the asynchronous task identifier as returned by the initial function in *hAsyncTaskID*.

If the outstanding verb relates to a conversation (for example, SEND_DATA or RECEIVE_AND_WAIT), the verb is purged and the session is closed. If the verb relates to a TP (for example, RECEIVE_ALLOCATE or TP_STARTED), the TP is ended. In both cases, while the implementation closes conversations and sessions as cleanly as possible, it does not flush send buffers, wait for confirmations, and so on. This call is synchronous, and after the processing described above is complete, a completion message is posted for the canceled verb.

If an attempt to cancel an existing asynchronous **WinAsyncAPPC** routine fails with an error code of WAPPCALREADY, one of two things has occurred. Either the original routine has already completed and the application has dealt with the resulting message, or the original routine has already completed and the resulting message is still waiting in the application window queue.

WinAPPCCancelBlockingCall

The **WinAPPCCancelBlockingCall** function cancels any outstanding blocking operation for its thread. Any outstanding blocked call canceled will cause an error code of WAPPCCANCEL to be generated.

Syntax

```
BOOL WINAPI WinAPPCCancelBlockingCall(
void
);
```

Return Value

The return value specifies whether the cancellation request was successful. If the value is zero, the request was canceled. Otherwise, the value is the following:

WAPPCINVALID

An error code indicating that there is no outstanding blocking call.

Remarks

If the outstanding verb relates to a conversation (for example, SEND_DATA or RECEIVE_AND_WAIT), the verb is purged and the session is closed. If the verb relates to a TP (for example, RECEIVE_ALLOCATE or TP_STARTED), the TP is ended. In both cases, while the implementation brings down conversations and sessions as cleanly as possible, it does not flush send buffers, wait for confirmations, and so on. This call is synchronous and after the processing described above is complete, the function is finished.

In Microsoft® Windows® 2000, a multithreaded application can have multiple blocking operations outstanding, but only one per thread. To distinguish between multiple outstanding calls, **WinAPPCCancelBlockingCall** cancels the outstanding operation on the current, or calling, application thread if one exists; otherwise, it fails. By default in Windows 2000, Windows APPC suspends the calling application thread while an operation is outstanding. As a result, the thread on which the blocking operation was initiated will not regain control (and therefore, will not be able to issue a call to **WinAPPCCancelBlockingCall**) unless a blocking hook is registered for the thread using WinAPPCSetBlockingHook.

WinAPPCCleanup

The **WinAPPCCleanup** function terminates and deregisters an application from a Windows APPC implementation.

Syntax

```
BOOL WINAPI WinAPPCCleanup(
void
);
```

Return Value

The return value specifies whether the deregistration was successful. If the value is nonzero, the application was successfully deregistered. The application was not deregistered if a value of zero is returned.

Remarks

Use **WinAPPCCleanup** to indicate deregistration of a Windows APPC application from a Windows APPC implementation.

Conversations that are still active will be terminated and TPs ended. This function is equivalent to issuing TP_ENDED (HARD) on all TPs owned by the application.

Reference

WinAPPCStartup

WinAPPCIsBlocking

The **WinAPPCIsBlocking** function determines if a thread is executing while waiting for a previous blocking call to finish.

Syntax

```
BOOL WINAPI WinAPPCIsBlocking(
void
);
```

Return Value

The return value specifies the outcome of the function. If the value is nonzero, there is an outstanding blocking call awaiting completion. A zero indicates the absence of an outstanding blocking call.

Remarks

Although a call issued on a blocking function appears to an application as though it blocks, the Windows APPC DLL has to relinquish the processor to allow other applications to run. This means that it is possible for the application that issued the blocking call to be re-entered, depending on the message(s) it receives. In this instance, the **WinAPPCIsBlocking** call can be used to determine whether the application task currently has been re-entered while waiting for an outstanding blocking call to finish. Note that Windows APPC prohibits more than one outstanding blocking call per thread.

The Windows APPC DLL prohibits more than one blocking call per thread and returns AP_THREAD_BLOCKING if this occurs.

WinAPPCSetBlockingHook
WinAPPCUnhookBlockingHook
WinAPPCCancelBlockingCall

WinAPPCStartup

The **WinAPPCStartup** function allows an application to specify the version of Windows APPC required and to retrieve details of the specific Windows APPC implementation. An application must call this function to register itself with a Windows APPC implementation before issuing any further Windows APPC calls.

Syntax

```
            int WINAPI WinAPPCStartup(
        WORDwVersionRequired,
        LPWAPPCDATAlpAPPCData
);

typedef struct {
    WORD wVersion;
    char szDescription[WAPPCDESCRIPTION_LEN+1];
} WAPPCDATA, FAR * LPWAPPCDATA;

where WAPPCDESCRIPTION_LEN is defined as 127
```

Parameters

wVersionRequired

Specifies the version of Windows APPC support required. The high-order byte specifies the minor version (revision) number; the low-order byte specifies the major version number. The current version of the Windows APPC API is 1.0.

lpAPPCData

Pointer to a returned structure containing a Windows APPC version number and a description of the Windows APPC implementation.

Return Value

The return value specifies whether the application was registered successfully and whether the Windows APPC implementation can support the specified version number. If the value is zero, it was registered successfully and the specified version can be supported. Otherwise, the return value is one of the following:

WAPPCSYSNOTREADY

The underlying network system is not ready for network communication.

WAPPCVERNOTSUPPORTED

The version of Windows APPC support requested is not provided by this particular Windows APPC implementation.

WAPPCINVALID

The Windows APPC version specified by the application is not supported by this DLL.

Remarks

To support future Windows APPC implementations and applications that may have functionality differences from Windows APPC version 1.0, a negotiation takes place in **WinAPPCStartup**. An application passes to **WinAPPCStartup** the Windows APPC version that it can use. If this version is lower than the lowest version supported by the Windows APPC DLL, the DLL cannot support the application and **WinAPPCStartup** fails. If the version is not lower, however, the call succeeds and returns the highest version of Windows APPC supported by the DLL. If this version is lower than the lowest version supported by the application, the application either fails its initialization or attempts to find another Windows APPC DLL on the system.

This negotiation allows both a Windows APPC DLL and a Windows APPC application to support a range of Windows APPC versions. An application can successfully use a DLL if there is any overlap in the versions. The following table illustrates how **WinAPPCStartup** works in conjunction with different application and DLL versions.

Application versions	DLL versions	To WinAPPCStartup	From WinAPPCStartup	Result
1.0	1.0	1.0	1.0	Use 1.0

1.0, 2.0	1.0	2.0	1.0	Use 1.0
1.0	1.0, 2.0	1.0	2.0	Use 1.0
1.0	2.0, 3.0	1.0	WAPPCINVALID	Fail
2.0, 3.0	1.0	3.0	1.0	App Fails
1.0, 2.0, 3.0	1.0, 2.0, 3.0	3.0	3.0	Use 3.0

Details of the actual Windows APPC implementation are described in the **WAPPCDATA** structure defined as follows that is returned by **WinAPPCStartup**:

```
typedef struct tagWAPPCDDATA { WORD wVersion;
char szDescription[WAPPCDESCRIPTION_LEN+1];
} WAPPCDATA, FAR *LPWAPPCDATA;
```

The structure members are as follows:

wVersion

The highest APPC version number supported by the Windows APPC DLL.

szDescription

A descriptive string describing the WinAPPC implementation.

After it makes its last Windows APPC call, an application should call the WinAPPCCleanup routine.

Each Windows APPC implementation must make a **WinAPPCStartup** call before issuing any other Windows APPC calls.

WinAPPCSetBlockingHook

The **WinAPPCSetBlockingHook** function allows a Windows APPC implementation to block APPC function calls by means of a new function. By default in Microsoft Windows 2000, blocking calls suspend the calling application's thread until the request is finished.

Syntax

```
        FARPROC WINAPI WinAPPCSetBlockingHook (
    FARPROC lpBlockFunc);
```

Parameters

lpBlockFunc

Specifies the procedure instance address of the blocking function to be installed.

Return Value

The return value points to the procedure instance of the previously installed blocking function. The application or library that calls **WinAPPCSetBlockingHook** should save this return value so that it can be restored if needed. (If nesting is not important, the application can simply discard the value returned by **WinAPPCSetBlockingHook** and eventually use WinAPPCUnhookBlockingHook to restore the default mechanism.)

Remarks

A Windows APPC implementation has a default mechanism by which blocking APPC functions are implemented. This function gives the application the ability to execute its own function at blocking time in place of the default function.

The default blocking function is equivalent to:

```
BOOL DefaultBlockingHook (void)  {
    MSG msg;
    /* get the next message if any */
    if ( PeekMessage (&msg,0,0,PM_NOREMOVE)  )  {
        if ( msg.message = = WM_QUIT  )
            return FALSE;   // let app process WM_QUIT
        PeekMessage (&msg,0,0,PM_REMOVE) ;
        TranslateMessage (&msg) ;
        DispatchMessage (&msg) ;
    }
    /* TRUE if no WM_QUIT received */
    return TRUE;
}
```

A blocking function must return FALSE if it receives a WM_QUIT message so Windows APPC can return control to the application to process the message and terminate gracefully. Otherwise, the function should return TRUE.

This function is implemented on a per-thread basis. It provides for a particular thread to replace the blocking mechanism without affecting other threads.

The **WinAPPCSetBlockingHook** function is provided to support those applications that require more complex message processing—for example, those employing the multiple document interface (MDI) model.

WinAPPCIsBlocking

WinAPPCCancelBlockingCall

WinAPPCUnhookBlockingHook

The **WinAPPCUnhookBlockingHook** function removes any previous blocking hook that has been installed and reinstalls the default blocking mechanism.

Syntax

```
BOOL WINAPI WinAPPCUnhookBlockingHook(
void
);
```

Return Value

The return value specifies the outcome of the function. It is nonzero if the default mechanism is successfully reinstalled. The value is zero if the mechanism did not reinstall.

WinAPPCSetBlockingHook

Host Integration Server Enhancements to the Windows Environment

This section describes the extensions to Windows Advanced Program-to-Program Communications (APPC) and the Common Service Verb (CSV) API that are specific to Host Integration Server 2009.

The GetAppcConfig function takes a local logical unit (LU) and returns the remote LUs that are accessible to the user through that LU. If left blank, and a default local LU has been configured, the user's default local LU will be used. In all instances, if one of the returned remote LUs is the user's default, it is indicated as such.

The call is asynchronous and completion is normally signaled by the posting of a Microsoft Windows message. However, an alternative completion mechanism is provided for console applications.

The GetAppcReturnCode and GetCsvReturnCode functions convert the primary and secondary return codes in the verb control block (VCB) to a printable string. These functions provide a standard set of error strings for use by applications.

For each extension, this section provides a definition of the function, syntax, returns, and remarks for using the function.

In This Section

GetAppcConfig

The **GetAppcConfig** function provides an asynchronous entry point for retrieving the remote systems to which a particular local LU can connect.

Syntax

```
HANDLE WINAPI GetAppcConfig(
HANDLE hWnd,
LPSTR pLocalLu,
LPSTR pMode,
LPINT pNumRemLu,
INT iMaxRemLu,
PSTR pRemLu,
LPINT pAsyncRetCode
);
```

Parameters

hWnd

Supplied parameter. Contains the handle of the window that is to receive an asynchronous completion message when the call has completed. If non-null, the completion message will be posted to this window handle. In this case, *pAsyncRetCode* (the last parameter) must be null. Asynchronous message completion is the recommended approach for Windows applications to use this function.

pLocalLu

Supplied parameter. Specifies the address of a buffer containing the local LU name for which information is returned. This local LU name must be specified as follows:

- Nonpadded
- Null-terminated
- ASCII string
- Maximum length of eight bytes (excluding the terminator)

To request that the user's default local LU be used, the buffer should contain eight spaces followed by a null.

pMode

Supplied parameter. Specifies the address of a buffer containing the mode name for which information is returned. In Microsoft Host Integration Server, this parameter is not used, but for compatibility with earlier versions of SNA Server a mode name must be specified as follows:

- Nonpadded
- Null-terminated
- ASCII string
- Maximum length of eight bytes (excluding the terminator)

pNumRemLu

Supplied parameter. Specifies the address of an integer variable that when the function completes will contain the number of remote LUs that would have been returned, had the buffer specified by *pRemLu* been large enough to accommodate all of the remote LUs.

iMaxRemLu

Supplied parameter. Specifies the number of remote LU names that can be held by the buffer indicated by *pRemLu*.

pRemLu

Supplied parameter. Specifies the address of the buffer that will hold the remote LU names after the function completes. The information will be returned as an array of strings. Each remote LU name will be stored in the buffer as follows:

- Nonpadded
- Null-terminated
- ASCII string
- Maximum length of eight bytes (excluding the terminator)

The strings start every nine bytes in the buffer, and thus (*pRemLu* + (*i*–1)*9) gives the start of the *i*th string. In the case where the buffer is too small to hold all the names, only *iMaxRemLu* strings will be returned.

pAsyncRetCode

Supplied parameter. Specifies the address of an integer variable used to store the return code from this function, if the supplied address is non-null. The return codes will be the same as those returned by an asynchronous completion message. While the call is completing, the value of this variable will be APPC_CFG_PENDING. When this asynchronous call is completed, the value of this variable will contain some return code other than APPC_CFG_PENDING.

This variable is used by polling for completion when asynchronous message completion to a window handle is not used.

Note that if *pAsyncRetCode* is used, *hWnd* must be null.

Return Value

The meaning of the immediate return value depends on whether or not the asynchronous request was accepted. To test for acceptance, evaluate the expression:

(<*Returned Handle*> & APPC_CFG_SUCCESS)

If the expression is FALSE, the request was rejected. The return value is then one of the synchronous return codes in the following list. If the expression is TRUE, the request was accepted, and one of the following cases will apply.

- If *hWnd* was non-null, a completion message will arrive in the following form:

Message parameter	**Description**
hWnd	The handle of the target window. This value is the same as the value passed in *hWnd* on the initial call.
uMsg	Matches the number returned by a call to **RegisterWindowMessage**, with WinAppcCfg used as the identifying string. This string is available by the **#define WIN_APPC_CFG_COMPLETION_MSG**.
wParam	Matches the *HANDLE* returned from the initial call. It is used as a correlator.
lParam	Contains one of the asynchronous return codes in the following list.

- If *pAsyncRetCode* was non-null, then the specified integer variable will be set to APPC_CFG_PENDING. After this function completes asynchronously, its value will change to one of the asynchronous return codes listed below.

Synchronous Return Codes
APPC_CFG_ERROR_NO_APPC_INIT

The Windows APPC library needs to be initialized by a call to WinAPPCStartup before calling **GetAppcConfig** and this has not been done.

APPC_CFG_ERROR_INVALID_HWND

The handle passed in *hWnd* was non-null, yet not a valid window handle.

APPC_CFG_ERROR_BAD_POINTER

The *hWnd* parameter was null, indicating that completion was signaled by setting the integer variable pointed to by *pAsyncRetCode*, but *pAsyncRetCode* was not a valid pointer.

APPC_CFG_ERROR_UNCLEAR_COMPLETION_MODE

Both *hWnd* and *pAsyncCompletion* were non-null, so **GetAppcConfig** was unable to decide how completion should be signaled.

APPC_CFG_ERROR_TOO_MANY_REQUESTS

Too many **GetAppcConfig** calls are already being processed (currently, this indicates 16 requests are outstanding). Try the call again after a delay. For the Microsoft Windows version 3.*x* system, you must yield during this period.

APPC_CFG_ERROR_GENERAL_FAILURE

An unexpected error occurred, probably of a system nature.

Asynchronous Return Codes
APPC_CFG_SUCCESS_NO_DEFAULT_REMOTE

The configuration information has been retrieved, and either no default remote LU was defined or it was not accessible by the specified local LU.

APPC_CFG_SUCCESS_DEFAULT_REMOTE

The configuration information has been retrieved, and there is a default remote LU that is accessible by the specified local LU.

APPC_CFG_ERROR_NO_DEFAULT_LOCAL_LU

An attempt was made to retrieve remote LUs partnered with the default local LU, but no default local LU was configured.

APPC_CFG_ERROR_BAD_LOCAL_LU

The local LU specified is either not configured, or is not valid for the calling verb.

APPC_CFG_ERROR_GENERAL_FAILURE

An unexpected error occurred, probably of a system nature.

Remarks

WinAPPCStartup must be called before using **GetAppcConfig**.

Whether an error code represents success or failure can be determined by evaluating either (*RetCode*& APPC_CFG_SUCCESS) to test for success or (*RetCode*& APPC_CFG_FAILURE) to test for failure.

The following code fragment shows how a console application can test completion:

```
while (*pAsyncRetCode == APPC_CFG_PENDING)
{
    sleep(250);
}
```

GetAppcReturnCode

The **GetAppcReturnCode** function converts the primary and secondary return codes in the verb control block to a printable string. This function provides a standard set of error strings for use by APPC applications such as 5250 emulators.

Syntax

```
    int WINAPI GetAppcReturnCode(
struct appc_hdr FAR * vpb,
UINTbuffer_length,
unsigned char FAR * buffer_addr);
```

Parameters

vpb

Supplied parameter. Specifies the address of the verb control block.

buffer_length

Supplied parameter. Specifies the length of the buffer pointed to by *buffer_addr*. The recommended length is 256.

buffer_addr

Supplied parameter. Specifies the address of the buffer that will hold the formatted, null-terminated string.

Return Value

The **GetAppcReturnCode** function returns a positive value on success that indicates the length of the error string passed back in *buffer_addr*.

A return value of zero indicates an error. On Microsoft® Windows® 2000 a call to **GetLastError** provides the actual error return code as follows:

0x20000001

The parameters are invalid; the function could not read from the specified verb control block or could not write to the specified buffer.

0x20000002

The specified buffer is too small.

0x20000003

The APPC string library APPCST32.DLL could not be loaded.

Remarks

The descriptive error string returned in *buffer_addr* does not terminate with a new line character (**\n**).

The descriptive error strings are contained in APPCST32.DLL and can be customized for different languages.

GetCsvReturnCode

The **GetCsvReturnCode** function converts the primary and secondary return codes in the verb control block to a printable string. This function provides a standard set of error strings for use by applications using common service verbs (CSVs).

Syntax

```
    int WINAPI GetCsvReturnCode(
struct csv_hdr FAR * vpb,
UINTbuffer_length,
unsigned char FAR * buffer_addr);
```

Parameters

vpb

Supplied parameter. Specifies the address of the verb control block.

buffer_length

Supplied parameter. Specifies the length of the buffer pointed to by *buffer_addr*. The recommended length is 256.

buffer_addr

Supplied parameter. Specifies the address of the buffer that will hold the formatted, null-terminated string when the function completes.

Return Value

The **GetCsvReturnCode** function returns a positive value on success that indicates the length of the error string passed back in *buffer_addr*.

A return value of zero indicates an error. On Microsoft® Windows® 2000 a call to **GetLastError** provides the actual error return code as follows:

0x20000001

The parameters are invalid; the function could not read from the specified verb parameter block or could not write to the specified buffer.

0x20000002

The specified buffer is too small.

0x20000003

The CSV string library CSVST32.DLL could not be loaded.

Remarks

The descriptive error string returned in *buffer_addr* does not terminate with a newline character (**\n**).

The descriptive error strings are contained in CSVST32.DLL and can be customized for different languages.

Common Service Verbs

This section describes each of the common service verbs (CSVs) and provides:

- A definition of the verb.
- The structure that defines the verb control block (VCB) used by the verb. The structure is declared in the WINCSV.H file.
- The parameters (VCB fields) supplied to and returned by the verb. A description of each parameter is provided, along with its possible values and other information.
- Additional information describing the use of the verb.

Most parameters supplied to and returned by CSVs are hexadecimal values. To simplify coding, these values are represented by meaningful symbolic constants, which are established by **#define** statements in the header file WINCSV.H. For example, the **opcode** (operation code) parameter for CONVERT is the hexadecimal value represented by the symbolic constant SV_CONVERT. Use only the symbolic constants when programming CSVs.

This section contains:

CONVERT

The **CONVERT** verb translates an ASCII character string to EBCDIC or an EBCDIC character string to ASCII. The string to be converted is called the source string. The converted string is called the target string.

The following structure describes the verb control block (VCB) used by the **CONVERT** verb.

Syntax

```
struct convert {
    unsigned short       opcode;
    unsigned char        opext;
    unsigned char        reserv2;
    unsigned short       primary_rc;
    unsigned long        secondary_rc;
    unsigned char        direction;
    unsigned char        char_set;
    unsigned short       len;
    unsigned char FAR *  source;
    unsigned char FAR *  target;
};
```

Members

opcode

Supplied parameter. The verb identifying the operation code, SV_CONVERT.

opext

A reserved field.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

direction

Supplied parameter. Specifies the direction of the conversion. To convert from ASCII to EBCDIC, use SV_ASCII_TO_EBCDIC. To convert from EBCDIC to ASCII, use SV_EBCDIC_TO_ASCII.

char_set

Supplied parameter. Specifies the character set to use in converting the source string. Allowed values include SV_A (type A character set), SV_AE (type AE character set), and SV_G (user-defined type G character set).

len

Supplied parameter. Specifies the number of characters to be converted.

This length plus the offset from the beginning of the source or target buffer must not exceed the segment boundary.

source

Supplied parameter. Specifies the address of the buffer containing the character string to be converted.

target

Supplied parameter. Specifies the address of the buffer to contain the converted character string.

This buffer can overlap or coincide with the buffer pointed to by the **source** parameter. In this case, the converted data string

overwrites the source data string.

Return Codes

SV_OK

Primary return code; the verb executed successfully.

SV_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

SV_CONVERSION_ERROR

Secondary return code; one or more characters in the source string were not found in the conversion table. These characters were converted to nulls (0x00). The verb still executed.

SV_INVALID_CHARACTER_SET

Secondary return code; the **char_set** parameter contained an invalid value.

SV_INVALID_DATA_SEGMENT

Secondary return code; the data buffer containing the source or target string did not fit in one segment, or the target segment was not a read/write segment.

SV_INVALID_DIRECTION

Secondary return code; the direction contained an invalid value.

SV_INVALID_FIRST_CHARACTER

Secondary return code; the first character of a type A source string was invalid.

SV_TABLE_ERROR

Secondary return code; one of the following occurred:

- The file containing the user-written type G conversion table was not specified by the environment variable CSVTBLG.
- The table was not in the correct format.
- The file specified by the CSVTBLG variable was not found.

SV_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

SV_INVALID_VERB

Primary return code; the **opcode** parameter did not match the operation code of any verb. No verb executed.

SV_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

SV_UNEXPECTED_DOS_ERROR

Primary return code; one of the following conditions occurred:

- The Microsoft® Windows® 2000 system encountered an error while processing the verb. The operating system return code was returned through the secondary return code. If the problem persists, contact the system administrator for corrective action.
- A CSV was issued from a message loop that was invoked by another application issuing a Windows **SendMessage** function call, rather than the more common Windows **PostMessage** function call. Verb processing cannot take place.
- A CSV was issued when **SendMessage** invoked your application. You can determine whether your application has been invoked with **SendMessage** by using the **InSendMessage** Windows API function call.

Remarks

The type A character set consists of:

- Uppercase letters.
- Numerals 0 through 9.
- Special characters $, #, @, and space.

This character set is supported by a system-supplied type A conversion table.

The first character of the source string must be an uppercase letter or the special character $, #, or @. Spaces are allowed only in trailing positions. Lowercase ASCII letters are translated to uppercase EBCDIC letters when the direction is ASCII to EBCDIC.

The type AE character set consists of:

- Uppercase letters.
- Lowercase letters.
- Numerals 0 through 9.
- Special characters $, #, @, period, and space.

This character set is supported by a system-supplied type AE conversion table.

The first character of the source string can be any character in the character set, except the space. Spaces are allowed only in trailing positions.

During conversion, embedded blanks (including blanks in the first position) are converted to 0x00. Although such a conversion will complete, CONVERSION_ERROR is returned as the secondary return code, indicating that the CSV library has completed an irreversible conversion on the supplied data.

For Windows 2000 a description of COMTBLG should point to the Windows 2000 registry under **\SnaBase\Parameters\Client**.

The data for a type G conversion table must be an ASCII file 32 lines long. Each line must consist of 32 hexadecimal digits, representing 16 characters, and be terminated by a carriage return and line feed. The first 16 lines (256 characters) specify the EBCDIC characters to which ASCII characters are converted; the remaining 16 lines specify the ASCII characters to which EBCDIC characters are converted.

The hexadecimal digits A through F can be either uppercase or lowercase. However, you may want to make these digits uppercase to ensure compatibility with IBM ES for OS/2 version 1.0.

Note
You can use GET_CP_CONVERT_TABLE to build a type G user-written conversion table in memory, and then store the table in a file.

COPY_TRACE_TO_FILE

The **COPY_TRACE_TO_FILE** verb concatenates individual API/link service trace files to form a single file.

The following structure describes the verb control block (VCB) used by the **COPY_TRACE_TO_FILE** verb.

Syntax

```
struct copy_trace_to_file {
    unsigned short       opcode;
    unsigned char        opext;
    unsigned char        reserv2;
    unsigned short       primary_rc;
    unsigned long        secondary_rc;
    unsigned char        reserv3[8];
    unsigned char        file_name[64];
    unsigned char        file_option;
    unsigned char        reserv4[12];
};
```

Remarks

Members

opcode

Supplied parameter. The verb identifying the operation code, SV_COPY_TRACE_TO_FILE.

opext

A reserved field.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

reserv3

A reserved field.

file_name

Supplied parameter. Specifies the name of the file to which trace data is to be copied. This parameter is a 64-byte character string, and it can include a path. If the name is fewer than 64 bytes, use spaces to pad it on the right.

file_option

Supplied parameter. Specifies the output file copy option:

- Use SV_NEW to copy the trace only if the specified file does not already exist.
- Use SV_OVERWRITE to copy the trace to an existing file, overwriting the current data. The size of the file is increased if necessary; and the file is created if it does not already exist.

reserv4

The address at which supplied data resides.

Return Codes

SV_OK

Primary return code; the verb executed successfully.

SV_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

SV_INVALID_FILE_OPTION

Secondary return code; a value other than SV_NEW or SV_OVERWRITE was specified for **file_option**.

SV_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

SV_COPY_TRACE_IN_PROGRESS

Secondary return code; a previously issued **COPY_TRACE_TO_FILE** verb is still in progress.

SV_TRACE_FILE_EMPTY

Secondary return code; there is no data in the trace files.

SV_TRACE_NOT_STOPPED

Secondary return code; a trace was in progress when the verb was issued.

SV_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

SV_FILE_ALREADY_EXISTS

Primary return code; when the SV_NEW file option was used, the file name specified was the name of an existing file.

SV_INVALID_VERB

Primary return code; the **opcode** parameter did not match the operation code of any verb. No verb executed.

SV_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

SV_OUTPUT_DEVICE_FULL

Primary return code; there is insufficient space on the device where the output file resides. Retry the operation after freeing additional disk space.

SV_UNEXPECTED_DOS_ERROR

Primary return code; one of the following conditions occurred:

- The Microsoft® Windows® 2000 system encountered an error while processing the verb. The operating system return code was returned through the secondary return code. If the problem persists, contact the system administrator for corrective action.

- A CSV was issued from a message loop that was invoked by another application issuing a Windows **SendMessage** function call, rather than the more common Windows **PostMessage** function call. Verb processing cannot take place.

- A CSV was issued when **SendMessage** invoked your application. You can determine whether your application has been invoked with **SendMessage** by using the **InSendMessage** Windows API function call.

Remarks

There are two API/link-service trace files. The files are used alternately; tracing switches from one file to the other when one file is full (larger than 250K). When **COPY_TRACE_TO_FILE** is called, these trace files are concatenated and copied to a single file, the name of which is specified as a parameter to the call.

API/link-service tracing is stopped before issuing the verb, and restarted after the copy is complete. The trace files are reset when this verb is successfully completed.

DEFINE_TRACE

The **DEFINE_TRACE** verb enables or disables tracing for specified APIs and controls the amount of tracing.

The following structure describes the verb control block (VCB) used by the **DEFINE_TRACE** verb.

Syntax

```
struct define_trace {
    unsigned short       opcode;
    unsigned char        opext;
    unsigned char        reserv2;
    unsigned short       primary_rc;
    unsigned long        secondary_rc;
    unsigned char        reserv3[8];
    unsigned char        dt_set;
    unsigned char        appc;
    unsigned char        reserv4;
    unsigned char        srpi;
    unsigned char        sdlc;
    unsigned char        tkn_rng_dlc;
    unsigned char        pcnet_dlc;
    unsigned char        dft;
    unsigned char        acdi;
    unsigned char        reserv5;
    unsigned char        ehllapi;
    unsigned char        x25_api;
    unsigned char        x25_dlc;
    unsigned char        twinax;
    unsigned char        reserv6;
    unsigned char        lua_api;
    unsigned char        etherand;
    unsigned char        subsym;
    unsigned char        reserv7[8];
    unsigned char        reset_trc;
    unsigned short       trunc;
    unsigned short       strg_size;
    unsigned char        reserv8;
    unsigned char        phys_link[8];
    unsigned char        reserv9[56];
};
```

Remarks

Members

opcode

Supplied parameter. The verb identifying the operation code, SV_DEFINE_TRACE.

opext

A reserved field.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

reserv3

A reserved field.

dt_set

Supplied parameter. Sets the trace state.

- Use SV_ON to enable tracing for a particular API if the parameter pertaining to the API (such as **appc** or **comm_serv**) is set to SV_CHANGE.
- Use SV_OFF to disable tracing for a particular API if the parameter pertaining to the API is set to SV_CHANGE.

appc

Supplied parameter. Indicates whether tracing of APPC is desired.

- Use SV_CHANGE to enable or disable tracing for APPC, depending on the **dt_set** parameter.
- Use SV_IGNORE to leave tracing in its current state for APPC.

The allowed values turn bit 0 on or off; bits 1 through 7 are reserved.

reserv4

A reserved field.

srpi

Supplied parameter. Indicates whether tracing of SRPI is desired.

- Use SV_CHANGE to enable or disable tracing for APPC, depending on the **dt_set** parameter.
- Use SV_IGNORE to leave tracing in its current state for APPC.

sdlc

A reserved field.

tkn_rng_dlc

A reserved field.

pcnet_dlc

A reserved field.

dft

A reserved field.

acdi

A reserved field.

reserv5

A reserved field.

comm_serv

Supplied parameter. Indicates whether tracing of COMM_SERV_API is desired.

- Use SV_CHANGE to enable or disable tracing for APPC, depending on the **dt_set** parameter.
- Use SV_IGNORE to leave tracing in its current state for APPC.

ehllapi

A reserved field.

x25_api

A reserved field.

x25_dlc

A reserved field.

twinax

A reserved field.

reserv6

A reserved field.

lua_api

A reserved field.

etherand

A reserved field.

subsym

A reserved field.

reserv7

A reserved field.

reset_trc

Supplied parameter. Indicates whether the trace file pointer should be reset.

- Use SV_NO to not reset the trace file pointer to the start of the trace file. Previous trace records are not overwritten.
- Use SV_YES to reset the trace file pointer to the start of the trace file. Previous trace records are overwritten.

trunc

Supplied parameter. Specifies the maximum number of bytes for each trace record. Excess bytes are truncated. Set this value to zero if you do not want truncation.

strg_size

A reserved field.

reserv8

A reserved field.

phys_link

A reserved field.

reserv9

A reserved field.

Return Codes

SV_OK

Primary return code; the verb executed successfully.

SV_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

SV_INVALID_RESET_TRACE

Secondary return code; the **reset_trc** parameter contained an invalid value.

SV_INVALID_SET

Secondary return code; the **dt_set** parameter contained an invalid value.

SV_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

SV_COPY_TRACE_IN_PROGRESS

Secondary return code; a previously issued COPY_TRACE_TO_FILE is still in progress. Traces cannot be active while using **DEFINE_TRACE**.

SV_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

SV_INVALID_VERB

Primary return code; the **opcode** parameter did not match the operation code of any verb. No verb executed.

SV_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

SV_UNEXPECTED_DOS_ERROR

Primary return code; one of the following conditions occurred:

- The Microsoft® Windows® 2000 system encountered an error while processing the verb. The operating system return code was returned through the secondary return code. If the problem persists, contact the system administrator for corrective action.

- A CSV was issued from a message loop that was invoked by another application issuing a Windows **SendMessage** function call, rather than the more common Windows **PostMessage** function call. Verb processing cannot take place.

- A CSV was issued when **SendMessage** invoked your application. You can determine whether your application has been invoked with **SendMessage** by using the **InSendMessage** Windows API function call.

Remarks

For information on how to run and use traces, see the appropriate manual for your product.

GET_CP_CONVERT_TABLE

The **GET_CP_CONVERT_TABLE** verb creates and returns a 256-byte conversion table to translate character strings from a source code page to a target code page.

The following structure describes the verb control block (VCB) used by the **GET_CP_CONVERT_TABLE** verb.

Syntax

```
struct get_cp_convert_table {
    unsigned short       opcode;
    unsigned char        opext;
    unsigned char        reserv2;
    unsigned short       primary_rc;
    unsigned long        secondary_rc;
    unsigned char        reserv3[8];
    unsigned short       source_cp;
    unsigned short       target_cp;
    unsigned char FAR *  conv_tbl_addr;
    unsigned char        char_not_fnd;
    unsigned char        substitute_char;
};
```

Remarks

Members

opcode

Supplied parameter. The verb identifying the operation code, SV_GET_CP_CONVERT_TABLE.

opext

A reserved field.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

reserv3

A reserved field.

source_cp

Supplied parameter. Specifies the source code page from which characters are converted. The allowed code pages (decimal values) are as follows:

- ASCII 437, 850, 860, 863, 865
- EBCDIC 037, 273, 277, 278, 280, 284, 285, 297, 500

User-defined code pages in the range from 65280 through 65535 are also allowed.

ASCII code pages are sometimes referred to as PC code pages; EBCDIC code pages are sometimes referred to as host code pages.

target_cp

Supplied parameter. Specifies the target code page to which characters are converted. For allowed code pages, see the preceding definition for **source_cp**.

conv_tbl_addr

Supplied parameter. Specifies the address of the buffer to contain the 256-byte conversion table. The buffer must be in a writable segment and long enough to contain the table.

char_not_fnd

Supplied parameter. Specifies the action to take if a character in the source code page does not exist in the target code page:

- Use SV_ROUND_TRIP to store a unique value in the conversion table for each source code page character.
- Use SV_SUBSTITUTE to store a substitute character (specified by **substitute_char**) in the conversion table.

substitute_char

Supplied parameter. Specifies the character to store in the conversion table when a character from the source code page has no equivalent in the target code page.

Return Codes

SV_OK

Primary return code; the verb executed successfully.

SV_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

SV_INVALID_CHAR_NOT_FOUND

Secondary return code; the **char_not_fnd** parameter contained an invalid value.

SV_INVALID_DATA_SEGMENT

Secondary return code; the 256-byte area specified for the conversion table extended beyond the segment boundary, or the segment was not writable.

SV_INVALID_SOURCE_CODE_PAGE

Secondary return code; the code page specified by **source_cp** is not supported.

SV_INVALID_TARGET_CODE_PAGE

Secondary return code; the code page specified by **target_cp** is not supported.

SV_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

SV_INVALID_VERB

Primary return code; the **opcode** parameter did not match the operation code of any verb. No verb executed.

SV_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

SV_UNEXPECTED_DOS_ERROR

Primary return code; one of the following conditions occurred:

- The Microsoft® Windows® 2000 system encountered an error while processing the verb. The operating system return code was returned through the secondary return code. If the problem persists, contact the system administrator for corrective action.
- A CSV was issued from a message loop that was invoked by another application issuing a Windows **SendMessage** function call, rather than the more common Windows **PostMessage** function call. Verb processing cannot take place.
- A CSV was issued when **SendMessage** invoked your application. You can determine whether your application has

been invoked with **SendMessage** by using the **InSendMessage** Windows API function call.

Remarks

The type A character set consists of:

- Uppercase letters.
- Numerals 0 through 9.
- Special characters $, #, @, and space.

This character set is supported by a system-supplied type A conversion table.

The first character of the source string must be an uppercase letter or the special character $, #, or @. Spaces are allowed only in trailing positions. Lowercase ASCII letters are translated to uppercase EBCDIC letters when the direction is ASCII to EBCDIC.

The type AE character set consists of:

- Uppercase letters.
- Lowercase letters.
- Numerals 0 through 9.
- Special characters $, #, @, period, and space.

This character set is supported by a system-supplied type AE conversion table.

The first character of the source string can be any character in the character set except the space.

During conversion, embedded blanks (including blanks in the first position) are converted to 0x00. Although such a conversion will complete, CONVERSION_ERROR is returned as the secondary return code, indicating that the CSV library has completed an irreversible conversion on the supplied data.

For Windows 2000, a description of COMTBLG should point to the Windows 2000 registry under **\SnaBase\Parameters\Client**. For the OS/2 operating system, the directory and file containing the table must be specified by the environment variable COMTBLG. (If the file is not found, the system returns the SV_TABLE_ERROR parameter check.).

The SV_ROUND_TRIP value for **char_not_fnd** is useful only if you build a second conversion table to convert between the same two code pages in the reverse direction. If you specify the SV_ROUND_TRIP value in building both conversion tables, any character translated from one code page to the other and then back will be unchanged.

When using the SV_SUBSTITUTE value for **char_not_fnd**, converting the translated character string back to the original code page will not necessarily re-create the original character string.

Use **substitute_char** only if **char_not_fnd** is set to SV_SUBSTITUTE.

The value stored in the conversion table is the ASCII value associated with the character. If the table is used for conversion from ASCII to EBCDIC, the character that appears in the converted string is the character associated with the numeric EBCDIC value rather than ASCII.

For example, if you supply the underscore (_) character (ASCII value F6) while creating an ASCII to EBCDIC conversion table, the character that appears in the converted strings will be 6, the character associated with the value F6 in EBCDIC. To use the _ character as the substitute character in an ASCII to EBCDIC conversion table, you should supply the value E1 (the value associated with the _ character in EBCDIC) rather than the actual character.

A code page is a table that associates specific ASCII or EBCDIC values with specific characters. If a character from the source code page does not exist in the target code page, the translated (target) string differs from the original (source) string.

LOG_MESSAGE

For OS/2 only, the **LOG_MESSAGE** verb records a message in the error log file and optionally displays the message on the users screen. This verb is included for compatibility with existing applications.

The following structure describes the verb control block (VCB) used by the **LOG_MESSAGE** verb.

Syntax

```
struct log_message {
    unsigned short       opcode;
    unsigned char        opext;
    unsigned char        reserv2;
    unsigned short       primary_rc;
    unsigned long        secondary_rc;
    unsigned short       msg_num;
    unsigned char        orignтr_id[8];
    unsigned char        msg_file_name[3];
    unsigned char        msg_act;
    unsigned short       msg_ins_len;
    unsigned char FAR *  msg_ins_ptr;
};
```

Remarks

Members

opcode

Supplied parameter. The verb identifying the operation code, SV_LOG_MESSAGE.

opext

A reserved field.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

msg_num

Supplied parameter. Specifies the number of the message in the message file specified by **msg_file_name**.

orignтr_id

Supplied parameter. Specifies the name of the component issuing **LOG_MESSAGE** or an 8-byte, user-supplied string.

msg_file_name

Supplied parameter. Specifies the name of the file containing the message to be logged.

msg_act

Supplied parameter. Specifies the action to be taken when processing the message:

- Use SV_INTRV to log the intervention with a severity level of 12 and display the message on the users screen. The user must press a key to remove the message from the screen.
- Use SV_NO_INTRV to log the intervention with a severity level of 12 but not display the message.

msg_ins_len

Supplied parameter. Specifies the length of data to be inserted into the message. Set this parameter to zero if no data is to be inserted.

msg_ins_ptr

Supplied parameter. Specifies the address of the data to be inserted into the message.

Use this parameter only if **msg_ins_len** is greater than zero.

Return Codes

SV_OK

Primary return code; the verb executed successfully.

SV_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

SV_INVALID_DATA_SEGMENT

Secondary return code; the data that was to be inserted into the message extended beyond the segment boundary.

SV_INVALID_MESSAGE_ACTION

Secondary return code; the **msg_act** parameter contained an invalid value.

SV_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

SV_INVALID_VERB

Primary return code; the **opcode** parameter did not match the operation code of any verb. No verb executed.

SV_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

SV_UNEXPECTED_DOS_ERROR

Primary return code; one of the following conditions occurred:

- The Microsoft® Windows® 2000 system encountered an error while processing the verb. The operating system return code was returned through the secondary return code. If the problem persists, contact the system administrator for corrective action.
- A CSV was issued from a message loop that was invoked by another application issuing a Windows **SendMessage** function call, rather than the more common Windows **PostMessage** function call. Verb processing cannot take place.
- A CSV was issued when **SendMessage** invoked your application. You can determine whether your application has been invoked with **SendMessage** by using the **InSendMessage** Windows API function call.

Remarks

The value for **msg_file_name** must be three characters long. Pad with spaces if necessary. The .MSG extension is added automatically.

The total length of **msg_ins_len**, including header information (40 bytes), message text, and inserted data, should not exceed 256 bytes. If the length is greater than 256 bytes, the communication system will attempt to log only the header information and inserted text; the message text will be left out.

When you create the log message file, you can specify where in the message the additional data is to be inserted. Further information is provided below.

The data for **msg_ins_ptr** consists of a series of up to nine null-terminated strings. (Because IBM OS/2 ES version 1.0 supports only three data strings, you may want to limit the inserted text to three strings to ensure compatibility.)

Creating a Message File

If you want to create your own message file, you must use the utility MKMSGF.

The first three characters of the message number must match the three-character name of the log message file. These three characters are declared at the top of the file as well.

The system finds the message file as follows:

- If you use your own message file, the system assumes the file is in the same directory as your programs executable file.
- If you use the default message file, COM.MSG, the system finds the file automatically, provided the SnaBase for Microsoft Host Integration Server 2009 is loaded.
- If you use the default message file without loading the previously-mentioned software, the system expects DPATH to indicate the path to the message file. This applies only to the Windows version 3.*x* and OS/2 operating systems.

TRANSFER_MS_DATA

The **TRANSFER_MS_DATA** verb builds an SNA request unit containing Network Management Vector Transport (NMVT) data. The verb can send the NMVT data to NetView for centralized problem diagnosis and resolution. The data is logged in the local audit file.

The following structure describes the verb control block (VCB) used by the **TRANSFER_MS_DATA** verb.

Syntax

```
struct transfer_ms_data {
    unsigned short       opcode;
    unsigned char        data_type;
    unsigned char        reserv2;
    unsigned short       primary_rc;
    unsigned long        secondary_rc;
    unsigned char        options;
    unsigned char        reserv3;
    unsigned char        orignтr_id[8];
    unsigned short       dlen;
    unsigned char FAR *  dptr;
};
```

Members

opcode

Supplied parameter. The verb identifying the operation code, SV_TRANSFER_MS_DATA.

data_type

Supplied parameter. Specifies the type of data provided by this verb:

- Use SV_NMVT to generate an NMVT (including the NS header, the major network management vector, and subvectors).
- Use SV_ALERT_SUBVECTORS to generate an RU containing data for an alert in the appropriate format, without the NS header or major NMVT vector.
- Use SV_PDSTATS_SUBVECTORS to generate an RU containing data for problem determination statistics in the appropriate format, without the NS header or major NMVT vector.
- Use SV_USER_DEFINED to generate user-defined data; this data is recorded in the error log but cannot be sent on the systems services control point-physical unit (SSCP-PU) session on the connection configured for diagnostics.

reserv2

A reserved field.

primary_rc

Returned parameter. Specifies the primary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

secondary_rc

Returned parameter. Specifies the secondary return code set by APPC at the completion of the verb. The valid return codes vary depending on the APPC verb issued. See Return Codes for valid error codes for this verb.

options

Supplied parameter. Specifies the desired options by turning individual bits on or off. (Bits 1, 2, and 3 are ignored if **data_type** is set to SV_USER_DEFINED.) See the Remarks section.

reserv3

A reserved field.

A reserved field.

orignt_id

Supplied parameter. Specifies the name of the component issuing **TRANSFER_MS_DATA**. This parameter is optional. Set it to 0x00 if you want the system to ignore it.

dlen

Supplied parameter. Specifies the length of data to be supplied to this verb. The total length of the data (user-supplied data and any added headers or subvectors) must fit into one RU. The maximum RU length is 512 bytes.

dptr

Supplied parameter. Specifies the address of the data to be sent.

Return Codes

SV_OK

Primary return code; the verb executed successfully.

SV_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

SV_DATA_EXCEEDS_RU_SIZE

Secondary return code; the data to be sent was too long. The length of the user-supplied data plus headers and added subvectors must fit in a single RU that is not more than 512 bytes long.

SV_INVALID_DATA_SEGMENT

Secondary return code; the buffer pointed to by **dptr** was not a readable segment or extended beyond the segment boundary.

SV_INVALID_DATA_TYPE

Secondary return code; the **data_type** parameter contained an invalid value.

SV_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

SV_SSCP_PU_SESSION_NOT_ACTIVE

Secondary return code; the NMVT was not sent; either the SSCP-PU session was not active, the node configured to receive diagnostic information was not active, or no network management connection was configured.

SV_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

SV_INVALID_VERB

Primary return code; the **opcode** parameter did not match the operation code of any verb. No verb executed.

SV_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

SV_UNEXPECTED_DOS_ERROR

Primary return code; one of the following conditions occurred:

- The Microsoft® Windows® 2000 system encountered an error while processing the verb. The operating system return code was returned through the secondary return code. If the problem persists, contact the system administrator for corrective action.

- A CSV was issued from a message loop that was invoked by another application issuing a Windows **SendMessage** function call, rather than the more common Windows **PostMessage** function call. Verb processing cannot take place.

- A CSV was issued when **SendMessage** invoked your application. You can determine whether your application has been invoked with **SendMessage** by using the **InSendMessage** Windows API function call.

SV_CANCELLED

Primary return code; this code is returned for an asynchronous verb when it has been shut down by a WinCSVCleanup call.

SV_SERVER_RESOURCE_NOT_FOUND

Primary return code; no communication server was found that could provide the requested function.

SV_SERVER_RESOURCES_LOST

Primary return code; the communications server that was providing the function was lost due to a connection failure.

SV_SERVER_CONN_FAILURE

Secondary return code; the connection to the server was lost due to physical path problems; for example, the server may have been powered off.

SV_THREAD_BLOCKING

Primary return code; this verb exceeds the maximum number of simultaneous synchronous verbs allowed.

Remarks

To specify options, turn bits on or off as follows:

Bit	**Description**
0	TIME_STAMP_SUBVECTOR. Adds date/time subvector to data. Allowed values include SV_ADD and SV_NO_ADD.
1	PRODUCT_SET_ID_SUBVECTOR. Adds Product_Set_ID subvector to data. This allows network management services to identify the sender of an alert. Allowed values include SV_ADD and SV_NO_ADD.
2	SSCP_PU_SESSION. Sends the data on the SSCP-PU session on the connection configured for diagnostics if the session is active. (The data is added to the error log regardless of whether it is sent on the session or whether SV_STATE_CHECK or SV_COMM_SUBSYSTEM_NOT_LOADED is returned.) Allowed values include SV_SEND and SV_NO_SEND.
3	LOCAL_LOGGING. Logs local alerts that are retrieved from the error log and forwarded to the host. This option is valid only when **data_type** SV_NMVT or **data_type** SV_ALERT_SUBVECTORS with option SV_SEND is specified. Allowed values include SV_LOG and SV_NO_LOG.
4 through 7	Reserved

CSV Extensions for the Windows Environment

This section describes API extensions to the Windows® Common Service Verb (CSV) API. Windows CSV allows multithreaded Microsoft® Windows-based processes. Multithreading is the running of several processes in rapid sequence within a single program. A process contains one or more threads of execution. All references to threads in this document refer to actual threads in multithreaded Windows environments.

For each extension, this section provides a definition of the function, syntax, returns, and remarks for using the function.

This section contains:

WinAsyncCSV

The **WinAsyncCSV** function provides an asynchronous entry point for TRANSFER_MS_DATA only. If this function is used for any other verb, the behavior will be synchronous. This function was used instead of the blocking version of the verb under Microsoft Windows version 3.*x*. Windows version 3.x is no longer supported.

HANDLE WINAPI WinAsyncCSV(

Syntax

```
    HWND hWnd,
    long lpVcb
);
```

Parameters

hWnd

Handle of window to receive message.

lpVcb

Pointer to the verb control block.

Return Value

The return value specifies whether the asynchronous resolution request was successful. If the function was successful, the return value is an asynchronous task handle. If the function was not successful, a zero is returned.

Remarks

When the asynchronous operation is complete, the applications window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinAsyncCSV" as the input string. The *wParam* argument contains the asynchronous task handle returned by the original function call. The *lParam* argument contains the original VCB pointer and can be dereferenced to determine the final return code.

If the function returns successfully, a "WinAsyncCSV" message will be posted to the application when the operation completes or the conversation is canceled.

WinCSVCleanup

The **WinCSVCleanup** function terminates and deregisters an application from a Windows® CSV implementation.

Syntax

```
BOOL WINAPI WinCSVCleanup(void);
```

Return Value

The return value specifies whether the deregistration was successful. If the value is nonzero, the application was successfully deregistered. The application was not deregistered if a value of zero is returned.

Remarks

Use **WinCSVCleanup** to indicate deregistration of a Windows CSV application from a Windows CSV implementation. This function can be used, for example, to free up resources allocated to the specific application.

WinCSVStartup

The **WinCSVStartup** function allows an application to specify the version of Windows CSV required and to retrieve details of the specific Windows CSV implementation. This function must be called by an application to register itself with a Windows CSV implementation before issuing any further Windows CSV calls.

Syntax

```
int WINAPI WinCSVStartup(
WORD wVersionRequired,
LPWCSVDATA lpwcsvdata
);
```

Parameters

wVersionRequired

Specifies the version of Windows CSV support required. The high-order byte specifies the minor version (revision) number; the low-order byte specifies the major version number. The current version of the Windows CSV API is 1.0.

lpwcsvdata

A pointer to the CSV data structure. The **CSVDATA** structure is defined as follows:

```
typedef struct tagWCSVDATA {
    WORD wVersion;
    char szDescription[WCSVDESCRIPTION_LEN+1];
}  CSVDATA, FAR * LPWCSVCDATA;
```

where **WCSVDESCRIPTION** is defined to be 127 and the structure members are as follows:

wVersion

The version of Windows CSV supported. The high-order byte specifies the minor version (revision) number; the low-order byte specifies the major version number.

szDescription

A description string identifying the vendor of the Windows CSV DLL.

This **CVSDATA** structure provides information about the underlying Windows CSV DLL implementation. The first *wVersion* field has the same structure as the *wVersionRequired* parameter, and the *szDescription* field contains a string identifying the vendor of the Windows CSV DLL. The description field is only meant to provide a display string for the application and should not be used to programmatically distinguish between Windows CSV implementations.

Return Values

The return value specifies whether the application was registered successfully and whether the Windows CSV implementation can support the specified version number. If the value is zero, it was registered successfully. Otherwise, the return value is one of the following:

WCSVSYSNOTREADY

Indicates that the underlying network system is not ready for network communication.

WCSVVERNOTSUPPORTED

The version of Windows CSV support requested is not provided by this particular Windows CSV implementation.

WCSVINVALID

The Windows CSV version specified by the application is not supported by this DLL.

Remarks

To support future Windows CSV implementations and applications that may have functionality differences from Windows CSV version 1.0, a negotiation takes place in **WinCSVStartup**. An application passes to **WinCSVStartup** the Windows CSV version that it can use. If this version is lower than the lowest version supported by the Windows CSV DLL, the DLL cannot support the

application and **WinCSVStartup** fails. If the version is not lower, however, the call succeeds and returns the highest version of Windows CSV supported by the DLL. If this version is lower than the lowest version supported by the application, the application either fails its initialization or attempts to find another Windows CSV DLL on the system.

This negotiation allows both a Windows CSV DLL and a Windows CSV application to support a range of Windows CSV versions. An application can successfully use a DLL if there is any overlap in the versions. The following table illustrates how **WinCSVStartup** works in conjunction with different application and DLL versions.

Application versions	DLL versions	To WinCSVStartup	From WinCSVStartup	Result
1.0	1.0	1.0	1.0	Use 1.0
1.0, 2.0	1.0	2.0	1.0	Use 1.0
1.0	1.0, 2.0	1.0	2.0	Use 1.0
1.0	2.0, 3.0	1.0	WCSVINVALID	Fail
2.0, 3.0	1.0	3.0	1.0	App Fails
1.0, 2.0, 3.0	1.0, 2.0, 3.0	3.0	3.0	Use 3.0

After making its last Windows CSV call, an application should call WinCSVCleanup.

Each Windows CSV implementation must make a **WinCSVStartup** call before issuing any other Windows CSV calls. Consequently, this function can be used for initialization purposes.

Common APPC Return Codes

This section describes the primary and, if applicable, secondary return codes for the Advanced Program-to-Program Communications (APPC) verbs. The return codes are listed in hexadecimal order.

This section contains:

Primary APPC Return Codes

0000
AP_OK

The verb executed successfully.

0001
AP_PARAMETER_CHECK

The verb did not execute because of a parameter error.

0002
AP_STATE_CHECK

The verb did not execute because it was issued in an invalid state.

0003
AP_ALLOCATION_ERROR

APPC failed to allocate a conversation. The conversation state is set to RESET.

This code can be returned through a verb issued after ALLOCATE or MC_ALLOCATE.

0005
AP_DEALLOC_ABEND (for a mapped conversation)

The conversation has been deallocated for one of the following reasons:

- The partner transaction program (TP) issued MC_DEALLOCATE with **dealloc_type** set to AP_ABEND.
- The partner TP encountered an ABEND, causing the partner logical unit (LU) to send an **MC_DEALLOCATE** request.

0006
AP_DEALLOC_ABEND_PROG (for a basic conversation)

The conversation has been deallocated for one of the following reasons:

- The partner TP issued DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG.
- The partner TP encountered an ABEND, causing the partner LU to send a **DEALLOCATE** request.

0007
AP_DEALLOC_ABEND_SVC (for a basic conversation)

The conversation has been deallocated because the partner TP issued DEALLOCATE with **dealloc_type** set to AP_ABEND_SVC.

0008
AP_DEALLOC_ABEND_TIMER (for a basic conversation)

The conversation has been deallocated because the partner TP issued DEALLOCATE with **dealloc_type** set to AP_ABEND_TIMER.

0009
AP_DEALLOC_NORMAL

The partner TP has deallocated the conversation without requesting confirmation.

000C
AP_PROG_ERROR_NO_TRUNC

The partner TP has issued one of the following verbs while the conversation was in SEND state:

- SEND_ERROR with **err_type** set to AP_PROG

- MC_SEND_ERROR

Data was not truncated.

000F
AP_CONV_FAILURE_RETRY

The conversation was terminated because of a temporary error. Restart the TP to see if the problem occurs again. If it does, the system administrator should examine the error log to determine the cause of the error.

0010
AP_CONV_FAILURE_NO_RETRY

The conversation was terminated because of a permanent condition, such as a session protocol error. The system administrator should examine the system error log to determine the cause of the error. Do not retry the conversation until the error has been corrected.

0011
AP_SVC_ERROR_NO_TRUNC

While in SEND state, the partner TP (or partner LU) issued SEND_ERROR with **err_type** set to AP_SVC. Data was not truncated.

0012
AP_PROG_ERROR_TRUNC/AP_SVC_ERROR_TRUNC

In SEND state, after sending an incomplete logical record, the partner TP issued SEND_ERROR. The local TP may have received the first part of the logical record.

0013
AP_SVC_ERROR_PURGING

The partner TP (or partner LU) issued SEND_ERROR with **err_type** set to AP_SVC while in RECEIVE, PENDING_POST, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state. Data sent to the partner TP may have been purged.

0014
AP_UNSUCCESSFUL

No data is immediately available from the partner TP.

0017
AP_CNOS_LOCAL_RACE_REJECT

APPC is currently processing a CNOS verb issued by a local LU.

0018
AP_CNOS_PARTNER_LU_REJECT

The partner LU rejected a CNOS request from the local LU.

0019
AP_CONVERSATION_TYPE_MIXED

The TP has issued both basic and mapped conversation verbs. Only one type can be issued in a single conversation.

0021
AP_CANCELED

The local TP issued one of the following verbs, which canceled RECEIVE_AND_POST or MC_RECEIVE_AND_POST:

- DEALLOCATE with **dealloc_type** set to AP_ABEND_PROG, AP_ABEND_SVC, or AP_ABEND_TIMER
- MC_DEALLOCATE with **dealloc_type** set to AP_ABEND
- SEND_ERROR or MC_SEND_ERROR
- TP_ENDED

Issuing one of these verbs causes the semaphore to be cleared.

F002
AP_TP_BUSY

The local TP has issued a call to APPC while APPC was processing another call for the same TP. This can occur if the local TP has multiple threads, and more than one thread is issuing APPC calls using the same **tp_id**.

F003
AP_COMM_SUBSYSTEM_ABENDED

Indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the TP and the PU 2.1 node has been broken (a LAN error).
- The SnaBase at the TP's computer encountered an ABEND.

The system administrator should examine the error log to determine the reason for the ABEND.

F004
AP_COMM_SUBSYSTEM_NOT_LOADED

A required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

F005
AP_CONV_BUSY

There can only be one outstanding conversation verb at a time on any conversation.

F006
AP_THREAD_BLOCKING

The calling thread is already in a blocking call.

F008
AP_INVALID_VERB_SEGMENT

The verb control block (VCB) extended beyond the end of the data segment.

F011
AP_UNEXPECTED_DOS_ERROR

The operating system returned an error to APPC while processing an APPC call from the local TP. The operating system return code is returned through the **secondary_rc**. It appears in Intel byte-swapped order. If the problem persists, consult the system administrator.

F015
AP_STACK_TOO_SMALL

The stack size of the application is too small to execute the verb. Increase the stack size of your application.

F020
AP_INVALID_KEY

The supplied **key** was incorrect.

Secondary APPC Return Codes

00000000
AP_CNOS_ACCEPTED

APPC accepts the session lines and responsibility as specified.

00000001
AP_BAD_TP_ID

The value of **tp_id** did not match a transaction program (TP) identifier assigned by APPC.

00000002
AP_BAD_CONV_ID

The value of **conv_id** did not match a conversation identifier assigned by APPC.

00000003
AP_BAD_LU_ALIAS

APPC cannot find the specified **lu_alias** among those defined.

000000C4
AP_RCV_IMMD_BAD_FILL (for a basic conversation)

The **fill** parameter was set to an invalid value.

00000004
AP_ALLOCATION_FAILURE_NO_RETRY

The conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

00000005
AP_ALLOCATION_FAILURE_RETRY

The conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

00000006
AP_INVALID_DATA_SEGMENT

The program initiation parameters (PIP) data was longer than the allocated data segment, or the address of the PIP data buffer was wrong.

00000007
AP_CNOS_NEGOTIATED

APPC accepts the session limits and responsibility as negotiable by the partner logical unit (LU). Values that can be negotiated are:

plu_mode_session_limit

min_conwinners_source

min_conwinners_target

responsible

drain_target

000000D7
AP_BAD_RETURN_STATUS_WITH_DATA

The specified **rtn_status** value was not recognized by APPC.

00000011
AP_BAD_CONV_TYPE (for a basic conversation)

The value specified for **conv_type** was invalid.

00000012
AP_BAD_SYNC_LEVEL

The value specified for **sync_level** was invalid.

00000013
AP_BAD_SECURITY

The value specified for **security** was invalid.

00000014
AP_BAD_RETURN_CONTROL

The value specified for **rtn_ctl** was invalid.

00000016
AP_PIP_LEN_INCORRECT

The value of **pip_dlen** was greater than 32767.

00000017
AP_NO_USE_OF_SNASVCMG (for a mapped conversation)

SNASVCMG is not a valid value for **mode_name**.

00000018
AP_UNKNOWN_PARTNER_MODE

The value specified for **mode_name** was invalid.

00000031
AP_CONFIRM_ON_SYNC_LEVEL_NONE

The local TP attempted to use CONFIRM or MC_CONFIRM in a conversation with a synchronization level of AP_NONE. The synchronization level, established by ALLOCATE or MC_ALLOCATE, must be AP_CONFIRM_SYNC_LEVEL.

00000032
AP_CONFIRM_BAD_STATE

The conversation was not in SEND state.

00000033
AP_CONFIRM_NOT_LL_BDY

The conversation for the local TP was in SEND state, and the local TP did not finish sending a logical record.

00000051
AP_DEALLOC_BAD_TYPE

The **dealloc_type** parameter was not set to a valid value.

00000052
AP_DEALLOC_FLUSH_BAD_STATE

The conversation was not in SEND state and the TP attempted to flush the send buffer. This attempt occurred because the value of **dealloc_type** was AP_FLUSH or because the value of **dealloc_type** was AP_SYNC_LEVEL and the synchronization level of the conversation was AP_NONE. In either case, the conversation must be in SEND state.

00000053
AP_DEALLOC_CONFIRM_BAD_STATE

The conversation was not in SEND state, and the TP attempted to flush the send buffer and send a confirmation request.

00000055
AP_DEALLOC_NOT_LL_BDY (for a basic conversation)

The conversation was in SEND state, and the TP did not finish sending a logical record. The **dealloc_type** parameter was set to AP_SYNC_LEVEL or AP_FLUSH.

00000057
AP_DEALLOC_LOG_LL_WRONG

The LL field of the general data stream (GDS) error log variable did not match the actual length of the log data.

00000061
AP_FLUSH_NOT_SEND_STATE

The conversation was not in SEND state.

000000A1
AP_P_TO_R_INVALID_TYPE

The **ptr_type** parameter was not set to a valid value.

000000A2
AP_P_TO_R_NOT_LL_BDY

The local TP did not finish sending a logical record.

000000A3
AP_P_TO_R_NOT_SEND_STATE

The conversation was not in SEND state.

000000B1
AP_RCV_AND_WAIT_BAD_STATE

The conversation was not in RECEIVE or SEND state when the TP issued this verb.

000000B2
AP_RCV_AND_WAIT_NOT_LL_BDY (for a basic conversation)

The conversation was in SEND state; the TP began but did not finish sending a logical record.

000000B5
AP_RCV_AND_WAIT_BAD_FILL (for a basic conversation)

The **fill** parameter was set to an invalid value.

000000C1
AP_RCV_IMMD_BAD_STATE

The conversation was not in RECEIVE state.

000000D1
AP_RCV_AND_POST_BAD_STATE

The conversation was not in RECEIVE or SEND state when the TP issued this verb.

000000D2
AP_RCV_AND_POST_NOT_LL_BDY

The conversation was in SEND state; the TP began but did not finish sending a logical record.

000000D5
AP_RCV_AND_POST_BAD_FILL

The **fill** parameter was set to an invalid value.

000000D6
AP_INVALID_SEMAPHORE_HANDLE

The address of the RAM semaphore or system semaphore handle was invalid.

Note
APPC cannot trap all invalid semaphore handles. If the TP passes a bad RAM semaphore handle, a protection violation results.

000000D7
AP_BAD_RETURN_STATUS_WITH_DATA

The specified **rtn_status** value was not recognized by APPC.

000000E1
AP_R_T_S_BAD_STATE

The conversation is not in an allowed state when the TP issued this verb.

000000F1
AP_BAD_LL (for a basic conversation)

The logical record length field of a logical record contained an invalid value — 0x0000, 0x0001, 0x8000, or 0x8001. See About Transaction Programs for information on logical records.

000000F2
AP_SEND_DATA_NOT_SEND_STATE

The local TP issued SEND_DATA or MC_SEND_DATA, but the conversation was not in SEND state.

000000F5
AP_SEND_DATA_CONFIRM_ON_SYNC_NONE

The type CONFIRM is not permitted for a conversation that was allocated with a **sync_level** of NONE.

000000F6
AP_SEND_DATA_NOT_LL_BDY (for a basic conversation)

The TP started but did not finish sending a logical record. This occurs only when **type** is one of the following:

AP_SEND_DATA_CONFIRM

AP_SEND_DATA_DEALLOC_FLUSH

AP_SEND_DATA_DEALLOC_SYNC_LEVEL

AP_SEND_DATA_P_TO_R_FLUSH

AP_SEND_DATA_P_TO_R_SYNC_LEVEL

00000102
AP_SEND_ERROR_LOG_LL_WRONG (for a basic conversation)

The LL field of the error log GDS variable did not match the actual length of the data.

00000103
AP_SEND_ERROR_BAD_TYPE (for a basic conversation)

The value of **err_type** was invalid.

00000105
AP_BAD_ERROR_DIRECTION

The specified **err_dir** was not recognized by APPC.

00000150
AP_CNOS_IMPLICIT_PARALLEL

APPC does not permit a program to change the session limit for a mode other than SNASVCMG mode for the implicit partner template when the template specifies parallel sessions. (The term "template" is used because many of the actual values are yet to be filled in.)

00000151
AP_CANT_RAISE_LIMITS

APPC does not permit setting session limits to a nonzero value unless the limits currently are zero.

00000152
AP_AUTOACT_EXCEEDS_SESSLIM

On the CNOS verb, the value for **auto_activate** is greater than the value for **partner_lu_mode_session_limit**.

00000153
AP_ALL_MODE_MUST_RESET

APPC does not permit a nonzero session limit when **mode_name_select** indicates ALL.

00000154
AP_BAD_SNASVCMG_LIMITS

Your program specified invalid settings for the **partner_lu_mode_session_limit**, **min_conwinners_source**, or

min_conwinners_target parameters when **mode_name** was supplied.

00000155
AP_MIN_GT_TOTAL

The sum of **min_conwinners_source** and **min_conwinners_target** specifies a number greater than **partner_lu_mode_session_limit**.

00000156
AP_MODE_CLOSED

The local LU cannot negotiate a nonzero session limit because the local maximum session limit at the partner LU is zero.

00000156
AP_CNOS_MODE_CLOSED

The local LU cannot negotiate a nonzero session limit because the local maximum session limit at the partner LU is zero.

00000157
AP_CNOS_MODE_NAME_REJECT

The partner LU does not recognize the specified mode name.

00000159
AP_RESET_SNA_DRAINS

The SNASVCMG mode does not support the **drain** parameter values.

0000015A
AP_SINGLE_NOT_SRC_RESP

For a single-session CNOS verb, APPC permits only the local (source) LU to be responsible for deactivating sessions.

0000015B
AP_BAD_PARTNER_LU_ALIAS

APPC did not recognize the supplied **partner_lu_alias**.

0000015C
AP_EXCEEDS_MAX_ALLOWED

Your program issued a CNOS verb, specifying a **partner_lu_mode_session_limit** number and **set_negotiable** (NO).

0000015D
AP_CHANGE_SRC_DRAINS

APPC does not permit **mode_name_select** (ONE) and **drain_source** (YES) when **drain_source** (NO) is currently in effect for the specified mode.

0000015E
AP_LU_DETACHED

A command reset the definition of the local LU before the CNOS verb tried to specify the LU.

0000015F
AP_CNOS_COMMAND_RACE_REJECT

The local LU is currently processing a CNOS verb issued by the partner LU.

00000167
AP_SNASVCMG_RESET_NOT_ALLOWED

Your local program attempted to issue the CNOS verbs for the mode named SNASVCMG, specifying a session limit of zero.

000001B4
AP_DISPLAY_INFO_EXCEEDS_LENGTH

The returned DISPLAY information did not fit in the buffer.

000001B5
DISPLAY_INVALID_CONSTANT

The value supplied for NUM_SECTIONS or INIT_SEC_LEN is invalid.

00000506
AP_UNDEFINED_TP_NAME

In the configuration file for your application, APPC could not find an invokable TP name matching the value of **tp_name**.

00000509
AP_ALLOCATE_NOT_PENDING

APPC did not find an incoming allocate (from the invoking TP) to match the value of **tp_name**, supplied by RECEIVE_ALLOCATE. **RECEIVE_ALLOCATE** waited for the incoming allocate and eventually timed out.

00000519
AP_CPSVCMG_MODE_NOT_ALLOWED

The mode named CPSVCMG cannot be specified as the **mode_name** on the deactivate session verb.

00000525
AP_INVALID_PROCESS

The process issuing RECEIVE_ALLOCATE was different from the one started by APPC.

080F6051
AP_SECURITY_NOT_VALID

The user identifier or password specified in the allocation request was not accepted by the partner LU.

084B6031
AP_TRANS_PGM_NOT_AVAIL_RETRY

The remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition may be temporary, such as a time-out. The reason for the error may be logged on the remote node. Retry the allocation.

084C0000
AP_TRANS_PGM_NOT_AVAIL_NO_RETRY

The remote LU rejected the allocation request because it was unable to start the requested partner TP. The condition is permanent. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

10086021
AP_TP_NAME_NOT_RECOGNIZED

The partner LU does not recognize the TP name specified in the allocation request.

10086031
AP_PIP_NOT_ALLOWED

The allocation request specified PIP data, but either the partner TP does not require this data, or the partner LU does not support it.

10086032
AP_PIP_NOT_SPECIFIED_CORRECTLY

The partner TP requires PIP data, but the allocation request specified either no PIP data or an incorrect number of parameters.

10086034
AP_CONVERSATION_TYPE_MISMATCH

The partner LU or TP does not support the conversation type (basic or mapped) specified in the allocation request.

10086041
AP_SYNC_LEVEL_NOT_SUPPORTED

The partner TP does not support the **sync_level** (AP_NONE or AP_CONFIRM_SYNC_LEVEL) specified in the allocation request, or the **sync_level** was not recognized.

Common CSV Return Codes

This section describes the primary and, if applicable, secondary return codes for the Microsoft® Windows® Common Service Verb (CSV) API. The return codes are listed in hexadecimal order.

In This Section

- Primary CSV Return Codes
- Secondary CSV Return Codes

Primary CSV Return Codes

0000
SV_OK

The verb executed successfully.

0001
SV_PARAMETER_CHECK

The verb did not execute because of a parameter error.

0002
SV_STATE_CHECK

The verb did not execute because it was issued in an invalid state.

0021
SV_CANCELLED

This code is returned for an asynchronous verb when it has been shut down by a WinCSVCleanup call.

0030
SV_FILE_ALREADY_EXISTS

When the SV_NEW file option was used, the file name specified was the name of an existing file.

0031
SV_OUTPUT_DEVICE_FULL

There is insufficient space on the device where the output file resides. Retry the operation after freeing additional disk space.

F006
SV_THREAD_BLOCKING

This verb exceeds the maximum number of simultaneous synchronous verbs allowed.

F008
SV_INVALID_VERB_SEGMENT

The verb control block (VCB) extended beyond the end of the data segment.

F011
SV_UNEXPECTED_DOS_ERROR

One of the following conditions occurred:

- The Microsoft® Windows® 2000 system encountered an error while processing the verb. The operating system return code was returned through the secondary return code. If the problem persists, contact the system administrator for corrective action.
- A CSV was issued from a message loop that was invoked by another application issuing a Windows environment **SendMessage** function call, rather than the more common Windows environment **PostMessage** function call. Verb processing cannot take place.
- A CSV was issued when **SendMessage** invoked your application. You can determine whether your application has been invoked with **SendMessage** by using the **InSendMessage** Windows API function call.

F012
SV_COMM_SUBSYSTEM_NOT_LOADED

A required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

F024
SV_SERVER_RESOURCE_NOT_FOUND

No communication server was found that could provide the requested function.

F026
SV_SERVER_RESOURCE_LOST

The communications server that was providing the function was lost due to a connection failure.

FFFF
SV_INVALID_VERB

The **opcode** parameter did not match the operation code of any verb. No verb executed.

Secondary CSV Return Codes

00000006
SV_INVALID_DATA_SEGMENT

The data buffer containing the source or target string did not fit in one segment, or the target segment was not a read/write segment. This applies only to the Microsoft® Windows® and OS/2 systems.

00000301
SV_SSCP_PU_SESSION_NOT_ACTIVE

The Network Management Vector Transport (NMVT) was not sent; either the system services control point-physical unit (SSCP-PU) session was not active, the node configured to receive diagnostic information was not active, or no network management connection was configured.

00000302
SV_DATA_EXCEEDS_RU_SIZE

The data to be sent was too long. The length of the user-supplied data plus headers and added subvectors must fit in a single request unit (RU) that is not more than 512 bytes long.

00000303
SV_INVALID_DATA_TYPE

The **data_type** parameter contained an invalid value.

00000401
SV_INVALID_DIRECTION

The **direction** parameter contained an invalid value.

00000402
SV_INVALID_CHARACTER_SET

The **char_set** parameter contained an invalid value.

00000404
SV_INVALID_FIRST_CHARACTER

The first character of a type A source string was invalid.

00000405
SV_TABLE_ERROR

One of the following occurred:

- The file containing the user-written type G conversion table was not specified by the environment variable CSVTBLG.
- The table was not in the correct format.
- The file specified by the CSVTBLG variable was not found.

00000406
SV_CONVERSION_ERROR

One or more characters in the source string were not found in the conversion table. These characters were converted to nulls (0x00). The verb still executed.

00000621
SV_INVALID_MESSAGE_ACTION

The **msg_act** parameter contained an invalid value.

00000624
SV_INVALID_SET

The **dt_set** parameter contained an invalid value.

00000629
SV_COPY_TRACE_IN_PROGRESS

A previously issued COPY_TRACE_TO_FILE is still in progress.

0000062A
SV_TRACE_NOT_STOPPED

A trace was in progress when the verb was issued.

0000062B
SV_INVALID_FILE_OPTION

A value other than SV_NEW or SV_OVERWRITE was specified for **file_option**.

0000062C
SV_TRACE_BUFFER_EMPTY

The trace storage buffer did not contain any data.

0000062F
SV_INVALID_RESET_TRACE

The **reset_trc** parameter contained an invalid value.

00000630
SV_INVALID_CHAR_NOT_FOUND

The **char_not_fnd** parameter contained an invalid value.

00000631
SV_INVALID_SOURCE_CODE_PAGE

The code page specified by **source_cp** is not supported.

00000632
SV_INVALID_TARGET_CODE_PAGE

The code page specified by **target_cp** is not supported.

030000AB
SV_SERVER_COMM_FAILURE

The connection to the server was lost due to physical path problems; for example, the server may have been powered off.

CPI-C Programmer's Reference

This section of the Host Integration Server 2009 Developer's Guide provides information about the calls, extensions, and return codes that make up the CPI-C.

For general information about programming for CPI-C, see the CPI-C Programmer's Guide section of the SDK.

For sample code that uses CPI-C, see CPI-C Samples.

In This Section

CPI-C Calls

Extensions for the Windows Environment

CPI-C Common Return Codes

CPI-C Calls

This section describes the Common Programming Interface for Communications (CPI-C) calls. The following information is supplied for each call:

- The pseudonym for the call and the actual C function name.
- A definition of the call.
- A list of the parameters used by the call and the data type for each parameter. The prototype of each function is declared in the WINCPIC.H file.
- A description of each input and output parameter. The parameter names are pseudonyms and the actual names for these parameters are declared by the application program. The description includes the possible values of the parameter.
- The conversation states in which the call can be issued.
- The states to which the conversation can change upon return from the call. Conditions that do not cause a state change are not noted. For example, parameter checks and state checks do not cause a state change.
- Additional information describing the use of the call.

Data Types

The data types for the parameters supplied to and received from CPI-C are established as symbolic constants by **#define** statements in the WINCPIC.H file. For example, CM_INT32 represents **signed long int** and CM_PTR represents **far ***. Using symbolic constants improves the portability of CPI-C applications.

For ease of understanding, this reference presents the data types in absolute (not **#defined**) terms.

In writing applications, you should use the symbolic constants from the WINCPIC.H file.

Symbolic Constants

Most parameters supplied to and returned by CPI-C are 32-bit integers. To simplify coding, the values for these parameters are represented by meaningful symbolic constants, which are established by **#define** statements in the WINCPIC.H header file. For example, the value CM_MAPPED_CONVERSATION represents the integer 1. For the sake of readability, use only the symbolic constants when writing programs.

Strings

All strings are in ASCII format when passed across the CPI-C interface.

Validity of output parameters

The parameters returned by CPI-C are valid only if the CPI-C call is executed successfully, as indicated by a return code of CM_OK.

Accept_Conversation

The **Accept_Conversation** call (function name **cmaccp**) is issued by the invoked program to accept the incoming conversation and set certain conversation characteristics. For a list of initial conversation characteristics, see Initial Conversation Characteristics.

Syntax

```
CM_ENTRY Accept_Conversation(
   unsigned char FAR *conversation_ID,
      CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Returned parameter. Specifies the identifier for the conversation. It is used by subsequent CPI-C calls and is returned if the return code is either CM_OK or CM_OPERATION_INCOMPLETE. If the return code is CM_OPERATION_INCOMPLETE, the *conversation_ID* parameter can be used by the application to wait for or cancel the conversation.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_STATE_CHECK

Primary return code; there is no incoming conversation (blocking mode only), or no local transaction program (TP) name has been set up.

CM_OPERATION_INCOMPLETE

Primary return code; a nonblocking operation has been started on the conversation but is not complete. The program can issue Wait_For_Conversation to wait for the operation to complete or Cancel_Conversation to cancel the operation and conversation.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation must be in RESET state when **Accept_Conversation** is issued.

If the call is successful, the conversation changes to RECEIVE state. If the call fails, the state remains unchanged.

Remarks

Upon successful execution of this call, CPI-C generates an 8-byte conversation identifier. This identifier is a required parameter for all other CPI-C calls issued by the invoked program on this conversation.

Incoming conversations will be accepted according to the target TP name that they specify, which must match local TP names that have been set up. Local TP names can be set up by implementation-dependent methods, or by the program calling Specify_Local_TP_Name. In this way, a program can have more than one local TP name. The program can call Extract_TP_Name to discover the name specified on the incoming conversation.

The operation is performed in nonblocking mode if the program has called **Specify_Local_TP_Name** previously; otherwise it is performed in blocking mode.

Allocate

The **Allocate** call (function name **cmallc**) is issued by the invoking program to allocate a conversation with the partner program, using the current conversation characteristics. CPI-C can also allocate a session between the local logical unit (LU) and partner LU if one does not already exist.

Syntax

```
CM_ENTRY Allocate(
  unsigned char FAR *conversation_ID,
    CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the conversation identifier. The value of this parameter was returned by Initialize_Conversation.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_OPERATION_NOT_ACCEPTED

Primary return code; this value indicates that a previous operation on this conversation is incomplete.

CM_OPERATION_INCOMPLETE

Primary return code; a nonblocking operation has been started on the conversation but is not complete. The program can issue Wait_For_Conversation to wait for the operation to complete or Cancel_Conversation to cancel the operation and conversation.

CM_PARAMETER_ERROR

Primary return code; one of the following occurred:

- The mode name derived from the side information or set by Set_Mode_Name is not valid.
- The mode name is used by SNA service transaction programs (TPs); the invoking program does not have the authority to use this mode name. An example is SNASVCMG.
- The partner program derived from the side information is an SNA service TP; the local program does not have the privilege required to allocate a conversation to an SNA service TP.
- The partner program is a service TP, which participates in basic conversations, but the conversation is set to CM_MAPPED_CONVERSATION.
- The partner LU name derived from the side information or set by Set_Partner_LU_Name is not valid.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is not valid, or the address of a variable is invalid.

CM_PROGRAM_STATE_CHECK

Primary return code; the conversation is not in INITIALIZE state.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

CM_UNSUCCESSFUL

Primary return code; the conversations return-control characteristic is set to CM_IMMEDIATE and the local LU did not have an available contention-winner session.

The following return codes can be generated if the conversations return-control type is set to CM_WHEN_SESSION_ALLOCATED.

CM_ALLOCATE_FAILURE_NO_RETRY

Primary return code; the conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

CM_ALLOCATE_FAILURE_RETRY

Primary return code; the conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

State Changes

The conversation must be in INITIALIZE state when **Allocate** is issued.

State changes, summarized in the following table, are based on the value of the *return_code* parameter.

return_code	**New state**
CM_OK	SEND
CM_ALLOCATE_FAILURE_NO_RETRY	RESET
CM_ALLOCATE_FAILURE_RETRY	RESET
All others	No change

Remarks

The type of conversation allocated is based on the conversation type characteristic: mapped or basic.

When the conversation has been allocated by this call, the following conversation characteristics cannot be changed:

- Conversation type
- Mode name
- Partner LU name
- Partner program name
- Return control
- Synchronization level
- Conversation security
- User identifier
- Password

To send the allocation request immediately, the invoking program can issue Flush or Confirm immediately after **Allocate**. Otherwise, the allocate request accumulates with other data in the local LUs send buffer until the buffer is full.

By issuing **Confirm** after **Allocate**, the invoking program can immediately determine whether the allocation was successful (if

the conversation synchronization level is set to CM_CONFIRM).

If the partner LU rejects the allocation request generated by **Allocate**, the error is returned to the invoking program on a subsequent call.

Cancel_Conversation

The **Cancel_Conversation** call (function name **cmcanc**) cancels any outstanding operation on a conversation (an operation returned with CM_OPERATION_INCOMPLETE) and the conversation itself.

Syntax

```
CM_ENTRY Cancel_Conversation(
  unsigned char FAR *conversation_ID,
    CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Returned parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation must be in any state except RESET.

When the return code is CM_OK, the conversation state becomes RESET.

Remarks

Cancel_Conversation can be called while another operation is active for the specified *conversation_ID*. This allows an application to end any CPI-C action, but will terminate the conversation. This call can be issued regardless of the current application processing mode. Any outstanding operations will return with CM_DEALLOCATED_ABEND as the return code.

The conversation is terminated by a Deallocate with *deallocate_type* set to ABEND_SVC. No *log_data* is sent. The system may be unable to do this immediately, but any delay is transparent to the program.

Note

If **Cancel_Conversation** is called while there are outstanding Specify_Windows_Handle asynchronous calls, these calls are canceled. The return codes are set to canceled, and a completion message is posted.

Confirm

The **Confirm** call (function name **cmcfm**) sends the contents of the send buffer of the local logical unit (LU) and a confirmation request to the partner program and waits for confirmation. For Microsoft® Windows Server™ 2003 and Windows® 2000, run a background thread for all CPI-C communications and preserve the foreground thread for user interface only.

Syntax

```
CM_ENTRY Confirm(
  unsigned char FAR *conversation_ID,
    CM_INT32 FAR *request_to_send_received,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

request_to_send_received

Returned parameter. Provides the request-to-send-received indicator. Possible values are:

CM_REQ_TO_SEND_RECEIVED

The partner program issued Request_To_Send, which requests the local program to change the conversation to RECEIVE state.

CM_REQ_TO_SEND_NOT_RECEIVED

The partner program did not issue **Request_To_Send**. This value is not relevant if *return_code* is set to CM_PROGRAM_PARAMETER_CHECK or CM_PROGRAM_STATE_CHECK.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully. The partner program issued the Confirmed call.

CM_OPERATION_NOT_ACCEPTED

Primary return code; a previous operation on this conversation is incomplete.

CM_OPERATION_INCOMPLETE

Primary return code; the operation has not completed (processing mode is nonblocking only) and is still in progress. The program can issue Wait_For_Conversation to await the completion of the operation, or Cancel_Conversation to cancel the operation and conversation. If Specify_Windows_Handle has been called, the application should wait for notification by a Windows message and not call **Wait_For_Conversation**.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *conversation_ID* is invalid.
- The local program attempted to use **Confirm** in a conversation with a synchronization level of CM_NONE. The synchronization level must be CM_CONFIRM.

CM_PROGRAM_STATE_CHECK

Primary return code; one of the following occurred:

- The conversation was not in SEND or SEND_PENDING state.
- The basic conversation for the local program was in SEND state, and the local program did not finish sending a logical record.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

CM_CONVERSATION_TYPE_MISMATCH

Primary return code; the partner LU or program does not support the conversation type (basic or mapped) specified in the allocation request.

CM_PIP_NOT_SPECIFIED_CORRECTLY

Primary return code; the allocation request was rejected by a non-CPI-C LU 6.2 transaction program (TP). The partner program requires one or more PIP data variables, which are not supported by CPI-C.

CM_SECURITY_NOT_VALID

Primary return code; the user identifier or password specified in the allocation request is not accepted by the partner LU.

CM_SYNC LEVEL_NOT_SUPPORTED_PGM

Primary return code; the partner program does not support the synchronization level specified in the allocation request.

CM_TPN_NOT_RECOGNIZED

Primary return code; the partner LU does not recognize the program name specified in the allocation request.

CM_TP_NOT_AVAILABLE_NO_RETRY

Primary return code; the partner LU cannot start the program specified in the allocation request because of a permanent condition. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

CM_TP_NOT_AVAILABLE_RETRY

Primary return code; the partner LU cannot start the program specified in the allocation request because of a temporary condition. The reason for the error may be logged on the remote node. Retry the allocation.

CM_PROGRAM_ERROR_PURGING

Primary return code; one of the following occurred:

- While in RECEIVE or CONFIRM state, the partner program issued Send_Error. Data sent but not yet received is purged.
- While in SEND_PENDING state with the error direction set to CM_RECEIVE_ERROR, the partner program issued **Send_Error**. Data was not purged.

CM_RESOURCE_FAILURE_NO_RETRY

Primary return code; one of the following occurred:

- The conversation was terminated prematurely because of a permanent condition. Do not retry until the error has been corrected.
- The partner program did not deallocate the conversation before terminating normally.

CM_RESOURCE_FAILURE_RETRY

Primary return code; the conversation was terminated prematurely because of a temporary condition, such as modem failure. Retry the conversation.

CM_DEALLOCATED_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The remote program issued Deallocate with the type parameter set to CM_DEALLOCATE_ABEND. If the conversation for the remote program was in RECEIVE state when the call was issued, information sent by the local program and not yet received by the remote program is purged.

- The partner program terminated normally but did not deallocate the conversation before terminating.

CM_DEALLOCATED_ABEND_SVC

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner program issued **Deallocate** with the type parameter set to ABEND_SVC.

- The partner program did not deallocate the conversation before terminating.

If the conversation is in RECEIVE state for the partner program when this call is issued by the local program, data sent by the local program and not yet received by the partner program is purged.

CM_DEALLOCATED_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner program issued **Deallocate** with the type parameter set to ABEND_TIMER. If the conversation is in RECEIVE state for the partner program when this call is issued by the local program, data sent by the local program and not yet received by the partner program is purged.

CM_SVC_ERROR_PURGING

Primary return code; while in SEND state, the partner program or partner LU issued Send_Error with the type parameter set to SVC. Data sent to the partner program may have been purged.

State Changes

The conversation can be in SEND or SEND_PENDING state when **Confirm** is issued.

State changes, summarized in the following table, are based on the value of the *return_code* parameter.

return_code	**New state**
CM_OK	No change
Call was issued in SEND state	No change
Call was issued in SEND_PENDING state	SEND
CM_PROGRAM_ERROR_PURGING	RECEIVE
CM_SVC_ERROR_PURGING	RECEIVE
CM_CONVERSATION_TYPE_MISMATCH	RESET
CM_PIP_NOT_SPECIFIED_CORRECTLY	RESET
CM_SECURITY_NOT_VALID	RESET
CM_SYNC_LEVEL_NOT_SUPPORTED_PGM	RESET
CM_TPN_NOT_RECOGNIZED	RESET
CM_TP_NOT_AVAILABLE_NO_RETRY	RESET
CM_TP_NOT_AVAILABLE_RETRY	RESET

CM_RESOURCE_FAILURE_NO_RETRY	RESET
CM_RESOURCE_FAILURE_RETRY	RESET
CM_DEALLOCATED_ABEND	RESET
CM_DEALLOCATED_ABEND_SVC	RESET
CM_DEALLOCATED_ABEND_TIMER	RESET
All others	No change

Remarks

In response to **Confirm**, the partner program normally issues Confirmed to confirm that it has received the data without error. (If the partner program encounters an error, it issues Send_Error or uses Deallocate to abnormally deallocate the conversation.)

The program can issue **Confirm** only if the conversations synchronization level is CM_CONFIRM.

Confirm waits for a response from the partner program. A response is generated by one of the following CPI-C calls in the partner program:

- Confirmed
- Send_Error
- 5Deallocate with the conversations deallocate type set to CM_DEALLOCATE_ABEND

Confirmed

The **Confirmed** call (function name **cmcfmd**) replies to a confirmation request from the partner program. It informs the partner program that the local program has not detected an error in the received data. Because the program issuing the confirmation request waits for a confirmation, **Confirmed** synchronizes the processing of the two programs.

Syntax

```
CM_ENTRY Confirmed(
  unsigned char FAR *conversation_ID,
    CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_OPERATION_NOT_ACCEPTED

Primary return code; a previous operation on this conversation is incomplete.

CM_OPERATION_INCOMPLETE

Primary return code; the operation has not completed (processing mode is nonblocking only) and is still in progress. The program can issue Wait_For_Conversation to await the completion of the operation, or Cancel_Conversation to cancel the operation and conversation. If Specify_Windows_Handle has been called, the application should wait for notification by a Microsoft® Windows® message and not call **Wait_For_Conversation**.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid.

CM_PROGRAM_STATE_CHECK

Primary return code; the conversation was not in CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state when the program issued this call.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation must be in one of the following states when the program issues **Confirmed**:

- CONFIRM
- CONFIRM_SEND
- CONFIRM_DEALLOCATE

The new state is determined by the old state—the state of the conversation when the local program issued **Confirmed**. The old state is indicated by the *status_received* value of the preceding Receive call. The following table summarizes the possible state changes when *return_code* is set to CM_OK.

Old state	New state

CONFIRM	RECEIVE
CONFIRM_SEND	SEND
CONFIRM_DEALLOCATE	RESET

Other return codes result in no state change.

Remarks

A confirmation request is issued by one of the following calls in the partner program:

- Confirm.
- Prepare_To_Receive if the prepare-to-receive type is set to CM_PREP_TO_RECEIVE_CONFIRM or to CM_PREP_TO_RECEIVE_SYNC_LEVEL and the conversations synchronization level is set to CM_CONFIRM.
- Deallocate if the deallocate type is set to CM_DEALLOCATE_CONFIRM or to CM_DEALLOCATE_SYNC_LEVEL and the conversations synchronization level is set to CM_CONFIRM.
- Send_Data under the following circumstances:
    - The send type is set to CM_SEND_AND_CONFIRM.
    - The send type is set to CM_SEND_AND_PREPARE_TO_RECEIVE and the prepare-to-receive type is set to CM_PREPARE_TO_RECEIVE_CONFIRM.
    - The send type is set to CM_SEND_AND_PREPARE_TO_RECEIVE, the prepare-to-receive type is set to CM_PREPARE_TO_RECEIVE_SYNC_LEVEL, and the synchronization level is set to CM_CONFIRM.
    - The send type is set to CM_SEND_AND_DEALLOCATE and the deallocate type is set to CM_DEALLOCATE_CONFIRM.
    - The send type is set to CM_SEND_AND_DEALLOCATE, the deallocate type is set to CM_DEALLOCATE_SYNC_LEVEL, and the synchronization level is set to CM_CONFIRM.

A confirmation request is received by the local program through the *status_received* parameter of Receive. The local program can issue **Confirmed** only if the *status_received* parameter is set to one of the following values:

- CM_CONFIRM_RECEIVED
- CM_CONFIRM_SEND_RECEIVED
- CM_CONFIRM_DEALLOC_RECEIVED

Convert_Incoming

The **Convert_Incoming** call (function name **cmcnvi**) converts a string of EBCDIC characters into ASCII. Note that the return conversion can be performed using **Convert_Outgoing**.

Syntax

```
CM_ENTRY Convert_Incoming(
  unsigned char FAR *string,
  CM_INT32 FAR *string_length,
    CM_INT32 FAR *return_code
);
```

Parameters

string

Supplied parameter. Specifies the EBCDIC string to be converted. The string may contain any of the following characters:

- Uppercase A–Z
- Lowercase a–z
- Numbers 0–9
- The period (.)
- Space characters
- The special characters < > + - ( ) & * ; : , ' ? / _ = ".

string_length characters of this string will be replaced by ASCII equivalents.

string_length

Supplied parameter. Specifies the number of characters to be converted (1–32767).

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully, and the *string* parameter now contains the converted ASCII string.

CM_OPERATION_NOT_ACCEPTED

Primary return code; the *string_length* parameter specified an invalid value.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state.

There is no state change.

Remarks

When data is being received in buffer format in a basic conversation, the data buffer may contain multiple logical records, each consisting of a 2-byte length field (NN) followed by the data. The application must extract and convert each data string separately (excluding the length field value). The applications must not attempt to convert the whole buffer in one operation, because this will make the length field values invalid.

Convert_Outgoing

The **Convert_Outgoing** call (function name **cmcnvo**) converts a string of ASCII characters into EBCDIC. Note that the return conversion can be performed using **Convert_Incoming**.

Syntax

```
CM_ENTRY Convert_Outgoing(
    unsigned char FAR *string,
    CM_INT32 FAR *string_length,
    CM_INT32 FAR *return_code
);
```

Parameters

string

Supplied parameter. Specifies the ASCII string to be converted. The string may contain any of the following characters:

- Uppercase A–Z
- Lowercase a–z
- Numbers 0–9
- The period (.)
- Space characters
- The special characters < > + - ( ) & * ; : , ' ? / _ = ".

string_length characters of this string will be replaced by EBCDIC equivalents.

string_length

Supplied parameter. Specifies the number of characters to be converted (1–32767).

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully and the *string* parameter now contains the converted EBCDIC string.

CM_OPERATION_NOT_ACCEPTED

Primary return code; the *string_length* parameter specified an invalid value.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state.

There is no state change.

Remarks

When data is being received in buffer format in a basic conversation, the data buffer may contain multiple logical records, each consisting of a two-byte length field (NN) followed by the data. The application must extract and convert each data string separately (excluding the length field value). The applications must not attempt to convert the whole buffer in one operation, because this will make the length field values invalid.

Deallocate

The **Deallocate** call (function name **cmdeal**) deallocates a conversation between two programs.

Syntax

```
CM_ENTRY Deallocate(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully; the conversation is deallocated.

CM_OPERATION_NOT_ACCEPTED

Primary return code; a previous operation on this conversation is incomplete.

CM_OPERATION_INCOMPLETE

Primary return code; the operation has not completed (processing mode is nonblocking only) and is still in progress. The program can issue Wait_For_Conversation to await the completion of the operation, or Cancel_Conversation to cancel the operation and conversation. If Specify_Windows_Handle has been called, the application should wait for notification by a Microsoft® Windows® message and not call **Wait_For_Conversation**.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid.

CM_PROGRAM_STATE_CHECK

Primary return code; the following state errors can occur when the deallocate type indicates a normal deallocation (CM_DEALLOCATE_SYNC_LEVEL, CM_DEALLOCATE_FLUSH, CM_DEALLOCATE_CONFIRM):

- The conversation is not in SEND or SEND_PENDING state.
- For a basic conversation, the conversation is in SEND state, but the program did not finish sending a logical record.

The following return codes can be returned when the *deallocate_type* is set to CM_DEALLOCATE_CONFIRM or to CM_DEALLOCATE_SYNC_LEVEL and the conversations synchronization level is set to CM_CONFIRM.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

CM_CONVERSATION_TYPE_MISMATCH

Primary return code; the partner logical unit (LU) or program does not support the conversation type (basic or mapped) specified in the allocation request.

CM_PIP_NOT_SPECIFIED_CORRECTLY

Primary return code; the allocation request was rejected by a non-CPI-C LU 6.2 transaction program (TP). The partner program requires one or more PIP data variables, which are not supported by CPI-C.

CM_SECURITY_NOT_VALID

Primary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

CM_SYNC LEVEL_NOT_SUPPORTED_PGM

Primary return code; the partner program does not support the synchronization level specified in the allocation request.

CM_TPN_NOT_RECOGNIZED

Primary return code; the partner LU does not recognize the program name specified in the allocation request.

CM_TP_NOT_AVAILABLE_NO_RETRY

Primary return code; the partner LU cannot start the program specified in the allocation request because of a permanent condition. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

CM_TP_NOT_AVAILABLE_RETRY

Primary return code; the partner LU cannot start the program specified in the allocation request because of a temporary condition. The reason for the error may be logged on the remote node. Retry the allocation.

CM_PROGRAM_ERROR_PURGING

Primary return code; one of the following occurred:

- While in RECEIVE or CONFIRM state, the partner program issued Send_Error. Data sent but not yet received is purged.
- While in SEND_PENDING state with the error direction set to CM_RECEIVE_ERROR, the partner program issued **Send_Error**. Data was not purged.

CM_RESOURCE_FAILURE_NO_RETRY

Primary return code; one of the following occurred:

- The conversation was terminated prematurely because of a permanent condition. Do not retry until the error has been corrected.
- The partner program did not deallocate the conversation before terminating normally.

CM_RESOURCE_FAILURE_RETRY

Primary return code; the conversation was terminated prematurely because of a temporary condition, such as modem failure. Retry the conversation.

CM_DEALLOCATED_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The remote program issued **Deallocate** with the type parameter set to CM_DEALLOCATE_ABEND, or the remote LU did so because of a remote program abnormal-ending condition. If the conversation for the remote program was in RECEIVE state when the call was issued, information sent by the local program and not yet received by the remote program is purged.
- The remote TP terminated normally but did not deallocate the conversation before terminating. Node services at the remote LU deallocated the conversation on behalf of the remote TP.

CM_DEALLOCATED_ABEND_SVC

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner program issued **Deallocate** with the type parameter set to ABEND_SVC.
- The partner program did not deallocate the conversation before terminating.

If the conversation is in RECEIVE state for the partner program when this call is issued by the local program, data sent by the

local program and not yet received by the partner program is purged.

CM_DEALLOCATED_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner program issued **Deallocate** with the type parameter set to ABEND_TIMER. If the conversation is in RECEIVE state for the partner program when this call is issued by the local program, data sent by the local program and not yet received by the partner program is purged.

CM_SVC_ERROR_PURGING

Primary return code; while in SEND state, the partner program or partner LU issued **Send_Error** with the type parameter set to SVC. Data sent to the partner program may have been purged.

State Changes

Depending on the value of the conversations deallocate type parameter (set by Set_Deallocate_Type), the conversation can be in one of the states indicated in the following table when the program issues **Deallocate**:

Deallocate type	**Allowed state**
CM_DEALLOCATE_FLUSH	SEND or SEND_PENDING
CM_DEALLOCATE_CONFIRM	SEND or SEND_PENDING
CM_DEALLOCATE_SYNC_LEVEL	SEND or SEND_PENDING
CM_DEALLOCATE_ABEND	Any except RESET

State changes, summarized in the following table, are based on the value of the *return_code* parameter.

return_code	**New state**
CM_OK	RESET
CM_PROGRAM_ERROR_PURGING	RECEIVE
CM_SVC_ERROR_PURGING	RECEIVE
CM_CONVERSATION_TYPE_MISMATCH	RESET
CM_PIP_NOT_SPECIFIED_CORRECTLY	RESET
CM_SECURITY_NOT_VALID	RESET
CM_SYNC_LEVEL_NOT_SUPPORTED_PGM	RESET
CM_TPN_NOT_RECOGNIZED	RESET
CM_TP_NOT_AVAILABLE_NO_RETRY	RESET
CM_TP_NOT_AVAILABLE_RETRY	RESET
CM_RESOURCE_FAILURE_NO_RETRY	RESET
CM_RESOURCE_FAILURE_RETRY	RESET
CM_DEALLOCATED_ABEND	RESET
CM_DEALLOCATED_ABEND_SVC	RESET

CM_DEALLOCATED_ABEND_TIMER	RESET
All others	No change

Remarks

Before deallocating the conversation, this call performs the equivalent of either the Flush or Confirmed call, depending on the current conversation synchronization level and deallocate type. The deallocate type is set by Set_Deallocate_Type.

The partner program receives the deallocation notification through one of the following parameters:

- status_received is CM_CONFIRM_DEALLOC_RECEIVED
- *return_code* is CM_DEALLOCATED_NORMAL
- *return_code* is CM_DEALLOCATED_ABEND

After this call has successfully executed, the *conversation_ID* is no longer valid.

For a basic conversation, if the conversations deallocate type is set to CM_DEALLOCATE_ABEND and the log data length is greater than zero, the local LU writes the log data (specified by Set_Log_Data) to the local error log and to the partner LU.

After **Deallocate** has been executed, the log data length is set to zero and the log data is set to null.

Delete_CPIC_Side_Information

The **Delete_CPIC_Side_Information** call (function name **xcmdsi**) deletes an entry from the side information table in memory. The side information entry is identified through the symbolic destination name.

Syntax

```
CM_ENTRY Delete_CPIC_Side_Information(
  unsigned char FAR *key_lock,
    unsigned char FAR *sym_dest_name,
    CM_INT32 FAR *return_code
);
```

Parameters

key_lock

Supplied parameter. This parameter is ignored.

sym_dest_name

Supplied parameter. Specifies the symbolic destination name of the entry to be deleted.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the *sym_dest_name* parameter specified a nonexistent side information entry.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The call is not associated with a conversation and can be in any state.

There is no state change.

Remarks

The side information entry is removed immediately from the side information table in memory.

While this call is being executed, any calls issued by other CPI-C applications that set or extract side information are suspended. These calls include the following:

- Set_CPIC_Side_Information
- Extract_CPIC_Side_Information
- Initialize_Conversation

Extract_Conversation_Security_Type

The **Extract_Conversation_Security_Type** call (function name **xcecst**) returns the security type for a specified conversation.

Syntax

```
CM_ENTRY Extract_Conversation_Security_Type(
  unsigned char FAR *conversation_ID,
    CM_INT32 FAR *conversation_security_type,
    CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

conversation_security_type

Returned parameter. Specifies the information the partner logical unit (LU) requires to validate access to the invoked program. Possible values are:

CM_SECURITY_NONE

The invoked program uses no conversation security.

CM_SECURITY_PROGRAM

The invoked program uses conversation security and thus requires a user identifier and password.

CM_SECURITY_SAME

The invoked program, invoked with a valid user identifier and password, in turn invokes another program (as illustrated in Communication Between TPs). For example, assume that program A invokes program B with a valid user identifier and password, and program B in turn invokes program C. If program B specifies the value CM_SECURITY_SAME, CPI-C sends the LU for program C, the user identifier from program A, and an already-verified indicator. This indicator tells program C not to require the password (if program C is configured to accept an already-verified indicator).

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid, or the address of a variable is invalid.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Extract_Conversation_Security_User_ID

The **Extract_Conversation_Security_User_ID** call (function name **cmecsu**) returns the user identifier being used in a specified conversation.

Syntax

```
CM_ENTRY Extract_Conversation_Security_User_ID(
  unsigned char FAR *conversation_ID,
  unsigned char FAR *security_user_ID,
  CM_INT32 FAR *security_user_ID_length,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

security_user_ID

Returned parameter. Specifies the user identifier that was used to establish the conversation.

security_user_ID_length

Returned parameter. Specifies the length of *security_user_ID*.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Remarks

The *security_user_ID* value is not padded with spaces. It is meaningful only up to *security_user_ID_length*.

Extract_Conversation_State

The **Extract_Conversation_State** call (function name **cmecs**) returns the state of the specified conversation.

Syntax

```
CM_ENTRY Extract_Conversation_State(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *conversation_state,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

conversation_state

Returned parameter. Specifies the conversation state. Possible values are:

- CM_INITIALIZE_STATE
- CM_SEND_STATE
- CM_RECEIVE_STATE
- CM_SEND_PENDING_STATE
- CM_CONFIRM_STATE
- CM_CONFIRM_SEND_STATE
- CM_CONFIRM_DEALLOCATE_STATE

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Extract_Conversation_Type

The **Extract_Conversation_Type** call (function name **cmect**) returns the conversation type—mapped or basic—of the specified conversation.

Syntax

```
CM_ENTRY Extract_Conversation_Type(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *conversation_type,
    CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

conversation_type

Returned parameter. Specifies the conversation type. Possible values are:

- CM_BASIC_CONVERSATION
- CM_MAPPED_CONVERSATION

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Extract_CPIC_Side_Information

The **Extract_CPIC_Side_Information** call (function name **xcmesi**) returns the side information for an entry number or symbolic destination name.

Syntax

```
CM_ENTRY Extract_CPIC_Side_Information(
  CM_INT32 FAR *entry_number,
  unsigned char FAR *sym_dest_name,
  SIDE_INFO FAR *side_info_entry,
  CM_INT32 FAR *side_info_entry_length,
    CM_INT32 FAR *return_code
);
```

Parameters

entry_number

Supplied parameter. Specifies the number (index) of the side information entry to be returned. The first entry is 1.

The program can look up the side information entry by the symbolic destination name instead. To accomplish this, set the entry number to zero.

sym_dest_name

Supplied parameter. Specifies the symbolic destination name to search for.

If *entry_number* is set to a number greater than zero, this parameter is ignored.

side_info_entry

Returned parameter. Specifies the side information entry. For a detailed explanation of the side information entry, see Set_CPIC_Side_Information.

Each field in the side information structure is left-aligned and padded with spaces on the right as necessary.

side_info_entry_length

Supplied parameter. Always 124.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The *entry_number* specified a number larger than the maximum number of entries in the side information table or a number that is less than zero.
- The *sym_dest_name* parameter is invalid and *entry_number* is set to zero.
- The *side_info_entry_length* parameter is not set to 124.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

This call is not associated with a conversation and can be in any state.

There is no state change.

Remarks

The security password is never returned. If the security user identifier in the side information is not set, the security user identifier field is returned as all spaces.

Extract_Mode_Name

The **Extract_Mode_Name** call (function name **cmemn**) returns the mode name and mode name length for a specified conversation.

Syntax

```
CM_ENTRY Extract_Mode_Name(
  unsigned char FAR *conversation_ID,
  unsigned char FAR *mode_name,
  CM_INT32 FAR *mode_name_length,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

mode_name

Returned parameter. Specifies the starting address of the mode name.

mode_name_length

Returned parameter. Specifies the length of the mode name.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Extract_Partner_LU_Name

The **Extract_Partner_LU_Name** call (function name **cmepln**) returns the partner LU name and partner LU name length for a specified conversation. This can be an alias name of up to eight bytes or a fully qualified network name of up to 17 bytes.

Syntax

```
CM_ENTRY Extract_Partner_LU_Name(
  unsigned char FAR *conversation_ID,
  unsigned char FAR *partner_LU_name,
  CM_INT32 FAR *partner_LU_name_length,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

partner_LU_name

Returned parameter. Specifies the variable containing the partner LU name. (The program must supply a pointer to a suitable variable.)

partner_LU_name_length

Returned parameter. Specifies the length of the partner LU name.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Remarks

An invokable CPI-C transaction program (TP) will only receive the fully qualified network name upon successful completion of this function call. An invokable CPI-C TP is unable to retrieve the alias name using this call.

Extract_Sync_Level

The **Extract_Sync_Level** call (function name **cmesl**) returns the synchronization level for a specified conversation.

Syntax

```
CM_ENTRY Extract_Sync_Level(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *sync_level,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

sync_level

Returned parameter. Indicates the synchronization level of the conversation. Possible values are:

CM_NONE

The programs will not perform confirmation processing.

CM_CONFIRM

The programs can perform confirmation processing.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Extract_TP_Name

The **Extract_TP_Name** call (function name **cmetpn**) returns the *TP_name* characteristic.

Syntax

```
CM_ENTRY Extract_TP_Name(
  unsigned char FAR *conversation_ID,
  unsigned char FAR *TP_name,
  CM_INT32 FAR *TP_name_length,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

TP_name

Returned parameter. Specifies the variable containing the transaction program (TP) name.

TP_name_length

Returned parameter. Specifies the length of the TP name.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Remarks

For an invoking program, the *TP_name* characteristic is the value in the side information referenced in the *sym_dest_name* parameter of the Initialize_Conversation call. For an invokable program, it is the name specified in the conversation startup request (which will have been matched with a name specified locally or in a Specify_Local_TP_Name call), and will therefore be the same as the *TP_name* characteristic of the partner program.

The name returned can be up to 64 bytes in length.

Flush

The **Flush** call (function name **cmflus**) sends the contents of the send buffer of the local logical unit (LU) to the partner LU (and program). If the send buffer is empty, no action takes place.

Syntax

```
CM_ENTRY Flush(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_OPERATION_NOT_ACCEPTED

Primary return code; a previous operation on this conversation is incomplete.

CM_OPERATION_INCOMPLETE

Primary return code; the operation has not completed (processing mode is nonblocking only) and is still in progress. The program can issue Wait_For_Conversation to await the completion of the operation, or Cancel_Conversation to cancel the operation and conversation. If Specify_Windows_Handle has been called, the application should wait for notification by a Microsoft® Windows® message and not call **Wait_For_Conversation**.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid.

CM_PROGRAM_STATE_CHECK

Primary return code; the conversation was not in SEND or SEND_PENDING state when the program issued this call.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation must be in SEND or SEND_PENDING state.

If the call completes successfully, (*return_code* is CM_OK), the conversation is in SEND state.

Other return codes result in no state change.

Remarks

Data processed by Send_Data accumulates in the local LUs send buffer until one of the following happens:

- The local program issues the Flush call or other call that flushes the LUs send buffer. (Some send types, set by Set_Send_Type, include flush functionality.)
- The buffer is full.

The allocation request generated by Allocate and error information generated by Send_Error are also buffered.

Initialize_Conversation

The **Initialize_Conversation** call (function name **cminit**) is issued by the invoking program to obtain an 8-byte conversation identifier and to set the initial values for the conversations characteristics.

Syntax

```
CM_ENTRY Initialize_Conversation(
  unsigned char FAR *conversation_ID,
  unsigned char FAR *sym_dest_name,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Returned parameter. Specifies the identifier for the conversation. It is used by subsequent CPI-C calls.

sym_dest_name

Supplied parameter. Specifies the symbolic destination name—the name associated with a side information entry loaded from the configuration file or defined by Set_CPIC_Side_Information calls.

This parameter is an 8-byte ASCII character string. The allowed characters are as follows:

- Uppercase letters
- Numerals from 0 through 9

This parameter can also be set to eight spaces. In this case, the invoking program must issue the following calls before issuing Allocate:

- Set_Mode_Name
- Set_Partner_LU_Name
- Set_TP_Name

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *sym_dest_name* does not match a symbolic destination name in the side information table and is not a space.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation is in RESET state.

If the *return_code* is CM_OK, the conversation changes to INITIALIZE state. For other return codes, the conversation state remains unchanged.

Remarks

The initial values are CPI-C defaults or are derived from side information associated with the symbolic destination name. For more information about initial values and side information, see Initial Conversation Characteristics and Side Information for CPI-C Programs.

Initial values can be changed by the **Set_** calls.

If the side information contains an invalid value or a **Set_** call sets a conversation characteristic to an invalid value, the error is returned on the **Allocate** call.

If a CPI-C application attempts to invoke more than one concurrent conversation, only a single local APPC logical unit (LU) is used by all conversations. This prevents concurrent conversations across two or more dependent LU 6.2 LUs, causing subsequent Initialize_Conversation (CMALLC) calls to wait for the first conversation to be deallocated.

If the CPI-C application needs to invoke more than one concurrent conversation, independent LU 6.2 must be used between Host Integration Server and the remote system.

Upon successful execution of this call, CPI-C generates a conversation identifier. This identifier is a required parameter for all other CPI-C calls issued for this conversation by the invoking program.

Under normal circumstances, a CPI-C application cannot invoke two concurrent conversations using two different local APPC LUs. A registry key is available that when set forces CPI-C to issue a new TP_STARTED verb on every Initialize_Conversation (cminit) call. This is necessary to force APPC resource location for each call. The registry key that must be defined to force this behavior is the following:

\HKLM\CurrentControlSet\Services\SnaBase\Parameters\Client\GETNEWTPID

Prepare_To_Receive

The **Prepare_To_Receive** call (function name **cmptr**) changes the state of the conversation for the local program from SEND to RECEIVE.

Syntax

```
CM_ENTRY Prepare_To_Receive(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_OPERATION_NOT_ACCEPTED

Primary return code; a previous operation on this conversation is incomplete.

CM_OPERATION_INCOMPLETE

Primary return code; the operation has not completed (processing mode is nonblocking only) and is still in progress. The program can issue Wait_For_Conversation to await the completion of the operation, or Cancel_Conversation to cancel the operation and conversation. If Specify_Windows_Handle has been called, the application should wait for notification by a Microsoft® Windows® message and not call **Wait_For_Conversation**.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid.

CM_PROGRAM_STATE_CHECK

Primary return code; one of the following occurred:

- The conversation state is not SEND or SEND_PENDING.
- For a basic conversation, the conversation is in SEND state. However, the program did not finish sending a logical record.

These return codes can occur if the conversations prepare-to-receive type is set to CM_PREP_TO_RECEIVE_CONFIRM or if the prepare-to-receive type is set to CM_PREP_TO_RECEIVE_SYNC_LEVEL and the conversations synchronization level is set to CM_CONFIRM.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

CM_CONVERSATION_TYPE_MISMATCH

Primary return code; the partner logical unit (LU) or program does not support the conversation type (basic or mapped) specified in the allocation request.

CM_PIP_NOT_SPECIFIED_CORRECTLY

Primary return code; the allocation request was rejected by a non-CPI-C LU 6.2 transaction program (TP). The partner

program requires one or more PIP data variables, which are not supported by CPI-C.

CM_SECURITY_NOT_VALID

Primary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

CM_SYNC_LEVEL_NOT_SUPPORTED_PGM

Primary return code; the partner program does not support the synchronization level specified in the allocation request.

CM_TPN_NOT_RECOGNIZED

Primary return code; the partner LU does not recognize the program name specified in the allocation request.

CM_TP_NOT_AVAILABLE_NO_RETRY

Primary return code; the partner LU cannot start the program specified in the allocation request because of a permanent condition. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

CM_TP_NOT_AVAILABLE_RETRY

Primary return code; the partner LU cannot start the program specified in the allocation request because of a temporary condition. The reason for the error may be logged on the remote node. Retry the allocation.

CM_PROGRAM_ERROR_PURGING

Primary return code; one of the following occurred:

- While in RECEIVE or CONFIRM state, the partner program issued Send_Error. Data sent but not yet received is purged.
- While in SEND_PENDING state with the error direction set to CM_RECEIVE_ERROR, the partner program issued **Send_Error**. Data was not purged.

CM_RESOURCE_FAILURE_NO_RETRY

Primary return code; one of the following occurred:

- The conversation was terminated prematurely because of a permanent condition. Do not retry until the error has been corrected.
- The partner program did not deallocate the conversation before terminating normally.

CM_RESOURCE_FAILURE_RETRY

Primary return code; the conversation was terminated prematurely because of a temporary condition, such as modem failure. Retry the conversation.

CM_DEALLOCATED_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The remote program issued Deallocate with the type parameter set to CM_DEALLOCATE_ABEND, or the remote LU did so because of a remote program abnormal-ending condition. If the conversation for the remote program was in RECEIVE state when the call was issued, information sent by the local program and not yet received by the remote program is purged.
- The remote TP terminated normally but did not deallocate the conversation before terminating. Node services at the remote LU deallocated the conversation on behalf of the remote TP.

CM_DEALLOCATED_ABEND_SVC

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner program issued **Deallocate** with the type parameter set to ABEND_SVC.

- The partner program did not deallocate the conversation before terminating.

If the conversation is in RECEIVE state for the partner program when this call is issued by the local program, data sent by the local program and not yet received by the partner program is purged.

CM_DEALLOCATED_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner program issued **Deallocate** with the type parameter set to ABEND_TIMER. If the conversation is in RECEIVE state for the partner program when this call is issued by the local program, data sent by the local program and not yet received by the partner program is purged.

CM_SVC_ERROR_PURGING

Primary return code; while in SEND state, the partner program or partner LU issued Send_Error with the type parameter set to SVC. Data sent to the partner program may have been purged.

State Changes

The conversation can be in SEND or SEND_PENDING state.

State changes, summarized in the following table, are based on the value of the *return_code* parameter.

return_code	**New state**
CM_OK	RECEIVE
CM_PROGRAM_ERROR_PURGING	RECEIVE
CM_SVC_ERROR_PURGING	RECEIVE
CM_CONVERSATION_TYPE_MISMATCH	RESET
CM_PIP_NOT_SPECIFIED_CORRECTLY	RESET
CM_SECURITY_NOT_VALID	RESET
CM_SYNC_LEVEL_NOT_SUPPORTED_PGM	RESET
CM_TPN_NOT_RECOGNIZED	RESET
CM_TP_NOT_AVAILABLE_NO_RETRY	RESET
CM_TP_NOT_AVAILABLE_RETRY	RESET
CM_DEALLOCATED_ABEND	RESET
CM_RESOURCE_FAILURE_NO_RETRY	RESET
CM_RESOURCE_FAILURE_RETRY	RESET
CM_DEALLOCATED_ABEND_SVC	RESET
CM_DEALLOCATED_ABEND_TIMER	RESET
All others	No change

Before changing the conversation state, this call performs the equivalent of one of the following:

- The Flush call, sending the contents of the local LUs send buffer to the partner LU and program, if either of the following conditions is true:

    - The conversations prepare-to-receive type is set to CM_PREP_TO_RECEIVE_FLUSH.
    - The conversations prepare-to-receive type is set to CM_PREP_TO_RECEIVE_SYNC_LEVEL and the conversations synchronization level is set to CM_NONE.
- The Confirm call, sending the contents of the local LUs send buffer and a confirmation request to the partner program, if either of the following conditions is true:
    - The conversations prepare-to-receive type is set to CM_PREP_TO_RECEIVE_CONFIRM.
    - The conversations prepare-to-receive type is set to CM_PREP_TO_RECEIVE_SYNC_LEVEL and the conversations synchronization level is set to CM_CONFIRM.

The prepare-to-receive type is set by Set_Prepare_To_Receive_Type; the synchronization level is set by Set_Sync_Level.

The conversation cannot change to SEND or SEND_PENDING for the partner program until the partner program receives one of the following values through the *status_received* parameter of the Receive call:

- CM_SEND_RECEIVED
- CM_CONFIRM_SEND_RECEIVED and replies with the Confirmed or Send_Error call

Remarks

After this call has successfully executed, the local program can receive data.

Receive

The **Receive** call (function name **cmrcv**) receives any data currently available from the partner program. For Microsoft® Windows Server™ 2003 and Windows® 2000, run a background thread for all CPI-C communications and preserve the foreground thread for user interface only.

Syntax

```
CM_ENTRY Receive(
unsigned char FAR *conversation_ID,
unsigned char FAR *buffer,
CM_INT32 FAR *requested_length,
CM_INT32 FAR *data_received,
CM_INT32 FAR *received_length,
CM_INT32 FAR *status_received,
CM_INT32 FAR *request_to_send_received,
CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

buffer

Returned parameter. Specifies the address of the buffer to contain the data received by the local program.

The buffer contains data if the following conditions are true:

- The *data_received* parameter is set to a value other than CM_NO_DATA_RECEIVED.
- The *return_code* parameter is set to CM_OK or to CM_DEALLOCATED_NORMAL.

requested_length

Supplied parameter. Indicates the maximum number of bytes of data the local program is to receive. The range is from 0 through 32767.

data_received

Returned parameter. Indicates whether the program received data. Possible values are listed following the Parameters section.

received_length

Returned parameter. Indicates the number of bytes of data the local program received on this **Receive** call. If *return_code* or *data_received* indicates that the program received no data, this number is not relevant.

status_received

Returned parameter. Indicates changes in the status of the conversation. The following are possible values. These codes are not relevant unless *return_code* is set to CM_OK. Possible values are listed following the Parameters section.

request_to_send_received

Returned parameter. Specifies the request-to-send-received indicator. Values are listed following the Parameters section.

return_code

The code returned from this call. Values are listed following the Parameters section.

Values returned in the data_received parameter

These codes are not relevant unless *return_code* is set to CM_OK or CM_DEALLOCATED_NORMAL.

CM_DATA_RECEIVED

Can be returned for a basic conversation if the conversations fill characteristic is set to CM_FILL_BUFFER, indicating that the program is receiving data independent of its logical format. The local program received data until *requested_length* or end of data was reached.

The end of the data is indicated by either a change to another conversation state, based on the *return_code*, *status_received*, and *data_received* parameters, or an error condition. If the conversations receive type is set to CM_RECEIVE_IMMEDIATE, the data received can be less than *requested_length* if a smaller amount of data has arrived from the partner program.

CM_COMPLETE_DATA_RECEIVED

In a mapped conversation, indicates that the local program has received a complete data record or the last part of a data record.

In a basic conversation with the fill characteristic set to CM_FILL_LL, this value indicates that the local program has received a complete logical record or the end of a logical record.

CM_INCOMPLETE_DATA_RECEIVED

In a mapped conversation, indicates that the local program has received an incomplete data record. The *requested_length* parameter specified a value less than the length of the data record (or less than the remainder of the data record if this is not the first **Receive** to read the record). The amount of data received is equal to the *requested_length* parameter.

In a basic conversation with the fill characteristic set to CM_FILL_LL, this value indicates that the local program has received an incomplete logical record. The amount of data received is equal to the *requested_length* parameter. (If the received data was truncated, the length of the data will be less than *requested_length*.)

Upon receiving this value, the local program normally reissues **Receive** to receive the next part of the record.

CM_NO_DATA_RECEIVED

The program did not receive data.

Note that if the *return_code* parameter is set to CM_OK, status information may be available through the *status_received* parameter.

Values returned in the status_received parameter
CM_NO_STATUS_RECEIVED

No conversation status change was received on this call.

CM_SEND_RECEIVED

Indicates, for the partner program, that the conversation has entered RECEIVE state. For the local program, the conversation is now in SEND state if no data was received on this call, or SEND_PENDING state if data was received on this call.

Upon receiving this value, the local program normally uses Send_Data to begin sending data.

CM_CONFIRM_DEALLOC_RECEIVED

Indicates that the partner program issued Deallocate with confirmation requested. For the local program, the conversation is now in CONFIRM_DEALLOCATE state.

Upon receiving this value, the local program normally issues the Confirmed call.

CM_CONFIRM_RECEIVED

Indicates that the partner program issued the Confirm call. For the local program, the conversation is in CONFIRM state.

Upon receiving this value, the local program normally issues the **Confirmed** call.

CM_CONFIRM_SEND_RECEIVED

Indicates, for the partner program, that the conversation has entered RECEIVE state and a request for confirmation has been received by the local program. For the local program, the conversation is now in CONFIRM_SEND state.

The program normally responds by issuing the **Confirmed** call. Upon successful execution of the **Confirmed** call, the conversation changes to SEND state for the local program.

Values returned in the request_to_send_received parameter
CM_REQ_TO_SEND_RECEIVED

The partner program issued the Request_To_Send call, which requests the local program to change the conversation to RECEIVE state.

CM_REQ_TO_SEND_NOT_RECEIVED

The partner program did not issue the **Request_To_Send** call. This value is not relevant if the *return_code* parameter is set to CM_PROGRAM_PARAMETER_CHECK or CM_PROGRAM_STATE_CHECK.

Values returned in the return_code parameter
CM_OK

Primary return code; the call executed successfully.

CM_OPERATION_NOT_ACCEPTED

Primary return code; a previous operation on this conversation is incomplete.

CM_OPERATION_INCOMPLETE

Primary return code; the operation has not completed (processing mode is nonblocking only) and is still in progress. The program can issue Wait_For_Conversation to await the completion of the operation, or Cancel_Conversation to cancel the operation and conversation. If Specify_Windows_Handle has been called, the application should wait for notification by a Windows® message and not call **Wait_For_Conversation**.

CM_UNSUCCESSFUL

Primary return code; the receive type is set to CM_RECEIVE_IMMEDIATE and no data is immediately available from the partner program.

CM_DEALLOCATED_NORMAL

Primary return code; the conversation has been deallocated normally. The partner program issued Deallocate with the conversations deallocate type set to CM_DEALLOCATE_FLUSH or CM_DEALLOCATE_SYNC_LEVEL with the synchronization level of the conversation specified as CM_NONE.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *conversation_ID* is invalid.
- The value specified by *requested_length* is out of range (greater than 32767).

If the program receives this return code, the other returned parameters are not valid.

CM_PROGRAM_STATE_CHECK

Primary return code; one of the following occurred:

- The receive type is set to CM_RECEIVE_AND_WAIT and the conversation state is not RECEIVE, SEND, or SEND_PENDING.
- The receive type is set to CM_RECEIVE_IMMEDIATE and the conversation state is not RECEIVE.
- In a basic conversation, the conversation is in SEND state, the receive type is set to CM_RECEIVE_AND_WAIT, and the program did not finish sending a logical record.

If the program receives this return code, the other returned parameters are not valid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

CM_CONVERSATION_TYPE_MISMATCH

Primary return code; the partner logical unit (LU) or program does not support the conversation type (basic or mapped) specified in the allocation request.

CM_PIP_NOT_SPECIFIED_CORRECTLY

Primary return code; the allocation request was rejected by a non-CPI-C LU 6.2 transaction program (TP). The partner program requires one or more PIP data variables, which are not supported by CPI-C.

CM_SECURITY_NOT_VALID

Primary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

CM_SYNC_LEVEL_NOT_SUPPORTED_PGM

Primary return code; the partner program does not support the synchronization level specified in the allocation request.

CM_TPN_NOT_RECOGNIZED

Primary return code; the partner LU does not recognize the program name specified in the allocation request.

CM_TP_NOT_AVAILABLE_NO_RETRY

Primary return code; the partner LU cannot start the program specified in the allocation request because of a permanent condition. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

CM_TP_NOT_AVAILABLE_RETRY

Primary return code; the partner LU cannot start the program specified in the allocation request because of a temporary condition. The reason for the error may be logged on the remote node. Retry the allocation.

CM_PROGRAM_ERROR_NO_TRUNC

Primary return code; while in SEND state or in SEND_PENDING state with the error direction set to CM_SEND_ERROR, the partner program issued Send_Error. Data was not truncated.

CM_PROGRAM_ERROR_PURGING

Primary return code; one of the following occurred:

- While in RECEIVE or CONFIRM state, the partner program issued **Send_Error**. Data sent but not yet received is purged.
- While in SEND_PENDING state with the error direction set to CM_RECEIVE_ERROR, the partner program issued **Send_Error**. Data was not purged.

CM_RESOURCE_FAILURE_NO_RETRY

Primary return code; one of the following occurred:

- The conversation was terminated prematurely because of a permanent condition. Do not retry until the error has been corrected.
- The partner program did not deallocate the conversation before terminating normally.

CM_RESOURCE_FAILURE_RETRY

Primary return code; the conversation was terminated prematurely because of a temporary condition, such as modem failure. Retry the conversation.

CM_DEALLOCATED_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The remote program issued Deallocate with the type parameterset to CM_DEALLOCATE_ABEND, or the remote LU did so because of a remote program abnormal-ending condition. If the conversation for the remote program was in RECEIVE state when the call was issued, information sent by the local program and not yet received by the remote program is purged.
- The remote TP terminated normally but did not deallocate the conversation before terminating. Node services at the remote LU deallocated the conversation on behalf of the remote TP.

CM_DEALLOCATED_ABEND_SVC

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner program issued **Deallocate** with the type parameter set to ABEND_SVC.
- The partner program did not deallocate the conversation before terminating.

If the conversation is in RECEIVE state for the partner program when this call is issued by the local program, data sent by the local program and not yet received by the partner program is purged.

CM_DEALLOCATED_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner program issued **Deallocate** with the type parameter set to ABEND_TIMER. If the conversation is in RECEIVE state for the partner program when this call is issued by the local program, data sent by the local program and not yet received by the partner program is purged.

CM_SVC_ERROR_PURGING

Primary return code; while in SEND state, the partner program or partner LU issued Send_Error with the type parameter set to SVC. Data sent to the partner program may have been purged.

CM_SVC_ERROR_NO_TRUNC

Primary return code; while in SEND state, the partner program or partner LU issued **Send_Error** with the type parameter set to SVC. Data sent to the partner program may have been purged.

CM_PROGRAM_ERROR_TRUNC

Primary return code; in SEND state, before finishing sending a complete logical record, the partner program issued **Send_Error**. The local program may have received the first part of the logical record through a **Receive** call.

CM_SVC_ERROR_TRUNC

Primary return code; while in RECEIVE or CONFIRM state, the partner program or partner LU issued **Send_Error** with the type parameter set to SVC before it finished sending a complete logical record. The local program may have received the first part of the logical record.

State Changes

The conversation can be in RECEIVE, SEND, or SEND_PENDING state.

If *receive_type* is set to CM_RECEIVE_IMMEDIATE, the conversation must be in RECEIVE state.

Issuing **Receive** while the conversation is in SEND or SEND_PENDING state causes the local LU to send the information in its send buffer and a send indicator to the partner program. Based on *data_received* and *status_received* the conversation can change to RECEIVE state for the local program.

The new conversation state is determined by:

- The state the conversation is in when the program issues the call.
- The *return_code* parameter.
- The data_received and status_received parameters.

If no data is currently available and the receive type (set by Set_Receive_Type) is set to CM_RECEIVE_AND_WAIT, the local program waits for data to arrive. If the receive type is set to CM_RECEIVE_IMMEDIATE, the local program does not wait.

The process for receiving data is as follows:

- The local program issues a Receive call until it finishes receiving a complete unit of data. The local program may need to issue Receive several times to receive a complete unit of data. The *data_received* parameter indicates whether the receipt of data is finished.

  The data received can be:

  - One data record transmitted in a mapped conversation.
  - One logical record transmitted in a basic conversation with the conversations fill characteristic set to CM_FILL_LL.

- A buffer of data received independent of its logical-record format in a basic conversation with the fill characteristic set to CM_FILL_BUFFER.

When a complete unit of data has been received, the local program can manipulate it.

- The local program determines the next action to take based on the control information received through *status_received*. The local program may have to reissue **Receive** to receive the control information.

The conversation type is set by Set_Conversation_Type. The fill characteristic is set by Set_Fill.

The following table summarizes the state changes that can occur when **Receive** is issued with the conversation in RECEIVE state and *return_code* is CM_OK.

data_received	***status_received***	**New state**
CM_DATA_RECEIVED	CM_NO_STATUS_RECEIVED	No change
CM_COMPLETE_DATA_ RECEIVED	CM_NO_STATUS_RECEIVED	No change
CM_INCOMPLETE_DATA_ RECEIVED	CM_SEND_RECEIVED	SEND_PENDING
CM_NO_DATA_RECEIVED	CM_SEND_RECEIVED	SEND

If *return_code* is set to CM_UNSUCCESSFUL, meaning that the *receive_type* is set to CM_RECEIVE_IMMEDIATE and no data is available, there is no state change.

The following table summarizes the state changes that can occur when **Receive** is issued with the conversation in SEND state and *return_code* is CM_OK.

data_received	***status_received***	**New state**
CM_DATA_RECEIVED	CM_NO_STATUS_RECEIVED	RECEIVE
CM_COMPLETE_DATA_ RECEIVED	CM_NO_STATUS_RECEIVED	RECEIVE
CM_INCOMPLETE_DATA_ RECEIVED	CM_SEND_RECEIVED	SEND_PENDING
CM_NO_DATA_RECEIVED	CM_SEND_RECEIVED	No change

The following table summarizes the state changes that can occur when **Receive** is issued with the conversation in SEND_PENDING state and *return_code* is CM_OK.

data_received	***status_received***	**New state**
CM_DATA_RECEIVED	CM_NO_STATUS_RECEIVED	RECEIVE
CM_COMPLETE_DATA_ RECEIVED	CM_NO_STATUS_RECEIVED	RECEIVE
CM_INCOMPLETE_DATA_ RECEIVED	CM_SEND_RECEIVED	No change
CM_NO_DATA_RECEIVED	CM_SEND_RECEIVED	SEND

The following topics summarize state changes that can occur when **Receive** is issued in any allowed state.

In This Section

- Confirmation
- Normal Deallocation

- ABEND
- Errors

Confirmation

The following table summarizes state changes that occur under the following conditions:

- The return_code parameter is CM_OK.
- The *data_received* parameter is set to CM_DATA_RECEIVED, CM_COMPLETE_DATA_RECEIVED, or CM_NO_DATA_RECEIVED.
- The *status_received* parameter indicates a change to a CONFIRM state.

status_received	**New state**
CM_CONFIRM_DEALLOC_RECEIVED	CONFIRM_DEALLOCATE
CM_CONFIRM_SEND_RECEIVED	CONFIRM_SEND
CM_CONFIRM_RECEIVED	CONFIRM

Normal Deallocation

If *return_code* is set to CM_DEALLOCATED_NORMAL, the conversation changes to RESET state.

ABEND

The following ABEND conditions, indicated by *return_code*, cause the conversation to change to RESET state:

- CM_CONVERSATION_TYPE_MISMATCH
- CM_PIP_NOT_SPECIFIED_CORRECTLY
- CM_SECURITY_NOT_VALID
- CM_SYNC_LEVEL_NOT_SUPPORTED_PGM
- CM_TPN_NOT_RECOGNIZED
- CM_TP_NOT_AVAILABLE_NO_RETRY
- CM_TP_NOT_AVAILABLE_RETRY
- CM_DEALLOCATED_ABEND
- CM_DEALLOCATED_ABEND_SVC
- CM_DEALLOCATED_ABEND_TIMER
- CM_SVC_ERROR_TRUNC
- CM_RESOURCE_FAILURE_NO_RETRY
- CM_RESOURCE_FAILURE_RETRY

Errors

The following table summarizes state changes that occur when a data transmission error is encountered.

return_code	**Old state**	**New state**
CM_PROGRAM_ERROR_PURGING	RECEIVE	No change
CM_PROGRAM_ERROR_NO_TRUNC	RECEIVE	No change
CM_SVC_ERROR_PURGING	SEND	RECEIVE
CM_SVC_ERROR_NO_TRUNC	SEND_PENDING	RECEIVE

If the partner program truncates a logical record, the local program receives notification of the truncation through *return_code* on the next **Receive** call.

If a program issues **Receive** with *requested_length* set to zero, the call is executed as usual. However, *data_received* and *status_received* are not set on the same **Receive** call. (One exception to this situation is the null record sent over a mapped conversation, described in the next paragraph.)

In a mapped conversation in which data is available from the partner program, *data_received* is set to CM_INCOMPLETE_DATA_RECEIVED. If a null record is available (*send_length* in the Send_Data call issued by the partner program is set to zero), *data_received* is set to CM_COMPLETE_RECORD_RECEIVED with *received_length* set to zero.

In a basic conversation in which data is available and the fill characteristic is set to CM_FILL_LL, *data_received* is set to CM_INCOMPLETE_DATA_RECEIVED. If the fill characteristic is set to CM_FILL_BUFFER, *data_received* is set to CM_DATA_RECEIVED.

The logical unit (LU) does not automatically perform any conversion between EBCDIC and ASCII on the received string of data before putting it in *buffer*. If necessary, the program can use the Common Service Verb (CSV) CONVERT to translate a string from one character set to the other.

Request_To_Send

The **Request_To_Send** call (function name **cmrts**) notifies the partner program that the local program wants to send data.

Syntax

```
CM_ENTRY Request_To_Send(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_OPERATION_NOT_ACCEPTED

Primary return code; a previous operation on this conversation is incomplete.

CM_OPERATION_INCOMPLETE

Primary return code; the operation has not completed (processing mode is nonblocking only) and is still in progress. The program can issue Wait_For_Conversation to await the completion of the operation, or Cancel_Conversation to cancel the operation and conversation. If Specify_Windows_Handle has been called, the application should wait for notification by a Microsoft® Windows® message and not call **Wait_For_Conversation**.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid.

CM_PROGRAM_STATE_CHECK

Primary return code; the conversation is not in the RECEIVE, SEND, SEND_PENDING, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any of the following states: RECEIVE, SEND, SEND_PENDING, CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE.

There is no state change.

In response to this request, the partner program can change the conversation to RECEIVE state by issuing one of the following calls:

- Receive with receive type set to CM_RECEIVE_AND_WAIT
- Prepare_To_Receive
- **Send_Data** with send type set to CM_SEND_AND_PREP_TO_RECEIVE

The partner program can also ignore the request to send.

The conversation state changes to SEND for the local program when the local program receives one of the following values through the *status_received* parameter of a subsequent **Receive** call:

- CM_SEND_RECEIVED
- CM_CONFIRM_SEND_RECEIVED and the local program replies with a Confirmed call

Remarks

The request-to-send notification is received by the partner program through the *request_to_send_received* parameter of the following calls:

- Confirmed
- Receive
- Send_Data
- Send_Error
- Test_Request_To_Send_Received

Request-to-send notification is sent to the partner program immediately. CPI-C does not wait until the send buffer fills up or is flushed. Consequently, the request-to-send notification can arrive out of sequence. For example, if the local program is in SEND state and issues the Prepare_To_Receive call followed by the **Request_To_Send** call, the partner program, in RECEIVE state, can receive the request-to-send notification before it receives the send notification. For this reason, *request_to_send* can be reported to a program through the Receive call.

Upon receiving a request-to-send notification, the partner logical unit (LU) retains the notification until the partner issues a call that returns *request_to_send_received*. The LU keeps only one request-to-send notification per conversation. Thus the local program can issue more **Request_To_Send** calls than are explicitly handled by the partner transaction program (TP).

Send_Data

The **Send_Data** call (function name **cmsend**) puts data in the send buffer of the local logical unit (LU) for transmission to the partner program.

Syntax

```
CM_ENTRY Send_Data(
  unsigned char FAR *conversation_ID,
  unsigned char FAR *buffer,
    CM_INT32 FAR *send_length,
    CM_INT32 FAR *request_to_send_received,
    CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

buffer

Supplied parameter. Specifies the address of the buffer containing the data to be put in the local LUs send buffer.

send_length

Supplied parameter. Specifies the number of bytes of data to be put in the local LUs send buffer. The range is from 0 through 32767.

For a mapped conversation, if *send_length* is set to zero, a null data record is sent to the partner program.

For a basic conversation, if *send_length* is set to zero, no data is sent. The *buffer* parameter is not relevant. However, the other parameters are processed.

request_to_send_received

Returned parameter. It is the request-to-send-received indicator. Possible values are:

CM_REQ_TO_SEND_RECEIVED

The partner program issued the Request_To_Send call, which requests the local program to change the conversation to RECEIVE state.

CM_REQ_TO_SEND_NOT_RECEIVED

The partner program did not issue the **Request_To_Send** call. This value is not relevant if *return_code* is set to CM_PROGRAM_PARAMETER_CHECK or CM_PROGRAM_STATE_CHECK.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_OPERATION_NOT_ACCEPTED

Primary return code; a previous operation on this conversation is incomplete.

CM_OPERATION_INCOMPLETE

Primary return code; the operation has not completed (processing mode is nonblocking only) and is still in progress. The program can issue Wait_For_Conversation to await the completion of the operation, or Cancel_Conversation to cancel the operation and conversation. If Specify_Windows_Handle has been called, the application should wait for notification by a Microsoft® Windows® message and not call **Wait_For_Conversation**.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *conversation_ID* is invalid.
- The value specified by *send_length* is out of range (greater than 32767).
- This is a basic conversation and the first two bytes of *buffer* contain an invalid logical record length (0x0000, 0x0001, 0x8000, or 0x8001).

CM_PROGRAM_STATE_CHECK

Primary return code; one of the following occurred:

- The conversation state is not SEND or SEND_PENDING.
- The basic conversation is in SEND state and *send_type* is set to CM_SEND_AND_CONFIRM, CM_SEND_AND_DEALLOCATE, or CM_SEND_AND_PREP_TO_RECEIVE. However, the data does not end on a logical record boundary. This condition is allowed only when *deallocate_type* is set to CM_DEALLOCATE_ABEND and the *send_type* is set to CM_SEND_AND_DEALLOCATE.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

CM_CONVERSATION_TYPE_MISMATCH

Primary return code; the partner LU or program does not support the conversation type (basic or mapped) specified in the allocation request.

CM_PIP_NOT_SPECIFIED_CORRECTLY

Primary return code; the allocation request was rejected by a non-CPI-C LU 6.2 transaction program (TP). The partner program requires one or more PIP data variables, which are not supported by CPI-C.

CM_SECURITY_NOT_VALID

Primary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

CM_SYNC_LEVEL_NOT_SUPPORTED_PGM

Primary return code; the partner program does not support the synchronization level specified in the allocation request.

CM_TPN_NOT_RECOGNIZED

Primary return code; the partner LU does not recognize the program name specified in the allocation request.

CM_TP_NOT_AVAILABLE_NO_RETRY

Primary return code; the partner LU cannot start the program specified in the allocation request because of a permanent condition. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

CM_TP_NOT_AVAILABLE_RETRY

Primary return code; the partner LU cannot start the program specified in the allocation request because of a temporary condition. The reason for the error may be logged on the remote node. Retry the allocation.

CM_PROGRAM_ERROR_PURGING

Primary return code; one of the following occurred:

- While in RECEIVE or CONFIRM state, the partner program issued Send_Error. Data sent but not yet received is purged.
- While in SEND_PENDING state with the error direction set to CM_RECEIVE_ERROR, the partner program issued **Send_Error**. Data was not purged.

CM_RESOURCE_FAILURE_NO_RETRY

Primary return code; one of the following occurred:

- The conversation was terminated prematurely because of a permanent condition. Do not retry until the error has been corrected.
- The partner program did not deallocate the conversation before terminating normally.

CM_RESOURCE_FAILURE_RETRY

Primary return code; the conversation was terminated prematurely because of a temporary condition, such as modem failure. Retry the conversation.

CM_DEALLOCATED_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The remote program issued Deallocate with the type parameter set to CM_DEALLOCATE_ABEND, or the remote LU did so because of a remote program abnormal-ending condition. If the conversation for the remote program was in RECEIVE state when the call was issued, information sent by the local program and not yet received by the remote program is purged.
- The remote TP terminated normally but did not deallocate the conversation before terminating. Node services at the remote LU deallocated the conversation on behalf of the remote TP.

CM_DEALLOCATED_ABEND_SVC

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner program issued **Deallocate** with the type parameter set to ABEND_SVC.
- The partner program did not deallocate the conversation before terminating.

If the conversation is in RECEIVE state for the partner program when this call is issued by the local program, data sent by the local program and not yet received by the partner program is purged.

CM_DEALLOCATED_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner program issued **Deallocate** with the type parameter set to ABEND_TIMER. If the conversation is in RECEIVE state for the partner program when this call is issued by the local program, data sent by the local program and not yet received by the partner program is purged.

CM_SVC_ERROR_PURGING

Primary return code; while in SEND state, the partner program or partner LU issued Send_Error with the type parameter set to SVC. Data sent to the partner program may have been purged.

State Changes

The conversation must be in SEND or SEND_PENDING state when the program issues this call.

The following table summarizes state changes that are possible when *return_code* is set to CM_OK.

send_type	**Old state**	**New state**
CM_BUFFER_DATA	SEND	No change
CM_BUFFER_DATA	SEND_PENDING	SEND
CM_SEND_AND_FLUSH	SEND	No change
CM_SEND_AND_FLUSH	SEND_PENDING	SEND

CM_SEND_AND_CONFIRM	SEND	No change
CM_SEND_AND_CONFIRM	SEND_PENDING	SEND
CM_SEND_AND_PREP_TO_ RECEIVE	Not available	RECEIVE
CM_SEND_AND_DEALLOCATE	Not available	RESET

For a *return_code* value of CM_PROGRAM_ERROR_PURGING or CM_SVC_ERROR_PURGING, the conversation changes to RECEIVE state. For other non-CM_OK values, the conversation changes to RESET state.

Remarks

The data collected in the local LUs send buffer is transmitted to the partner LU and partner program when one of the following occurs:

- The send buffer fills up.
- The local program issues a Flush, Confirm, or Deallocate call or other call that flushes the LUs send buffer. (Some send types, set by Set_Send_Type, include flush functionality.)

The data to be sent can be either:

- A complete data record on a mapped conversation. A complete data record is a string of the length specified by the *send_length* parameter.
- A complete logical record or portion thereof on a basic conversation. A complete logical record is determined by the LL value. (One logical record can end and a new one begin in the middle of the string of data to be sent.)

The LU does not automatically perform any conversion between ASCII and EBCDIC on the string of data to be sent. If necessary, the program can use the Common Service Verb (CSV) CONVERT to translate a string from one character set to the other.

Send_Error

The **Send_Error** call (function name **cmserr**) notifies the partner program that the local program has encountered an application-level error.

Syntax

```
CM_ENTRY Send_Error(
  unsigned char FAR *conversation_ID,
    CM_INT32 FAR *request_to_send_received,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

request_to_send_received

Returned parameter. Specifies the request-to-send-received indicator. Possible values are:

CM_REQ_TO_SEND_RECEIVED

The partner program issued Request_To_Send, which requests the local program to change the conversation to RECEIVE state.

CM_REQ_TO_SEND_NOT_RECEIVED

The partner program did not issue **Request_To_Send**. This value is not relevant if *return_code* is set to CM_PROGRAM_PARAMETER_CHECK or CM_STATE_CHECK.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

The value of *return_code* varies depending on the conversation state when the call is issued.

SEND State

If the program issues the call with the conversation in SEND state, the following return codes are possible:

CM_OK

Primary return code; the call executed successfully.

CM_OPERATION_NOT_ACCEPTED

Primary return code; a previous operation on this conversation is incomplete.

CM_OPERATION_INCOMPLETE

Primary return code; the operation has not completed (processing mode is nonblocking only) and is still in progress. The program can issue Wait_For_Conversation to await the completion of the operation, or Cancel_Conversation to cancel the operation and conversation. If Specify_Windows_Handle has been called, the application should wait for notification by a Microsoft® Windows® message and not call **Wait_For_Conversation**.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

CM_CONVERSATION_TYPE_MISMATCH

Primary return code; the partner logical unit (LU) or program does not support the conversation type (basic or mapped) specified in the allocation request.

CM_PIP_NOT_SPECIFIED_CORRECTLY

Primary return code; the allocation request was rejected by a non-CPI-C LU 6.2 transaction program (TP). The partner program requires one or more PIP data variables, which are not supported by CPI-C.

CM_SECURITY_NOT_VALID

Primary return code; the user identifier or password specified in the allocation request was not accepted by the partner LU.

CM_SYNC LEVEL_NOT_SUPPORTED_PGM

Primary return code; the partner program does not support the synchronization level specified in the allocation request.

CM_TPN_NOT_RECOGNIZED

Primary return code; the partner LU does not recognize the program name specified in the allocation request.

CM_TP_NOT_AVAILABLE_NO_RETRY

Primary return code; the partner LU cannot start the program specified in the allocation request because of a permanent condition. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

CM_TP_NOT_AVAILABLE_RETRY

Primary return code; the partner LU cannot start the program specified in the allocation request because of a temporary condition. The reason for the error may be logged on the remote node. Retry the allocation.

CM_PROGRAM_ERROR_PURGING

Primary return code; one of the following occurred:

- While in RECEIVE or CONFIRM state, the partner program issued **Send_Error**. Data sent but not yet received is purged.
- While in SEND_PENDING state with the error direction set to CM_RECEIVE_ERROR, the partner program issued **Send_Error**. Data was not purged.

CM_RESOURCE_FAILURE_NO_RETRY

Primary return code; one of the following occurred:

- The conversation was terminated prematurely because of a permanent condition. Do not retry until the error has been corrected.
- The partner program did not deallocate the conversation before terminating normally.

CM_RESOURCE_FAILURE_RETRY

Primary return code; the conversation was terminated prematurely because of a temporary condition, such as modem failure. Retry the conversation.

CM_DEALLOCATED_ABEND

Primary return code; the conversation has been deallocated for one of the following reasons:

- The remote program issued Deallocate with the type parameterset to CM_DEALLOCATE_ABEND, or the remote LU has done so because of a remote program abnormal-ending condition. If the conversation for the remote program was in RECEIVE state when the call was issued, information sent by the local program and not yet received by the remote program is purged.
- The remote TP terminated normally but did not deallocate the conversation before terminating. Node services at the remote LU deallocated the conversation on behalf of the remote TP.

CM_DEALLOCATED_ABEND_SVC

Primary return code; the conversation has been deallocated for one of the following reasons:

- The partner program issued **Deallocate** with the type parameter set to ABEND_SVC.

- The partner program did not deallocate the conversation before terminating.

If the conversation is in RECEIVE state for the partner program when this call is issued by the local program, data sent by the local program and not yet received by the partner program is purged.

CM_DEALLOCATED_ABEND_TIMER

Primary return code; the conversation has been deallocated because the partner program issued **Deallocate** with the type parameter set to ABEND_TIMER. If the conversation is in RECEIVE state for the partner program when this call is issued by the local program, data sent by the local program and not yet received by the partner program is purged.

CM_SVC_ERROR_PURGING

Primary return code; while in SEND state, the partner program or partner LU issued **Send_Error** with the type parameter set to SVC. Data sent to the partner program may have been purged.

RECEIVE State

If the call is issued in RECEIVE state, the following return codes are possible:

CM_OK

Primary return code; because incoming information is purged when the **Send_Error** call is issued in RECEIVE state, CM_OK is generated instead of the following:

- CM_PROGRAM_ERROR_NO_TRUNC
- CM_PROGRAM_ERROR_PURGING
- CM_SVC_ERROR_NO_TRUNC
- CM_SVC_ERROR_PURGING
- CM_PROGRAM_ERROR_TRUNC
- CM_SVC_ERROR_TRUNC (basic conversation only)
- CM_PRODUCT_SPECIFIC_ERROR
- CM_RESOURCE_FAILURE_NO_RETRY
- CM_RESOURCE_FAILURE_RETRY

For an explanation of these return codes, see CPI-C Common Return Codes.

CM_DEALLOCATED_NORMAL

Primary return code; because incoming information is purged when **Send_Error** is issued in RECEIVE state, CM_DEALLOCATED_NORMAL is generated instead of the following:

- CM_CONVERSATION_TYPE_MISMATCH
- CM_PIP_NOT_SPECIFIED_CORRECTLY
- CM_SECURITY_NOT_VALID
- CM_SYNC_LEVEL_NOT_SUPPORTED_PGM
- CM_TPN_NOT_RECOGNIZED
- CM_TP_NOT_AVAILABLE_NO_RETRY

- CM_TP_NOT_AVAILABLE_RETRY
- CM_DEALLOCATED_ABEND
- CM_DEALLOCATED_ABEND_SVC
- CM_DEALLOCATED_ABEND_TIMER

SEND_PENDING State

If the call is issued in SEND_PENDING state, the following return codes are possible:

- CM_OK (Primary return code; the call executed successfully.)
- CM_PRODUCT_SPECIFIC_ERROR
- CM_PROGRAM_ERROR_PURGING
- CM_RESOURCE_FAILURE_NO_RETRY
- CM_RESOURCE_FAILURE_RETRY
- CM_DEALLOCATED_ABEND
- CM_DEALLOCATED_ABEND_SVC
- CM_DEALLOCATED_ABEND_TIMER
- CM_SVC_ERROR_PURGING

For an explanation of these return codes, see CPI-C Common Return Codes.

CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE State

If the call is issued in CONFIRM, CONFIRM_SEND, or CONFIRM_DEALLOCATE state, the following return codes are possible:

- CM_OK (Primary return code; the call executed successfully.)
- CM_PRODUCT_SPECIFIC_ERROR
- CM_RESOURCE_FAILURE_NO_RETRY
- CM_RESOURCE_FAILURE_RETRY

For an explanation of these return codes, see CPI-C Common Return Codes.

Other States

Issuing **Send_Error** with the conversation in RESET or INITIALIZE state is illegal. The following return codes are possible:

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid.

CM_PROGRAM_STATE_CHECK

Primary return code; the conversation state is not SEND, RECEIVE, CONFIRM, CONFIRM_SEND, CONFIRM_DEALLOCATE, or SEND_PENDING.

State Changes

The conversation can be in any state except INITIALIZE or RESET.

State changes, summarized in the following table, are based on the value of the *return_code* parameter.

return_code	**New state**
CM_OK	SEND
CM_CONVERSATION_TYPE_MISMATCH	RESET
CM_PIP_NOT_SPECIFIED_CORRECTLY	RESET
CM_SECURITY_NOT_VALID	RESET
CM_SYNC_LEVEL_NOT_SUPPORTED_PGM	RESET
CM_TPN_NOT_RECOGNIZED	RESET
CM_TP_NOT_AVAILABLE_NO_RETRY	RESET
CM_TP_NOT_AVAILABLE_RETRY	RESET
CM_RESOURCE_FAILURE_RETRY	RESET
CM_RESOURCE_FAILURE_NO_RETRY	RESET
CM_DEALLOCATED_ABEND	RESET
CM_DEALLOCATED_ABEND_PROG	RESET
CM_DEALLOCATED_ABEND_SVC	RESET
CM_DEALLOCATED_ABEND_TIMER	RESET
CM_DEALLOCATED_NORMAL	RESET
CM_PROGRAM_ERROR_PURGING	RECEIVE
CM_SVC_ERROR_PURGING	RECEIVE
All others	No change

Upon successful execution of this call, the conversation is in SEND state for the local program and in RECEIVE state for the partner program.

In a basic conversation, the local program can use Set_Log_Data to specify that error log data be sent to the partner LU and added to the local error log. If the conversations log data length characteristic is greater than zero, the LU formats the data and stores it in the send buffer.

After **Send_Error** is completed, the log data length is set to zero and the log data to null.

If the conversation is in RECEIVE state when the program issues **Send_Error**, incoming data is purged by CPI-C. This data includes:

- Data sent by Send_Data.
- Confirmation requests.
- Deallocation requests if the conversations deallocate type is set to CM_DEALLOCATE_CONFIRM or to

CM_DEALLOCATE_SYNC_LEVEL with the synchronization level set to CM_CONFIRM.

CPI-C does notpurge an incoming request-to-send indicator.

If the conversation is in SEND_PENDING state, the local program can issue Set_Error_Direction to specify whether the error being reported resulted from the received data or from the processing of the local program after successfully receiving the data.

Remarks

The local program can use **Send_Error** for such purposes as informing the partner program of an error encountered in received data, rejecting a confirmation request, or truncating an incomplete logical record it is sending.

Send_Error flushes the local LUs send buffer and sends the partner program the contents of the send buffer followed by the error notification.

The error notification is sent to the partner as one of the following *return_code* values:

- CM_PROGRAM_ERROR_TRUNC
- CM_PROGRAM_ERROR_NO_TRUNC
- CM_PROGRAM_ERROR_PURGING

Set_Conversation_Security_Password

The **Set_Conversation_Security_Password** call (function name **cmscsp**) is issued by the invoking program to specify the password required to gain access to the invoked program.

Syntax

```
CM_ENTRY Set_Conversation_Security_Password(
  unsigned char FAR *conversation_ID,
  unsigned char FAR *security_password,
  CM_INT32 FAR *security_password_length,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation.

security_password

Supplied parameter. Specifies the password required to gain access to the partner program. This parameter is a character string of up to eight ASCII characters and is case-sensitive. It must match the password for the user identifier configured for the partner program.

The allowed characters are:

- Uppercase and lowercase letters.
- Numerals from 0 through 9.
- Special characters, except the space.

If the CPI-C automatic logon feature is to be used, this parameter must be set to the MS$SAME string. For details, see the Remarks section later in this topic.

security_password_length

Supplied parameter. Specifies the length of *security_password*. The range is from 0 through 8.

If the CPI-C automatic logon feature is to be used, this parameter must be set to 7. For details, see the Remarks section later in this topic.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *conversation_ID* is invalid.
- The value specified by *security_password_length* is out of range.

CM_PROGRAM_STATE_CHECK

Primary return code; one of the following occurred:

- The conversation is not in INITIALIZE state.
- The conversations security type is not set to CM_SECURITY_PROGRAM.

State Changes

The conversation must be in INITIALIZE state.

There is no state change.

Remarks

This call has an effect on the conversation only if the conversation security type is CM_SECURITY_PROGRAM or CM_SECURITY_SAME. It overrides the initial password from the side information specified by Initialize_Conversation. This call cannot be issued after Allocate has been issued.

An invalid password is not detected until the allocation request, generated by **Allocate**, is sent to the partner logical unit (LU). The error is returned to the invoking program on a subsequent call.

Automatic logon for CPI-C applications is supported by Host Integration Server 2009. This feature requires specific configuration by the network administrator: The CPI-C application must be invoked on the LAN side from a client of SNA Server. The client must be logged into a Microsoft Windows Server 2003 or Windows 2000 domain, but can be any platform that supports Host Integration Server CPI-C APIs.

The client application is coded to use program level security, with a special hard-coded CPI-C user name MS$SAME and password MS$SAME. When this session allocation flows from client to SNA Server, the SNA Server looks up the host account and password corresponding to the Windows Server 2003 or Windows 2000 account under which the client is logged in, and substitutes the host account information into the APPC attach message it sends to the host.

Set_Conversation_Security_Type

The **Set_Conversation_Security_Type** call (function name **cmscst**) is issued by the invoking program to specify the information the partner logical unit (LU) requires to validate access to the invoked program.

Syntax

```
CM_ENTRY Set_Conversation_Security_Type(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *conversation_security_type,
    CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation.

conversation_security_type

Supplied parameter. Specifies the information the partner LU requires to validate access to the invoked program. Based on the conversation security established for the invoked program during configuration, use one of the following values:

CM_SECURITY_NONE

To indicate that the invoked program uses no conversation security.

CM_SECURITY_PROGRAM

To indicate that the invoked program uses conversation security and thus requires a user identifier and password.

CM_SECURITY_SAME

To indicate that the user ID is sent on the allocate request to node services in the partner LU. This setting is also used to specify that the invoked program, invoked with a valid user identifier and password, in turn invokes another program (as illustrated in Communication Between TPs). For example, assume that program A invokes program B with a valid user identifier and password, and program B in turn invokes program C. If program B specifies the value CM_SECURITY_SAME, CPI-C will send the LU for program C, the user identifier from program A, and an already-verified indicator. This indicator tells program C not to require the password (if program C is configured to accept an already-verified indicator).

When CM_SECURITY_SAME is used, your application must always call Set_Conversation_Security_User_ID and Set_Conversation_Security_Password to provide values for the *security_user_ID* and *security_password* parameters. Depending on the properties negotiated between SNA Server and the peer LU, the **Allocate** function will send one of 3 kinds of Attach (FMH-5) messages, in this order of precedence:

1. If the LUs have negotiated already verified security, the Attach sent by SNA Server will not include the contents of the security_password parameter field specified by Set_Conversation_Security_Password.

2. If the LUs have negotiated persistent verification security, the Attach sent by SNA Server will include the security_password parameter specified by Set_Conversation_Security_Password, but only when the Attach is the first for the specified security_user_ID parameter set by Set_Conversation_Security_User_ID since the start of the LU-LU session, and will omit the security_password parameter on all subsequent Attaches (issued by your application or any other application using this LU-LU-mode triplet).

3. Your application cannot tell which mode of security has been negotiated between the LUs, nor can it tell whether the **Allocate** function it is issuing is the first for that LU-LU-mode triplet. So your application must always call Set_Conversation_Security_User_ID and Set_Conversation_Security_Password to set the security_user_ID and security_password parameters when conversation_security_type is set to CM_SECURITY_SAME.

For more information on persistent verification and already verified security, see the SNA Formats Guide, section "FM Header 5: Attach (LU 6.2)."

If the CPI-C automatic logon feature is to be used, this parameter must be set to CM_SECURITY_PROGRAM. For details, see the Remarks section later in this topic.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_STATE_CHECK

Primary return code; the conversation is not in INITIALIZE state.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* or *conversation_security_type* is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation must be in INITIALIZE state.

There is no state change.

Remarks

This call overrides the initial security type from the side information specified by Initialize_Conversation. This call cannot be issued after Allocate has been issued.

If the conversation security type is set to CM_SECURITY_NONE, the user identifier and password are ignored when the conversation is allocated.

A conversation security type of CM_SECURITY_SAME is intended for use between nodes which have the same set of user IDs and which accept user validation performed on one node as validating the user for all nodes. A password is not used in this case except for the initial validation of the user ID.

Automatic logon for CPI-C applications is supported by Host Integration Server 2009. This feature requires specific configuration by the network administrator. The CPI-C application must be invoked on the LAN side from a client of SNA Server. The client must be logged into a Microsoft Windows Server 2003 or Windows 2000 domain, but can be any platform that supports SNA Server CPI-C APIs.

The client application is coded to use program level security, with a special hard-coded CPI-C user name MS$SAME and password MS$SAME. When this session allocation flows from client to SNA Server, the SNA Server looks up the host account and password corresponding to the Windows Server 2003 or Windows 2000 account under which the client is logged on, and substitutes the host account information into the APPC attach message it sends to the host.

Set_Conversation_Security_User_ID

The **Set_Conversation_Security_User_ID** call (function name **cmscsu**) is issued by the invoking program to specify the user identifier required to gain access to the invoked program.

Syntax

```
CM_ENTRY Set_Conversation_Security_User_ID(
  unsigned char FAR *conversation_ID,
  unsigned char FAR *security_user_ID,
  CM_INT32 FAR *security_user_ID_length,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation.

security_user_ID

Supplied parameter. Specifies the user identifier required to gain access to the partner program. This parameter is a character string of up to eight ASCII characters and is case-sensitive.

The allowed characters are:

- Uppercase and lowercase letters.
- Numerals from 0 through 9.
- Special characters, except the space.

If the CPI-C automatic logon feature is to be used, this parameter must be set to the MS$SAME string. For details, see the Remarks section later in this topic.

security_user_ID_length

Supplied parameter. Specifies the length of *security_user_ID*. The range is from 0 through 8.

If the CPI-C automatic logon feature is to be used, this parameter must be set to 7. For details, see the Remarks section later in this topic.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *conversation_ID* is invalid.
- The value specified by *security_user_ID_length* is out of range.

CM_PROGRAM_STATE_CHECK

Primary return code; one of the following occurred:

- The conversation is not in INITIALIZE state.

- The conversations security type is not set to CM_SECURITY_PROGRAM.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation must be in INITIALIZE state.

There is no state change.

Remarks

This call has an effect on the conversation only if the conversation security type is CM_SECURITY_PROGRAM or CM_SECURITY_SAME. It overrides the initial user identifier from the side information specified by Initialize_Conversation. This call cannot be issued after Allocate has been issued.

An invalid user identifier is not detected until the allocation request, generated by **Allocate**, is sent to the partner logical unit (LU). The error is returned to the invoking program on a subsequent call.

Automatic logon for CPI-C applications is supported by Host Integration Server 2009. This feature requires specific configuration by the network administrator. The CPI-C application must be invoked on the LAN side from a client of SNA Server. The client must be logged into a Microsoft Windows Server 2003 or Windows 2000 domain, but can be any platform that supports SNA Server CPI-C APIs.

The client application is coded to use program level security, with a special hard-coded CPI-C user name MS$SAME and password MS$SAME. When this session allocation flows from client to SNA Server, the SNA Server looks up the host account and password corresponding to the Windows Server 2003 or Windows 2000 account under which the client is logged on, and substitutes the host account information into the APPC attach message it sends to the host.

Set_Conversation_Type

The **Set_Conversation_Type** call (function name **cmsct**) is issued by the invoking program to define a conversation as being mapped or basic. This call overrides the default conversation type established by Initialize_Conversation. The default conversation type is CM_MAPPED_CONVERSATION. This call cannot be issued after Allocate has been issued.

Syntax

```
CM_ENTRY Set_Conversation_Type(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *conversation_type,
    CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation.

conversation_type

Supplied parameter. Specifies the type of conversation to be allocated by **Allocate**. Possible values are:

- CM_BASIC_CONVERSATION
- CM_MAPPED_CONVERSATION

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_STATE_CHECK

Primary return code; the conversation is not in INITIALIZE state.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *conversation_ID* or *conversation_type* is invalid.
- The *conversation_type* parameter specifies a mapped conversation, but the fill characteristic is set to CM_FILL_BUFFER, which is incompatible with mapped conversations. Before changing the conversation type to mapped, you must issue the Set_Fill call to change the fill type to CM_FILL_LL.
- The *conversation_type* parameter specifies a mapped conversation. However, a previous Set_Log_Data call, allowed only in basic conversations, is still in effect.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation must be in INITIALIZE state.

There is no state change.

Set_CPIC_Side_Information

The **Set_CPIC_Side_Information** call (function name **xcmssi**) adds or replaces a side information entry in memory. A CPI-C side information entry associates a set of conversation characteristics with a symbolic definition name. This call overrides entries having the same symbolic destination name.

Syntax

```
CM_ENTRY Set_CPIC_Side_Information(
  unsigned char FAR *key_lock,
  SIDE_INFO FAR *side_info_entry,
  CM_INT32 FAR *side_info_entry_length,
  CM_INT32 FAR *return_code
);
```

Parameters

key_lock

Supplied parameter. This parameter is ignored.

side_info_entry

Supplied parameter. Specifies the contents of a side information entry. The following table describes the *side_info_entry* structure, which defines the format of the side information entry.

Offset	Description	Type	Length
0	*sym_dest_name*	unsigned char	8 bytes
8	*partner_LU_name*	unsigned char	17 bytes
25	*reserved*	unsigned char	3 bytes
28	*TP_name_type*	signed long int	32 bits
32	*TP_name*	unsigned char	64 bytes
96	*mode_name*	unsigned char	8 bytes
104	*conversation_ security_type*	signed long int	32 bits
108	*security_user_ID*	unsigned char	8 bytes
116	*security_password*	unsigned char	8 bytes

The allowed characters for *sym_dest_name* are the uppercase letters (A through Z) and the numerals from 0 through 9.

Set_CPIC_Side_Information is the only CPI-C call that lets you specify an SNA service transaction program (TP) as the partner program. The SNA convention for naming a service TP is up to four characters. The first character is a hexadecimal byte between 0x00 and 0x3F. The remaining characters are translated from ASCII to EBCDIC.

For the allowed characters for the other fields, see the description of the corresponding **Set_** call. For example, for the *mode_name* field, see the description of the Set_Mode_Name call.

Each field in the structure must be left-aligned. Pad fields on the right with spaces as necessary.

side_info_entry_length

Supplied parameter. Specifies the length of *side_info_entry*. It is always 124.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- A value specified in the *side_info_entry* structure is invalid.
- The left character of the *side_info_entry* contains a space.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state.

There is no state change.

Remarks

Invalid string parameters in the side information (for example, specifying a nonexistent partner logical unit (LU)) are not detected until Allocate is issued. The error is returned on a call following **Allocate**.

Set_Deallocate_Type

The **Set_Deallocate_Type** call (function name **cmsdt**) specifies how the conversation is to be deallocated.

Syntax

```
CM_ENTRY Set_Deallocate_Type(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *deallocate_type,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

deallocate_type

Supplied parameter. Specifies how to perform the deallocation. Possible values are:

CM_DEALLOCATE_ABEND

Indicates that the conversation is to be deallocated abnormally and unconditionally. A program should specify CM_DEALLOCATE_ABEND when it encounters an error preventing the successful completion of a transaction.

If the conversation is in SEND state, CPI-C sends the contents of the send buffer of the local logical unit (LU) to the partner program before deallocating the conversation. If the conversation is in RECEIVE state, incoming data can be purged. For a basic conversation in SEND state, logical record truncation can occur.

CM_DEALLOCATE_CONFIRM

Used to send the partner program the contents of the local LUs send buffer and a request to confirm the deallocation.

This request for deallocation confirmation is sent by Deallocate or by Send_Data with the send type set to CM_SEND_AND_DEALLOCATE. The conversation is deallocated normally when the partner program issues Confirmed, responding to the confirmation request.

CM_DEALLOCATE_FLUSH

Used to send the contents of the local LUs send buffer to the partner program before deallocating the conversation normally.

CM_DEALLOCATE_SYNC_LEVEL

Uses the conversations synchronization level to determine how to deallocate the conversation. A default synchronization level is established by Initialize_Conversation and can be overridden by Set_Sync_Level.

If the synchronization level of the conversation is CM_NONE, the default, the contents of the local LUs send buffer are sent to the partner program and the conversation is deallocated normally.

If the synchronization level of the conversation is CM_CONFIRM, the contents of the local LUs send buffer and a request to confirm the deallocation are sent to the partner program. This request for deallocation confirmation is sent by Deallocate or by Send_Data with the send type set to CM_SEND_AND_DEALLOCATE. The conversation is deallocated normally when the partner program issues the Confirmed call, responding to the confirmation request.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *conversation_ID* or *deallocate_type* is invalid.
- The *deallocate_type* parameter specifies CM_DEALLOCATE_CONFIRM, but the conversations synchronization level is set to CM_NONE.
- The address of a variable is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Remarks

This call overrides the default deallocate type established by Initialize_Conversation or Accept_Conversation. The default deallocate type is CM_DEALLOCATE_SYNC_LEVEL.

The deallocation instructions specified by this call take effect when Deallocate is issued or when the send type is set to CM_SEND_AND_DEALLOCATE and Send_Data is issued.

You can set *deallocate_type* to CM_FLUSH if the synchronization level of the conversation is set to CM_NONE or CM_CONFIRM.

The value CM_DEALLOCATE_FLUSH is functionally the same as CM_DEALLOCATE_SYNC_LEVEL with the conversations synchronization level set to CM_NONE.

The value CM_DEALLOCATE_CONFIRM is functionally the same as CM_DEALLOCATE_SYNC_LEVEL with the conversations synchronization level set to CM_CONFIRM.

Set_Error_Direction

The **Set_Error_Direction** call (function name **cmsed**) specifies whether a program detected an error while receiving data or while preparing to send data.

Syntax

```
CM_ENTRY Set_Error_Direction(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *error_direction,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

error_direction

Supplied parameter. Specifies the direction in which data was flowing when the program encountered an error. Possible values are:

- CM_RECEIVE_ERROR

  An error occurred in the data received from the partner program.

- CM_SEND_ERROR

  An error occurred while the local program prepared to send data to the partner program.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* or *error_direction* is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Remarks

This call overrides the default error direction established by Initialize_Conversation or Accept_Conversation. The default error direction is CM_RECEIVE_ERROR.

Error direction is relevant only when a program issues Send_Error in SEND_PENDING state, immediately after issuing Receiveand receiving data (*data_received* is a value other than CM_NO_DATA_RECEIVED) and a send indicator (*status_received* is CM_SEND_RECEIVED).

When the conversation is in SEND_PENDING state, the program issues **Send_Error** if it detects errors in the received data or if an error occurred while the local program prepared to send data. The program must supply the error direction information

using **Set_Error_Direction** before issuing **Send_Error** because the logical unit (LU) cannot tell which kind of error occurred (receive or send). The new error direction remains in effect until a subsequent **Set_Error_Direction** changes it.

When **Send_Error** is issued, the partner program receives one of the following return codes:

- CM_PROGRAM_ERROR_PURGING if *error_direction* is set to CM_RECEIVE_ERROR
- CM_PROGRAM_ERROR_NO_TRUNC if *error_direction* is set to CM_SEND_ERROR

Set_Fill

The **Set_Fill** call (function name **cmsf**) specifies whether programs will receive data in the form of logical records or as a specified length of data. This call is allowed only in basic conversations.

Syntax

```
CM_ENTRY Set_Fill(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *fill,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

fill

Supplied parameter. Specifies the form in which programs will receive data. The following are possible choices:

CM_FILL_BUFFER

The local program receives data until the number of bytes specified by the *requested_length* parameter of the **Receive** call is reached or until the end of the data. Data is received without regard for the logical-record format.

CM_FILL_LL

Data is received in logical-record format. The data received can be a complete logical record, a portion of a logical record equal to the *requested_length* parameter of the Receive call, or the end of a logical record.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *conversation_ID* or *fill* is invalid.
- The current conversation is mapped.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Remarks

Set_Fill overrides the default *fill* established by Initialize_Conversation or Accept_Conversation. The default *fill* is CM_FILL_LL.

The *fill* value affects all subsequent Receive calls. It can be changed by reissuing the **Set_Fill** call.

Set_Log_Data

The **Set_Log_Data** call (function name **cmsld**) specifies a log message (log data) and its length to be sent to the partner logical unit (LU). This call is allowed only in basic conversations. It overrides the default log data, which is null, and the default log data length, which is zero.

Syntax

```
CM_ENTRY Set_Log_Data(
  unsigned char FAR *conversation_ID,
  unsigned char FAR *log_data,
  CM_INT32 FAR *log_data_length,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

log_data

Supplied parameter. Specifies the starting address of the data to be sent to the partner LU. It can contain up to 512 ASCII characters. The allowed characters are:

- Uppercase and lowercase letters.
- Numerals from 0 through 9.
- Special characters.
- The space.

log_data_length

Supplied parameter. Specifies the length of the log data. The range is from 0 through 512 bytes.

A length of 0 indicates that there is no log data, and the *log_data* parameter is ignored.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *conversation_ID* is invalid.
- The conversation type is set to mapped.
- The value specified by *log_data_length* is out of range (greater than 512 or less than 0).

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Remarks

The log data specified by **Set_Log_Data** is sent to the partner LU when the local program issues one of the following calls:

- Send_Error
- Deallocate with the conversations deallocate type set to CM_DEALLOCATE_ABEND
- Send_Data with the conversations send type set to CM_SEND_AND_DEALLOCATE and the deallocate type set to CM_DEALLOCATE_ABEND

After sending the log data to the partner LU, the local LU resets the log data to null and the log data length to zero.

CPI-C automatically converts the log data from ASCII to other encoding standards, such as EBCDIC, as required.

Set_Mode_Name

The **Set_Mode_Name** call (function name **cmsmn**) is issued by the invoking program to specify the mode name for a conversation. This call overrides the system-defined mode name derived from the side information when the Initialize_Conversation call was issued. This call cannot be issued after Allocatehas been issued. Issuing this call has no effect on the side information itself.

Syntax

```
CM_ENTRY Set_Mode_Name(
  unsigned char FAR *conversation_ID,
  unsigned char FAR *mode_name,
  CM_INT32 FAR *mode_name_length,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation.

mode_name

Supplied parameter. Specifies the starting address of the mode name (the name of a set of networking characteristics defined during configuration). The mode name can contain up to eight ASCII characters. The allowed characters are:

- Uppercase letters.
- Numerals from 0 through 9.

The value of *mode_name* must match the name of a mode associated with the partner logical unit (LU) during configuration. The mode name cannot be SNASVCMG or CPSVCMG.

mode_name_length

Supplied parameter. Specifies the length of the mode name. The range is from 0 through 8 bytes.

If *mode_name_length* is set to zero, **Set_Mode_Name** is ignored.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_STATE_CHECK

Primary return code; the conversation is not in INITIALIZE state.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *conversation_ID* is invalid.
- The value specified by *mode_name_length* is out of range (greater than 8 or less than 0).

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation must be in INITIALIZE state.

There is no state change.

Remarks

Specifying an invalid value for *mode_name* is not detected until Allocate is issued.

Set_Partner_LU_Name

The **Set_Partner_LU_Name** call (function name **cmspln**) is issued by the invoking program to specify the partner logical unit (LU) name. This call overrides the partner LU name derived from the side information when the Initialize_Conversation call was issued. This call cannot be issued after Allocate has been issued. Issuing this call has no effect on the side information itself.

Syntax

```
CM_ENTRY Set_Partner_LU_Name(
  unsigned char FAR *conversation_ID,
    unsigned char FAR *partner_LU_name,
  CM_INT32 FAR *partner_LU_name_length,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation.

partner_LU_name

Supplied parameter. Specifies the starting address of the partner LU name. The mode name can contain up to 17 ASCII characters. The allowed characters are:

- Uppercase letters.
- Numerals from 0 through 9.

The partner LU name can be either:

- An alias consisting of one through eight characters.
- A fully qualified network name consisting of from 2 through 17 characters. A period separates the network identifier (which can be from zero through eight characters) from the network LU name (which can be from one through eight characters). If the network identifier is zero characters long, the period is still required.

The partner LU name must match the name of a partner LU established during configuration.

partner_LU_name_length

Supplied parameter. Specifies the length of the partner LU name. The range is from 1 through 17.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_STATE_CHECK

Primary return code; the conversation is not in INITIALIZE state.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *conversation_ID* is invalid.
- The value specified by *partner_LU_name_length* is out of range (greater than 17 or less than 1).

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation must be in INITIALIZE state.

There is no state change.

Remarks

Specifying an invalid value for *partner_LU_name* is not detected until Allocate is issued.

Set_Prepare_To_Receive_Type

The **Set_Prepare_To_Receive_Type** call (function name **cmsptr**) specifies how the subsequent Prepare_To_Receive calls will be executed. It overrides the default prepare-to-receive processing established by Initialize_Conversation or Accept_Conversation. By default, the prepare-to-receive processing is based on the synchronization level of the conversation.

The prepare-to-receive type affects all subsequent **Prepare_To_Receive** calls. It can be changed by reissuing **Set_Prepare_To_Receive_Type**.

Syntax

```
CM_ENTRY Set_Prepare_To_Receive_Type(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *prepare_to_receive_type,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

prepare_to_receive_type

Supplied parameter. Specifies how subsequent Prepare_To_Receive calls will be executed. Possible values are:

CM_PREP_TO_RECEIVE_CONFIRM

Used to send the partner program the contents of the send buffer of the logical unit (LU) and a confirmation request. Upon receipt of confirmation, the conversation changes to RECEIVE state.

CM_PREP_TO_RECEIVE_FLUSH

Used to send the partner program the contents of the local LUs send buffer and changes the conversation to RECEIVE state.

CM_PREP_TO_RECEIVE_SYNC_LEVEL

Used by the conversations synchronization level to determine prepare-to-receive processing. A default synchronization level is established by Initialize_Conversation and can be overridden by Set_Sync_Level.

If the synchronization level of the conversation is CM_NONE, the default, the contents of the local LUs send buffer are sent to the partner program and the conversation changes to RECEIVE state. If the synchronization level of the conversation is CM_CONFIRM, the contents of the local LUs send buffer and a request for confirmation are sent to the partner program. The conversation changes to RECEIVE state when the partner program issues Confirmed, responding to the confirmation request.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *prepare_to_receive_type* or *conversation_ID* is invalid.
- The *prepare_to_receive_type* parameter is set to CM_PREP_TO_RECEIVE_CONFIRM, but the conversations synchronization level is set to CM_NONE.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Set_Processing_Mode

The **Set_Processing_Mode** call (function name **cmspm**) specifies for the conversation whether subsequent calls will be returned when the operation they have requested is complete (blocking) or immediately after the operation is initiated (nonblocking).

Note

A program is notified of the completion of nonblocking calls when it issues Wait_For_Conversation or through a Microsoft® Windows® message sent to a WndProc identified by the *hWnd* in the Specify_Windows_Handle call.

Syntax

```
CM_ENTRY Set_Processing_Mode(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *receive_type,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

receive_type

Supplied parameter. Specifies whether subsequent calls on the conversation will be blocking or nonblocking. Possible values are:

CM_BLOCKING

Subsequent calls will return only when the operation is complete.

CM_NON_BLOCKING

Subsequent calls will return immediately after the operation has been initiated.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_STATE_CHECK

Primary return code; the previous incomplete operation on the conversation has not yet completed.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* or *processing_mode* is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Set_Receive_Type

The **Set_Receive_Type** call (function name **cmsrt**) specifies how the program will receive data on subsequent Receive calls. It overrides the default receive type established by the Initialize_Conversation or Accept_Conversation call. By default, the program waits for data to arrive if it is not available when the **Receive** call is issued.

The receive type value affects all subsequent **Receive** calls. It can be changed by reissuing **Set_Receive_Type**.

Syntax

```
CM_ENTRY Set_Receive_Type(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *receive_type,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

receive_type

Supplied parameter. Specifies how data is to be received by the program on the subsequent Receive calls. Possible values are:

CM_RECEIVE_AND_WAIT

The local program receives any data currently available from the partner program. If no data is available, the local program waits for data to arrive.

CM_RECEIVE_IMMEDIATE

The local program receives any data currently available from the partner program. If no data is available, the local program does not wait.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* or *receive_type* is invalid, or the address of a variable is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Set_Return_Control

The **Set_Return_Control** call (function name **cmsrc**) is issued by the invoking program to specify when the local logical unit (LU), acting on the session request from the local programs Allocate call, should return control to the local program.

Syntax

```
CM_ENTRY Set_Return_Control(
  unsigned char FAR *conversation_ID,
    CM_INT32 FAR *return_control,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation.

return_control

Supplied parameter. Specifies when the local LU, acting on the Allocate call, should return control to the local program. The following are allowed values:

CM_IMMEDIATE

The LU allocates a contention-winner session, if one is immediately available, and returns control to the program.

CM_WHEN_SESSION_ALLOCATED

The LU does not return control to the program until it allocates a session or encounters errors. If a session is not available, the program waits for one. (If the session limit is zero, the LU returns control immediately.)

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_STATE_CHECK

Primary return code; the conversation is not in INITIALIZE state.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* or *return_control* is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation must be in INITIALIZE state.

There is no state change.

Remarks

This call overrides the default return control established by Initialize_Conversation. By default, control is returned when the session is allocated. This call cannot be issued after the Allocate call has been issued.

For further information about sessions, see Writing CPI-C Applications.

If the LU is unable to allocate a session, the notification is returned on the **Allocate** call.

Set_Send_Type

The **Set_Send_Type** call (function name **cmsst**) specifies how data will be sent by the next Send_Data call. It overrides the default send type established by Initialize_Conversation or Accept_Conversation. The default send type is CM_BUFFER_DATA, indicating that data only (and no control information) is to be sent.

The *send_type* value affects all subsequent **Send_Data** calls. It can be changed by reissuing **Set_Send_Type**.

Syntax

```
CM_ENTRY Set_Send_Type(
  unsigned char FAR *conversation_ID,
    CM_INT32 FAR *send_type,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

send_type

Supplied parameter. Specifies how data is sent by the next Send_Data call. Possible values are:

CM_BUFFER_DATA

The data pointed to by **Send_Data** is stored in a buffer until the buffer fills up or is flushed.

CM_SEND_AND_FLUSH

The data pointed to by **Send_Data** is to be sent immediately.

CM_SEND_AND_CONFIRM

The data is to be sent immediately with a request for confirmation.

CM_SEND_AND_PREP_TO_RECEIVE

The data is to be sent immediately along with notification to the partner program that the conversation state for the sending program is changing to RECEIVE.

CM_SEND_AND_DEALLOCATE

The data is to be sent immediately along with deallocation notification.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *conversation_ID* or *send_type* is invalid.
- The *send_type* parameter is set to CM_SEND_AND_CONFIRM, but the conversations synchronization level is set to CM_NONE.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation can be in any state except RESET.

There is no state change.

Remarks

The *send_type* values that cause additional information to be sent with the data pointed to by Send_Data let you economize on the number of calls issued. The following table summarizes **Send_Data** equivalences.

Send_Data with *send_type* set to this value	**Equates to Send_Data with *send_type* set to CM_BUFFER_DATA followed by**
CM_SEND_AND_FLUSH	Flush
CM_SEND_AND_CONFIRM	Confirm
CM_SEND_AND_PREP_TO_RECEIVE	Prepare_To_Receive
CM_SEND_AND_DEALLOCATE	Deallocate

Set_Sync_Level

The **Set_Sync_Level** call (function name **cmssl**) is issued by the invoking program to specify the synchronization level of the conversation. The synchronization level determines whether the programs synchronize their processing through the Confirm and Confirmed calls.

This call overrides the synchronization level established by the Initialize_Conversation call. The default synchronization level is CM_NONE, indicating no synchronization. This call cannot be issued after the Allocate call has been issued.

Syntax

```
CM_ENTRY Set_Sync_Level(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *sync_level,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by **Initialize_Conversation**.

sync_level

Supplied parameter. Specifies the synchronization level of the conversation. Possible values are:

CM_NONE

The programs will not perform confirmation processing.

CM_CONFIRM

The programs can perform confirmation processing.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_STATE_CHECK

Primary return code; the conversation is not in INITIALIZE state.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *conversation_ID* or *sync_level* is invalid.
- The *sync_level* parameter specifies CM_NONE but one of the following has occurred: the *send_type* parameter is set to CM_SEND_AND_CONFIRM, the *prepare_to_receive_type* parameter is set to CM_PREP_TO_RECEIVE_CONFIRM, or the *deallocate_type* is set to CM_DEALLOCATE_CONFIRM.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation must be in INITIALIZE state.

There is no state change.

Set_TP_Name

The **Set_TP_Name** call (function name **cmstpn**) is issued by the invoking program to specify the partner (invokable) program name. This call overrides the partner program name derived from the side information when the Initialize_Conversation call was issued. This call cannot be issued after the Allocate call has been issued. Issuing this call has no effect on the side information itself.

Syntax

```
CM_ENTRY Set_TP_Name(
  unsigned char FAR *conversation_ID,
    unsigned char FAR *TP_name,
    CM_INT32 FAR *TP_name_length,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation.

TP_name

Supplied parameter. Specifies the starting address of the partner program name. The program name can contain up to 64 ASCII characters. The allowed characters are:

- Uppercase and lowercase letters.
- Numerals from 0 through 9.
- Special characters, except the space.

You cannot use **Set_TP_Name** to specify the name of an SNA service transaction program (TP). You can, however, use Set_CPIC_Side_Information to do this.

Double-byte character sets, such as Kanji, are not supported.

TP_name_length

Supplied parameter. Specifies the length of the partner program name. The range is from 1 through 64.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_STATE_CHECK

Primary return code; the conversation is not in INITIALIZE state.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The value specified by *conversation_ID* is invalid.
- The value specified by *TP_name_length* is out of range (greater than 64 or less than 1).
- The address of a variable is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation must be in INITIALIZE state.

There is no state change.

Specify_Local_TP_Name

The **Specify_Local_TP_Name** call (function name **cmsltp**) is issued by the program to indicate that it is able to accept incoming conversations that are directed to the name given.

Syntax

```
CM_ENTRY Specify_Local_TP_Name(
  unsigned char FAR *TP_name,
  CM_INT32 FAR *TP_name_length,
  CM_INT32 FAR *return_code
);
```

Parameters

TP_name

Supplied parameter. Specifies the starting address of the local transaction program (TP) name. The program name can contain up to 64 ASCII characters. The allowed characters are:

- Uppercase and lowercase letters.
- Numerals from 0 through 9.
- Special characters, except the space.

You cannot use **Specify_Local_TP_Name** to specify the name of an SNA service TP.

Double-byte character sets, such as Kanji, are not supported.

TP_name_length

Supplied parameter. Specifies the length of the local program name. The range is from 1 through 64.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; one of the following occurred:

- The *TP_name* supplied is invalid.
- The value specified by *TP_name_length* is out of range (greater than 64 or less than 1).

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The call is not associated with a particular conversation, and no state restrictions apply.

There is no state change.

Remarks

A program can issue this call more than once to handle incoming conversations with more than one TP name. The program can discover the actual name on the incoming conversation by calling Extract_TP_Name.

Specify_Windows_Handle

The **Specify_Windows_Handle** call (function name **xchwnd**) sets the Microsoft® Windows® handle to which a message is sent on completion of an operation in nonblocking mode.

Syntax

```
CM_ENTRY Specify_Windows_Handle(
  HWND hwndNotify,
  CM_INT32 FAR *return_code
);
```

Parameters

hwndNotify

Supplied parameter. Specifies the Windows handle to be notified when the outstanding operation completes.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

The Windows handle is invalid.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The state change is dependent on the operation that completed and its return code.

Remarks

An application can set the processing mode by calling Set_Processing_Mode. If the Windows handle is set to NULL, or this call is never issued, the application must call Wait_For_Conversation to be notified when the outstanding operation completes.

When an asynchronous operation is complete, the applications window *hwndNotify* receives the message returned by **RegisterWindowMessage** with "WinAsyncCPIC" as the input string. The *wParam* value contains the *conversation_return_code* from the operation that is completing. Its values will depend on which operation was originally issued. The *lParam* argument contains the CM_PTR to the *conversation_ID* specified in the original function call.

Test_Request_To_Send_Received

The **Test_Request_To_Send_Received** call (function name **cmtrts**) determines whether a request-to-send notification has been received from the partner program.

Syntax

```
CM_ENTRY Test_Request_To_Send_Received(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *request_to_send_received,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Supplied parameter. Specifies the identifier for the conversation. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

request_to_send_received

Returned parameter. The request-to-send-received indicator. Possible values are:

CM_REQ_TO_SEND_RECEIVED

The partner program issued Request_To_Send, which requests the local program to change the conversation to RECEIVE state.

CM_REQ_TO_SEND_NOT_RECEIVED

The partner program did not issue **Request_To_Send**. This value is not relevant if *return_code* contains a value other than CM_OK.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_PROGRAM_PARAMETER_CHECK

Primary return code; the value specified by *conversation_ID* is invalid, or the address of a variable is invalid.

CM_PROGRAM_STATE_CHECK

Primary return code; the conversation is in a state other than SEND, RECEIVE, or SEND_PENDING.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error occurred and has been logged in the products error log.

State Changes

The conversation must be in SEND, RECEIVE, or SEND_PENDING state.

There is no state change.

Wait_For_Conversation

The **Wait_For_Conversation** call (function name **cmwait**) waits for an operation to complete that has been initiated when the *processing_mode* conversation characteristic was set to CM_NON_BLOCKING and CM_OPERATION_INCOMPLETE was returned in the *return_code* parameter.

Syntax

```
CM_ENTRY Wait_For_Conversation(
  unsigned char FAR *conversation_ID,
  CM_INT32 FAR *conversation_return_code,
  CM_INT32 FAR *return_code
);
```

Parameters

conversation_ID

Returned parameter. Specifies the identifier for the conversation on which the operation completed. The value of this parameter was returned by Initialize_Conversation or Accept_Conversation.

conversation_return_code

Returned parameter. Specifies the *return_code* from the operation that is completing. Its values will depend on which operation was originally issued.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

Primary return code; the call executed successfully.

CM_SYSTEM_EVENT

Primary return code; the wait completed not because the operation completed but because some system event occurred.

CM_PROGRAM_STATE_CHECK

Primary return code; the program has no incomplete operation outstanding.

CM_PRODUCT_SPECIFIC_ERROR

Primary return code; a product-specific error has occurred and has been logged in the products error log.

State Changes

The state change is dependent on the operation that completed and its return code.

Remarks

The program must have an incomplete operation outstanding on some conversation.

Extensions for the Windows Environment

This section describes API extensions to Microsoft® Windows® Common Programming Interface for Communications (CPI-C) that allow nonblocking or asynchronous verb completion. Asynchronous verbs return control to the program immediately, without waiting for full execution, and must notify the application later when the verb has been completed. An application is also notified in response to the completion of a Wait_For_Conversation call. In contrast, synchronous verbs block, that is, the function call does not return until the call has completed.

Under Microsoft® Windows Server™ 2003 and Windows 2000, two methods are available for handling asynchronous verb completion:

- Message posting using window handles.
- Waiting on Win32® events.

The first method uses messages posted to a window handle to notify an application of verb completion. There is one such window for each CPI-C application. Each CPI-C conversation can have one asynchronous verb outstanding at any time. When a verb completes, the posting to the window takes as parameters the CPI-C conversation identifier of the verb that has completed, and the return code of the verb.

Note
The extensions using window handles and message posting described in this section were designed for all implementations and versions of Microsoft Windows. They are now supported only for Windows Server2003 and Windows2000.

A second method using Win32 events for notification is supported on Microsoft® Host Integration Server. The extensions using Win32 events described in this section (WinCPICSetEvent and WinCPICExtractEvent)operate only on Windows Server 2003 and Windows 2000 and offer the optimum application performance in the 32-bit operating environment. If an event has been registered with the conversation, an application can call the Win32 **WaitForSingleObject** or **WaitForMultipleObjects** function to wait to be notified of the completion of the verb.

Windows CPI-C allows multithreaded Windows-based processes. Multithreading is the running of several processes in rapid sequence within a single program. A process contains one or more threads of execution.

The extension descriptions in this section provide a definition of the function, syntax, return values, and remarks for using these Windows extensions in CPI-C programs.

In This Section

- WinCPICCleanup
- WinCPICExtractEvent
- WinCPICIsBlocking
- WinCPICSetBlockingHook
- WinCPICSetEvent
- WinCPICStartup
- WinCPICUnhookBlockingHook

WinCPICCleanup

The **WinCPICCleanup** function terminates and deregisters an application from a Microsoft® Windows® Common Programming Interface for Communications (CPI-C) implementation.

Syntax

```
BOOL WINAPI WinCPICCleanup(void);
```

Return Value

The return value specifies whether the deregistration was successful. If the value is not zero, the application was successfully deregistered. The application was not deregistered if a value of zero is returned.

Remarks

Use **WinCPICCleanup** to indicate deregistration of a Windows CPI-C application from a Windows CPI-C implementation.

WinCPICExtractEvent

The **WinCPICExtractEvent** function provides a method for an application to determine the event handle being used for a Microsoft® Windows® Common Programming Interface for Communications (CPI-C) conversation.

Syntax

```
            VOID WINAPI WinCPICExtractEvent(
    unsigned char FAR*conversation_ID,HANDLE FAR*event_handle,    CM_INT32 FAR*return_code)
;
```

Parameters

conversation_ID

Specifies the identifier for the conversation for which this event is used. This parameter is returned by the initial Accept_Conversation call.

event_handle

Returned parameter. The handle of the event being used by this conversation. If no handle has been registered, this parameter returns as a NULL.

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

The function executed successfully.

CM_PROGRAM_PARAMETER_CHECK

One or more of the parameters passed to this function are invalid.

Remarks

When a verb is issued on a nonblocking conversation, it returns CM_OPERATION_INCOMPLETE if it is going to complete asynchronously. If an event has been registered with the conversation, the application can call **WaitForSingleObject** or **WaitForMultipleObjects** to be notified of the completion of the verb. **WinCPICExtractEvent** allows a CPI-C applicationto determine this event handle. When the verb has completed, the application must call Wait_For_Conversationto determine the return code for the asynchronous verb. The Cancel_Conversationfunction can be called to cancel an operation and conversation.

If no event has been registered, the asynchronous verb completes as it does at present, which is by posting a message to the window that the application has registered with the CPI-C library.

WinCPICIsBlocking

The **WinCPICIsBlocking** function determines if a task is executing while waiting for a previous blocking call to finish.

Syntax

```
BOOL WINAPI WinCPICIsBlocking(void);
```

Return Value

The return value specifies the outcome of the function. If the value is not zero, there is an outstanding blocking call awaiting completion. A value of zero indicates the absence of an outstanding blocking call.

Remarks

This call does not infer any information about a particular conversation; it is only intended to provide help to an application written to use the CM_BLOCKING characteristic of Set_Processing_Mode. **WinCPICIsBlocking** serves the same purpose as **InSendMessage** in the Microsoft® Windows® API. Legacy applications targeted at Windows version 3.*x* that support multiple conversations must specify CM_NONBLOCKING in **Set_Processing_Mode** so they can support multiple outstanding operations simultaneously. Applications are still limited to one outstanding operation per conversation in all environments.

Although a call issued on a blocking function appears to an application as though it blocks, the Windows CPI-C dynamic-link library (DLL) has to relinquish the processor to allow other applications to run. This means that it is possible for the application that issued the blocking call to be re-entered, depending on the messages it receives. In this instance, **WinCPICIsBlocking** can be used to determine whether the application task currently has been re-entered while waiting for an outstanding blocking call to finish. Note that Windows CPI-C prohibits more than one outstanding blocking call per thread.

Specify_Windows_Handle
WinCPICSetBlockingHook
WinCPICUnhookBlockingHook

WinCPICSetBlockingHook

The **WinCPICSetBlockingHook** function allows a Microsoft® Windows® Common Programming Interface for Communications (CPI-C) implementation to block CPI-C function calls by means of a new function. This legacy call was used by Microsoft® Windows® version 3.*x* applications to make blocking calls without blocking the rest of the system. By default in the Microsoft® Windows Server™ 2003 or Windows 2000 system, blocking calls suspend the calling applications thread until the request is finished.

Parameters
lpBlockFunc

Specifies the procedure instance address of the blocking function to be installed.

Return Values

The return value points to the procedure instance of the previously installed blocking function. The application or library that calls **WinCPICSetBlockingHook** should save this return value so that it can be restored if needed. (If nesting is not important, the application can simply discard the value returned by **WinCPICSetBlockingHook** and eventually use WinCPICUnhookBlockingHook to restore the default mechanism.)

Remarks

A Windows CPI-C implementation has a default mechanism by which blocking CPI-C functions are implemented. This function gives the application the ability to execute its own function at blocking time in place of the default function.

The default blocking function is equivalent to:

```
BOOL DefaultBlockingHook (void)  {
    MSG msg;
    /* get the next message if any */
    if ( PeekMessage (&msg,0,0,PM_NOREMOVE)  )  {
        if ( msg.message = = WM_QUIT  )
            return FALSE;   // let app process WM_QUIT
        PeekMessage (&msg,0,0,PM_REMOVE) ;
        TranslateMessage (&msg) ;
        DispatchMessage (&msg) ;
    }
    /* TRUE if no WM_QUIT received */
    return TRUE;
}
```

The **WinCPICSetBlockingHook** function is provided to support applications that require more complex message processing, for example, those employing the multiple document interface (MDI) model or applications with Menu accelerators (TranslateAccelerator).

Blocking functions must return FALSE in response to a WM_QUIT message so Windows CPI-C can return control to the application to process the message and terminate gracefully. Otherwise, the function should return TRUE.

Set_Processing_Mode
Specify_Windows_Handle

WinCPICSetEvent

The **WinCPICSetEvent** function associates an event handle with a verb completion.

Syntax

```
        VOID WINAPI WinCPICSetEvent(
unsigned char FAR* conversation_ID,HANDLE FAR* event_handle,
CM_INT32 FAR*return_code);
```

Parameters

conversation_ID

Specifies the identifier for the conversation for which this event is used. This parameter is returned by the initial Accept_Conversation call.

event_handle

The handle of the event that is to be cleared when an asynchronous verb on the conversation completes. This parameter can replace an already defined event or remove an already defined event (by having NULL as the parameter).

return_code

The code returned from this call. The valid return codes are listed later in this topic.

Return Codes

CM_OK

The function executed successfully.

CM_PROGRAM_PARAMETER_CHECK

One or more of the parameters passed to this function are invalid.

CM_OPERATION_NOT_ACCEPTED

This value indicates that a previous operation on this conversation is incomplete and the **WinCPICSetEvent** call was not accepted.

Remarks

When a verb is issued on a nonblocking conversation, it returns CM_OPERATION_INCOMPLETE if it is going to complete asynchronously. If an event has been registered with the conversation, the application can call **WaitForSingleObject** or **WaitForMultipleObjects** to be notified of the completion of the verb. When the verb has completed, the application must call Wait_For_Conversationto determine the return code for the asynchronous verb.

It is the responsibility of the application to reset the event, as it is with other APIs.

Reference

Cancel_Conversation

WinCPICStartup

The **WinCPICStartup** function allows an application to specify the version of Microsoft Windows Common Programming Interface for Communications (CPI-C) required and to retrieve details of the specific Windows CPI-C implementation. This function must be called by an application to register itself with a Windows CPI-C implementation before issuing any further Windows CPI-C calls.

Syntax

```
          INT WINAPI WinCPICStartup(
    WORDwVersionRequired,
        LPWCPICDATAlpwcpicdata);
```

Parameters

wVersionRequired

Specifies the version of Windows CPI-C support required. The high-order byte specifies the minor version (revision) number. The low-order byte specifies the major version number.

lpwcpicdata

A pointer to the CPI-C data structure. The **CPICDATA** structure is defined as follows:

```
typedef struct {
....WORD wVersion;
    char szDescription[WCPICDESCRIPTION_LEN+1];
}  CPICDATA, FAR * LPWCPICDATA;
```

WCPIDESCRIPTION is defined to be 127 and the structure members are as follows:

wVersion

The version of Windows CPI-C supported. The high-order byte specifies the minor version (revision) number. The low-order byte specifies the major version number.

szDescription

The description string describing the CPI-C version supported.

Return Value

The return value specifies whether the application was registered successfully and whether the Windows CPI-C implementation can support the specified version number. If the value is zero, it was registered successfully. Otherwise, the return value is one of the following:

WCPICSYSNOTRERADY

The underlying network system is not ready for network communication.

WCPICVERNOTSUPPORTED

The version of Windows CPI-C support requested is not provided by this particular Windows CPI-C implementation.

WCPICINVALID

The Windows CPI-C version specified by the application is not supported by this dynamic-link library (DLL).

Remarks

To support future Windows CPI-C implementations and applications that may have functionality differences from Windows CPI-C version 1.0, a negotiation takes place in **WinCPICStartup**. An application passes to **WinCPICStartup** the Windows CPI-C version that it can use. If this version is lower than the lowest version supported by the Windows CPI-C DLL, the DLL cannot support the application and the **WinCPICStartup** call fails. If the version is not lower, however, the call succeeds and returns the highest version of Windows CPI-C supported by the DLL. If this version is lower than the lowest version supported by the application, the application either fails its initialization or attempts to find another Windows CPI-C DLL on the system.

This negotiation allows both a Windows CPI-C DLL and a Windows CPI-C application to support a range of Windows CPI-C versions. An application can successfully use a DLL if there is any overlap in the versions. The following table illustrates how **WinCPICStartup** works in conjunction with different application and DLL versions.

Application versions	DLL versions	To WinCPICStartup	From WinCPICStartup	Result
1.0	1.0	1.0	1.0	Use 1.0
1.0, 2.0	1.0	2.0	1.0	Use 1.0
1.0	1.0, 2.0	1.0	2.0	Use 1.0
1.0	2.0, 3.0	1.0	WCPICINVALID	Fail
2.0, 3.0	1.0	3.0	1.0	App Fails
1.0, 2.0, 3.0	1.0, 2.0, 3.0	3.0	3.0	Use 3.0

Details of the actual Windows CPI-C implementation are described in the **WHLLDATA** structure defined as follows:

```
typedef struct tagWCPICDATA { WORD wVersion;
            char szDescription[WHLLDESCRIPTION_LEN+1];
            } WCPICDATA, FAR *LPWCPICDATA;
```

Having made its last Windows CPI-C call, an application should call the WinCPICCleanuproutine.

Each Windows CPI-C implementation must make a **WinCPICStartup** call before issuing any other Windows CPI-C calls.

WinCPICUnhookBlockingHook

The **WinCPICUnhookBlockingHook** function removes any previous blocking hook that has been installed and reinstalls the default blocking mechanism.

Syntax

```
BOOL WINAPI WinCPICUnhookBlockingHook(void);
```

Return Value

The return value specifies the outcome of the function. It is not zero if the default mechanism is successfully reinstalled. The value is zero if the mechanism did not reinstall.

WinCPICSetBlockingHook

CPI-C Common Return Codes

This section describes the return codes for Common Programming Interface for Communications (CPI-C) calls. The return codes are listed in integer order.

Call-specific return codes are described for the individual calls in CPI-C Calls.

0
CM_OK

The call executed successfully.

1
CM_ALLOCATION_FAILURE_NO_RETRY

The conversation cannot be allocated because of a permanent condition, such as a configuration error or session protocol error. To determine the error, the system administrator should examine the error log file. Do not retry the allocation until the error has been corrected.

2
CM_ALLOCATION_FAILURE_RETRY

The conversation could not be allocated because of a temporary condition, such as a link failure. The reason for the failure is logged in the system error log. Retry the allocation.

3
CM_CONVERSATION_TYPE_MISMATCH

The partner LU or program does not support the conversation type (basic or mapped) specified in the allocation request.

5
CM_PIP_NOT_SPECIFIED_CORRECTLY

The allocation request was rejected by a non-CPI-C LU 6.2 transaction program (TP). The partner program requires one or more PIP data variables, which are not supported by CPI-C.

6
CM_SECURITY_NOT_VALID

The user identifier or password specified in the allocation request was not accepted by the partner logical unit (LU).

8
CM_SYNC_LVL_NOT_SUPPORTED_PGM

The partner program does not support the synchronization level specified in the allocation request.

9
CM_TPN_NOT_RECOGNIZED

The partner LU does not recognize the program name specified in the allocation request.

10
CM_TP_NOT_AVAILABLE_NO_RETRY

The partner LU cannot start the program specified in the allocation request because of a permanent condition. The reason for the error may be logged on the remote node. Do not retry the allocation until the error has been corrected.

11
CM_TP_NOT_AVAILABLE_RETRY

The partner LU cannot start the program specified in the allocation request because of a temporary condition. The reason for the error may be logged on the remote node. Retry the allocation.

17
CM_DEALLOCATED_ABEND

The conversation has been deallocated for one of the following reasons:

- The remote program issued Deallocate with the type parameter set to CM_DEALLOCATE_ABEND. If the conversation for the remote program was in RECEIVE state when the call was issued, information sent by the local program and not

yet received by the remote program is purged.

- The partner program terminated normally but did not deallocate the conversation before terminating.

18
CM_DEALLOCATED_NORMAL

This return code does not indicate an error.

The partner program issued the Deallocate call with *deallocate_type* set to one of the following:

- CM_DEALLOCATE_FLUSH.
- CM_DEALLOCATE_SYNC_LEVEL with the synchronization level of the conversation specified as CM_NONE.

19
CM_PARAMETER_ERROR

The local program specified an invalid argument in one of its parameters.

20
CM_PRODUCT_SPECIFIC_ERROR

A product-specific error occurred and has been logged in the products error log.

21
CM_PROGRAM_ERROR_NO_TRUNC

While in SEND state or in SEND-PENDING state with the error direction set to CM_SEND_ERROR, the partner program issued Send_Error. Data was not truncated.

22
CM_PROGRAM_ERROR_PURGING

One of the following occurred:

- While in RECEIVE or CONFIRM state, the partner program issued Send_Error. Data sent but not yet received is purged.
- While in SEND-PENDING state with the error direction set to CM_RECEIVE_ERROR, the partner program issued **Send_Error**. Data was not purged.

23
CM_PROGRAM_ERROR_TRUNC (for a basic conversation)

In SEND state, before finishing sending a complete logical record, the partner program issued Send_Error. The local program may have received the first part of the logical record through a Receive call.

24
CM_PROGRAM_PARAMETER_CHECK

A parameter or the address of a variable is invalid. For details, see individual calls in CPI-C Calls.

25
CM_PROGRAM_STATE_CHECK

The call was not issued in an allowed conversation state. For details, see individual calls in CPI-C Calls.

26
CM_RESOURCE_FAILURE_NO_RETRY

One of the following occurred:

- The conversation was terminated prematurely because of a permanent condition. Do not retry until the error has been corrected.
- The partner program did not deallocate the conversation before terminating normally.

27
CM_RESOURCE_FAILURE_RETRY

The conversation was terminated prematurely because of a temporary condition, such as modem failure. Retry the conversation.

28
CM_UNSUCCESSFUL

The verb issued by the local program was not executed successfully.

30
CM_DEALLOCATED_ABEND_SVC

The conversation has been deallocated for one of the following reasons:

- The partner program issued Deallocate with the type parameter set to ABEND_SVC.
- The partner program did not deallocate the conversation before terminating.

If the conversation is in RECEIVE state for the partner program when this call is issued by the local program, data sent by the local program and not yet received by the partner program is purged.

31
CM_DEALLOCATED_ABEND_TIMER

The conversation has been deallocated because the partner program issued Deallocate with the type parameter set to ABEND_TIMER. If the conversation is in RECEIVE state for the partner program when this call is issued by the local program, data sent by the local program and not yet received by the partner program is purged.

32
CM_SVC_ERROR_NO_TRUNC (for a basic conversation)

While in SEND state, the partner program or partner LU issued Send_Error with the typeparameter set to SVC. Data was not truncated.

33
CM_SVC_ERROR_PURGING

While in SEND state, the partner program or partner LU issued Send_Error with the type parameter set to SVC. Data sent to the partner program may have been purged.

34
CM_SVC_ERROR_TRUNC (for a basic conversation)

While in RECEIVE or CONFIRM state, the partner program or partner LU issued Send_Error with the type parameter set to SVC before it finished sending a complete logical record. The local program may have received the first part of the logical record.

35
CM_OPERATION_INCOMPLETE

The operation has not completed and is still in progress. The program can issue Wait_For_Conversation to await the completion of the operation, or Cancel_Conversation to cancel the operation and conversation. If Specify_Windows_Handle has been called, the application should wait for notification by a windows message and not call **Wait_For_Conversation**.

36
CM_SYSTEM_EVENT

This error code is not used by Host Integration Server 2009.

37
CM_OPERATION_NOT_ACCEPTED

A previous operation on this conversation is incomplete.

LUA Programmer's Reference

This section of the Host Integration Server 2009 Developer's Guide lists the verbs, extensions, control blocks, and return codes that describe the logical unit application (LUA) programming interface.

For general information about programming for LUA, see LUA Programmer's Guide.

For sample code that uses LUA, see LUA Samples.

In This Section

LUA RUI Verbs

This section describes the Microsoft® Windows® logical unit application (LUA) Request Unit Interface (RUI) verbs. It provides the following information for each RUI verb:

- Details of the LUA verb control block (VCB) structure.
- A description of the verb and its purpose.
- Parameters (VCB structure members) supplied to and returned by LUA. The description of each parameter includes information about the valid values for that parameter.
- Interaction with other verbs.

The verb descriptions in this section include parameter values specific to each verb. For a complete description of the VCB structure for both RUI and Session Level Interface (SLI) verbs, see LUA Verb Control Blocks.

This section contains:

- RUI_BID
- RUI_INIT
- RUI_PURGE
- RUI_READ
- RUI_TERM
- RUI_WRITE

RUI_BID

The **RUI_BID** verb notifies the Request Unit Interface (RUI) application that a message is waiting to be read using RUI_READ.

The following structure describes the **LUA_COMMON** member of the verb control block (VCB) used by **RUI_BID**:

The second syntax union describes the **LUA_SPECIFIC** member of the verb control block (VCB) used by **RUI_BID**. Other union members are omitted for clarity:

Syntax

```
struct LUA_COMMON {
    unsigned short lua_verb;
    unsigned short lua_verb_length;
    unsigned short lua_prim_rc;
    unsigned long  lua_sec_rc;
    unsigned short lua_opcode;
    unsigned long  lua_correlator;
    unsigned char  lua_luname[8];
    unsigned short lua_extension_list_offset;
    unsigned short lua_cobol_offset;
    unsigned long  lua_sid;
    unsigned short lua_max_length;
    unsigned short lua_data_length;
    char FAR *     lua_data_ptr;
    unsigned long  lua_post_handle;
    struct LUA_TH  lua_th;
    struct LUA_RH  lua_rh;
    struct LUA_FLAG1 lua_flag1;
    unsigned char  lua_message_type;
    struct LUA_FLAG2 lua_flag2;
    unsigned char  lua_resv56[7];
    unsigned char  lua_encr_decr_option;
};
union LUA_SPECIFIC {
    unsigned char lua_peek_data[12];
};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_RUI for RUI verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the logical unit application (LUA) VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_RUI_BID.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

RUI_BID only requires this parameter if **lua_sid** is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by RUI in Microsoft® Host Integration Server and should be set to zero.

lua_cobol_offset

Not used by LUA in Host Integration Server and should be zero.

lua_sid

Supplied parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Not used by **RUI_BID** and should be set to zero.

lua_data_length

Returned parameter. Specifies the length of data returned in **lua_peek_data** for **RUI_BID**.

lua_data_ptr

This parameter is not used and should be set to zero.

lua_post_handle

Supplied parameter. Used under Microsoft Windows Server™ 2003 or Windows® 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Returned parameter. Contains the SNA transmission header (TH) of the message received. Various subparameters are set for write functions and returned for read and bid functions. Its subparameters are as follows:

lua_th.flags_fid

Format identification type 2, four bits.

lua_th.flags_mpf

Segmenting mapping field, two bits. Defines the type of data segment. The following values are valid:

0x00 Middle segment**0x04** Last segment**0x08** First segment**0x0C** Only segment

lua_th.flags_odai

Originating address field–destination address field (OAF–DAF) assignor indicator, one bit.

lua_th.flags_efi

Expedited flow indicator, one bit.

lua_th.daf

Destination address field (DAF), an unsigned char.

lua_th.oaf

Originating address field (OAF), an unsigned char.

lua_th.snf

Sequence number field, an unsigned char[2].

lua_rh

Returned parameter. Contains the SNA request/response header (RH) of the message sent or received. It is set for the write function and returned by the read and bid functions. Its subparameters are as follows:

lua_rh.rri

Request-response indicator, one bit.

lua_rh.ruc

RU category, two bits. The following values are valid:

LUA_RH_FMD (**0x00**) FM data segment**LUA_RH_NC** (**0x20**) Network control**LUA_RH_DFC** (**0x40**) Data flow control**LUA_RH_SC** (**0x60**) Session control

lua_rh.fi

Format indicator, one bit.

lua_rh.sdi

Sense data included indicator, one bit.

lua_rh.bci

Begin chain indicator, one bit.

lua_rh.eci

End chain indicator, one bit.

lua_rh.dr1i

Definite response 1 indicator, one bit.

lua_rh.dr2i

Definite response 2 indicator, one bit.

lua_rh.ri

Exception response indicator (for a request), or response type indicator (for a response), one bit.

lua_rh.qri

Queued response indicator, one bit.

lua_rh.pi

Pacing indicator, one bit.

lua_rh.bbi

Begin bracket indicator, one bit.

lua_rh.ebi

End bracket indicator, one bit.

lua_rh.cdi

Change direction indicator, one bit.

lua_rh.csi

Code selection indicator, one bit.

lua_rh.edi

Enciphered data indicator, one bit.

lua_rh.pdi

Padded data indicator, one bit.

lua_flag1

Supplied parameter. Contains a data structure containing flags for messages supplied by the application. Its subparameters are as follows:

lua_flag1.bid_enable

Bid enable indicator, one bit.

lua_flag1.close_abend

Close immediate indicator, one bit.

lua_flag1.nowait

No wait for data flag, one bit.

lua_flag1.sscp_exp

SSCP expedited flow, one bit.

lua_flag1.sscp_norm

SSCP normal flow, one bit.

lua_flag1.lu_exp

LU expedited flow, one bit.

lua_flag1.lu_norm

LU normal flow, one bit.

lua_message_type

Returned parameter. Specifies the type of SNA message indicated to **RUI_BID**. Possible values are:

LUA_MESSAGE_TYPE_LU_DATA

LUA_MESSAGE_TYPE_SSCP_DATA

LUA_MESSAGE_TYPE_BID

LUA_MESSAGE_TYPE_BIND

LUA_MESSAGE_TYPE_BIS

LUA_MESSAGE_TYPE_CANCEL

LUA_MESSAGE_TYPE_CHASE

LUA_MESSAGE_TYPE_CLEAR

LUA_MESSAGE_TYPE_CRV

LUA_MESSAGE_TYPE_LUSTAT_LU

LUA_MESSAGE_TYPE_LUSTAT_SSCP

LUA_MESSAGE_TYPE_QC

LUA_MESSAGE_TYPE_QEC

LUA_MESSAGE_TYPE_RELQ

LUA_MESSAGE_TYPE_RQR

LUA_MESSAGE_TYPE_RTR

LUA_MESSAGE_TYPE_SBI

LUA_MESSAGE_TYPE_SHUTD

LUA_MESSAGE_TYPE_SIGNAL

LUA_MESSAGE_TYPE_SDT

LUA_MESSAGE_TYPE_STSN

LUA_MESSAGE_TYPE_UNBIND

The Session Level Interface (SLI) receives and responds to the BIND, CRV, and STSN requests through the LUA interface extension routines.

LU_DATA, LUSTAT_LU, LUSTAT_SSCP, and SSCP_DATA are not SNA commands.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA. Its subparameters are as follows:

lua_flag2.bid_enable

Indicates that **RUI_BID** was successfully re-enabled if set to 1.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_flag2.sscp_exp

Indicates SSCP expedited flow if set to 1.

lua_flag2.sscp_norm

Indicates SSCP normal flow if set to 1.

lua_flag2.lu_exp

Indicates LU expedited flow if set to 1.

lua_flag2.lu_norm

Indicates LU normal flow if set to 1.

lua_resv56

Reserved and should be set to zero.

lua_encr_decr_option

Reserved and should be set to zero.

lua_peek_data

The union member of **LUA_SPECIFIC** used by the **RUI_BID** and SLI_BIDverbs. Returned parameter. Contains up to 12 bytes of the data waiting to be read.

Return Codes

LUA_OK

Primary return code; the verb executed successfully.

LUA_CANCELED

Primary return code; the verb did not complete successfully because it was canceled by another verb.

LUA_TERMINATED

Secondary return code; RUI_TERM was issued while this verb was pending.

LUA_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

LUA_BAD_SESSION_ID

Secondary return code; an invalid value for **lua_sid** was specified in the VCB.

LUA_BID_ALREADY_ENABLED

Secondary return code; **RUI_BID** was rejected because a previous **RUI_BID** was already outstanding. Only one **RUI_BID** can be outstanding at any one time.

LUA_INVALID_POST_HANDLE

Secondary return code; for a Windows Server 2003 or Windows 2000 system using events as the asynchronous posting method, the Windows LUA VCB does not contain a valid event handle.

LUA_RESERVED_FIELD_NOT_ZERO

Secondary return code; a reserved field in the verb record, or a parameter not used by this verb, was set to a nonzero value.

LUA_VERB_LENGTH_INVALID

Secondary return code; an LUA verb was issued with the value of **lua_verb_length** unexpected by LUA.

LUA_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

LUA_NO_RUI_SESSION

Secondary return code; RUI_INIT has not yet completed successfully for the LU name specified on this verb.

LUA_UNSUCCESSFUL

Primary return code; the verb record supplied was valid, but the verb did not complete successfully.

LUA_INVALID_PROCESS

Secondary return code; the process that issued this verb was not the same process that issued **RUI_INIT** for this session. Only the process that started a session can issue verbs on that session.

LUA_NEGATIVE_RSP

Primary return code; LUA detected an error in the data received from the host. Instead of passing the received message to the application on RUI_READ, LUA discards the message (and the rest of the chain if it is in a chain), and sends a negative response to the host.

LUA informs the application on a subsequent **RUI_READ** or **RUI_BID** that a negative response was sent.

The secondary return code contains the sense code sent to the host on the negative response. For information about interpreting the sense code values that can be returned, see SNA Considerations Using LUA.

A zero secondary return code indicates that, following a previous RUI_WRITE of a negative response to a message in the middle of a chain, LUA has now received and discarded all messages from this chain.

LUA_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the transaction program (TP) and the physical unit (PU) 2.1 node has been broken (a LAN error).
- The SnaBase at the TPs computer encountered an ABEND.

LUA_SESSION_FAILURE

Primary return code; a required Host Integration Server component has terminated.

LUA_LU_COMPONENT_DISCONNECTED

Secondary return code; indicates that the LUA session has failed because of a problem with the link service or with the host LU.

LUA_RUI_LOGIC_ERROR

Secondary return code; an internal error was detected within LUA. This error should not occur during normal operation.

LUA_INVALID_VERB

Primary return code; either the verb code or the operation code, or both, is invalid. The verb did not execute.

LUA_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

LUA_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

LUA_UNEXPECTED_DOS_ERROR

Primary return code; after issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

Remarks

RUI_BID is used by applications that require notification that a message is waiting to be read. This allows the application to determine how it will handle the message before issuing RUI_READ.

When a message is available, **RUI_BID** returns with details of the message flow on which it was received, the message type, the TH and RH of the message, and up to 12 bytes of message data.

The main difference between **RUI_BID** and **RUI_READ** is that **RUI_BID** allows the application to check the data without removing it from the incoming message queue, so it can be left and accessed later. **RUI_READ** removes the message from the queue, so when the application reads the data it must also process it.

Note the following when using **RUI_BID**:

- RUI_INIT must complete successfully before this verb is issued.
- Only one **RUI_BID** can be outstanding at any one time.
- After **RUI_BID** has completed successfully, it can be reissued by setting **lua_flag1.bid_enable** on a subsequent RUI_READ. If the verb is reissued in this way, the application must not free or modify the storage associated with the **RUI_BID** record.
- If a message arrives from the host when **RUI_READ** and **RUI_BID** are both outstanding, **RUI_READ** completes and **RUI_BID** is left in progress.

Each message that arrives is bid only once. After **RUI_BID** indicates that data is waiting on a particular session flow, the application issues **RUI_READ** to receive the data. Any subsequent **RUI_BID** does not report data arriving on that session flow until the message that was bid has been accepted by issuing **RUI_READ**.

In general, the **lua_data_length** parameter returned on this verb indicates only the length of data in **lua_peek_data**, not the total length of data on the waiting message (except when a value of less than 12 is returned). The application should ensure that the data length on **RUI_READ** that accepts the data is sufficient to contain the message.

RUI_INIT

The **RUI_INIT** verb transfers control of the specified logical unit (LU) to the Microsoft® Windows® logical unit application (LUA) application. **RUI_INIT** establishes a session between the system services control point (SSCP) and the specified LU.

Note
For 3270 emulator users, a Microsoft Host Integration Server extension has been added that enables you to use 3270 LUs rat her than the LUA LUs. For more information, see Remarks in this topic.

The following structure describes the **LUA_COMMON** member of the verb control block (VCB) used by **RUI_INIT**.

Syntax

```
struct LUA_COMMON {
    unsigned short lua_verb;
    unsigned short lua_verb_length;
    unsigned short lua_prim_rc;
    unsigned long  lua_sec_rc;
    unsigned short lua_opcode;
    unsigned long  lua_correlator;
    unsigned char  lua_luname[8];
    unsigned short lua_extension_list_offset;
    unsigned short lua_cobol_offset;
    unsigned long  lua_sid;
    unsigned short lua_max_length;
    unsigned short lua_data_length;
    char FAR *     lua_data_ptr;
    unsigned long  lua_post_handle;
    struct LUA_TH  lua_th;
    struct LUA_RH  lua_rh;
    struct LUA_FLAG1 lua_flag1;
    unsigned char  lua_message_type;
    struct LUA_FLAG2 lua_flag2;
    unsigned char  lua_resv56[7];
    unsigned char  lua_encr_decr_option;
};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_RUI for Request Unit Interface (RUI) verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the LUA VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_RUI_INIT.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

RUI_INIT requires this parameter.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by RUI in Host Integration Server and should be set to zero.

lua_cobol_offset

Not used by LUA in Host Integration Server and should be zero.

lua_sid

Returned parameter. Specifies the session identifier.

lua_max_length

Not used by **RUI_INIT** and should be set to zero.

lua_data_length

Not used by **RUI_INIT** and should be set to zero.

lua_data_ptr

Not used by **RUI_INIT** and should be set to zero.

lua_post_handle

Supplied parameter. Used under Microsoft® Windows Server™ 2003 or Windows® 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Not used by **RUI_INIT** and should be set to zero.

lua_rh

Not used by **RUI_INIT** and should be set to zero.

lua_flag1

Not used by **RUI_INIT** and should be set to zero.

lua_message_type

Specifies the type of the inbound or outbound SNA commands and data. This is a returned parameter for **RUI_INIT**. Possible values are:

LUA_MESSAGE_TYPE_LU_DATA

LUA_MESSAGE_TYPE_SSCP_DATA

LUA_MESSAGE_TYPE_BID

LUA_MESSAGE_TYPE_BIND

LUA_MESSAGE_TYPE_BIS

LUA_MESSAGE_TYPE_CANCEL

LUA_MESSAGE_TYPE_CHASE

LUA_MESSAGE_TYPE_CLEAR

LUA_MESSAGE_TYPE_CRV

LUA_MESSAGE_TYPE_LUSTAT_LU

LUA_MESSAGE_TYPE_LUSTAT_SSCP

LUA_MESSAGE_TYPE_QC

LUA_MESSAGE_TYPE_QEC

LUA_MESSAGE_TYPE_RELQ

LUA_MESSAGE_TYPE_RQR

LUA_MESSAGE_TYPE_RTR

LUA_MESSAGE_TYPE_SBI

LUA_MESSAGE_TYPE_SHUTD

LUA_MESSAGE_TYPE_SIGNAL

LUA_MESSAGE_TYPE_SDT

LUA_MESSAGE_TYPE_STSN

LUA_MESSAGE_TYPE_UNBIND

The Session Level Interface (SLI) receives and responds to the BIND, CRV, and STSN requests through the LUA interface extension routines.

LU_DATA, LUSTAT_LU, LUSTAT_SSCP, and SSCP_DATA are not SNA commands.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

RUI_INIT always completes asynchronously unless it returns an error such as LUA_PARAMETER_CHECK).

lua_resv56

Supplied parameter. A reserved field used by **RUI_INIT** and SLI_OPEN. All other reserved fields in the array must be left blank. For more information, see the discussion of these Host Integration Server extensions in the Remarks section.

lua_resv56[1]

Supplied parameter. Indicates whether an RUI application can access LUs configured as 3270 LUs, in addition to LUA LUs. If this parameter is nonzero, 3270 LUs can be accessed.

lua_resv56[2]

Supplied parameter. Indicates whether the RUI library will release the LU when the LU-SSCP session or connection goes away. If this parameter is nonzero, the LU will not be released.

lua_resv56[3]

Supplied parameter. Indicates whether incomplete reads are supported. If this parameter is set to a nonzero value, incomplete or truncated reads are supported. For more details, see the remarks for RUI_READ.

lua_resv56[4]

Supplied parameter. Indicates whether the RUI library will allow the application to keep hold of the LU if it is recycled at the host. If this parameter is nonzero, the application can keep hold of the LU.

lua_encr_decr_option

Field for cryptography options. On **RUI_INIT**, only the following are supported:

lua_encr_decr_option = 0

lua_encr_decr_option = 128

Values from 1 through 127 are not supported.

Return Codes
LUA_OK

Primary return code; the verb executed successfully.

LUA_CANCELED

Primary return code; the verb did not complete successfully because it was canceled by another verb.

LUA_TERMINATED

Secondary return code; RUI_TERM was issued before **RUI_INIT** completed.

LUA_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

LUA_INVALID_LUNAME

Secondary return code; the **lua_luname** parameter did not match any LUA LU name or LU pool name in the configuration file.

LUA_INVALID_POST_HANDLE

Secondary return code; for a Windows Server 2003 or Windows 2000 system using events as the asynchronous posting method, the Windows LUA VCB does not contain a valid event handle.

LUA_RESERVED_FIELD_NOT_ZERO

Secondary return code; a reserved field in the verb record, or a parameter not used by this verb, was set to a nonzero value.

LUA_VERB_LENGTH_INVALID

Secondary return code; an LUA verb was issued with the value of **lua_verb_length** unexpected by LUA.

LUA_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

LUA_DUPLICATE_RUI_INIT

Secondary return code; the **lua_luname** parameter specified an LU name or LU pool name already in use by this application (or for which this application already has **RUI_INIT** in progress).

LUA_UNSUCCESSFUL

Primary return code; the verb record supplied was valid, but the verb did not complete successfully.

LUA_COMMAND_COUNT_ERROR

Secondary return code, which indicates one of the following errors occurred:

The verb could not be issued because the application had already reached its maximum number of active sessions. On Windows Server 2003 or Windows 2000, an application can have as many as 15,000 sessions active at any time.

The verb specified the name of an LU pool or the name of an LU in a pool, but all the LUs in the pool are in use.

LUA_ENCR_DECR_LOAD_ERROR

Secondary return code; the verb specified a value for **lua_encr_decr_option** other than 0 or 128.

LUA_INVALID_PROCESS

Secondary return code; the LU specified by **lua_luname** is in use by another process.

LUA_LINK_NOT_STARTED

Secondary return code; the connection to the host has not been started; none of the link services it could use are active.

LUA_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the transaction program (TP) and the physical unit (PU) 2.1 node has been broken (a LAN error).
- The SnaBase at the TPs computer encountered an ABEND.

LUA_SESSION_FAILURE

Primary return code; a required Host Integration Server component has terminated.

LUA_LU_COMPONENT_DISCONNECTED

Secondary return code; indicates that the LUA session failed because of a problem with the link service or with the host LU.

LUA_INVALID_VERB

Primary return code; either the verb code or the operation code, or both, is invalid. The verb did not execute.

LUA_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

LUA_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

LUA_UNEXPECTED_DOS_ERROR

Primary return code; after issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

Remarks

This verb must be the first LUA verb issued for the session. Until this verb has completed successfully, the only other LUA verb that can be issued for this session is RUI_TERM (which terminates a pending **RUI_INIT**).

All other verbs issued on this session must identify the session using one of the following parameters from this verb:

- The session identifier, returned to the application in **lua_sid**.
- The LU name or LU pool name, supplied by the application in the **lua_luname** parameter.

RUI_INIT completes after an ACTLU message is received from the host. If necessary, the verb waits indefinitely. If an ACTLU has already been received prior to **RUI_INIT**, LUA sends a NOTIFY to the host to inform it that the LU is ready for use.

Neither ACTLU nor NOTIFY is visible to the LUA application.

After **RUI_INIT** has completed successfully, this session uses the LU for which the session was started. No other LUA session (from this or any other application) can use the LU until **RUI_TERM** is issued, or until an LUA_SESSION_FAILURE primary return code is received.

Using 3270 LUs

To provide 3270 emulator users the ability to use the Emulator Interface Specification (EIS) configuration call with the RUI API, a Host Integration Server extension has been added to the RUI. This extension allows you to use 3270 LUs rather than LUA LUs. If an application sets **lua_resv56[1]** to a nonzero value on the **RUI_INIT** call, 3270 LUs can be used.

Do Not Release the LU

If an application sets **lua_resv56[2]** to a nonzero value on the **RUI_INIT** call, the RUI library will not release the LU when the LU-SSCP session or connection goes away. When this Host Integration Server extension is enabled, the application does not have to issue a new **RUI_INIT** after a session failure or connection failure. When the LU-SSCP session comes back up (the application can use **WinRUIGetLastInitStatus** to detect this), the application can start using it again.

Support Chunking on this Session

If an application sets **lua_resv56[3]** to a nonzero value on the **RUI_INIT** session establishment, this enables a Host Integration Server extension that can change the behavior of **RUI_READ**. The default behavior for an **RUI_READ** call is to truncate data (discarding any data remaining) if the application's data buffer is not large enough to receive all of the data in the RU, returning an error code. When **lua_resv56[3]** is set to a nonzero value on the **RUI_INIT** call, an **RUI_READ** issued where the application's data buffer is not large enough will not result in the RU data being discarded. The **RUI_READ** verb will return success (LUA_OK) for the primary return code and LUA_DATA_INCOMPLETE for the secondary return code. Subsequent **RUI_READ** requests can then be issued to retrieve the data that exceeded the application's data buffer.

Ignore DACTLUs

If an application sets **lua_resv56[4]** to a nonzero value on the **RUI_INIT** session establishment, this enables a Host Integration Server extension, and the RUI library will allow the application to keep hold of the LU if it is recycled at the host (that is,

deactivated and reactivated).

Note
All other reserved fields must be left blank.

For more information, see the description of the sepdcrec function in the section of the Software Development Kit (SDK) Help on the 3270 Emulator Interface Specification.

Encryption

Session-level cryptography is implemented through Cryptography Verification (CRV) requests. RUI applications must perform all necessary processing of these requests. For all interfaces other than RUI, CRV requests are rejected with a negative response by Host Integration Server.

For **RUI_INIT**, the following options are supported:

- **lua_encr_decr_option** = 0
- **lua_encr_decr_option** = 128

Values from 1 through 127 (ACSRENCR and ACSROECR routines) are not supported.

The sending application is responsible for padding data to a multiple of eight bytes and for setting the padded data indicator bit in the RH as well as for encryption. The receiving application is responsible for removing the padding after decryption.

RUI_PURGE

The **RUI_PURGE** verb cancels a previous RUI_READ.

The following structure describes the **LUA_COMMON** member of the verb control block (VCB) used by **RUI_PURGE**.

Syntax

```
struct LUA_COMMON {
    unsigned short lua_verb;
    unsigned short lua_verb_length;
    unsigned short lua_prim_rc;
    unsigned long  lua_sec_rc;
    unsigned short lua_opcode;
    unsigned long  lua_correlator;
    unsigned char  lua_luname[8];
    unsigned short lua_extension_list_offset;
    unsigned short lua_cobol_offset;
    unsigned long  lua_sid;
    unsigned short lua_max_length;
    unsigned short lua_data_length;
    char FAR *      lua_data_ptr;
    unsigned long  lua_post_handle;
    struct LUA_TH  lua_th;
    struct LUA_RH  lua_rh;
    struct LUA_FLAG1 lua_flag1;
    unsigned char  lua_message_type;
    struct LUA_FLAG2 lua_flag2;
    unsigned char  lua_resv56[7];
    unsigned char  lua_encr_decr_option;
};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_RUI for Request Unit Interface (RUI) verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the logical unit application (LUA) VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_RUI_PURGE.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

RUI_PURGE only requires this parameter if **lua_sid** is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by RUI in Microsoft® Host Integration Server and should be set to zero.

lua_cobol_offset

Not used by LUA in Host Integration Server and should be zero.

lua_sid

Supplied parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Not used by **RUI_PURGE** and should be set to zero.

lua_data_length

Not used by **RUI_PURGE** and should be set to zero.

lua_data_ptr

Points to the location of the RUI_READ verbs VCB that is to be canceled.

lua_post_handle

Supplied parameter. Used under Microsoft® Windows Server™ 2003 or Windows® 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Not used by **RUI_PURGE** and should be set to zero.

lua_rh

Not used by **RUI_PURGE** and should be set to zero.

lua_flag1

Not used by **RUI_PURGE** and should be set to zero.

lua_message_type

Not used by **RUI_PURGE** and should be set to zero.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_resv56

Reserved and should be set to zero.

lua_encr_decr_option

Reserved and should be set to zero.

Return Codes
LUA_OK

Primary return code; the verb executed successfully.

LUA_CANCELED

Primary return code; the verb did not complete successfully because it was canceled by another verb.

LUA_TERMINATED

Secondary return code; RUI_TERM was issued while **RUI_PURGE** was pending.

LUA_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

LUA_BAD_DATA_PTR

Secondary return code; the **lua_data_ptr** parameter was set to null.

LUA_BAD_SESSION_ID

Secondary return code; an invalid value for **lua_sid** was specified in the VCB.

LUA_INVALID_POST_HANDLE

Secondary return code; for a Windows Server 2003 or Windows 2000 system using events as the asynchronous posting method, the Windows LUA VCB does not contain a valid event handle.

LUA_RESERVED_FIELD_NOT_ZERO

Secondary return code; a reserved field in the verb record, or a parameter not used by this verb, was set to a nonzero value.

LUA_VERB_LENGTH_INVALID

Secondary return code; an LUA verb was issued with the value of **lua_verb_length** unexpected by LUA.

LUA_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

LUA_NO_RUI_SESSION

Secondary return code; RUI_INIT has not yet completed successfully for the LU name specified on this verb.

LUA_UNSUCCESSFUL

Primary return code; the verb supplied was valid, but the verb did not complete successfully.

LUA_INVALID_PROCESS

Secondary return code; the OS/2 process that issued this verb was not the same process that issued **RUI_INIT** for this session. Only the process that started a session can issue verbs on that session.

LUA_NO_READ_TO_PURGE

Secondary return code; either **lua_data_ptr** did not contain a pointer to an RUI_READ VCB, or **RUI_READ** completed before **RUI_PURGE** was issued.

LUA_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the transaction program (TP) and the physical unit (PU) 2.1 node was broken (a LAN error).
- The SnaBase at the TPs computer encountered an ABEND.

LUA_SESSION_FAILURE

Primary return code; a required Host Integration Server component has terminated.

LUA_LU_COMPONENT_DISCONNECTED

Secondary return code; indicates that the LUA session failed because of a problem with the link service or with the host LU.

LUA_RUI_LOGIC_ERROR

Secondary return code; an internal error was detected within LUA. This error should not occur during normal operation.

LUA_INVALID_VERB

Primary return code; either the verb code or the operation code, or both, is invalid. The verb did not execute.

LUA_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

LUA_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

LUA_UNEXPECTED_DOS_ERROR

Primary return code; after issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

Remarks

RUI_READ can wait indefinitely if it is sent without using the **lua_flag1.nowait** (immediate return) option and no data is available on the specified flow. **RUI_PURGE** forces the waiting verb to return (with the primary return code LUA_CANCELED).

This verb is used only when **RUI_READ** has been issued and is pending completion. (The primary return code is LUA_IN_PROGRESS.)

RUI_READ

The **RUI_READ** verb receives responses, SNA commands, and data into a Microsoft® Windows® logical unit application (LUA) applications buffer.

The following structure describes the **LUA_COMMON** member of the verb control block (VCB) used by **RUI_READ**.

Syntax

```
struct LUA_COMMON {
    unsigned short lua_verb;
    unsigned short lua_verb_length;
    unsigned short lua_prim_rc;
    unsigned long  lua_sec_rc;
    unsigned short lua_opcode;
    unsigned long  lua_correlator;
    unsigned char  lua_luname[8];
    unsigned short lua_extension_list_offset;
    unsigned short lua_cobol_offset;
    unsigned long  lua_sid;
    unsigned short lua_max_length;
    unsigned short lua_data_length;
    char FAR *     lua_data_ptr;
    unsigned long  lua_post_handle;
    struct LUA_TH  lua_th;
    struct LUA_RH  lua_rh;
    struct LUA_FLAG1 lua_flag1;
    unsigned char  lua_message_type;
    struct LUA_FLAG2 lua_flag2;
    unsigned char  lua_resv56[7];
    unsigned char  lua_encr_decr_option;
};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_RUI for Request Unit Interface (RUI) verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the LUA VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_RUI_READ.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

RUI_READ only requires this parameter if **lua_sid** is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by RUI in Host Integration Server and should be set to zero.

lua_cobol_offset

Not used by LUA in Microsoft® Host Integration Server and should be zero.

lua_sid

Supplied and returned parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Specifies the length of received buffer for **RUI_READ** and SLI_RECEIVE. Not used by other RUI and SLI verbs and should be set to zero.

lua_data_length

Returned parameter. Specifies the length of data returned in **lua_peek_data** for the RUI_BID verb.

lua_data_ptr

Pointer to the application-supplied buffer that is to receive the data from an **RUI_READ** verb. Both SNA commands and data are placed in this buffer, and they can be in an EBCDIC format.

When **RUI_READ** is issued, this parameter points to the location to receive the data from the host.

lua_post_handle

Supplied parameter. Used under Microsoft Windows Server™ 2003 or Windows 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Returned parameter. Contains the SNA transmission header (TH) of the message sent or received. Various subparameters are set for write functions and returned for read and bid functions. Its subparameters are as follows:

lua_th.flags_fid

Format identification type 2, four bits.

lua_th.flags_mpf

Segmenting mapping field, two bits. Defines the type of data segment. The following values are valid:

0x00 Middle segment**0x04** Last segment**0x08** First segment**0x0C** Only segment

lua_th.flags_odai

Originating address field–destination address field (OAF–DAF) assignor indicator, one bit.

lua_th.flags_efi

Expedited flow indicator, one bit.

lua_th.daf

Destination address field (DAF), an unsigned char.

lua_th.oaf

Originating address field (OAF), an unsigned char.

lua_th.snf

Sequence number field, an unsigned char[2].

lua_rh

Returned parameter. Contains the SNA request/response header (RH) of the message sent or received. It is set for the write function and returned by the read and bid functions. Its subparameters are as follows:

lua_rh.rri

Request-response indicator, one bit.

lua_rh.ruc

RU category, two bits. The following values are valid:

LUA_RH_FMD (**0x00**) FM data segment**LUA_RH_NC** (**0x20**) Network control**LUA_RH_DFC** (**0x40**) Data flow control**LUA_RH_SC** (**0x60**) Session control

lua_rh.fi

Format indicator, one bit.

lua_rh.sdi

Sense data included indicator, one bit.

lua_rh.bci

Begin chain indicator, one bit.

lua_rh.eci

End chain indicator, one bit.

lua_rh.dr1i

Definite response 1 indicator, one bit.

lua_rh.dr2i

Definite response 2 indicator, one bit.

lua_rh.ri

Exception response indicator (for a request), or response type indicator (for a response), one bit.

lua_rh.qri

Queued response indicator, one bit.

lua_rh.pi

Pacing indicator, one bit.

lua_rh.bbi

Begin bracket indicator, one bit.

lua_rh.ebi

End bracket indicator, one bit.

lua_rh.cdi

Change direction indicator, one bit.

lua_rh.csi

Code selection indicator, one bit.

lua_rh.edi

Enciphered data indicator, one bit.

lua_rh.pdi

Padded data indicator, one bit.

lua_flag1

Supplied parameter. Contains a data structure containing flags for messages supplied by the application. Its subparameters are as follows:

lua_flag1.bid_enable

Bid enable indicator, one bit.

lua_flag1.close_abend

Close immediate indicator, one bit.

lua_flag1.nowait

No wait for data flag, one bit.

lua_flag1.sscp_exp

SSCP expedited flow, one bit.

lua_flag1.sscp_norm

SSCP normal flow, one bit.

lua_flag1.lu_exp

LU expedited flow, one bit.

lua_flag1.lu_norm

LU normal flow, one bit.

Set **lua_flag1.nowait** to 1 to indicate that you want **RUI_READ** to return immediately whether or not data is available to be read, or set it to zero if you want the verb to wait for data before returning.

Set **lua_flag1.bid_enable** to 1 to re-enable the most recent RUI_BID (equivalent to issuing **RUI_BID** again with exactly the same parameters as before), or set it to zero if you do not want to re-enable **RUI_BID**.

Re-enabling the previous **RUI_BID** reuses the VCB originally allocated for it, so this VCB must not have been freed or modified.

Set one or more of the following flags to 1 to indicate from which message flow to read data:

lua_flag1.sscp_exp

lua_flag1.lu_exp

lua_flag1.sscp_norm

lua_flag1.lu_norm

If more than one flag is set, the highest-priority data available is returned. The order of priorities (highest first) is: SSCP expedited, LU expedited, SSCP normal, LU normal. The equivalent flag in the **lua_flag2** group is set to indicate from which flow the data was read.

lua_message_type

Specifies the type of the inbound or outbound SNA commands and data. Returned parameter. Specifies the type of SNA message indicated to **RUI_READ**. Possible values are:

LUA_MESSAGE_TYPE_LU_DATA

LUA_MESSAGE_TYPE_SSCP_DATA

LUA_MESSAGE_TYPE_RQR

LUA_MESSAGE_TYPE_BID

LUA_MESSAGE_TYPE_BIND

LUA_MESSAGE_TYPE_BIS

LUA_MESSAGE_TYPE_CANCEL

LUA_MESSAGE_TYPE_CHASE

LUA_MESSAGE_TYPE_CLEAR

LUA_MESSAGE_TYPE_CRV

LUA_MESSAGE_TYPE_LUSTAT_LU

LUA_MESSAGE_TYPE_LUSTAT_SSCP

LUA_MESSAGE_TYPE_QC

LUA_MESSAGE_TYPE_QEC

LUA_MESSAGE_TYPE_RELQ

LUA_MESSAGE_TYPE_RTR

LUA_MESSAGE_TYPE_SBI

LUA_MESSAGE_TYPE_SHUTD

LUA_MESSAGE_TYPE_SIGNAL

LUA_MESSAGE_TYPE_SDT

LUA_MESSAGE_TYPE_STSN

LUA_MESSAGE_TYPE_UNBIND

LU_DATA, LUSTAT_LU, LUSTAT_SSCP, and SSCP_DATA are not SNA commands.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA. Its subparameters are as follows:

lua_flag2.bid_enable

Indicates that RUI_BID was successfully re-enabled if set to 1.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_flag2.sscp_exp

Indicates SSCP expedited flow if set to 1.

lua_flag2.sscp_norm

Indicates SSCP normal flow if set to 1.

lua_flag2.lu_exp

Indicates LU expedited flow if set to 1.

lua_flag2.lu_norm

Indicates LU normal flow if set to 1.

lua_resv56

Reserved and should be set to zero.

lua_encr_decr_option

Reserved and should be set to zero.

Return Codes

LUA_OK

Primary return code; the verb executed successfully.

LUA_DATA_INCOMPLETE

Secondary return code; **RUI_READ** was not able to return all of the data received because the application's data buffer (indicated by **lua_max_length**) was not large enough. Subsequent **RUI_READ** requests can be issued to retrieve the remaining RUI data.

This is not the default behavior for **RUI_READ** and is only enabled when **lua_resv56[3]** is set to a nonzero value in the verb control block when calling RUI_INIT during session establishment. For more details, see Remarks.

LUA_CANCELED

Primary return code; the verb did not complete successfully because it was canceled by another verb or by an internal error.

LUA_PURGED

Secondary return code; **RUI_READ** has been canceled by RUI_PURGE.

LUA_TERMINATED

Secondary return code; RUI_TERM was issued while **RUI_READ** was pending.

LUA_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

LUA_BAD_DATA_PTR

Secondary return code; the **lua_data_ptr** parameter contained an invalid value.

LUA_BAD_SESSION_ID

Secondary return code; an invalid value for **lua_sid** was specified in the VCB.

LUA_BID_ALREADY_ENABLED

Secondary return code; **lua_flag1.bid_enable** was set to re-enable RUI_BID but the previous **RUI_BID** was still in progress.

LUA_DUPLICATE_READ_FLOW

Secondary return code; the flow flags in the **lua_flag1** group specified one or more session flows for which **RUI_READ** was already outstanding. Only one **RUI_READ** at a time can be waiting on each session flow.

LUA_INVALID_FLOW

Secondary return code; none of the **lua_flag1** flow flags was set. At least one of these flags must be set to 1, to indicate from which flow or flows to read.

LUA_INVALID_POST_HANDLE

Secondary return code; for a Windows Server 2003 or Windows 2000 system using events as the asynchronous posting method, the Windows LUA VCB does not contain a valid event handle.

LUA_NO_PREVIOUS_BID_ENABLED

Secondary return code; **lua_flag1.bid_enable** was set to re-enable RUI_BID, but there was no previous **RUI_BID** that could be enabled. (For more information, see Remarks.)

LUA_RESERVED_FIELD_NOT_ZERO

Secondary return code; a reserved field in the verb record or a parameter not used by this verb was set to a nonzero value.

LUA_VERB_LENGTH_INVALID

Secondary return code; an LUA verb was issued with the value of **lua_verb_length** unexpected by LUA.

LUA_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

LUA_NO_RUI_SESSION

Secondary return code; RUI_INIT has not yet completed successfully for the LU name specified on **RUI_READ**.

LUA_NEGATIVE_RSP

Primary return code; indicates one of the following two cases, which can be distinguished by the secondary return code:

- LUA detected an error in the data received from the host. Instead of passing the received message to the application on **RUI_READ**, LUA discards the message (and the rest of the chain if it is in a chain), and sends a negative response to the host. LUA informs the application on a subsequent **RUI_READ** or RUI_BID that a negative response was sent.

- The LUA application previously sent a negative response to a message in the middle of a chain. LUA has purged subsequent messages in this chain, and is now reporting to the application that all messages from the chain have been received and purged.

LUA_SEC_RC

Secondary return code; this parameter is a nonzero secondary return code containing the sense code sent to the host on the negative response. This indicates that LUA detected an error in the host data and sent a negative response to the host. For information about interpreting the sense code values that may be returned, see SNA Considerations Using LUA.

A secondary return code of zero indicates that, following a previous RUI_WRITE of a negative response to a message in the middle of a chain, LUA has now received and discarded all messages from this chain.

LUA_UNSUCCESSFUL

Primary return code; the verb record supplied was valid, but the verb did not complete successfully.

LUA_DATA_TRUNCATED

Secondary return code; the **lua_data_length** parameter was smaller than the actual length of data received on the message. Only **lua_data_length** bytes of data were returned to the verb; the remaining data was discarded. Additional parameters are also returned if this secondary return code is obtained.

LUA_NO_DATA

Secondary return code; **lua_flag1.nowait** was set to indicate immediate return without waiting for data, and no data was currently available on the specified session flow or flows.

LUA_INVALID_PROCESS

Secondary return code; the OS/2 process that issued this verb was not the same process that issued RUI_INIT for this session. Only the process that started a session can issue verbs on that session.

LUA_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the transaction program (TP) and the physical unit (PU) 2.1 node was broken (a LAN error).
- The SnaBase at the TPs computer encountered an ABEND.

LUA_SESSION_FAILURE

Primary return code; a required Host Integration Server component has terminated.

LUA_LU_COMPONENT_DISCONNECTED

Secondary return code; indicates that the LUA session failed because of a problem with the link service or with the host LU.

LUA_RUI_LOGIC_ERROR

Secondary return code; an internal error was detected within LUA. This error should not occur during normal operation.

LUA_INVALID_VERB

Primary return code; either the verb code or the operation code, or both, is invalid. The verb did not execute.

LUA_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

LUA_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

LUA_UNEXPECTED_DOS_ERROR

Primary return code; after issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

Remarks

RUI_INIT must have completed successfully before **RUI_READ** is issued.

While an existing **RUI_READ** is pending, you can issue another **RUI_READ** only if it specifies a different session flow or flows from pending **RUI_READ** verbs. You cannot have more than one **RUI_READ** outstanding for the same session flow.

You can specify a particular message flow (LU normal, LU expedited, SSCP normal, or SSCP expedited) from which to read

data, or you can specify more than one message flow. You can have multiple **RUI_READ** verbs outstanding, provided that no two of them specify the same flow.

Data is received by the application on one of four session flows. The four session flows, from highest to lowest priority are:

- SSCP expedited
- LU expedited
- SSCP normal
- LU normal

The data flow type that **RUI_READ** is to process is specified in the **lua_flag1** parameter. The application can also specify whether it wants to look at more than one type of data flow. When multiple flow bits are set, the highest priority is received first. When **RUI_READ** completes processing, **lua_flag2** indicates the specific type of flow for which data has been received by the Windows LUA application.

If RUI_BID successfully completes before an **RUI_READ** is issued, the Windows LUA interface can be instructed to reuse the last **RUI_BID** verbs VCB. To do this, issue the **RUI_READ** with **lua_flag1.bid_enable** set.

The **lua_flag1.bid_enable** parameter can be used only if the following are true:

- **RUI_BID** has already been issued successfully and has completed.
- The storage allocated for **RUI_BID** has not been freed or modified.
- No other **RUI_BID** is pending.

When using **lua_flag1.bid_enable**, the **RUI_BID** storage must not be freed because the last **RUI_BID** verbs VCB is used. Also, when using **lua_flag1.bid_enable**, the successful completion of **RUI_BID** will be posted.

If **RUI_READ** is issued with **lua_flag1.nowait** when no data is available to receive, LUA_NO_DATA will be the secondary return code set by the Windows LUA interface.

If the data received is longer than **lua_max_length**, it is truncated. Only **lua_max_length** bytes of data are returned. The primary return code LUA_UNSUCCESSFUL and the secondary return code LUA_DATA_TRUNCATED are also returned. The RUI library returns as much data as possible to the application's data buffer, but the remaining data in the RUI is discarded and cannot be extracted on subsequent **RUI_READ** requests. This forces the RUI application to allocate an **RUI_READ** data buffer large enough to handle the full RU size.

This default behavior can be changed by setting the value of **lua_resv56[3]** to a nonzero value in the verb control block when calling RUI_INIT during session establishment. In this case, if the data received is longer than **lua_max_length**, an **RUI_READ** request will return a primary return code of LUA_OK and a secondary return code of LUA_DATA_INCOMPLETE. An RUI application can then issue new **RUI_READ** calls and receive the remainder of the data.

This enhancement has not been adopted as part of the Microsoft Windows Open Services Architecture (WOSA) LUA API standard and differs from the implementation of RUI by IBM.

After a message has been read using **RUI_READ,** it is removed from the incoming message queue and cannot be accessed again. (RUI_BID can be used as a nondestructive read. The application can use it to check the type of data available, but the data remains on the incoming queue and does not need to be used immediately.)

Pacing can be used on the primary-to-secondary half-session (specified in the host configuration), to protect the LUA application from being flooded with messages. If the LUA application is slow to read messages, Host Integration Server delays the sending of pacing responses to the host to slow it down.

RUI_TERM

The **RUI_TERM** verb ends both the logical unit (LU) session and the system services control point (SSCP) session for a given LUA LU.

The following structure describes the **LUA_COMMON** member of the verb control block (VCB) used by **RUI_TERM**.

Syntax

```
struct LUA_COMMON {
    unsigned short lua_verb;
    unsigned short lua_verb_length;
    unsigned short lua_prim_rc;
    unsigned long  lua_sec_rc;
    unsigned short lua_opcode;
    unsigned long  lua_correlator;
    unsigned char  lua_luname[8];
    unsigned short lua_extension_list_offset;
    unsigned short lua_cobol_offset;
    unsigned long  lua_sid;
    unsigned short lua_max_length;
    unsigned short lua_data_length;
    char FAR *     lua_data_ptr;
    unsigned long  lua_post_handle;
    struct LUA_TH  lua_th;
    struct LUA_RH  lua_rh;

    unsigned char  lua_message_type;
    struct LUA_FLAG2 lua_flag2;
    unsigned char  lua_resv56[7];
    unsigned char  lua_encr_decr_option;
};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_RUI for Request Unit Interface (RUI) verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the logical unit application (LUA) VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_RUI_TERM.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

RUI_TERM only requires this parameter if **lua_sid** is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by RUI in Microsoft® Host Integration Server and should be set to zero.

lua_cobol_offset

Not used by LUA in Host Integration Server and should be set to zero.

lua_sid

Supplied and returned parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Not used by **RUI_TERM** and should be set to zero.

lua_data_length

Not used by **RUI_TERM** and should be set to zero.

lua_data_ptr

Not used by **RUI_TERM** and should be set to zero.

lua_post_handle

Supplied parameter. Used under Microsoft Windows Server™ 2003 or Windows® 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Not used by **RUI_TERM** and should be set to zero.

lua_rh

Not used by **RUI_TERM** and should be set to zero.

lua_flag1

Not used by **RUI_TERM** and should be set to zero.

lua_message_type

Not used by **RUI_TERM** and should be set to zero.

lua_flag2

Not used by **RUI_TERM** and should be set to zero.

lua_resv56

Reserved and should be set to zero.

lua_encr_decr_option

Reserved and should be set to zero.

Return Codes
LUA_OK

Primary return code; the verb executed successfully.

LUA_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

LUA_BAD_SESSION_ID

Secondary return code; an invalid value for **lua_sid** was specified in the VCB.

LUA_INVALID_POST_HANDLE

Secondary return code; for a Windows Server 2003 or Windows 2000 system using events as the asynchronous posting method, the Windows LUA VCB does not contain a valid event handle.

LUA_RESERVED_FIELD_NOT_ZERO

Secondary return code; a reserved field in the verb record or a parameter not used by this verb was set to a nonzero value.

LUA_VERB_LENGTH_INVALID

Secondary return code; an LUA verb was issued with the value of **lua_verb_length** unexpected by LUA.

LUA_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

LUA_NO_RUI_SESSION

Secondary return code; RUI_INIT has not yet completed successfully for the LU name specified on **RUI_TERM**.

LUA_UNSUCCESSFUL

Primary return code; the verb record supplied was valid, but the verb did not complete successfully.

LUA_COMMAND_COUNT_ERROR

Secondary return code; **RUI_TERM** was already pending when the verb was issued.

LUA_INVALID_PROCESS

Secondary return code; the OS/2 process that issued this verb was not the same process that issued **RUI_INIT** for this session. Only the process that started a session can issue verbs on that session.

LUA_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the transaction program (TP) and the physical unit (PU) 2.1 node was broken (a LAN error).
- The SnaBase at the TPs computer encountered an ABEND.

LUA_SESSION_FAILURE

Primary return code; a required Host Integration Server component has terminated.

LUA_LU_COMPONENT_DISCONNECTED

Secondary return code; indicates that the LUA session failed because of a problem with the link service or with the host LU.

LUA_RUI_LOGIC_ERROR

Secondary return code; an internal error was detected within LUA. This error should not occur during normal operation.

LUA_INVALID_VERB

Primary return code; either the verb code or the operation code, or both, is invalid. The verb did not execute.

LUA_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

LUA_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

LUA_UNEXPECTED_DOS_ERROR

Primary return code; after issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

Remarks

This verb can be issued at any time after RUI_INIT has been issued (whether or not it has completed). If any other LUA verb is pending when **RUI_TERM** is issued, no further processing on the pending verb takes place, and it returns with a primary return

code of LUA_CANCELED.

After this verb has completed, no other LUA verb can be issued for this session.

RUI_INIT

SLI_OPEN

RUI_WRITE

The **RUI_WRITE** verb sends an SNA request or response unit from the logical unit application (LUA) application to the host over either the LU session or the system services control point (SSCP) session, and sends responses, SNA commands, and data from a Microsoft® Windows® LUA application to the host LU.

The following structure describes the **LUA_COMMON** member of the verb control block (VCB) used by **RUI_WRITE**.

Syntax

```
struct LUA_COMMON {
    unsigned short lua_verb;
    unsigned short lua_verb_length;
    unsigned short lua_prim_rc;
    unsigned long  lua_sec_rc;
    unsigned short lua_opcode;
    unsigned long  lua_correlator;
    unsigned char  lua_luname[8];
    unsigned short lua_extension_list_offset;
    unsigned short lua_cobol_offset;
    unsigned long  lua_sid;
    unsigned short lua_max_length;
    unsigned short lua_data_length;
    char FAR *     lua_data_ptr;
    unsigned long  lua_post_handle;
    struct LUA_TH  lua_th;
    struct LUA_RH  lua_rh;
    struct LUA_FLAG1 lua_flag1;
    unsigned char  lua_message_type;
    struct LUA_FLAG2 lua_flag2;
    unsigned char  lua_resv56[7];
    unsigned char  lua_encr_decr_option;
};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_RUI for Request Unit Interface (RUI) verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the LUA VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_RUI_WRITE.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

RUI_WRITE only requires this parameter if **lua_sid** is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by RUI in Microsoft® Host Integration Server and should be set to zero.

lua_cobol_offset

Not used by LUA in Host Integration Server and should be zero.

lua_sid

Supplied and returned parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Not used by **RUI_WRITE** and should be set to zero.

lua_data_length

Returned parameter. Specifies the length of data returned in **lua_peek_data** for the RUI_BID verb.

lua_data_ptr

Points to the buffer containing the data to be sent to the host by **RUI_WRITE**.

Both SNA commands and data are placed in this buffer, and they can be in an EBCDIC format.

lua_post_handle

Supplied parameter. Used under Microsoft Windows Server™ 2003 or Windows 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Returned parameter. Contains the SNA transmission header (TH) of the message sent or received. Various subparameters are set for write functions and returned for read and bid functions. Its subparameters are as follows:

lua_th.flags_fid

Format identification type 2, four bits.

lua_th.flags_mpf

Segmenting mapping field, two bits. Defines the type of data segment. The following values are valid:

0x00 Middle segment**0x04** Last segment**0x08** First segment**0x0C** Only segment

lua_th.flags_odai

Originating address field–destination address field (OAF–DAF) assignor indicator, one bit.

lua_th.flags_efi

Expedited flow indicator, one bit.

lua_th.daf

Destination address field (DAF), an unsigned char.

lua_th.oaf

Originating address field (OAF), an unsigned char.

lua_th.snf

Sequence number field, an unsigned char[2].

lua_rh

Returned parameter. Contains the SNA request/response header (RH) of the message sent or received. For the RH for **RUI_WRITE**, all fields except the queued-response indicator (**lua_rh.qri**) and pacing indicator (**lua_rh.pi**) are used. Its subparameters are as follows:

lua_rh.rri

Request-response indicator, one bit.

lua_rh.ruc

RU category, two bits. The following values are valid:

LUA_RH_FMD (**0x00**) FM data segment**LUA_RH_NC** (**0x20**) Network control**LUA_RH_DFC** (**0x40**) Data flow control**LUA_RH_SC** (**0x60**) Session control

lua_rh.fi

Format indicator, one bit.

lua_rh.sdi

Sense data included indicator, one bit.

lua_rh.bci

Begin chain indicator, one bit.

lua_rh.eci

End chain indicator, one bit.

lua_rh.dr1i

Definite response 1 indicator, one bit.

lua_rh.dr2i

Definite response 2 indicator, one bit.

lua_rh.ri

Exception response indicator (for a request), or response type indicator (for a response), one bit.

lua_rh.qri

Queued response indicator, one bit.

lua_rh.pi

Pacing indicator, one bit.

lua_rh.bbi

Begin bracket indicator, one bit.

lua_rh.ebi

End bracket indicator, one bit.

lua_rh.cdi

Change direction indicator, one bit.

lua_rh.csi

Code selection indicator, one bit.

lua_rh.edi

Enciphered data indicator, one bit.

lua_rh.pdi

Padded data indicator, one bit.

lua_flag1

Supplied parameter. Contains a data structure containing flags for messages supplied by the application. Its subparameters are as follows:

lua_flag1.bid_enable

Bid enable indicator, one bit.

lua_flag1.close_abend

Close immediate indicator, one bit.

lua_flag1.nowait

No wait for data flag, one bit.

lua_flag1.sscp_exp

SSCP expedited flow, one bit.

lua_flag1.sscp_norm

SSCP normal flow, one bit.

lua_flag1.lu_exp

LU expedited flow, one bit.

lua_flag1.lu_norm

LU normal flow, one bit.

Set one of the following flags to 1 to indicate on which message flow the data is to be sent:

lua_flag1.sscp_exp

lua_flag1.sscp_norm

lua_flag1.lu_exp

lua_flag1.lu_norm

lua_message_type

Not used by **RUI_WRITE** and should be set to zero.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA. Its subparameters are as follows:

lua_flag2.bid_enable

Indicates that RUI_BID was successfully re-enabled if set to 1.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_flag2.sscp_exp

Indicates SSCP expedited flow if set to 1.

lua_flag2.sscp_norm

Indicates SSCP normal flow if set to 1.

lua_flag2.lu_exp

Indicates LU expedited flow if set to 1.

lua_flag2.lu_norm

Indicates LU normal flow if set to 1.

lua_resv56

Reserved and should be set to zero.

lua_encr_decr_option

Reserved and should be set to zero.

Return Codes

LUA_OK

Primary return code; the verb executed successfully.

LUA_CANCELED

Primary return code; the verb did not complete successfully because it was canceled by another verb.

LUA_TERMINATED

Secondary return code; the verb was canceled because RUI_TERM was issued for this session.

LUA_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

LUA_BAD_DATA_PTR

Secondary return code; the **lua_data_ptr** parameter contained an invalid value.

LUA_BAD_SESSION_ID

Secondary return code; an invalid value for **lua_sid** was specified in the VCB.

LUA_DUPLICATE_WRITE_FLOW

Secondary return code; **RUI_WRITE** was already outstanding for the session flow specified on this verb (the session flow is specified by setting one of the **lua_flag1** flow flags to 1). Only one **RUI_WRITE** at a time can be outstanding on each session flow.

LUA_INVALID_FLOW

Secondary return code; the **lua_flag1.sscp_exp** flow flag was set, indicating that the message should be sent on the SSCP expedited flow. LUA does not allow applications to send data on this flow.

LUA_INVALID_POST_HANDLE

Secondary return code; for a Windows Server 2003 or Windows 2000 system using events as the asynchronous posting method, the Windows LUA VCB does not contain a valid event handle.

LUA_MULTIPLE_WRITE_FLOWS

Secondary return code; more than one of the **lua_flag1** flow flags was set to 1. One and only one of these flags must be set to 1, to indicate which session flow the data is to be sent on.

LUA_REQUIRED_FIELD_MISSING

Secondary return code; indicates one of the following cases:

- None of the **lua_flag1** flow flags was set. One and only one of these flags must be set to 1.
- **RUI_WRITE** was used to send a response, and the response required more data than was supplied.

LUA_RESERVED_FIELD_NOT_ZERO

Secondary return code; a reserved field in the verb record or a parameter not used by this verb was set to a nonzero value.

LUA_VERB_LENGTH_INVALID

Secondary return code; an LUA verb was issued with the value of **lua_verb_length** unexpected by LUA.

LUA_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

LUA_MODE_INCONSISTENCY

Secondary return code; the SNA message sent on **RUI_WRITE** was not valid at this time. This is caused by trying to send data on the LU session before the session is bound. Check the sequence of SNA messages sent.

LUA_NO_RUI_SESSION

Secondary return code; RUI_INIT has not yet completed successfully for the LU name specified on this verb.

LUA_UNSUCCESSFUL

Primary return code; the verb record supplied was valid, but the verb did not complete successfully.

LUA_FUNCTION_NOT_SUPPORTED

Secondary return code; indicates one of the following cases:

- The **lua_rh.fi** bit (format indicator) was set to 1, but the first byte of the supplied RU was not a recognized request code.
- The **lua_rh.ruc** parameter (RU category) specified the network control (NC) category; LUA does not allow applications to send requests in this category.

LUA_INVALID_PROCESS

Secondary return code; the OS/2 process that issued this verb was not the same process that issued **RUI_INIT** for this session. Only the process that started a session can issue verbs on that session.

LUA_INVALID_SESSION_PARAMETERS

Secondary return code; the application used **RUI_WRITE** to send a positive response to a BIND message received from the host. However, Host Integration Server cannot accept the BIND parameters as specified, and has sent a negative response to the host. For more information about the BIND profiles accepted by Host Integration Server, see SNA Considerations Using LUA.

LUA_RSP_CORRELATION_ERROR

Secondary return code; when using **RUI_WRITE** to send a response, **lua_th.snf** (which indicates the sequence number of the received message being responded to) did not contain a valid value.

LUA_RU_LENGTH_ERROR

Secondary return code; the **lua_data_length** parameter contained an invalid value. When sending data on the LU normal flow, the maximum length is as specified in the BIND received from the host; for all other flows the maximum length is 256 bytes.

Note
Any other secondary return code is an SNA sense code indicating that the supplied SNA data was invalid or could not be sent. For information about interpreting the SNA sense codes that can be returned, see SNA Considerations Using LUA.

LUA_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the transaction program (TP) and the physical unit (PU) 2.1 node was broken (a LAN error).
- The SnaBase at the TPs computer encountered an ABEND.

LUA_SESSION_FAILURE

Primary return code; a required Host Integration Server component has terminated.

LUA_LU_COMPONENT_DISCONNECTED

Secondary return code; indicates that the LUA session has failed because of a problem with the link service or with the host LU.

LUA_RUI_LOGIC_ERROR

Secondary return code; an internal error was detected within LUA. This error should not occur during normal operation.

LUA_INVALID_VERB

Primary return code; either the verb code or the operation code, or both, is invalid. The verb did not execute.

LUA_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

LUA_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or has terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

LUA_UNEXPECTED_DOS_ERROR

Primary return code; after issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

Remarks

RUI_INIT must be issued successfully before this verb is issued.

When sending an SNA request, all applicable values in the **lua_rh** must be set. Chaining and bracketing are the responsibility of the application.

When sending a response, the type of response determines the **RUI_WRITE** information required. For all responses, you must:

- Set the selected **lua_rh.rri** flag to 1.
- Provide the sequence number in **lua_th.snf** for the request to which you are responding.

For multi-chain message responses, the sequence number of the last received chain element must be used. For a response to a multichain message ending with a CANCEL command, the CANCEL command sequence number is used.

For positive responses that only require the request code, set **lua_rh.ri** to zero (indicating that the response is positive) and **lua_data_length** to zero (indicating that no data is provided). The request code is filled in by the RUI, using the sequence number provided.

For negative responses, set **lua_rh.ri** to 1, **lua_data_ptr** to the SNA sense code address, and **lua_data_length** to the SNA sense code length (four bytes). The sequence number is used by the RUI to fill in the request code.

For positive responses to the BIND and STSN commands that require data in the responses, set **lua_data_ptr** to point to the response and set **lua_data_length** to the length of the data provided in **lua_data_ptr**.

While an existing **RUI_WRITE** is pending, you can issue a second **RUI_WRITE** only if it specifies a different session flow from the pending **RUI_WRITE**. You cannot have more than one **RUI_WRITE** outstanding for the same session flow.

RUI_WRITE can be issued on the SSCP normal flow at any time after a successful RUI_INIT. **RUI_WRITE** verbs on the LU expedited or LU normal flows are permitted only after a BIND has been received, and must abide by the protocols specified on the BIND.

The successful completion of **RUI_WRITE** indicates that the message was queued successfully to the data link. It does not necessarily indicate that the message was sent successfully, or that the host accepted it.

Pacing can be used on the secondary-to-primary half-session (specified on the BIND) to prevent the LUA application from sending more data than the local or remote LU can handle. If this is the case, an **RUI_WRITE** on the LU normal flow may be delayed by LUA and may take some time to complete.

LUA SLI Verbs

This section describes the Microsoft® Windows® logical unit application (LUA) Session Level Interface (SLI) verbs. It provides the following information for each SLI verb:

- Details of the LUA verb control block (VCB) structure.
- A description of the verb and its purpose.
- Parameters (VCB structure members) supplied to and returned by LUA. The description of each parameter includes information about the valid values for that parameter.
- Interaction with other verbs.

Cryptography is not defined as part of the Windows LUA standard.

The verb descriptions in this section include parameter values specific to each verb. For a complete description of the VCB structure for both Request Unit Interface (RUI) and SLI verbs, see LUA Verb Control Blocks.

In This Section

SLI_BID

The **SLI_BID** verb notifies the Session Level Interface (SLI) application that a message is waiting to be read using SLI_RECEIVE. **SLI_BID** also provides the current status of the session to the Windows logical unit application (LUA) application.

The following structure describes the LUA_COMMON member of the verb control block (VCB) used by SLI_BID.

The second syntax union describes the **LUA_SPECIFIC** member of the VCB used by **SLI_BID**. Other union members are omitted for clarity.

Syntax

```
struct LUA_COMMON {
    unsigned short lua_verb;
    unsigned short lua_verb_length;
    unsigned short lua_prim_rc;
    unsigned long  lua_sec_rc;
    unsigned short lua_opcode;
    unsigned long  lua_correlator;
    unsigned char  lua_luname[8];
    unsigned short lua_extension_list_offset;
    unsigned short lua_cobol_offset;
    unsigned long  lua_sid;
    unsigned short lua_max_length;
    unsigned short lua_data_length;
    char FAR *     lua_data_ptr;
    unsigned long  lua_post_handle;
    struct LUA_TH  lua_th;
    struct LUA_RH  lua_rh;
    struct LUA_FLAG1 lua_flag1;
    unsigned char  lua_message_type;
    struct LUA_FLAG2 lua_flag2;
    unsigned char  lua_resv56[7];
    unsigned char  lua_encr_decr_option;
};
union LUA_SPECIFIC {
    unsigned char  lua_peek_data[12];
};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_SLI for SLI verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the LUA VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_SLI_BID.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

SLI_BID only requires this parameter if lua_sid is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by **SLI_BID** and should be set to zero.

lua_cobol_offset

Not used by LUA in Microsoft® Host Integration Server and should be zero.

lua_sid

Supplied parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Not used by **SLI_BID** and should be set to zero.

lua_data_length

Returned parameter. Specifies the length of data returned in **lua_peek_data**.

lua_data_ptr

Pointer to the application-supplied buffer that contains the data to be sent for SLI_SEND and RUI_WRITE or that will receive data for SLI_RECEIVE and RUI_READ. Not used by other RUI and SLI verbs and should be set to zero.

lua_post_handle

Supplied parameter. Used under Microsoft Windows Server™ 2003 or Windows 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

For all other environments, this parameter is reserved and should be set to zero.

lua_th

Returned parameter. Contains the SNA transmission header (TH) of the message received. Various subparameters are returned for read and bid functions. Its subparameters are as follows:

lua_th.flags_fid

Format identification type 2, four bits.

lua_th.flags_mpf

Segmenting mapping field, two bits. Defines the type of data segment. The following values are valid:

0x00 Middle segment**0x04** Last segment**0x08** First segment**0x0C** Only segment

lua_th.flags_odai

Originating address field–destination address field (OAF–DAF) assignor indicator, one bit.

lua_th.flags_efi

Expedited flow indicator, one bit.

lua_th.daf

Destination address field (DAF), an unsigned char.

lua_th.oaf

Originating address field (OAF), an unsigned char.

lua_th.snf

Sequence number field, an unsigned char[2].

lua_rh

Returned parameter. Contains the SNA request/response header (RH) of the message sent or received. Its subparameters are as follows:

lua_rh.rri

Request-response indicator, one bit.

lua_rh.ruc

Request/response unit (RU) category, two bits. The following values are valid:

LUA_RH_FMD (**0x00**) FM data segment**LUA_RH_NC** (**0x20**) Network control**LUA_RH_DFC** (**0x40**) Data flow control**LUA_RH_SC** (**0x60**) Session control

lua_rh.fi

Format indicator, one bit.

lua_rh.sdi

Sense data included indicator, one bit.

lua_rh.bci

Begin chain indicator, one bit.

lua_rh.eci

End chain indicator, one bit.

lua_rh.dr1i

Definite response 1 indicator, one bit.

lua_rh.dr2i

Definite response 2 indicator, one bit.

lua_rh.ri

Exception response indicator (for a request), or response type indicator (for a response), one bit.

lua_rh.qri

Queued response indicator, one bit.

lua_rh.pi

Pacing indicator, one bit.

lua_rh.bbi

Begin bracket indicator, one bit.

lua_rh.ebi

End bracket indicator, one bit.

lua_rh.cdi

Change direction indicator, one bit.

lua_rh.csi

Code selection indicator, one bit.

lua_rh.edi

Enciphered data indicator, one bit.

lua_rh.pdi

Padded data indicator, one bit.

lua_flag1

Supplied parameter. Contains a data structure containing flags for messages supplied by the application. Its subparameters are as follows:

lua_flag1.bid_enable

Bid enable indicator, one bit.

lua_flag1.close_abend

Close immediate indicator, one bit.

lua_flag1.nowait

No wait for data flag, one bit.

lua_flag1.sscp_exp

System services control point (SSCP) expedited flow, one bit.

lua_flag1.sscp_norm

SSCP normal flow, one bit.

lua_flag1.lu_exp

LU expedited flow, one bit.

lua_flag1.lu_norm

LU normal flow, one bit.

lua_message_type

Returned parameter. Specifies the type of SNA message indicated to SLI_BID. Possible values are:

LUA_MESSAGE_TYPE_LU_DATA

LUA_MESSAGE_TYPE_SSCP_DATA

LUA_MESSAGE_TYPE_RSP

LUA_MESSAGE_TYPE_BID

LUA_MESSAGE_TYPE_BIND

LUA_MESSAGE_TYPE_BIS

LUA_MESSAGE_TYPE_CANCEL

LUA_MESSAGE_TYPE_CHASE

LUA_MESSAGE_TYPE_LUSTAT_LU

LUA_MESSAGE_TYPE_LUSTAT_SSCP

LUA_MESSAGE_TYPE_QC

LUA_MESSAGE_TYPE_QEC

LUA_MESSAGE_TYPE_RELQ

LUA_MESSAGE_TYPE_RTR

LUA_MESSAGE_TYPE_SBI

LUA_MESSAGE_TYPE_SIGNAL

LUA_MESSAGE_TYPE_STSN

The SLI receives and responds to the BIND and STSN requests through the LUA interface extension routines.

LU_DATA, LUSTAT_LU, LUSTAT_SSCP, and SSCP_DATA are not SNA commands.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA. Its subparameters are as follows:

lua_flag2.bid_enable

Indicates that **SLI_BID** was successfully re-enabled if set to 1.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_flag2.sscp_exp

Indicates SSCP expedited flow if set to 1.

lua_flag2.sscp_norm

Indicates SSCP normal flow if set to 1.

lua_flag2.lu_exp

Indicates LU expedited flow if set to 1.

lua_flag2.lu_norm

Indicates LU normal flow if set to 1.

lua_resv56

Reserved and should be set to zero.

lua_encr_decr_option

Not used by **SLI_BID** and should be set to zero.

lua_peek_data

The union member of **LUA_SPECIFIC** used by the RUI_BIDand **SLI_BID** verbs. Returned parameter. Contains up to 12 bytes of the data waiting to be read.

Return Codes
LUA_OK

Primary return code; the verb executed successfully.

LUA_SEC_OK

Secondary return code; no additional information exists for LUA_OK.

LUA_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

LUA_INVALID_LUNAME

Secondary return code; an invalid **lua_luname** name was specified.

LUA_BAD_SESSION_ID

Secondary return code; an invalid value for **lua_sid** was specified in the VCB.

LUA_RESERVED_FIELD_NOT_ZERO

Secondary return code; a reserved parameter for the verb just issued is not set to zero.

LUA_INVALID_POST_HANDLE

Secondary return code; for a Microsoft Windows Server 2003 or Windows 2000 system using events as the asynchronous posting method, the Windows LUA VCB does not contain a valid event handle.

LUA_VERB_LENGTH_INVALID

Secondary return code; an LUA verb was issued with the value of **lua_verb_length** unexpected by LUA.

LUA_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

LUA_NO_SLI_SESSION

Secondary return code; a session was not open or was down due to an SLI_CLOSE or session failure when a command was issued.

LUA_SLI_BID_PENDING

Secondary return code; an SLI verb was still active when another **SLI_BID** was issued. Only one **SLI_BID** can be active at a

time.

LUA_SESSION_FAILURE

Primary return code; an error condition, specified in the secondary return code, caused the session to fail.

LUA_RECEIVED_UNBIND

Secondary return code; the primary logical unit (PLU) sent an SNA UNBIND command to the LUA interface when a session was active. As a result, the session was stopped.

LUA_SLI_LOGIC_ERROR

Secondary return code; the LUA interface found an internal error in logic.

LUA_NO_RUI_SESSION

Secondary return code; no session has been initialized for the LUA verb issued, or some verb other than SLI_OPEN was issued before the session was initialized.

LUA_MODE_INCONSISTENCY

Secondary return code; performing this function is not allowed by the current status. The request sent to the half-session component was not executed even though it was understood and supported. This SNA sense code is also an exception request sense code.

LUA_RECEIVER_IN_TRANSMIT_MODE

Secondary return code; either resources needed to handle normal flow data were not available or the state of the half-duplex contention was not received when a normal-flow request was received. The result is a race condition. This SNA sense code is also an exception request sense code.

LUA_LU_COMPONENT_DISCONNECTED

Secondary return code; an LU component is unavailable because it is not connected properly. Make sure that the power is on.

LUA_FUNCTION_NOT_SUPPORTED

Secondary return code; LUA does not support the requested function. A control character, an RU parameter, or a formatted request code may have specified the function. Specific sense code information is in bytes 2 and 3.

LUA_CHAINING_ERROR

Secondary return code; the sequence of the chain indicator settings is in error. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_BRACKET

Secondary return code; the sender failed to enforce the session bracket rules. Note that contention and race conditions are exempt from this error. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DIRECTION

Secondary return code; while the half-duplex flip-flop state was NOT_RECEIVE, a request for normal flow was received. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DATA_TRAFFIC_QUIESCED

Secondary return code; a data flow control (DFC) or function management data (FMD) request was received from a half-session that sent either a SHUTC command or QC command, and the DFC or FMD request has not responded to a RELQ command. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_NO_BEGIN_BRACKET

Secondary return code; the receiver has already sent a positive response to a BIS command when a BID or an FMD request specifying BBI=BB was received. An invalid request header or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_IMMEDIATE_REQUEST_MODE_ERROR

Secondary return code; the request violated the immediate request mode protocol. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_QUEUED_RESPONSE_ERROR

Secondary return code; the request violated the queued response protocol. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_ERP_SYNC_EVENT_ERROR

Secondary return code; a violation of the ERP synchronous event protocol occurred. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_RSP_CORRELATION_ERROR

Secondary return code; a response was sent that does not correspond to a previously received request or a response was received that does not correspond to a previously sent request.

LUA_RSP_PROTOCOL_ERROR

Secondary return code; a violation of the response protocol was found in the response received from the primary half-session.

LUA_BB_NOT_ALLOWED

Secondary return code; the begin bracket indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_EB_NOT ALLOWED

Secondary return code; the end bracket indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_EXCEPTION_RSP_NOT_ALLOWED

Secondary return code; when an exception response was not allowed, one was requested. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_DEFINITE_RSP_NOT_ALLOWED

Secondary return code; when a definite response was not allowed, one was requested. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CD_NOT_ALLOWED

Secondary return code; the change-direction indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_NO_RESPONSE_NOT_ALLOWED

Secondary return code; a request other than an EXR contained a "NO RESPONSE" The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CHAINING_NOT_SUPPORTED

Secondary return code; the chaining indicators were incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was

prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_BRACKETS_NOT_SUPPORTED

Secondary return code; the bracket indicators were incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CD_NOT_SUPPORTED

Secondary return code; the change-direction indicator was set, but LUA does not support change-direction for this situation. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_FI

Secondary return code; the format indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_ALTERNATE_CODE_NOT_SUPPORTED

Secondary return code; the code selection indicator was set, but LUA does not support code selection for this session. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_RU_CATEGORY

Secondary return code; the request unit category indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_REQUEST_CODE

Secondary return code; the request code was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_SPEC_OF_SDI_RTI

Secondary return code; the sense-data-included indicator (SDI) and the response-type-indicator (RTI) were not specified correctly on a response. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_DR1I_DR2I_ERI

Secondary return code; the definite response 1 indicator (DR1I), the definite response 2 indicator (DR2I), and the exception response indicator (ERI) were specified incorrectly. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_QRI

Secondary return code; the queued response indicator (QRI) was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_EDI

Secondary return code; the enciphered data indicator (EDI) was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was

prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_PDI

Secondary return code; the padded data indicator (PDI) was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_UNSUCCESSFUL

Primary return code; the verb record supplied was valid, but the verb did not complete successfully.

LUA_VERB_RECORD_SPANS_SEGMENTS

Secondary return code; the LUA VCB length parameter plus the segment offset is beyond the segment end.

LUA_NOT_ACTIVE

Secondary return code; LUA was not active within Microsoft Host Integration Server when an LUA verb was issued.

LUA_INVALID_PROCESS

Secondary return code; the session for which an LUA verb was issued is unavailable because another process owns the session.

LUA_LU_INOPERATIVE

Secondary return code; a severe error occurred while attempting to stop the session. This LU is unavailable for any LUA requests until an activate logical unit (ACTLU) is received from the host.

LUA_RECEIVE_CORRELATION_TABLE_FULL

Secondary return code; the session receive correlation table for the flow requested reached its capacity.

LUA_NEGATIVE_RESPONSE

Primary return code; either LUA sent a negative response to a message received from the primary logical unit (PLU) because an error was found in the message, or the application responded negatively to a chain for which the end-of-chain has arrived.

LUA_FUNCTION_NOT_SUPPORTED

Secondary return code; the LUA does not support the requested function. A control character, an RU parameter, or a formatted request code may have specified the function. Specific sense code information is in bytes 2 and 3.

LUA_DATA_TRAFFIC_RESET

Secondary return code; a half-session of an active session but with inactive data traffic received a normal flow DFC or FMD request. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DATA_TRAFFIC_NOT_RESET

Secondary return code; while the data traffic state was not reset, the session control request was received. An invalid request header or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_SC_PROTOCOL_VIOLATION

Secondary return code; a violation of the session control (SC) protocol occurred. A request (that is permitted only after an SC request and a positive response to that request have been successfully exchanged) was received before the required exchange. Byte 4 of the sense data contains the request code. No user data exists for this sense code. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_INVALID_SC_OR_NC_RH

Secondary return code; the RH of an SC or NC request was invalid.

LUA_PACING_NOT_SUPPORTED

Secondary return code; the request contained a pacing indicator when support of pacing for this session does not exist for

the receiving half-session or boundary function half-session. The BIND options chosen previously or the architectural rules were violated by **lua_rh** values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_NAU_INOPERATIVE

Secondary return code; the network addressable unit (NAU) is not able to process responses or requests. Delivery to the receiver could not take place for one of the following reasons:

A path information unit error

A path outage

An invalid sequence of requests for activation

If a path error is received during an active session, that usually means there is no longer a valid path to the session partner.

LUA_CANCELED

Primary return code; the secondary return code gives the reason for canceling the command.

LUA_TERMINATED

Secondary return code; the session was terminated when a verb was pending. The verb process has been canceled.

LUA_IN_PROGRESS

Primary return code; an asynchronous command was received but is not completed.

LUA_STATUS

Primary return code; the secondary return code contains SLI status information for the application.

LUA_READY

Secondary return code; following a NOT_READY status, this status is issued to notify you that the SLI is ready to process commands.

LUA_NOT_READY

Secondary return code; an SNA UNBIND type 0x02 command was received, which means a new BIND is coming.

If the UNBIND type 0x02 is received after the beginning SLI_OPEN is complete, the session is suspended until a BIND, optional CRV and STSN, and SDT flows are received. These routines are re-entrant because they have to be called again. The session resumes after the SLI processes the SDT command.

If the UNBIND type 0x02 is received while SLI_OPEN is still processing, the primary return code is session-failure, not status. Or, the receipt of an SNA CLEAR caused the suspension. Receipt of an SNA SDT will cause the session to resume.

LUA_INIT_COMPLETE

Secondary return code; the LUA interface initialized the session while **SLI_OPEN** was processing. LUA applications that issue **SLI_OPEN** with the **lua_open_type_prim_sscp** parameter receive this status on SLI_RECEIVE or **SLI_BID**.

LUA_SESSION_END_REQUESTED

Secondary return code; the LUA interface received an SNA shutdown command (SHUTD) from the host, which means the host is ready to shut down the session.

LUA_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

The node used by this conversation encountered an ABEND.

The connection between the transaction program (TP) and the physical unit (PU) 2.1 node has been broken (a LAN error).

The SnaBase at the TPs computer encountered an ABEND.

LUA_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

LUA_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

Primary return code; the VCB extended beyond the end of the data segment.

LUA_UNEXPECTED_DOS_ERROR

Primary return code; after issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

LUA_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

LUA_INVALID_VERB

Primary return code; either the verb code or the operation code, or both, is invalid. The verb did not execute.

Remarks

SLI_BID does the following:

- Notifies a Windows LUA application that a message is waiting to be read.
- Provides the current session status.
- Provides a preview of the next message that will be read by SLI_RECEIVE.

  This preview contains a maximum of 12 bytes of information (peek data) that enables the Windows LUA application to define its processing strategy for the data.

To use **SLI_BID** within a Windows LUA application, issue **SLI_BID**. When the verb completes, it can be reactivated in the following two ways:

- Reissue **SLI_BID**.
- Issue SLI_RECEIVE with lua_flag1_bid_enable set to 1. This issues an SLI_BID that uses the most recently accepted address for the VCB and establishes the active bid.

Each session can have only one **SLI_BID** at a time.

If multiple messages are available when a Windows LUA application issues SLI_BID, the data flow with the highest priority is returned. The order in which the data can be returned is as follows:

- SSCP expedited
- LU expedited
- SSCP normal
- LU normal

If SLI_RECEIVE has flags set to read more than one type of message flow, the data returned by **SLI_BID** might be for a flow different than the one for which you actually receive data through **SLI_RECEIVE**. This situation occurs when higher priority data arrives from the host after **SLI_BID** completes processing, but before **SLI_RECEIVE** is issued.

To ensure that SLI_RECEIVE reads the data, the SLI_BID returned specifies the flow that matches lua_flag2 returned by the completed SLI_BID.

Session Status Return Values

If LUA_STATUS is the primary return code, the secondary return code can be LUA_READY, LUA_NOT_READY, LUA_SESSION_END_REQUESTED, or LUA_INIT_COMPLETE. In addition, if LUA_STATUS is the primary return code, the following parameters are used:

lua_sec_rc

lua_sid

LUA_READY is returned after LUA_NOT_READY status, and indicates that the SLI is again ready to perform all commands.

LUA_NOT_READY indicates that the SLI session is suspended because the SLI has received either an SNA CLEAR command or an SNA UNBIND command with an 0x02 UNBIND type (UNBIND with BIND forthcoming). Depending on what caused the suspension, the session can be reactivated as follows:

- When the suspension is caused by an SNA CLEAR, receiving an SNA SDT reactivates the session.
- When an SNA UNBIND type BIND forthcoming causes suspension of the session and the SLI_OPEN that opened the session is completed, the session is suspended until the SLI receives a BIND and SDT command. The session can also optionally receive an STSN command. As a result, user-supplied routines issued with the initial SLI_OPEN must be re-entered because they will be recalled.

The application can send SSCP data after a CLEAR or UNBIND type BIND forthcoming arrives and before the NOT READY status is read. The application can send and receive SSCP data after reading a NOT READY.

When an SNA UNBIND type BIND forthcoming arrives before completion of the SLI_OPEN that opened the session, LUA_SESSION_FAILURE (not LUA_STATUS) is the primary return code.

LUA_SESSION_END_REQUESTED indicates that the application received an SNA SHUTD from the host. The Windows LUA application should issue SLI_CLOSE to close the session when convenient.

LUA_INIT_COMPLETE is returned only when lua_init_type for SLI_OPEN is LUA_INIT_TYPE_PRIM_SSCP. The status means that SLI_OPEN has been processed sufficiently to allow SSCP data to now be sent or received.

Exception Requests

If a host application request unit is converted into an EXR, sense data will be returned. When an **SLI_BID** completes with the returned verb parameters set as shown, an EXR conversion occurs.

Member	**Set to**
lua_prim_rc	OK (0x0000)
lua_sec_rc	OK (0x00000000)
lua_rh.rri	bit off (request unit)
lua_rh.sdi	bit on (includes sense data)

Of the seven bytes of data in **lua_peek_data**, bytes 0 through 3 define the error detected. The following table indicates possible sense data and the values of bytes 0 through 3.

Sense data	**Value of bytes 0–3**
LUA_MODE_INCONSISTENCY	0x08090000
LUA_BRACKET_RACE_ERROR	0x080B0000
LUA_BB_REJECT_NO_RTR	0x08130000
LUA_RECEIVER_IN_TRANSMIT_MODE	0x081B0000
LUA_CRYPTOGRAPHY_FUNCTION_INOP	0x08480000
LUA_SYNC_EVENT_RESPONSE	0x10010000
LUA_RU_DATA_ERROR	0x10020000

LUA_RU_LENGTH_ERROR	0x10020000
LUA_INCORRECT_SEQUENCE_NUMBER	0x20010000

The information returned to bytes 3 through 6 in **lua_peek_data** is determined by the first 3 bytes of the initial request unit that caused the error.

SLI_CLOSE

SLI_OPEN

SLI_RECEIVE

SLI_CLOSE

The **SLI_CLOSE** verb ends a session opened with SLI_OPEN. The LU-LU and LU-SSCP resources are released.

The following structure describes the LUA_COMMON member of the verb control block (VCB) used by SLI_CLOSE.

Syntax

```
struct LUA_COMMON {
    unsigned short   lua_verb;
    unsigned short   lua_verb_length;
    unsigned short   lua_prim_rc;
    unsigned long    lua_sec_rc;
    unsigned short   lua_opcode;
    unsigned long    lua_correlator;
    unsigned char    lua_luname[8];
    unsigned short   lua_extension_list_offset;
    unsigned short   lua_cobol_offset;
    unsigned long    lua_sid;
    unsigned short   lua_max_length;
    unsigned short   lua_data_length;
    char FAR *       lua_data_ptr;
    unsigned long    lua_post_handle;
    struct LUA_TH    lua_th;
    struct LUA_RH    lua_rh;
    struct LUA_FLAG1 lua_flag1;
    unsigned char    lua_message_type;
    struct LUA_FLAG2 lua_flag2;
    unsigned char    lua_resv56[7];
    unsigned char    lua_encr_decr_option;

};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_SLI for Session Level Interface (SLI) verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the logical unit application (LUA) VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_SLI_CLOSE.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

SLI_CLOSE only requires this parameter if lua_sid is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by **SLI_CLOSE** and should be set to zero.

lua_cobol_offset

Not used by LUA in Microsoft® Host Integration Server and should be zero.

lua_sid

Supplied parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Not used by **SLI_CLOSE** and should be set to zero.

lua_data_length

Not used by **SLI_CLOSE** and should be set to zero.

lua_data_ptr

Not used by **SLI_CLOSE** and should be set to zero.

lua_post_handle

Supplied parameter. Used under Microsoft Windows Server™ 2003 or Windows® 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Not used by **SLI_CLOSE** and should be set to zero.

lua_rh

Not used by **SLI_CLOSE** and should be set to zero.

lua_flag1

Supplied parameter. Contains a data structure containing flags for messages supplied by the application. Its subparameters are as follows:

lua_flag1.bid_enable

Bid enable indicator, one bit.

lua_flag1.close_abend

Close immediate indicator, one bit. A supplied parameter used by **SLI_CLOSE** to specify whether the session is to be closed immediately (ON) or closed normally (OFF). For verbs other than **SLI_CLOSE**, this flag must be off.

lua_flag1.nowait

No wait for data flag, one bit.

lua_flag1.sscp_exp

System services control point (SSCP) expedited flow, one bit.

lua_flag1.sscp_norm

SSCP normal flow, one bit.

lua_flag1.lu_exp

LU expedited flow, one bit.

lua_flag1.lu_norm

LU normal flow, one bit.

lua_message_type

Not used by **SLI_CLOSE** and should be set to zero.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_resv56

Reserved and should be set to zero.

lua_encr_decr_option

Not used by **SLI_CLOSE** and should be set to zero.

Return Codes
LUA_OK

Primary return code; the verb executed successfully.

LUA_SEC_OK

Secondary return code; no additional information exists for LUA_OK.

LUA_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

LUA_INVALID_LUNAME

Secondary return code; an invalid **lua_luname** was specified.

LUA_BAD_SESSION_ID

Secondary return code; an invalid value for **lua_sid** was specified in the VCB.

LUA_RESERVED_FIELD_NOT_ZERO

Secondary return code; a reserved parameter for the verb just issued is not set to zero.

LUA_INVALID_POST_HANDLE

Secondary return code; for a Microsoft Windows Server 2003 or Windows 2000 system using events as the asynchronous posting method, the Windows LUA VCB does not contain a valid event handle.

LUA_VERB_LENGTH_INVALID

Secondary return code; an LUA verb was issued with a value for **lua_verb_length** unexpected by LUA.

LUA_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

LUA_NO_SLI_SESSION

Secondary return code; a session was not open or was down due to an **SLI_CLOSE** or session failure when a command was issued.

LUA_CLOSE_PENDING

Secondary return code; one of the following has occurred:

- A CLOSE_ABEND was still pending when another CLOSE_ABEND was issued. You can issue a CLOSE_ABEND if a CLOSE_NORMAL is pending.
- Either a CLOSE_ABEND or a CLOSE_NORMAL was still pending when a CLOSE_NORMAL was issued.

LUA_SESSION_FAILURE

Primary return code; an error condition, specified in the secondary return code, caused the session to fail.

LUA_NOT_ACTIVE

Secondary return code; LUA was not active within Microsoft Host Integration Server when an LUA verb was issued.

LUA_UNEXPECTED_SNA_SEQUENCE

Secondary return code; unexpected data or commands were received from the host while SLI_OPEN was processing.

LUA_NEGATIVE_RSP_CHASE

Secondary return code; a negative response to an SNA CHASE command from the host was received by the LUA interface while **SLI_CLOSE** was being processed. **SLI_CLOSE** continued processing to stop the session.

LUA_NEGATIVE_RSP_SHUTC

Secondary return code; a negative response to an SNA SHUTC command from the host was received by the SLI while **SLI_CLOSE** was still being processed. **SLI_CLOSE** continued processing to stop the session.

LUA_NEGATIVE_RSP_SHUTD

Secondary return code; a negative response to an SNA RSHUTD command from the host was received by the LUA interface while **SLI_CLOSE** was still being processed. **SLI_CLOSE** continued processing to stop the session.

LUA_RECEIVED_UNBIND

Secondary return code; the primary logical unit (PLU) sent an SNA UNBIND command to the LUA interface when a session was active. As a result, the session was stopped.

LUA_NO_RUI_SESSION

Secondary return code; no session has been initialized for the LUA verb issued, or some verb other than SLI_OPEN was issued before the session was initialized.

LUA_LU_COMPONENT_DISCONNECTED

Secondary return code; an LU component is unavailable because it is not connected properly. Make sure that the power is on.

LUA_IN_PROGRESS

Primary return code; an asynchronous command was received but is not completed.

LUA_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the transaction program (TP) and the physical unit (PU) 2.1 node has been broken (a LAN error).
- The SnaBase at the TPs computer encountered an ABEND.

LUA_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

LUA_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

LUA_UNEXPECTED_DOS_ERROR

Primary return code; after issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

LUA_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

LUA_INVALID_VERB

Primary return code; either the verb code or the operation code, or both, is invalid. The verb did not execute.

Remarks

There are two types of **SLI_CLOSE**: normal and ABEND. For a normal close, **lua_flag1.close_abend** is set to zero. The sequence for a normal close can be initiated either as primary (host-initiated) or secondary (requested by a Windows LUA application). During a primary normal close, the Windows LUA interface:

- Reads the SHUTD command and posts the SESSION_END_REQUESTED status to the application.
- Writes the CHASE command (if necessary).
- Reads and processes the CHASE command response (if necessary).
- Writes the shutdown complete (SHUTC) command.
- Reads and processes the SHUTC command response.
- Reads and processes the CLEAR command (if necessary).
- Writes the CLEAR command response (if necessary).
- Reads and processes the UNBIND command.
- Writes the UNBIND command response.
- Stops the session.

During a secondary normal close, the Windows LUA interface:

- Writes the RSHUTD command.
- Reads and processes the RSHUTD command response.
- Reads and processes the CLEAR command (if necessary).
- Writes the CLEAR command response (if necessary).
- Reads and processes the UNBIND command.
- Writes the UNBIND command response.
- Stops the session.

For an ABEND close, **lua_flag1.close_abend** is set to 1, which directs the Windows LUA interface to close the session immediately. After **SLI_CLOSE** starts processing, the LU-LU connection is terminated and the SSCP is informed that the LU is not capable of sustaining a session.

SLI_OPEN

SLI_OPEN

The **SLI_OPEN** verb transfers control of the specified logical unit (LU) to the Microsoft® Windows® logical unit application (LUA) application. **SLI_OPEN** establishes a session between the system services control point (SSCP) and the specified LU, as well as an LU-LU session.

The following structure describes the LUA_COMMON member of the verb control block (VCB) used by SLI_OPEN.

The second syntax union describes the **LUA_SPECIFIC** member of the VCB used by **SLI_OPEN**. Other union members are omitted for clarity.

Syntax

```
struct LUA_COMMON {
    unsigned short   lua_verb;
    unsigned short   lua_verb_length;
    unsigned short   lua_prim_rc;
    unsigned long    lua_sec_rc;
    unsigned short   lua_opcode;
    unsigned long    lua_correlator;
    unsigned char    lua_luname[8];
    unsigned short   lua_extension_list_offset;
    unsigned short   lua_cobol_offset;
    unsigned long    lua_sid;
    unsigned short   lua_max_length;
    unsigned short   lua_data_length;
    char FAR *       lua_data_ptr;
    unsigned long    lua_post_handle;
    struct LUA_TH    lua_th;
    struct LUA_RH    lua_rh;
    struct LUA_FLAG1 lua_flag1;
    unsigned char    lua_message_type;
    struct LUA_FLAG2 lua_flag2;
    unsigned char    lua_resv56[7];
    unsigned char    lua_encr_decr_option;
};
```

```
union LUA_SPECIFIC {
    struct union SLI_OPEN open;
};

The SLI_OPEN structure contains the following nested structures and members:
struct LUA_EXT_ENTRY {
    unsigned char lua_routine_type;
    unsigned char lua_module_name[9];
    unsigned char lua_procedure_name[33];
} ;

struct SLI_OPEN {
    unsigned char         lua_init_type;
    unsigned char         lua_resv65;
    unsigned short        lua_wait;
    struct LUA_EXT_ENTRY  lua_open_extension[3];
    unsigned char         lua_ending_delim;
} ;
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_SLI for Session Level Interface (SLI) verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the LUA VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_SLI_OPEN.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

SLI_OPEN requires this parameter.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Supplied parameter. Specifies the offset from the start of the VCB to the extension list of user-supplied dynamic-link libraries (DLLs). The value must be the beginning of a word boundary unless there is no extension list. In this case, the value must be set to zero.

If this option is not used by SLI_OPEN, this member should be set to zero.

lua_cobol_offset

Not used by LUA in Microsoft® Host Integration Server and should be zero.

lua_sid

Returned parameter. Specifies the session identifier.

lua_max_length

Not used by **SLI_OPEN** and should be set to zero.

lua_data_length

Supplied parameter. Specifies the actual length of the data being sent.

lua_data_ptr

Pointer to the application-supplied buffer that contains the data to be sent for **SLI_OPEN**.

Both SNA commands and data are placed in this buffer, and they can be in an Extended Binary Coded Decimal Interchange Code (EBCDIC) format.

When SLI_OPEN is issued, this parameter can be one of the following:

- The LOGON message for the SSCP normal flow when the initialization type is secondary with an unformatted LOGON message.
- The request/response unit (RU) for INITSELF. When the initialization type is secondary with INITSELF, the necessary data for the application is provided.
- For all other open types, this field should be set to zero.

This information is provided by the Windows LUA application.

lua_post_handle

Supplied parameter. Used under Microsoft Windows Server™ 2003 or Windows 2000 Server if asynchronous notification is

to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Not used by **SLI_OPEN** and should be set to zero.

lua_rh

Not used by **SLI_OPEN** and should be set to zero.

lua_flag1

Not used by **SLI_OPEN** and should be set to zero.

lua_message_type

Not used by **SLI_OPEN** and should be set to zero.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA. Its subparameters are as follows:

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_resv56

Supplied parameter. Reserved field used by **SLI_OPEN** and RUI_INIT. For more information, see the Remarks section.

lua_resv56[1]

Supplied parameter. This parameter must be set to zero.

lua_resv56[2]

Supplied parameter. Indicates whether an SLI application can access LUs configured as 3270 LUs, in addition to LUA LUs. If this parameter is set to 1, 3270 LUs can be accessed.

lua_resv56[3]

Supplied parameter. Indicates whether incomplete reads are supported. If this parameter is set to 1, incomplete or truncated reads are supported. For more details, see the remarks for RUI_READ.

lua_encr_decr_option

Not used by **SLI_OPEN** and should be set to zero.

open

The union member of **LUA_SPECIFIC** used by **SLI_OPEN**. A supplied set of parameters contained in an **SLI_OPEN** structure required with **SLI_OPEN**.

open.lua_init_type

Supplied parameter. Defines how the LU-LU session is initialized by the Windows LUA interface.

Valid values are as follows:

LUA_INIT_TYPE_SEC_IS

LUA_INIT_TYPE_SEC_LOG

LUA_INIT_TYPE_PRIM

LUA_INIT_TYPE_PRIM_SSCP

open.lua_resv65

Reserved field.

open.lua_wait

Supplied parameter. Represents a secondary retry wait time indicating the number of seconds the Windows LUA interface is to wait before retrying the transmission of the INITSELF or the LOGON message after the host sends any one of these messages:

- A negative response and the secondary return code is one of the following:

  RESOURCE_NOT_AVAILABLE (0x08010000)SESSION_LIMIT_EXCEEDED (0x08050000)
  SESSION_SERVICE_PATH_ERROR (0x087D0000)

  Note that SLI_OPEN terminates with an error if lua_wait is set to zero and one of the preceding occurs.

- A network services procedure error (NSPE) message.

- A NOTIFY command, which indicates a procedure error.

open.lua_open_extension

Supplied parameter. Contains a list of application-supplied extension DLLs to process the BIND, STSN, and CRV commands.

open.open_extension.lua_routine_type

The extension routine type. Legal values are:

LUA_ROUTINE_TYPE_BIND

LUA_ROUTINE_TYPE_CRV

LUA_ROUTINE_TYPE_END (indicates end of extension list)

LUA_ROUTINE_TYPE_STSN

open.open_extension.lua_module_name

Supplied parameter. Provides the ASCII module name for the user-supplied extension DLL. The module name can be up to eight characters long, with the remaining bytes set to 0x00.

open.open_extension.lua_procedure_name

Supplied parameter. Provides the procedure name in ASCII for the user-supplied extension DLL. The procedure name can be up to 32 characters long, with the remaining bytes set to 0x00.

open.lua_ending_delim

The extension list delimiter.

Return Codes

LUA_OK

Primary return code; the verb executed successfully.

LUA_SEC_OK

Secondary return code; no additional information exists for LUA_OK.

LUA_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

LUA_INVALID_LUNAME

Secondary return code; an invalid **lua_luname** name was specified.

LUA_BAD_SESSION_ID

Secondary return code; an invalid value for **lua_sid** was specified in the VCB.

LUA_BAD_DATA_PTR

Secondary return code; the **lua_data_ptr** parameter either does not contain a valid pointer or does not point to a read/write segment and supplied data is required.

LUA_DATA_SEGMENT_LENGTH_ERROR

Secondary return code; one of the following occurred:

- The supplied data segment for SLI_RECEIVE or SLI_SEND is not a read/write data segment as required.

- The supplied data segment for SLI_RECEIVE is not as long as that provided in lua_max_length.
- The supplied data segment for SLI_SEND is not as long as that provided in lua_data_length.

LUA_RESERVED_FIELD_NOT_ZERO

Secondary return code; a reserved parameter for the verb just issued is not set to zero.

LUA_INVALID_POST_HANDLE

Secondary return code; for a Microsoft Windows Server 2003 or Windows 2000 system using events as the asynchronous posting method, the Windows LUA VCB does not contain a valid event handle.

LUA_VERB_LENGTH_INVALID

Secondary return code; an LUA verb was issued with a value for **lua_verb_length** unexpected by LUA.

LUA_INVALID_OPEN_INIT_TYPE

Secondary return code; the value in the **lua_init_type** contained in **SLI_OPEN** is invalid.

LUA_INVALID_OPEN_DATA

Secondary return code; the **lua_init_type** for the **SLI_OPEN** issued is set to LUA_INIT_TYPE_SEC_IS when the buffer for data does not have a valid INITSELF command.

LUA_INVALID_OPEN_ROUTINE_TYPE

Secondary return code; the **lua_open_routine_type** for the **SLI_OPEN** list of extension routines is invalid.

LUA_DATA_LENGTH_ERROR

Secondary return code; the application did not provide user-supplied data required by the verb issued. Note that when SLI_SEND is issued for an SNA LUSTAT command, status (in four bytes) is required, and that when **SLI_OPEN** is issued with secondary initialization, data is required.

LUA_INVALID_SLI_ENCR_OPTION

Secondary return code; the **lua_encr_decr_option** parameter was set to 128 in **SLI_OPEN**, which is not supported for the encryption/decryption processing option.

LUA_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

LUA_NOT_ACTIVE

Secondary return code; LUA was not active within Microsoft Host Integration Server or SNA Server when an LUA verb was issued.

LUA_UNEXPECTED_SNA_SEQUENCE

Secondary return code; unexpected data or commands were received from the host while **SLI_OPEN** was processing.

LUA_NEG_RSP_FROM_BIND_ROUTINE

Secondary return code; the user-supplied SLI_BIND routine responded negatively to the BIND. **SLI_OPEN** ended unsuccessfully.

LUA_NEG_RSP_FROM_STSN_ROUTINE

Secondary return code; the user-supplied SLI STSN routine responded negatively to the STSN. **SLI_OPEN** ended unsuccessfully.

LUA_PROCEDURE_ERROR

Secondary return code; a host procedure error is indicated by the receipt of an NSPE or NOTIFY message. The return code is posted to **SLI_OPEN** when the retry option is not used. To use the reset option, set **lua_wait** to a value other than zero. The LOGON or INITSELF command will be retried until the host is ready or until you issue SLI_CLOSE.

LUA_RECEIVED_UNBIND

Secondary return code; the primary logical unit (PLU) sent an SNA UNBIND command to the LUA interface when a session was active. As a result, the session was stopped.

LUA_SLI_LOGIC_ERROR

Secondary return code; the LUA interface found an internal error in logic.

LUA_NO_RUI_SESSION

Secondary return code; no session has been initialized for the LUA verb issued, or some verb other than **SLI_OPEN** was issued before the session was initialized.

LUA_RESOURCE_NOT_AVAILABLE

Secondary return code; the logical unit, physical unit, link, or link station specified in the request unit is unavailable. This return code is posted to **SLI_OPEN** when a resource is unavailable unless you use the retry option.

To use the retry option, set **lua_wait** to a value other than zero. The LOGON or INITSELF command will be retried until the host is ready or until you issue SLI_CLOSE.

LUA_SESSION_LIMIT_EXCEEDED

Secondary return code; the session requested was not activated because an NAU is at its session limit. This SNA sense code applies to the following requests: BID, CINIT, INIT, and ACTDRM.

The code will be posted to **SLI_OPEN** when an NAU is at its limit, unless you use the RETRY option.

To use the reset option, set **lua_wait** to a value other than zero. The LOGON or INITSELF command will be retried until the host is ready or until you issue **SLI_CLOSE**.

LUA_LU_COMPONENT_DISCONNECTED

Secondary return code; an LU component is unavailable because it is not connected properly. Make sure that the power is on.

LUA_NEGOTIABLE_BIND_ERROR

Secondary return code; a negotiable BIND was received, which is only allowed by the SLI when a user-supplied SLI_BIND routine is provided with **SLI_OPEN**.

LUA_BIND_FM_PROFILE_ERROR

Secondary return code; only file management header profiles 3 and 4 are supported by the LUA interface. A file management profile other than 3 or 4 was found on the BIND.

LUA_BIND_TS_PROFILE_ERROR

Secondary return code; only Transmission Service (TS) profiles 3 and 4 are supported by the LUA interface. A TS profile other than 3 or 4 was found on the BIND.

LUA_BIND_LU_TYPE_ERROR

Secondary return code; only LU 0, LU 1, LU 2, and LU 3 are supported by LUA. An LU other than 0, 1, 2, or 3 was found.

LUA_SSCP_LU_SESSION_NOT_ACTIVE

Secondary return code; the required SSCP-LU is inactive. Specific sense code information is in bytes 2 and 3. Valid settings are 0x0000, 0x0001, 0x0002, 0x0003, and 0x0004.

LUA_SESSION_SERVICES_PATH_ERROR

Secondary return code; a request for session services cannot be rerouted to an SSCP-SSCP session path. Specific sense code information in bytes 2 and 3 gives more information about why the request cannot be rerouted.

LUA_UNSUCCESSFUL

Primary return code; the verb record supplied was valid but the verb did not complete successfully.

LUA_VERB_RECORD_SPANS_SEGMENTS

Secondary return code; the LUA VCB length parameter plus the segment offset is beyond the segment end.

LUA_SESSION_ALREADY_OPEN

Secondary return code; a session is already open for the LU name specified in **SLI_OPEN**.

LUA_INVALID_PROCESS

Secondary return code; the session for which an LUA verb was issued is unavailable because another process owns the session.

LUA_LINK_NOT_STARTED

Secondary return code; the LUA was not able to activate the data link during initialization of the session.

LUA_INVALID_ADAPTER

Secondary return code; the configuration for the data link control (DLC) is in error, or the configuration file is corrupted.

LUA_ENCR_DECR_LOAD_ERROR

Secondary return code; an unexpected return code was received from the OS/2 **DosLoadModule** function while attempting to load the user-provided encryption or decryption dynamic link module.

LUA_ENCR_DECR_PROC_ERROR

Secondary return code; an unexpected return code was received from the OS/2 **DosGetProcAddr** function while attempting to get the procedure address within the user-provided encryption or decryption dynamic link module.

LUA_NEG_NOTIFY_RSP

Secondary return code; the SSCP responded negatively to a NOTIFY request issued indicating that the secondary LU was capable of a session. The half-session component that received the request understood and supported the request but could not execute it.

LUA_LU_INOPERATIVE

Secondary return code; a severe error occurred while the SLI was attempting to stop the session. This LU is unavailable for any LUA requests until an activate logical unit (ACTLU) is received from the host.

LUA_CANCELED

Primary return code; the secondary return code gives the reason for canceling the command.

LUA_TERMINATED

Secondary return code; the session was terminated when a verb was pending. The verb process was canceled.

LUA_IN_PROGRESS

Primary return code; an asynchronous command was received but is not completed.

LUA_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the transaction program (TP) and the physical unit (PU) 2.1 node has been broken (a LAN error).
- The SnaBase at the TPs computer encountered an ABEND.

LUA_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

LUA_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

LUA_UNEXPECTED_DOS_ERROR

Primary return code; after issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

LUA_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your

application.

LUA_INVALID_VERB

Primary return code; either the verb code or the operation code, or both, is invalid. The verb did not execute.

Remarks

For each **SLI_OPEN**, the Windows LUA interface:

- Starts the communication session.
- Reads and verifies a BIND command from the host, and passes it to the application if a BIND extension routine is supplied.
- Writes a BIND response.
- Reads and processes the STSN command and passes it to the application if a BIND extension is supplied (if necessary).
- Writes the STSN response (if necessary).
- Reads the CRV command (if necessary).
- Writes the CRV response (if necessary).
- Reads and processes the SDT command.
- Writes the SDT response.

The Windows LUA interface does the following additional functions for sessions that issue **SLI_OPEN** with the open type set to LUA_INIT_TYPE_SEC_IS or LUA_INIT_TYPE_SEC_LOG:

- Writes an INITSELF or an unformatted LOGON message.
- Reads and processes an INITSELF response or LOGON message response.

All SNA message traffic is administered by **SLI_OPEN** through the SDT command response.

To choose a certain LU configured for Windows LUA, the application sets lua_luname to the LU name in ASCII, padded with trailing spaces if necessary.

When SLI_OPEN is posted with LUA_OK in the lua_prim_rc parameter, SLI_OPEN successfully completed and the LU-LU data-flow session was established. The application can now issue SLI_BID, SLI_CLOSE, SLI_PURGE, SLI_RECEIVE, and SLI_SEND.

When SLI_OPEN is posted with a primary return code other than LUA_OK or LUA_IN_PROGRESS, the command did not successfully establish a session.

When using SLI_OPEN, a Windows LUA application must provide a session initialization type. Valid types are:

- Secondary with INITSELF
- Secondary with an Unformatted LOGON Message
- Primary Waiting for a BIND Command
- Primary with SSCP Access
- Secondary with INITSELF
- Secondary with an Unformatted LOGON Message

- Primary Waiting for a BIND Command
- Primary with SSCP Access
- BIND, CRV, and STSN Routines
- BIND Example
- Recovering from SESSION_FAILURE
- Ending a Pending SLI_OPEN

See Also

Reference

RUI_INIT
SLI_OPEN
SLI_RECEIVE
SLI_SEND

Secondary with INITSELF

To initialize a session by having the secondary issue an INITSELF command, set **open.lua_init_type** to LUA_INIT_TYPE_SEC_IS. When this type of session initialization is chosen, the application has to format and provide the INITSELF command. The address of the INITSELF command is specified by **lua_data_ptr**. The actual length of the INITSELF command is specified by **lua_data_length**.

Secondary with an Unformatted LOGON Message

To initialize a session by having the secondary issue an unformatted LOGON message, set **open.lua_init_type** to LUA_INIT_TYPE_SEC_LOG. The length of the users EBCDIC LOGON message is then specified in **lua_data_length**. The address of the users EBCDIC LOGON message length is specified by **lua_data_ptr**.

Primary Waiting for a BIND Command

To initialize a session by having the secondary wait for the primary to issue a BIND and SDT, set **open.lua_init_type** to LUA_INIT_TYPE_PRIM. Until the host begins a session with the Windows logical unit application (LUA) application using the BIND command followed by an SDT command, the **SLI_OPEN** issued stays IN_PROGRESS.

Primary with SSCP Access

To initialize a session by having the Session Level Interface (SLI) wait for a BIND and SDT but allow system services control point (SSCP) access, set **open.lua_init_type** to LUA_INIT_TYPE_PRIM_SSCP. Rather than sending commands to the host to begin a session, the SLI enables the Windows logical unit application (LUA) application to issue SLI_SEND and SLI_RECEIVE for the SSCP normal flow only. This allows the INITSELF commands or LOGON messages and responses to be transmitted between the Windows LUA application and the host. The application can have more than one INITSELF and LOGON message. For this type of session only, other SLI verbs can be issued before SLI_OPEN completes. When issuing **SLI_SEND**, an application should not specify any flow flag unless the application is sending a response, as specified in the **lua_message_type** parameter of **SLI_OPEN**. To obtain the INIT_COMPLETE status, the application must first issue **SLI_OPEN**, and then issue either SLI_BID or **SLI_RECEIVE**. The INIT_COMPLETE status notifies the application that the **SLI_SEND** and **SLI_RECEIVE** verbs for SSCP normal flow data can be issued.

BIND, CRV, and STSN Routines

For BIND and STSN routines supplied by the application, the names of dynamic-link libraries (DLLs) and the entry points for procedures are passed in the SLI_OPEN verbs verb control block (VCB). During **SLI_OPEN**, the BIND and STSN routines are called if the appropriate SNA request is received. When a BIND routine is not supplied by the application, the Session Level Interface (SLI) performs a minimal check of the BIND commands and responds as necessary. If no STSN routine is supplied and an STSN request arrives, a positive response is issued by the SLI. If a CRV request arrives, a negative response is issued by the SLI.

Names for BIND and STSN routines are provided as extensions of the SLI_OPEN verbs VCB. The lua_extension_list_offset parameter provides the offset from the start of the VCB to the first name in the extension list.

The function prototype for a user-defined BIND or STSN routine on Microsoft Windows Server 2003 or Windows 2000 is as follows:

Syntax

```
lpVcb
```

Remarks

The *lpVcb* parameter is a pointer to a logical unit application (LUA) VCB.

BIND Example

The following example illustrates checking the incoming BIND image using these features of SLI_OPEN.

```
lua_vcb.specific.open.lua_open_extension[0].lua_routine_type  =
    LUA_ROUTINE_TYPE_BIND;
strcpy(lua_vcb.specific.open.lua_open_extension[0].lua_module_name,
    "WINSLI32");
strcpy(lua_vcb.specific.open.lua_open_extension[0].lua_procedure_name,
    "BindValidation");
lua_vcb.specific.open.lua_open_extension[1].lua_routine_type =
     LUA_ROUTINE_TYPE_END;
```

Note that for Microsoft Visual C++ 4.0 or later, and for Microsoft Windows Server 2003 or Windows 2000, the function prototype should be:

```
VOID WINAPI BindValidation (LUA_VERB_RECORD FAR * pVerb );
```

On Windows Server 2003 or Windows 2000, the WINAPI macro equates to _STDCall.

The BIND routine has access to the logical unit application (LUA) verb control block (VCB) passed to it. The BIND routine should validate the BIND and indicate the appropriate Session Level Interface (SLI) primary and secondary return code in the LUA verb record. Also, the routine may indicate the primary and secondary request/response unit (RU) sizes supported by the SLI program by setting bytes 10 and 11 in the common.lua_data_ptr field (where the BIND command is indicated).

The following are the Visual C++ compiler options for the module containing the callback:

```
 /FA -c -Zle -W3 -WX -Ge -Gy -Gz -Ox -Zd
 -DCONDITION_HANDLING -DSTD_CALL
 -Di386=1 -D_X86_ -DNT_UP -DWIN32 -DDEVL
 -D_DLL -D_MT  -DWIN32_SUPPORT
```

The following is the code generated for the callback:

```
PUBLIC _BindValidation@4
; COMDAT _BindValidation@4
_TEXT SEGMENT
   _pVerb$ = 8
   _BindValidation@4 PROC NEAR    ; COMDAT

   // pVerb->common.lua_prim_rc = LUA_STATE_CHECK;
   mov eax, DWORD PTR _pVerb$[esp-4]
   mov WORD PTR [eax+4], 512   ; 00000200H
   ret 4
_BindValidation@4 ENDP
_TEXT ENDS
```

The following is the code generated by SLI to call this callback:

```
   // (*aSCB->bind_rtn)(sliVCB);
   push    ebp
   call    DWORD PTR [ebx+188]
   // note there is no ADD ESP,4 following the call
```

The following is the client internal trace showing WINSLI detecting the user provided bind validation callback:

```
|00000157.000000f7 OUDMD  Opening User DLL Modules
```

```
|00000157.000000f7 OUDMD  Opening a Bind Routine
|00000157.000000f7 OUDMD  Opening DLL = WINSLI32
|00000157.000000f7 OUDMD  Loading Routine = BindValidation
```

The following is client internal trace showing the bind validation callback:

```
|00000157.0000015c CLUAD  Calling BIND Routine
|00000157.0000015c CLUAD  Return from BIND routine, prc=512
|00000157.0000015c CLUAD  Returned With Error From Routine
|00000157.0000015c FrRUI  Freeing RUI vcb = 0x14E424
|00000157.0000015c BINDP  USER BIND ROUTINE FAILED
```

The following is an API trace to show the bind validation error:

```

```

Recovering from SESSION_FAILURE

If the SLI_OPEN completes with the primary return code of SESSION_FAILURE, the Windows logical unit application (LUA) interface enables you to reissue **SLI_OPEN** without issuing SLI_CLOSE.

Ending a Pending SLI_OPEN

To end a pending SLI_OPEN, issue SLI_CLOSE with **lua_flag2.close_abend** set to ON.

SLI_PURGE

The **SLI_PURGE** verb cancels SLI_RECEIVE verbs issued with a wait condition.

The following structure describes the LUA_COMMON member of the verb control block (VCB) used by SLI_PURGE.

Syntax

```
struct LUA_COMMON {
    unsigned short    lua_verb;
    unsigned short    lua_verb_length;
    unsigned short    lua_prim_rc;
    unsigned long     lua_sec_rc;
    unsigned short    lua_opcode;
    unsigned long     lua_correlator;
    unsigned char     lua_luname[8];
    unsigned short    lua_extension_list_offset;
    unsigned short    lua_cobol_offset;
    unsigned long     lua_sid;
    unsigned short    lua_max_length;
    unsigned short    lua_data_length;
    char FAR *        lua_data_ptr;
    unsigned long     lua_post_handle;
    struct LUA_TH     lua_th;
    struct LUA_RH     lua_rh;
    struct LUA_FLAG1  lua_flag1;
    unsigned char     lua_message_type;
    struct LUA_FLAG2  lua_flag2;
    unsigned char     lua_resv56[7];
    unsigned char     lua_encr_decr_option;
};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_SLI for Session Level Interface (SLI) verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the logical unit application (LUA) VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_SLI_PURGE.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

SLI_PURGE only requires this parameter if lua_sid is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by **SLI_PURGE** and should be set to zero.

lua_cobol_offset

Not used by LUA in Microsoft® Host Integration Server or SNA Server and should be zero.

lua_sid

Supplied parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Not used by **SLI_PURGE** and should be set to zero.

lua_data_length

Not used by **SLI_PURGE** and should be set to zero.

lua_data_ptr

When **SLI_PURGE** is issued, this parameter points to the location of the SLI_RECEIVE verbs VCB that is to be canceled.

lua_post_handle

Supplied parameter. Used under Microsoft Windows Server™ 2003 or Windows® 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Not used by **SLI_PURGE** and should be set to zero.

lua_rh

Not used by **SLI_PURGE** and should be set to zero.

lua_flag1

Not used by **SLI_PURGE** and should be set to zero.

lua_message_type

Not used by **SLI_PURGE** and should be set to zero.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_resv56

Reserved and should be set to zero.

lua_encr_decr_option

Not used by **SLI_PURGE** and should be set to zero.

Return Codes
LUA_OK

Primary return code; the verb executed successfully.

LUA_SEC_OK

Secondary return code; no additional information exists for LUA_OK.

LUA_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

LUA_INVALID_LUNAME

Secondary return code; an invalid **lua_luname** was specified.

LUA_BAD_SESSION_ID

Secondary return code; an invalid value for **lua_sid** was specified in the VCB.

LUA_BAD_DATA_PTR

Secondary return code; the **lua_data_ptr** parameter either does not contain a valid pointer or does not point to a read/write segment and supplied data is required.

LUA_RESERVED_FIELD_NOT_ZERO

Secondary return code; a reserved parameter for the verb just issued is not set to zero.

LUA_INVALID_POST_HANDLE

Secondary return code; for the Microsoft Windows Server 2003 or Windows 2000 system using events as the asynchronous posting method, the Windows LUA VCB does not contain a valid event handle.

LUA_VERB_LENGTH_INVALID

Secondary return code; an LUA verb was issued with a value for **lua_verb_length** unexpected by LUA.

LUA_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

LUA_NO_SLI_SESSION

Secondary return code; a session was not open or was down due to an SLI_CLOSE or session failure when a command was issued.

LUA_NO_RECEIVE_TO_PURGE

Secondary return code; no SLI_RECEIVE was outstanding when you issued **SLI_PURGE**. One of two situations caused the problem:

- **SLI_RECEIVE** completed before **SLI_PURGE** finished processing. You can change the application to take care of this problem because it is not an error condition.
- The lua_data_ptr parameter does not correctly point to the SLI_RECEIVE you want to purge.

LUA_SLI_PURGE_PENDING

Secondary return code; an **SLI_PURGE** was still active when another **SLI_PURGE** was issued. Only one **SLI_PURGE** can be active at a time.

LUA_SESSION_FAILURE

Primary return code; an error condition, specified in the secondary return code, caused the session to fail.

LUA_RECEIVED_UNBIND

Secondary return code; the primary logical unit (PLU) sent an SNA UNBIND command to the LUA interface when a session was active. As a result, the session was stopped.

LUA_LU_COMPONENT_DISCONNECTED

Secondary return code; an LU component is unavailable because it is not connected properly. Make sure that the power is on.

LUA_UNSUCCESSFUL

Primary return code; the verb record supplied was valid but the verb did not complete successfully.

LUA_VERB_RECORD_SPANS_SEGMENTS

Secondary return code; the LUA VCB length parameter plus the segment offset is beyond the segment end.

LUA_NOT_ACTIVE

Secondary return code; LUA was not active within Microsoft Host Integration Server or SNA Server when an LUA verb was issued.

LUA_NOT_READY

Secondary return code; one of the following caused the SLI session to be temporarily suspended:

- An SNA UNBIND type 0x02 command was received, which indicates a new BIND is coming. If the UNBIND type 0x02 is received after the beginning SLI_OPEN is complete, the session is suspended until a BIND, optional CRV and STSN, and SDT flows are received. These routines are re-entrant because they have to be called again. The session resumes after the SLI processes the SDT command. If the UNBIND type 0x02 is received while the **SLI_OPEN** is still processing, the primary return code is SESSION_FAILURE, not LUA_STATUS.

- The receipt of an SNA CLEAR caused the suspension. Receipt of an SNA SDT will cause the session to resume.

LUA_INVALID_PROCESS

Secondary return code; the session for which a Request Unit Interface (RUI) verb was issued is unavailable because another OS/2 process owns the session.

LUA_LU_INOPERATIVE

Secondary return code; a severe error occurred while the RUI was attempting to stop the session. This LU is unavailable for any LUA requests until an activate logical unit (ACTLU) is received from the host.

LUA_CANCELED

Primary return code; the secondary return code gives the reason for canceling the command.

LUA_TERMINATED

Secondary return code; the session was terminated when a verb was pending. The verb process was canceled.

LUA_IN_PROGRESS

Primary return code; an asynchronous command was received but is not completed.

LUA_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.

- The connection between the transaction program (TP) and the physical unit (PU) 2.1 node has been broken (a LAN error).

- The SnaBase at the TPs computer encountered an ABEND.

LUA_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

LUA_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

LUA_UNEXPECTED_DOS_ERROR

Primary return code; after issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

LUA_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

LUA_INVALID_VERB

Primary return code; either the verb code or the operation code, or both, is invalid. The verb did not execute.

Remarks

SLI_PURGE cancels SLI_RECEIVE commands with a wait condition.

Typically, SLI_PURGE is issued if SLI_RECEIVE takes too long to complete. To cancel an SLI_RECEIVE, lua_data_ptr has to point to the SLI_RECEIVE VCB to cancel. The primary return code of the SLI_RECEIVE will be set to LUA_CANCELED when SLI_PURGE succeeds in canceling SLI_RECEIVE.

SLI_RECEIVE

The **SLI_RECEIVE** verb receives responses, SNA commands, and data into a Microsoft® Windows® logical unit application (LUA) applications buffer. **SLI_RECEIVE** also provides the current status of the session to the Windows LUA application.

The following structure describes the LUA_COMMON member of the verb control block (VCB) used by SLI_RECEIVE.

Syntax

```
struct LUA_COMMON {
    unsigned short    lua_verb;
    unsigned short    lua_verb_length;
    unsigned short    lua_prim_rc;
    unsigned long     lua_sec_rc;
    unsigned short    lua_opcode;
    unsigned long     lua_correlator;
    unsigned char     lua_luname[8];
    unsigned short    lua_extension_list_offset;
    unsigned short    lua_cobol_offset;
    unsigned long     lua_sid;
    unsigned short    lua_max_length;
    unsigned short    lua_data_length;
    char FAR *        lua_data_ptr;
    unsigned long     lua_post_handle;
    struct LUA_TH     lua_th;
    struct LUA_RH     lua_rh;
    struct LUA_FLAG1  lua_flag1;
    unsigned char     lua_message_type;
    struct LUA_FLAG2  lua_flag2;
    unsigned char     lua_resv56[7];
    unsigned char     lua_encr_decr_option;
};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_SLI for Session Level Interface (SLI) verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the LUA VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_SLI_RECEIVE.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

SLI_RECEIVE only requires this parameter if lua_sid is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by **SLI_RECEIVE** and should be set to zero.

lua_cobol_offset

Not used by LUA in Microsoft® Host Integration Server or SNA Server and should be zero.

lua_sid

Supplied and returned parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Specifies the length of received buffer for RUI_READand **SLI_RECEIVE**.

lua_data_length

Returned parameter. Specifies the length of data returned in the receive buffer.

lua_data_ptr

Pointer to the application-supplied buffer that is to receive the data from an **SLI_RECEIVE** verb. Both SNA commands and data are placed in this buffer, and they can be in an Extended Binary Coded Decimal Interchange Code (EBCDIC) format.

When SLI_RECEIVE is issued, this parameter points to the location to receive the data from the host.

lua_post_handle

Supplied parameter. Used under Microsoft® Windows Server™ 2003 or Windows 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Returned parameter. Contains the SNA transmission header (TH) of the message received. Various subparameters are returned for read and bid functions. Its subparameters are as follows:

lua_th.flags_fid

Format identification type 2, four bits.

lua_th.flags_mpf

Segmenting mapping field, two bits. Defines the type of data segment. The following values are valid:

0x0 Middle segment**0x04** Last segment**0x08** First segment**0x0C** Only segment

lua_th.flags_odai

Originating address field–destination address field (OAF–DAF) assignor indicator, one bit.

lua_th.flags_efi

Expedited flow indicator, one bit.

lua_th.daf

Destination address field (DAF), an unsigned char.

lua_th.oaf

Originating address field (OAF), an unsigned char.

lua_th.snf

Sequence number field, an unsigned char[2].

lua_rh

Returned parameter. Contains the SNA request/response header (RH) of the message sent or received. Its subparameters are as follows:

lua_rh.rri

Request-response indicator, one bit.

lua_rh.ruc

Request/response unit (RU) category, two bits. The following values are valid:

LUA_RH_FMD (**0x00**) FM data segment**LUA_RH_NC** (**0x20**) Network control**LUA_RH_DFC** (**0x40**) Data flow control**LUA_RH_SC** (**0x60**) Session control

lua_rh.fi

Format indicator, one bit.

lua_rh.sdi

Sense data included indicator, one bit.

lua_rh.bci

Begin chain indicator, one bit.

lua_rh.eci

End chain indicator, one bit.

lua_rh.dr1i

Definite response 1 indicator, one bit.

lua_rh.dr2i

Definite response 2 indicator, one bit.

lua_rh.ri

Exception response indicator (for a request), or response type indicator (for a response), one bit.

lua_rh.qri

Queued response indicator, one bit.

lua_rh.pi

Pacing indicator, one bit.

lua_rh.bbi

Begin bracket indicator, one bit.

lua_rh.ebi

End bracket indicator, one bit.

lua_rh.cdi

Change direction indicator, one bit.

lua_rh.csi

Code selection indicator, one bit.

lua_rh.edi

Enciphered data indicator, one bit.

lua_rh.pdi

Padded data indicator, one bit.

lua_flag1

Supplied parameter. Contains a data structure containing flags for messages supplied by the application. This parameter is used by RUI_BID, RUI_READ, RUI_WRITE, SLI_BID, **SLI_RECEIVE**, and SLI_SEND. Its subparameters are as follows:

lua_flag1.bid_enable

Bid enable indicator, one bit.

lua_flag1.close_abend

Close immediate indicator, one bit.

lua_flag1.nowait

No wait for data flag, one bit.

lua_flag1.sscp_exp

System services control point (SSCP) expedited flow, one bit.

lua_flag1.sscp_norm

SSCP normal flow, one bit.

lua_flag1.lu_exp

LU expedited flow, one bit.

lua_flag1.lu_norm

LU normal flow, one bit.

Set **lua_flag1.bid_enable** to 1 to re-enable the most recent SLI_BID (equivalent to issuing **SLI_BID** again with exactly the same parameters as before), or set it to zero if you do not want to re-enable **SLI_BID**. Note that re-enabling the previous **SLI_BID** reuses the VCB originally allocated for it, so this VCB must not have been freed or modified.

Set lua_flag1.nowait to 1 to indicate that you want SLI_RECEIVE to return immediately whether or not data is available to be read, or set it to zero if you want the verb to wait for data before returning.

Set one or more of the following flags to 1 to indicate from which message flow to read data:

lua_flag1.sscp_exp

lua_flag1.lu_exp

lua_flag1.sscp_norm

lua_flag1.lu_norm

If more than one flag is set, the highest-priority data available is returned. The order of priorities (highest first) is: SSCP expedited, LU expedited, SSCP normal, LU normal. The equivalent flag in the **lua_flag2** group is set to indicate from which flow the data was read.

lua_message_type

Specifies the type of the inbound or outbound SNA commands and data. Returned parameter. Specifies the type of SNA message indicated to **SLI_RECEIVE**. Possible values are:

LUA_MESSAGE_TYPE_LU_DATA

LUA_MESSAGE_TYPE_SSCP_DATA

LUA_MESSAGE_TYPE_RSP

LUA_MESSAGE_TYPE_BID

LUA_MESSAGE_TYPE_BIND

LUA_MESSAGE_TYPE_BIS

LUA_MESSAGE_TYPE_CANCEL

LUA_MESSAGE_TYPE_CHASE

LUA_MESSAGE_TYPE_LUSTAT_LU

LUA_MESSAGE_TYPE_LUSTAT_SSCP

LUA_MESSAGE_TYPE_QC

LUA_MESSAGE_TYPE_QEC

LUA_MESSAGE_TYPE_RELQ

LUA_MESSAGE_TYPE_RTR

LUA_MESSAGE_TYPE_SBI

LUA_MESSAGE_TYPE_SIGNAL

LUA_MESSAGE_TYPE_STSN

The SLI receives and responds to the BIND and STSN requests through the LUA interface extension routines.

LU-DATA, LUSTAT_LU, LUSTAT_SSCP, and SSCP_DATA are not SNA commands.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA. Returned by RUI_BID, RUI_READ, **RUI_WRITE**, **SLI_BID**, **SLI_RECEIVE**, and SLI_SEND. Its subparameters are as follows:

lua_flag2.bid_enable

Indicates that **RUI_BID** was successfully re-enabled if set to 1.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_flag2.sscp_exp

Indicates SSCP expedited flow if set to 1.

lua_flag2.sscp_norm

Indicates SSCP normal flow if set to 1.

lua_flag2.lu_exp

Indicates LU expedited flow if set to 1.

lua_flag2.lu_norm

Indicates LU normal flow if set to 1.

lua_resv56

Not used by **SLI_RECEIVE** and should be set to zero.

lua_encr_decr_option

Not used by **SLI_RECEIVE** and should be set to zero.

Return Codes

LUA_OK

Primary return code; the verb executed successfully.

LUA_SEC_OK

Secondary return code; no additional information exists for LUA_OK.

LUA_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

LUA_INVALID_LUNAME

Secondary return code; an invalid **lua_luname** was specified.

LUA_BAD_SESSION_ID

Secondary return code; an invalid value for **lua_sid** was specified in the VCB.

LUA_BAD_DATA_PTR

Secondary return code; the **lua_data_ptr** parameter either does not contain a valid pointer or does not point to a read/write segment and supplied data is required.

LUA_RESERVED_FIELD_NOT_ZERO

Secondary return code; a reserved parameter for the verb just issued is not set to zero.

LUA_INVALID_POST_HANDLE

Secondary return code; for a Microsoft Windows Server 2003 or Windows 2000 system using events as the asynchronous

posting method, the Windows LUA VCB does not contain a valid event handle.

LUA_BID_VERB_SEGMENT_ERROR

Secondary return code; the buffer with the SLI_BID VCB was released before the **SLI_RECEIVE** with **lua_flag1.bid_enable** set to 1 was issued.

LUA_NO_PREVIOUS_BID_ENABLED

Secondary return code; **SLI_BID** was not issued prior to issuing **SLI_RECEIVE** with **lua_flag1.bid_enable**.

LUA_BID_ALREADY_ENABLED

Secondary return code; **SLI_RECEIVE** was issued with **lua_flag1.bid_enable** when **SLI_BID** was already active.

LUA_INVALID_FLOW

Secondary return code; the **lua_flag1** flow flags were set incorrectly when a verb was issued:

- When issuing SLI_SEND to send an SNA response, set only one **lua_flag1** flow flag.
- When issuing SLI_RECEIVE, set at least one lua_flag1 flow flag.

LUA_VERB_LENGTH_INVALID

Secondary return code; an LUA verb was issued with a value for **lua_verb_length** unexpected by LUA.

LUA_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

LUA_NO_SLI_SESSION

Secondary return code; a session was not open or was down due to an SLI_CLOSE or session failure when a command was issued.

LUA_RECEIVE_ON_FLOW_PENDING

Secondary return code; an **SLI_RECEIVE** was still outstanding when this application issued another **SLI_RECEIVE** for an SNA flow.

LUA_SESSION_FAILURE

Primary return code; an error condition, specified in the secondary return code, caused the session to fail.

LUA_RUI_WRITE_FAILURE

Secondary return code; an unexpected error was posted to the SLI by RUI_WRITE.

LUA_RECEIVED_UNBIND

Secondary return code; the primary logical unit (PLU) sent an SNA UNBIND command to the LUA interface when a session was active. As a result, the session was stopped.

LUA_SLI_LOGIC_ERROR

Secondary return code; the LUA interface found an internal error in logic.

LUA_NO_RUI_SESSION

Secondary return code; no session has been initialized for the LUA verb issued or some verb other than SLI_OPEN was issued before the session was initialized.

LUA_MODE_INCONSISTENCY

Secondary return code; performing this function is not allowed by the current status. The request sent to the half-session component was not executed even though it was understood and supported. This SNA sense code is also an exception request sense code.

LUA_RECEIVER_IN_TRANSMIT_MODE

Secondary return code; either resources needed to handle normal flow data were not available or the state of the half-duplex contention was not received when a normal-flow request was received. The result is a race condition. This SNA sense code is

also an exception request sense code.

LUA_LU_COMPONENT_DISCONNECTED

Secondary return code; an LU component is unavailable because it is not connected properly. Make sure that the power is on.

LUA_FUNCTION_NOT_SUPPORTED

Secondary return code; LUA does not support the requested function. A control character, an RU parameter, or a formatted request code may have specified the function. Specific sense code information is in bytes 2 and 3.

LUA_CHAINING_ERROR

Secondary return code; the sequence of the chain indicator settings is in error. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_BRACKET

Secondary return code; the sender failed to enforce the session bracket rules. Note that contention and race conditions are exempt from this error. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DIRECTION

Secondary return code; while the half-duplex flip-flop state was NOT_RECEIVE, a request for normal flow was received. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DATA_TRAFFIC_QUIESCED

Secondary return code; a data flow control (DFC) or function management data (FMD) request was received from a half-session that sent either a SHUTC command or QC command, and the DFC or FMD request has not responded to a RELQ command. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_NO_BEGIN_BRACKET

Secondary return code; the receiver has already sent a positive response to a BIS command when a BID or an FMD request specifying BBI=BB was received. An invalid request header or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_IMMEDIATE_REQUEST_MODE_ERROR

Secondary return code; the request violated the immediate request mode protocol. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_QUEUED_RESPONSE_ERROR

Secondary return code; the request violated the queued response protocol. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_ERP_SYNC_EVENT_ERROR

Secondary return code; a violation of the ERP synchronous event protocol occurred. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_RSP_CORRELATION_ERROR

Secondary return code; a response was sent that does not correspond to a previously received request or a response was received that does not correspond to a previously sent request.

LUA_RSP_PROTOCOL_ERROR

Secondary return code; a violation of the response protocol was found in the response received from the primary half-session.

LUA_BB_NOT_ALLOWED

Secondary return code; the begin bracket indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was

prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_EB_NOT ALLOWED

Secondary return code; the end bracket indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_EXCEPTION_RSP_NOT_ALLOWED

Secondary return code; when an exception response was not allowed, one was requested. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_DEFINITE_RSP_NOT_ALLOWED

Secondary return code; when a definite response was not allowed, one was requested. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CD_NOT_ALLOWED

Secondary return code; the change-direction indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_NO_RESPONSE_NOT_ALLOWED

Secondary return code; a request other than an EXR contained a NO RESPONSE. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CHAINING_NOT_SUPPORTED

Secondary return code; the chaining indicators were incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_BRACKETS_NOT_SUPPORTED

Secondary return code; the bracket indicators were incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CD_NOT_SUPPORTED

Secondary return code; the change-direction indicator was set, but LUA does not support change-direction for this situation. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_FI

Secondary return code; the format indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_ALTERNATE_CODE_NOT_SUPPORTED

Secondary return code; the code selection indicator was set, but LUA does not support code selection for this session. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to

the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_RU_CATEGORY

Secondary return code; the request unit category indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_REQUEST_CODE

Secondary return code; the request code was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_SPEC_OF_SDI_RTI

Secondary return code; the SDI and the RTI were not specified correctly on a response. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_DR1I_DR2I_ERI

Secondary return code; the DR1I, the DR2I, and the ERI were specified incorrectly. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_QRI

Secondary return code; the queued response indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_EDI

Secondary return code; the EDI was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_PDI

Secondary return code; the PDI was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_UNSUCCESSFUL

Primary return code; the verb record supplied was valid but the verb did not complete successfully.

LUA_DATA_TRUNCATED

Secondary return code; the data was truncated because the data received was longer than the buffer length specified in **lua_max_length**.

LUA_DATA_SEGMENT_LENGTH_ERROR

Secondary return code; one of the following has occurred:

- The supplied data segment for **SLI_RECEIVE** or SLI_SEND is not a read/write data segment as required.
- The supplied data segment for SLI_RECEIVE is not as long as that provided in lua_max_length.
- The supplied data segment for SLI_SEND is not as long as that provided in lua_data_length.

LUA_NO_DATA

Secondary return code; no data was available to read when **SLI_RECEIVE** containing a no wait parameter was issued.

LUA_VERB_RECORD_SPANS_SEGMENTS

Secondary return code; the LUA VCB length parameter plus the segment offset is beyond the segment end.

LUA_NOT_ACTIVE

Secondary return code; LUA was not active within Microsoft Host Integration Server or SNA Server when an LUA verb was issued.

LUA_NOT_READY

Secondary return code; one of the following has caused the SLI session to be temporarily suspended:

- An SNA UNBIND type 0x02 command was received, which indicates a new BIND is coming. If the UNBIND type 0x02 is received after the beginning SLI_OPEN is complete, the session is suspended until a BIND, optional CRV and STSN, and SDT flows are received. These routines are re-entrant because they have to be called again. The session resumes after the SLI processes the SDT command. If the UNBIND type 0x02 is received while the **SLI_OPEN** is still processing, the primary return code is LUA_SESSION_FAILURE, not LUA_STATUS.

- The receipt of an SNA CLEAR caused the suspension. Receipt of an SNA SDT will cause the session to resume.

LUA_SLI_LOGIC_ERROR

Secondary return code; the LUA interface found an internal error in logic.

LUA_INVALID_PROCESS

Secondary return code; the session for which an LUA verb was issued is unavailable because another OS/2 process owns the session.

LUA_LU_INOPERATIVE

Secondary return code; a severe error occurred while the LUA was attempting to stop the session. This LU is unavailable for any LUA requests until an activate logical unit (ACTLU) is received from the host.

LUA_RECEIVE_CORRELATION_TABLE_FULL

Secondary return code; the session receive correlation table for the flow requested reached its capacity.

LUA_NEGATIVE_RESPONSE

Primary return code; either the LUA sent a negative response to a message received from the primary logical unit (PLU) because an error was found in the message, or the application responded negatively to a chain for which the end-of-chain has arrived.

LUA_MODE_INCONSISTENCY

Secondary return code; performing this function is not allowed by the current status. The request sent to the half-session component was not executed even though it was understood and supported. This SNA sense code is also an exception request sense code.

LUA_FUNCTION_NOT_SUPPORTED

Secondary return code; the LUA does not support the requested function. A control character, an RU parameter, or a formatted request code may have specified the function. Specific sense code information is in bytes 2 and 3.

LUA_DATA_TRAFFIC_RESET

Secondary return code; a half-session of an active session but with inactive data traffic received a normal flow DFC or FMD request. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DATA_TRAFFIC_NOT_RESET

Secondary return code; while the data traffic state was not reset, the session control request was received. An invalid request header or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_SC_PROTOCOL_VIOLATION

Secondary return code; a violation of SC protocol occurred. A request (that is permitted only after an SC request and a positive response to that request have been successfully exchanged) was received before the required exchange. Byte 4 of the sense data contains the request code. No user data exists for this sense code. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_INVALID_SC_OR_NC_RH

Secondary return code; the RH of an SC or NC request was invalid.

LUA_PACING_NOT_SUPPORTED

Secondary return code; the request contained a pacing indicator when support of pacing for this session does not exist for the receiving half-session or boundary function half-session. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_NAU_INOPERATIVE

Secondary return code; the network addressable unit is not able to process responses or requests. Delivery to the receiver could not take place for one of the following reasons:

- A path information unit error
- A path outage
- An invalid sequence of requests for activation

If a path error is received during an active session, it usually means there is no longer a valid path to the session partner.

LUA_CANCELED

Primary return code; the secondary return code gives the reason for canceling the command.

LUA_PURGED

Secondary return code; SLI_PURGE was issued and canceled **SLI_RECEIVE**.

LUA_NO_SLI_SESSION

Secondary return code; a session was not open or was down due to an SLI_CLOSE or session failure when a command was issued.

LUA_CANCEL_COMMAND_RECEIVED

Secondary return code; the host sent an SNA CANCEL command to cancel the data chain currently being received by **SLI_RECEIVE**.

LUA_TERMINATED

Secondary return code; the session was terminated when a verb was pending. The verb process has been canceled.

LUA_IN_PROGRESS

Primary return code; an asynchronous command was received but is not completed.

LUA_STATUS

Primary return code; the secondary return code contains SLI status information for the application.

LUA_READY

Secondary return code; following a NOT READY status, this status is issued to notify you that the SLI is ready to process commands.

LUA_NOT_READY

Secondary return code; the SLI session is temporarily suspended for the following reason:

- An SNA UNBIND type 0x02 command was received, which means a new BIND is coming. If the UNBIND type 0x02 is

received after the beginning SLI_OPEN is complete, the session is suspended until a BIND, optional CRV and STSN, and SDT flows are received. These routines are re-entrant because they have to be called again. The session resumes after the SLI processes the SDT command. If the UNBIND type 0x02 is received while the **SLI_OPEN** is still processing, the primary return code is session-failure, not status.

- The receipt of an SNA CLEAR caused the suspension. Receipt of an SNA SDT will cause the session to resume.

LUA_INIT_COMPLETE

Secondary return code; the LUA interface initialized the session while SLI_OPEN was processing. LUA applications that issue **SLI_OPEN** with **lua_open_type_prim_sscp** receive this status on **SLI_RECEIVE** or SLI_BID.

LUA_SESSION_END_REQUESTED

Secondary return code; the LUA interface received an SNA SHUTD from the host, which means the host is ready to shut down the session.

LUA_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the transaction program (TP) and the physical unit (PU) 2.1 node has been broken (a LAN error).
- The SnaBase at the TPs computer encountered an ABEND.

LUA_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

LUA_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

LUA_UNEXPECTED_DOS_ERROR

Primary return code; after issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

LUA_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

LUA_INVALID_VERB

Primary return code; either the verb code or the operation code, or both, is invalid. The verb did not execute.

Remarks

SLI_RECEIVE receives responses, SNA commands, and request unit data from the host. **SLI_RECEIVE** also provides the status of the session to the Windows LUA application. An SLI_OPEN request must complete before **SLI_RECEIVE** can be issued. However, if **SLI_OPEN** is issued with **lua_init_type** set to LUA_INIT_TYPE_PRIM_SSCP, an **SLI_RECEIVE** over the SSCP normal flow can be issued as soon as **SLI_OPEN** returns an IN_PROGRESS.

Data is received by the application in one of four session flows. The four session flows, from highest to lowest priority are:

- SSCP expedited
- LU expedited
- SSCP normal

- LU normal

The data flow type that **SLI_RECEIVE** will process is specified in **lua_flag1**. The application can also specify whether it wants to look at more than one type of data flow. When multiple flow bits are set, the highest priority is received first. When **SLI_RECEIVE** completes processing, **lua_flag2** indicates the specific type of flow for which data has been received by the Windows LUA application.

If SLI_BID successfully completes before SLI_RECEIVE is issued, the Windows LUA interface can be instructed to reuse the last SLI_BID verbs VCB. To do this, issue SLI_RECEIVE with lua_flag1.bid_enable set to 1.

When using lua_flag1.bid_enable, the SLI_BID storage must not be freed because the last SLI_BID verbs VCB is used. Also, when using lua_flag1.bid_enable, the successful completion of SLI_BID will be posted.

If SLI_RECEIVE is issued with lua_flag1.nowait when no data is available to receive, LUA_NO_DATA will be the secondary return code set by the Windows LUA interface.

Session Status Return Values

If LUA_STATUS is the primary return code, the secondary return code can be one of the following:

LUA_READY

LUA_NOT_READY

LUA_SESSION_END_REQUESTED

LUA_INIT_COMPLETE

In addition, if LUA_STATUS is the primary return code, the following parameters are used:

lua_sec_rc

lua_sid

LUA_READY is returned after an LUA_NOT_READY status and indicates that the SLI is again ready to perform all commands.

LUA_NOT_READY indicates that the SLI session is suspended because the SLI has received either an SNA CLEAR command or an SNA UNBIND command with an 0x02 UNBIND type (UNBIND with BIND forthcoming). Depending on what caused the suspension, the session can be reactivated as follows:

- When the suspension is caused by an SNA CLEAR, receiving an SNA SDT reactivates the session.

- When an SNA UNBIND type BIND forthcoming causes suspension of the session and the SLI_OPEN that opened the session is completed, the session is suspended until the SLI receives a BIND and SDT command. The session can also optionally receive an STSN command. As a result, user-supplied routines issued with the initial SLI_OPEN must be re-entered because they will be recalled.

The application can send SSCP data after a CLEAR or UNBIND type BIND forthcoming arrives and before the NOT_READY status is read. The application can send and receive SSCP data after reading a NOT_READY.

When an SNA UNBIND type BIND forthcoming arrives before completion of the SLI_OPEN that opened the session, LUA_SESSION_FAILURE (not LUA_STATUS) is the primary return code.

LUA_SESSION_END_REQUESTED indicates that the application received an SNA SHUTD from the host. The Windows LUA application should issue SLI_CLOSE to close the session when convenient.

LUA_INIT_COMPLETE is returned only when lua_init_type for SLI_OPEN is LUA_INIT_TYPE_PRIM_SSCP. The status means that the SLI_OPEN has been processed sufficiently to allow SSCP data to now be sent or received.

Exception Requests

If a host application request unit is converted into an EXR, sense data will be returned. When SLI_BID completes with the returned verb parameters set as shown, an EXR conversion occurs.

Member	Set to
lua_prim_rc	OK (0x0000)

lua_sec_rc	OK (0x00000000)
lua_rh.rri	bit off (request unit)
lua_rh.sdi	bit on (includes sense data)

Of the seven bytes of data in **lua_peek_data**, bytes 0 through 3 define the error detected. The following table indicates possible sense data and the values of bytes 0 through 3.

Sense data	Value of bytes 0–3
LUA_MODE_INCONSISTENCY	0x08090000
LUA_BRACKET_RACE_ERROR	0x080B0000
LUA_BB_REJECT_NO_RTR	0x08130000
LUA_RECEIVER_IN_TRANSMIT_MODE	0x081B0000
LUA_CRYPTOGRAPHY_FUNCTION_INOP	0x08480000
LUA_SYNC_EVENT_RESPONSE	0x10010000
LUA_RU_DATA_ERROR	0x10020000
LUA_RU_LENGTH_ERROR	0x10020000
LUA_INCORRECT_SEQUENCE_NUMBER	0x20010000

The information returned to bytes 3 through 6 in **lua_peek_data** is determined by the first three bytes of the initial request unit that caused the error.

SLI_RECEIVE_EX

The **SLI_RECEIVE_EX** verb receives responses, SNA commands, and data into a Microsoft® Windows® logical unit application (LUA) applications buffer. **SLI_RECEIVE_EX** also provides the current status of the session to the Windows LUA application.

The SLI_RECEIVE_EX verb also supports inbound chaining. The maximum length of data that can be received by a single verb is 4,294,967,295 bytes. This is compared to a maximum of 65,535 bytes that can be received by the SLI_RECEIVE verb.

The following structure describes the LUA_COMMON member of the verb control block (VCB) used by SLI_RECEIVE_EX.

The second syntax union describes the **LUA_SPECIFIC** member of the VCB used by **SLI_RECEIVE_EX**. Other union members are omitted for clarity.

Syntax

```
struct LUA_COMMON {
    unsigned short    lua_verb;
    unsigned short    lua_verb_length;
    unsigned short    lua_prim_rc;
    unsigned long     lua_sec_rc;
    unsigned short    lua_opcode;
    unsigned long     lua_correlator;
    unsigned char     lua_luname[8];
    unsigned short    lua_extension_list_offset;
    unsigned short    lua_cobol_offset;
    unsigned long     lua_sid;
    unsigned short    lua_max_length;
    unsigned short    lua_data_length;
    char FAR *        lua_data_ptr;
    unsigned long     lua_post_handle;
    struct LUA_TH     lua_th;
    struct LUA_RH     lua_rh;
    struct LUA_FLAG1  lua_flag1;
    unsigned char     lua_message_type;
    struct LUA_FLAG2  lua_flag2;
    unsigned char     lua_resv56[7];
    unsigned char     lua_encr_decr_option;
};
union LUA_SPECIFIC {
    struct SLI_RECEIVE_EX_SPECIFIC {
        unsigned long lua_data_length_ex;
        unsigned long lua_max_length_ex;
    };
};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_SLI for Session Level Interface (SLI) verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the LUA VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_SLI_RECEIVE_EX.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

SLI_RECEIVE_EX only requires this parameter if lua_sid is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by **SLI_RECEIVE_EX** and should be set to zero.

lua_cobol_offset

Not used by LUA in Microsoft® Host Integration Server and should be zero.

lua_sid

Supplied and returned parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

This supplied parameter is reserved and must be set to zero.

The maximum length of data returned in a receive buffer must be set in the lua_max_length_ex parameter.

lua_data_length

This parameter is reserved and must be set to zero.

The length of data returned in the receive buffer is set in the lua_data_length_ex parameter.

lua_data_ptr

Pointer to the application-supplied buffer that is to receive the data from an **SLI_RECEIVE_EX** verb. Both SNA commands and data are placed in this buffer, and they can be in an Extended Binary Coded Decimal Interchange Code (EBCDIC) format.

When SLI_RECEIVE_EX is issued, this parameter points to the location to receive the data from the host.

lua_post_handle

Supplied parameter. Used under Microsoft® Windows Server™ 2003 or Windows 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Returned parameter. Contains the SNA transmission header (TH) of the message received. Various subparameters are returned for read and bid functions. Its subparameters are as follows:

lua_th.flags_fid

Format identification type 2, four bits.

lua_th.flags_mpf

Segmenting mapping field, two bits. Defines the type of data segment. The following values are valid:

0x00 Middle segment**0x04** Last segment**0x08** First segment**0x0C** Only segment

lua_th.flags_odai

Originating address field–destination address field (OAF–DAF) assignor indicator, one bit.

lua_th.flags_efi

Expedited flow indicator, one bit.

lua_th.daf

Destination address field (DAF), an unsigned char.

lua_th.oaf

Originating address field (OAF), an unsigned char.

lua_th.snf

Sequence number field, an unsigned char[2].

lua_rh

Returned parameter. Contains the SNA request/response header (RH) of the message sent or received. Its subparameters are as follows:

lua_rh.rri

Request-response indicator, one bit.

lua_rh.ruc

RU category, two bits. The following values are valid:

LUA_RH_FMD (**0x00**) FM data segment**LUA_RH_NC** (**0x20**) Network control**LUA_RH_DFC** (**0x40**) Data flow control**LUA_RH_SC** (**0x60**) Session control

lua_rh.fi

Format indicator, one bit.

lua_rh.sdi

Sense data included indicator, one bit.

lua_rh.bci

Begin chain indicator, one bit.

lua_rh.eci

End chain indicator, one bit.

lua_rh.dr1i

Definite response 1 indicator, one bit.

lua_rh.dr2i

Definite response 2 indicator, one bit.

lua_rh.ri

Exception response indicator (for a request), or response type indicator (for a response), one bit.

lua_rh.qri

Queued response indicator, one bit.

lua_rh.pi

Pacing indicator, one bit.

lua_rh.bbi

Begin bracket indicator, one bit.

lua_rh.ebi

End bracket indicator, one bit.

lua_rh.cdi

Change direction indicator, one bit.

lua_rh.csi

Code selection indicator, one bit.

lua_rh.edi

Enciphered data indicator, one bit.

lua_rh.pdi

Padded data indicator, one bit.

lua_flag1

Supplied parameter. Contains a data structure containing flags for messages supplied by the application. This parameter is used by RUI_BID, RUI_READ, RUI_WRITE, SLI_BID, **SLI_RECEIVE_EX**, and SLI_SEND_EX. Its subparameters are as follows:

lua_flag1.bid_enable

Bid enable indicator, one bit.

lua_flag1.close_abend

Close immediate indicator, one bit.

lua_flag1.nowait

No wait for data flag, one bit.

lua_flag1.sscp_exp

System services control point (SSCP) expedited flow, one bit.

lua_flag1.sscp_norm

SSCP normal flow, one bit.

lua_flag1.lu_exp

LU expedited flow, one bit.

lua_flag1.lu_norm

LU normal flow, one bit.

Set **lua_flag1.bid_enable** to 1 to re-enable the most recent SLI_BID (equivalent to issuing **SLI_BID** again with exactly the same parameters as before), or set it to zero if you do not want to re-enable **SLI_BID**. Note that re-enabling the previous **SLI_BID** reuses the VCB originally allocated for it, so this VCB must not have been freed or modified.

Set lua_flag1.nowait to 1 to indicate that you want SLI_RECEIVE_EX to return immediately whether or not data is available to be read, or set it to zero if you want the verb to wait for data before returning.

Set one or more of the following flags to 1 to indicate from which message flow to read data:

lua_flag1.sscp_exp

lua_flag1.lu_exp

lua_flag1.sscp_norm

lua_flag1.lu_norm

If more than one flag is set, the highest-priority data available is returned. The order of priorities (highest first) is: SSCP expedited, LU expedited, SSCP normal, LU normal. The equivalent flag in the **lua_flag2** group is set to indicate from which flow the data was read.

lua_message_type

Specifies the type of the inbound or outbound SNA commands and data. Returned parameter. Specifies the type of SNA message indicated to **SLI_RECEIVE_EX**. Possible values are:

LUA_MESSAGE_TYPE_LU_DATA

LUA_MESSAGE_TYPE_SSCP_DATA

LUA_MESSAGE_TYPE_RSP

LUA_MESSAGE_TYPE_BID

LUA_MESSAGE_TYPE_BIND

LUA_MESSAGE_TYPE_BIS

LUA_MESSAGE_TYPE_CANCEL

LUA_MESSAGE_TYPE_CHASE

LUA_MESSAGE_TYPE_LUSTAT_LU

LUA_MESSAGE_TYPE_LUSTAT_SSCP

LUA_MESSAGE_TYPE_QC

LUA_MESSAGE_TYPE_QEC

LUA_MESSAGE_TYPE_RELQ

LUA_MESSAGE_TYPE_RTR

LUA_MESSAGE_TYPE_SBI

LUA_MESSAGE_TYPE_SIGNAL

LUA_MESSAGE_TYPE_STSN

The SLI receives and responds to the BIND and STSN requests through the LUA interface extension routines.

LU-DATA, LUSTAT_LU, LUSTAT_SSCP, and SSCP_DATA are not SNA commands.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA. Returned by RUI_BID, RUI_READ, **RUI_WRITE**, **SLI_BID**, **SLI_RECEIVE**, and SLI_SEND_EX. Its subparameters are as follows:

lua_flag2.bid_enable

Indicates that **RUI_BID** was successfully re-enabled if set to 1.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_flag2.sscp_exp

Indicates SSCP expedited flow if set to 1.

lua_flag2.sscp_norm

Indicates SSCP normal flow if set to 1.

lua_flag2.lu_exp

Indicates LU expedited flow if set to 1.

lua_flag2.lu_norm

Indicates LU normal flow if set to 1.

lua_resv56

Not used by **SLI_RECEIVE** and should be set to zero.

lua_encr_decr_option

Not used by **SLI_RECEIVE** and should be set to zero.

lua_max_length_ex

Specifies the length of received buffer for **SLI_RECEIVE_EX**.

lua_data_length_ex

The union member of **LUA_SPECIFIC** used by **SLI_RECEIVE_EX**. Returned parameter. Specifies the length of data returned in the receive buffer.

Return Codes
LUA_OK

Primary return code; the verb executed successfully.

LUA_SEC_OK

Secondary return code; no additional information exists for LUA_OK.

LUA_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

LUA_INVALID_LUNAME

Secondary return code; an invalid **lua_luname** was specified.

LUA_BAD_SESSION_ID

Secondary return code; an invalid value for **lua_sid** was specified in the VCB.

LUA_BAD_DATA_PTR

Secondary return code; the **lua_data_ptr** parameter either does not contain a valid pointer or does not point to a read/write segment and supplied data is required.

LUA_RESERVED_FIELD_NOT_ZERO

Secondary return code; a reserved parameter for the verb just issued is not set to zero.

LUA_INVALID_POST_HANDLE

Secondary return code; for a Microsoft Windows Server 2003 or Windows 2000 system using events as the asynchronous posting method, the Windows LUA VCB does not contain a valid event handle.

LUA_BID_VERB_SEGMENT_ERROR

Secondary return code; the buffer with the SLI_BID VCB was released before the **SLI_RECEIVE_EX** with **lua_flag1.bid_enable** set to 1 was issued.

LUA_NO_PREVIOUS_BID_ENABLED

Secondary return code; **SLI_BID** was not issued prior to issuing **SLI_RECEIVE_EX** with **lua_flag1.bid_enable**.

LUA_BID_ALREADY_ENABLED

Secondary return code; **SLI_RECEIVE_EX** was issued with **lua_flag1.bid_enable** when **SLI_BID** was already active.

LUA_INVALID_FLOW

Secondary return code; the **lua_flag1** flow flags were set incorrectly when a verb was issued:

When issuing SLI_SEND_EX_sna_SLI_SEND_EX_lua to send an SNA response, set only one lua_flag1 flow flag.

When issuing SLI_RECEIVE, set at least one lua_flag1 flow flag.

LUA_VERB_LENGTH_INVALID

Secondary return code; an LUA verb was issued with a value for **lua_verb_length** unexpected by LUA.

LUA_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

LUA_NO_SLI_SESSION

Secondary return code; a session was not open or was down due to an SLI_CLOSE or session failure when a command was issued.

LUA_RECEIVE_ON_FLOW_PENDING

Secondary return code; an **SLI_RECEIVE_EX** was still outstanding when this application issued another **SLI_RECEIVE_EX** for an SNA flow.

LUA_SESSION_FAILURE

Primary return code; an error condition, specified in the secondary return code, caused the session to fail.

LUA_RUI_WRITE_FAILURE

Secondary return code; an unexpected error was posted to the SLI by RUI_WRITE.

LUA_RECEIVED_UNBIND

Secondary return code; the primary logical unit (PLU) sent an SNA UNBIND command to the LUA interface when a session was active. As a result, the session was stopped.

LUA_SLI_LOGIC_ERROR

Secondary return code; the LUA interface found an internal error in logic.

LUA_NO_RUI_SESSION

Secondary return code; no session has been initialized for the LUA verb issued or some verb other than SLI_OPEN was issued before the session was initialized.

LUA_MODE_INCONSISTENCY

Secondary return code; performing this function is not allowed by the current status. The request sent to the half-session component was not executed even though it was understood and supported. This SNA sense code is also an exception request sense code.

LUA_RECEIVER_IN_TRANSMIT_MODE

Secondary return code; either resources needed to handle normal flow data were not available or the state of the half-duplex contention was not received when a normal-flow request was received. The result is a race condition. This SNA sense code is also an exception request sense code.

LUA_LU_COMPONENT_DISCONNECTED

Secondary return code; an LU component is unavailable because it is not connected properly. Make sure that the power is on.

LUA_FUNCTION_NOT_SUPPORTED

Secondary return code; LUA does not support the requested function. A control character, a request/response unit (RU) parameter, or a formatted request code may have specified the function. Specific sense code information is in bytes 2 and 3.

LUA_CHAINING_ERROR

Secondary return code; the sequence of the chain indicator settings is in error. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_BRACKET

Secondary return code; the sender failed to enforce the session bracket rules. Note that contention and race conditions are exempt from this error. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DIRECTION

Secondary return code; while the half-duplex flip-flop state was NOT_RECEIVE, a request for normal flow was received. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DATA_TRAFFIC_QUIESCED

Secondary return code; a data flow control (DFC) or function management data (FMD) request was received from a half-session that sent either a SHUTC command or QC command, and the DFC or FMD request has not responded to a RELQ command. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_NO_BEGIN_BRACKET

Secondary return code; the receiver has already sent a positive response to a BIS command when a BID or an FMD request specifying BBI=BB was received. An invalid request header or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_IMMEDIATE_REQUEST_MODE_ERROR

Secondary return code; the request violated the immediate request mode protocol. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_QUEUED_RESPONSE_ERROR

Secondary return code; the request violated the queued response protocol. An invalid header request or request unit for the

received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_ERP_SYNC_EVENT_ERROR

Secondary return code; a violation of the ERP synchronous event protocol occurred. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_RSP_CORRELATION_ERROR

Secondary return code; a response was sent that does not correspond to a previously received request or a response was received that does not correspond to a previously sent request.

LUA_RSP_PROTOCOL_ERROR

Secondary return code; a violation of the response protocol was found in the response received from the primary half-session.

LUA_BB_NOT_ALLOWED

Secondary return code; the begin bracket indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_EB_NOT ALLOWED

Secondary return code; the end bracket indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_EXCEPTION_RSP_NOT_ALLOWED

Secondary return code; when an exception response was not allowed, one was requested. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_DEFINITE_RSP_NOT_ALLOWED

Secondary return code; when a definite response was not allowed, one was requested. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CD_NOT_ALLOWED

Secondary return code; the change-direction indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_NO_RESPONSE_NOT_ALLOWED

Secondary return code; a request other than an EXR contained a NO RESPONSE. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CHAINING_NOT_SUPPORTED

Secondary return code; the chaining indicators were incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_BRACKETS_NOT_SUPPORTED

Secondary return code; the bracket indicators were incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was

prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CD_NOT_SUPPORTED

Secondary return code; the change-direction indicator was set, but LUA does not support change-direction for this situation. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_FI

Secondary return code; the format indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_ALTERNATE_CODE_NOT_SUPPORTED

Secondary return code; the code selection indicator was set, but LUA does not support code selection for this session. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_RU_CATEGORY

Secondary return code; the request unit category indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_REQUEST_CODE

Secondary return code; the request code was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_SPEC_OF_SDI_RTI

Secondary return code; the SDI and the RTI were not specified correctly on a response. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_DR1I_DR2I_ERI

Secondary return code; the DR1I, the DR2I, and the ERI were specified incorrectly. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_QRI

Secondary return code; the queued response indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_EDI

Secondary return code; the EDI was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_PDI

Secondary return code; the PDI was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_UNSUCCESSFUL

Primary return code; the verb record supplied was valid but the verb did not complete successfully.

LUA_DATA_TRUNCATED

Secondary return code; the data was truncated because the data received was longer than the buffer length specified in **lua_max_length_ex**.

LUA_DATA_SEGMENT_LENGTH_ERROR

Secondary return code; one of the following has occurred:

The supplied data segment for **SLI_RECEIVE_EX** or SLI_SEND_EX is not a read/write data segment as required.

The supplied data segment for SLI_RECEIVE_EX is not as long as that provided in lua_max_length_ex.

The supplied data segment for SLI_SEND_EX is not as long as that provided in lua_data_length_ex.

LUA_NO_DATA

Secondary return code; no data was available to read when **SLI_RECEIVE_EX** containing a no wait parameter was issued.

LUA_VERB_RECORD_SPANS_SEGMENTS

Secondary return code; the LUA VCB length parameter plus the segment offset is beyond the segment end.

LUA_NOT_ACTIVE

Secondary return code; LUA was not active within Microsoft Host Integration Server or SNA Server when an LUA verb was issued.

LUA_NOT_READY

Secondary return code; one of the following has caused the SLI session to be temporarily suspended:

An SNA UNBIND type 0x02 command was received, which indicates a new BIND is coming. If the UNBIND type 0x02 is received after the beginning SLI_OPEN is complete, the session is suspended until a BIND, optional CRV and STSN, and SDT flows are received. These routines are re-entrant because they have to be called again. The session resumes after the SLI processes the SDT command. If the UNBIND type 0x02 is received while the **SLI_OPEN** is still processing, the primary return code is LUA_SESSION_FAILURE, not LUA_STATUS.

The receipt of an SNA CLEAR caused the suspension. Receipt of an SNA SDT will cause the session to resume.

LUA_SLI_LOGIC_ERROR

Secondary return code; the LUA interface found an internal error in logic.

LUA_INVALID_PROCESS

Secondary return code; the session for which an LUA verb was issued is unavailable because another process owns the session.

LUA_LU_INOPERATIVE

Secondary return code; a severe error occurred while the LUA was attempting to stop the session. This LU is unavailable for any LUA requests until an activate logical unit (ACTLU) is received from the host.

LUA_RECEIVE_CORRELATION_TABLE_FULL

Secondary return code; the session receive correlation table for the flow requested reached its capacity.

LUA_NEGATIVE_RESPONSE

Primary return code; either the LUA sent a negative response to a message received from the primary logical unit (PLU) because an error was found in the message, or the application responded negatively to a chain for which the end-of-chain has arrived.

LUA_MODE_INCONSISTENCY

Secondary return code; performing this function is not allowed by the current status. The request sent to the half-session component was not executed even though it was understood and supported. This SNA sense code is also an exception request sense code.

LUA_FUNCTION_NOT_SUPPORTED

Secondary return code; the LUA does not support the requested function. A control character, an RU parameter, or a formatted request code may have specified the function. Specific sense code information is in bytes 2 and 3.

LUA_DATA_TRAFFIC_RESET

Secondary return code; a half-session of an active session but with inactive data traffic received a normal flow DFC or FMD request. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DATA_TRAFFIC_NOT_RESET

Secondary return code; while the data traffic state was not reset, the session control request was received. An invalid request header or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_SC_PROTOCOL_VIOLATION

Secondary return code; a violation of SC protocol occurred. A request (that is permitted only after an SC request and a positive response to that request have been successfully exchanged) was received before the required exchange. Byte 4 of the sense data contains the request code. No user data exists for this sense code. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_INVALID_SC_OR_NC_RH

Secondary return code; the RH of an SC or NC request was invalid.

LUA_PACING_NOT_SUPPORTED

Secondary return code; the request contained a pacing indicator when support of pacing for this session does not exist for the receiving half-session or boundary function half-session. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_NAU_INOPERATIVE

Secondary return code; the network addressable unit is not able to process responses or requests. Delivery to the receiver could not take place for one of the following reasons:

A path information unit error

A path outage

An invalid sequence of requests for activation

If a path error is received during an active session, it usually means there is no longer a valid path to the session partner.

LUA_CANCELED

Primary return code; the secondary return code gives the reason for canceling the command.

LUA_PURGED

Secondary return code; SLI_PURGE was issued and canceled **SLI_RECEIVE**.

LUA_NO_SLI_SESSION

Secondary return code; a session was not open or was down due to an SLI_CLOSE or session failure when a command was issued.

LUA_CANCEL_COMMAND_RECEIVED

Secondary return code; the host sent an SNA CANCEL command to cancel the data chain currently being received by **SLI_RECEIVE_EX**.

LUA_TERMINATED

Secondary return code; the session was terminated when a verb was pending. The verb process has been canceled.

LUA_IN_PROGRESS

Primary return code; an asynchronous command was received but is not completed.

LUA_STATUS

Primary return code; the secondary return code contains SLI status information for the application.

LUA_READY

Secondary return code; following a NOT READY status, this status is issued to notify you that the SLI is ready to process commands.

LUA_NOT_READY

Secondary return code; the SLI session is temporarily suspended for the following reason:

An SNA UNBIND type 0x02 command was received, which means a new BIND is coming. If the UNBIND type 0x02 is received after the beginning SLI_OPEN is complete, the session is suspended until a BIND, optional CRV and STSN, and SDT flows are received. These routines are re-entrant because they have to be called again. The session resumes after the SLI processes the SDT command. If the UNBIND type 0x02 is received while the **SLI_OPEN** is still processing, the primary return code is session-failure, not status.

The receipt of an SNA CLEAR caused the suspension. Receipt of an SNA SDT will cause the session to resume.

LUA_INIT_COMPLETE

Secondary return code; the LUA interface initialized the session while SLI_OPEN was processing. LUA applications that issue **SLI_OPEN** with **lua_open_type_prim_sscp** receive this status on **SLI_RECEIVE** or SLI_BID.

LUA_SESSION_END_REQUESTED

Secondary return code; the LUA interface received an SNA SHUTD from the host, which means the host is ready to shut down the session.

LUA_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

The node used by this conversation encountered an ABEND.

The connection between the transaction program (TP) and the physical unit (PU) 2.1 node has been broken (a LAN error).

The SnaBase at the TPs computer encountered an ABEND.

LUA_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

LUA_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

LUA_UNEXPECTED_DOS_ERROR

Primary return code; after issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

LUA_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

LUA_INVALID_VERB

Primary return code; either the verb code or the operation code, or both, is invalid. The verb did not execute.

Remarks

SLI_RECEIVE_EX receives responses, SNA commands, and request unit data from the host. **SLI_RECEIVE_EX** also provides the status of the session to the Windows LUA application.

The difference between SLI_RECEIVE_EX and SLI_RECEIVE is that the SLI_RECEIVE_EX verb supports inbound chaining and can receive up to 4,295 kilobytes (KB) in a single verb request. In contrast, SLI_RECEIVE is limited to receiving up to 64 KB in a verb request.

An SLI_OPEN request must complete before SLI_RECEIVE_EX can be issued. However, if SLI_OPEN is issued with lua_init_type set to LUA_INIT_TYPE_PRIM_SSCP, an SLI_RECEIVE_EX over the SSCP normal flow can be issued as soon as SLI_OPEN returns an IN_PROGRESS.

Data is received by the application in one of four session flows. The four session flows, from highest to lowest priority are:

- SSCP expedited
- LU expedited
- SSCP normal
- LU normal

The data flow type that **SLI_RECEIVE_EX** will process is specified in **lua_flag1**. The application can also specify whether it wants to look at more than one type of data flow. When multiple flow bits are set, the highest priority is received first. When **SLI_RECEIVE_EX** completes processing, **lua_flag2** indicates the specific type of flow for which data has been received by the Windows LUA application.

If SLI_BID successfully completes before SLI_RECEIVE is issued, the Windows LUA interface can be instructed to reuse the last SLI_BID verbs VCB. To do this, issue SLI_RECEIVE_EX with lua_flag1.bid_enable set to 1.

When using lua_flag1.bid_enable, the SLI_BID storage must not be freed because the last SLI_BID verbs VCB is used. Also, when using lua_flag1.bid_enable, the successful completion of SLI_BID will be posted.

If SLI_RECEIVE_EX is issued with lua_flag1.nowait when no data is available to receive, LUA_NO_DATA will be the secondary return code set by the Windows LUA interface.

Session Status Return Values

If LUA_STATUS is the primary return code, the secondary return code can be one of the following:

LUA_READY

LUA_NOT_READY

LUA_SESSION_END_REQUESTED

LUA_INIT_COMPLETE

In addition, if LUA_STATUS is the primary return code, the following parameters are used:

lua_sec_rc

lua_sid

LUA_READY is returned after an LUA_NOT_READY status and indicates that the SLI is again ready to perform all commands.

LUA_NOT_READY indicates that the SLI session is suspended because the SLI has received either an SNA CLEAR command or an SNA UNBIND command with an 0x02 UNBIND type (UNBIND with BIND forthcoming). Depending on what caused the suspension, the session can be reactivated as follows:

- When the suspension is caused by an SNA CLEAR, receiving an SNA SDT reactivates the session.
- When an SNA UNBIND type BIND forthcoming causes suspension of the session and the SLI_OPEN that opened the session is completed, the session is suspended until the SLI receives a BIND and SDT command. The session can also optionally receive an STSN command. As a result, user-supplied routines issued with the initial SLI_OPEN must be re-entered because they will be recalled.

The application can send SSCP data after a CLEAR or UNBIND type BIND forthcoming arrives and before the NOT_READY status is read. The application can send and receive SSCP data after reading a NOT_READY.

When an SNA UNBIND type BIND forthcoming arrives before completion of the SLI_OPEN that opened the session, LUA_SESSION_FAILURE (not LUA_STATUS) is the primary return code.

LUA_SESSION_END_REQUESTED indicates that the application received an SNA SHUTD from the host. The Windows LUA application should issue SLI_CLOSE to close the session when convenient.

LUA_INIT_COMPLETE is returned only when lua_init_type for SLI_OPEN is LUA_INIT_TYPE_PRIM_SSCP. The status means that the SLI_OPEN has been processed sufficiently to allow SSCP data to now be sent or received.

Exception Requests

If a host application request unit is converted into an EXR, sense data will be returned. When SLI_BID completes with the returned verb parameters set as shown, an EXR conversion occurs.

Member	Set to
lua_prim_rc	OK (0x0000)
lua_sec_rc	OK (0x00000000)
lua_rh.rri	bit off (request unit)
lua_rh.sdi	bit on (includes sense data)

Of the seven bytes of data in **lua_peek_data**, bytes 0 through 3 define the error detected. The following table indicates possible sense data and the values of bytes 0 through 3.

Sense data	Value of bytes 0–3
LUA_MODE_INCONSISTENCY	0x08090000
LUA_BRACKET_RACE_ERROR	0x080B0000
LUA_BB_REJECT_NO_RTR	0x08130000
LUA_RECEIVER_IN_TRANSMIT_MODE	0x081B0000
LUA_CRYPTOGRAPHY_FUNCTION_INOP	0x08480000
LUA_SYNC_EVENT_RESPONSE	0x10010000
LUA_RU_DATA_ERROR	0x10020000
LUA_RU_LENGTH_ERROR	0x10020000
LUA_INCORRECT_SEQUENCE_NUMBER	0x20010000

The information returned to bytes 3 through 6 in **lua_peek_data** is determined by the first three bytes of the initial request unit that caused the error.

SLI_SEND

The **SLI_SEND** verb sends responses, SNA commands, and data from a Microsoft® Windows® logical unit application (LUA) application to a host logical unit (LU).

The following structure describes the LUA_COMMON member of the verb control block (VCB) used by SLI_SEND.

The second syntax union below describes the **LUA_SPECIFIC** member of the VCB used by **SLI_SEND**. Other union members are omitted for clarity.

Syntax

```
struct LUA_COMMON {
    unsigned short    lua_verb;
    unsigned short    lua_verb_length;
    unsigned short    lua_prim_rc;
    unsigned long     lua_sec_rc;
    unsigned short    lua_opcode;
    unsigned long     lua_correlator;
    unsigned char     lua_luname[8];
    unsigned short    lua_extension_list_offset;
    unsigned short    lua_cobol_offset;
    unsigned long     lua_sid;
    unsigned short    lua_max_length;
    unsigned short    lua_data_length;
    char FAR *        lua_data_ptr;
    unsigned long     lua_post_handle;
    struct LUA_TH     lua_th;
    struct LUA_RH     lua_rh;
    struct LUA_FLAG1  lua_flag1;
    unsigned char     lua_message_type;
    struct LUA_FLAG2  lua_flag2;
    unsigned char     lua_resv56[7];
    unsigned char     lua_encr_decr_option;
};
union LUA_SPECIFIC {
    unsigned char lua_sequence_number[2];
};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_SLI for Session Level Interface (SLI) verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the LUA VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_SLI_SEND.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

SLI_SEND only requires this parameter if lua_sid is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by **SLI_SEND** and should be set to zero.

lua_cobol_offset

Not used by LUA in Microsoft® Host Integration Server or SNA Server and should be zero.

lua_sid

Supplied and returned parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Not used by **SLI_SEND** and should be set to zero.

lua_data_length

Supplied parameter. Specifies the length of data being sent.

lua_data_ptr

Pointer to the application-supplied buffer that contains the data to be sent to the host by **SLI_SEND**.

Both SNA commands and data are placed in this buffer, and they can be in an Extended Binary Coded Decimal Interchange Code (EBCDIC) format.

lua_post_handle

Supplied parameter. Used under Microsoft Windows Server™ 2003 or Windows 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Returned parameter. Contains the SNA transmission header (TH) of the message received. Various subparameters are set for write functions and returned for read and bid functions. Its subparameters are as follows:

lua_th.flags_fid

Format identification type 2, four bits.

lua_th.flags_mpf

Segmenting mapping field, two bits. Defines the type of data segment. The following values are valid:

0x00 Middle segment**0x04** Last segment**0x08** First segment**0x0C** Only segment

lua_th.flags_odai

Originating address field–destination address field (OAF–DAF) assignor indicator, one bit.

lua_th.flags_efi

Expedited flow indicator, one bit.

lua_th.daf

Destination address field (DAF), an unsigned char.

lua_th.oaf

Originating address field (OAF), an unsigned char.

lua_th.snf

Sequence number field, an unsigned char[2].

lua_rh

Supplied parameter. Contains the SNA request/response header (RH) of the message sent or received. It is set for RUI_WRITE and **SLI_SEND**, and returned by RUI_READ and RUI_BID. For the RH for **SLI_SEND**, all fields except the queued-response indicator (**lua_rh.qri**) and pacing indicator (**lua_rh.pi**) are used.

lua_rh.rri

Request-response indicator, one bit.

lua_rh.ruc

RU category, two bits.

lua_rh.fi

Format indicator, one bit.

lua_rh.sdi

Sense data included indicator, one bit.

lua_rh.bci

Begin chain indicator, one bit.

lua_rh.eci

End chain indicator, one bit.

lua_rh.dr1i

Definite response 1 indicator, one bit.

lua_rh.dr2i

Definite response 2 indicator, one bit.

lua_rh.ri

Exception response indicator (for a request), or response type indicator (for a response), one bit.

lua_rh.qri

Queued response indicator, one bit.

lua_rh.pi

Pacing indicator, one bit.

lua_rh.bbi

Begin bracket indicator, one bit.

lua_rh.ebi

End bracket indicator, one bit.

lua_rh.cdi

Change direction indicator, one bit.

lua_rh.csi

Code selection indicator, one bit.

lua_rh.edi

Enciphered data indicator, one bit.

lua_rh.pdi

Padded data indicator, one bit.

lua_flag1

Supplied parameter. Contains a data structure containing flags for messages supplied by the application. Its subparameters are as follows:

lua_flag1.bid_enable

Bid enable indicator, one bit.

lua_flag1.close_abend

Close immediate indicator, one bit.

lua_flag1.nowait

No wait for data flag, one bit.

lua_flag1.sscp_exp

System services control point (SSCP) expedited flow, one bit.

lua_flag1.sscp_norm

SSCP normal flow, one bit.

lua_flag1.lu_exp

LU expedited flow, one bit.

lua_flag1.lu_norm

LU normal flow, one bit.

Set one of the following flags to 1 to indicate on which message flow the data is to be sent:

lua_flag1.sscp_exp

lua_flag1.sscp_norm

lua_flag1.lu_exp

lua_flag1.lu_norm

lua_message_type

Specifies the type of the inbound or outbound SNA commands and data. This is a supplied parameter for **SLI_SEND**.

Possible values are as follows:

LUA_MESSAGE_TYPE_LU_DATA

LUA_MESSAGE_TYPE_SSCP_DATA

LUA_MESSAGE_TYPE_RSP

LUA_MESSAGE_TYPE_BID

LUA_MESSAGE_TYPE_BIS

LUA_MESSAGE_TYPE_CANCEL

LUA_MESSAGE_TYPE_CHASE

LUA_MESSAGE_TYPE_LUSTAT_LU

LUA_MESSAGE_TYPE_LUSTAT_SSCP

LUA_MESSAGE_TYPE_QC

LUA_MESSAGE_TYPE_QEC

LUA_MESSAGE_TYPE_RELQ

LUA_MESSAGE_TYPE_RQR

LUA_MESSAGE_TYPE_RTR

LUA_MESSAGE_TYPE_SBI

LUA_MESSAGE_TYPE_SIGNAL

The SLI receives and responds to the BIND and STSN requests through the LUA interface extension routines.

LU-DATA, LUSTAT_LU, LUSTAT_SSCP, and SSCP_DATA are not SNA commands.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA. Its subparameters are as follows:

lua_flag2.bid_enable

Indicates that RUI_BID was successfully re-enabled if set to 1.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_flag2.sscp_exp

Indicates SSCP expedited flow if set to 1.

lua_flag2.sscp_norm

Indicates SSCP normal flow if set to 1.

lua_flag2.lu_exp

Indicates LU expedited flow if set to 1.

lua_flag2.lu_norm

Indicates LU normal flow if set to 1.

lua_resv56

Reserved and should be set to zero.

lua_encr_decr_option

Not used by **SLI_SEND** and should be set to zero.

lua_sequence_number

The union member of **LUA_SPECIFIC** used by **SLI_SEND**. Returned parameter. Contains the sequence number for either the first in the chain request unit or the only segment in the chain request unit. Note that this parameter is not byte-reversed.

Return Codes

LUA_OK

Primary return code; the verb executed successfully.

LUA_SEC_OK

Secondary return code; no additional information exists for LUA_OK.

LUA_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

LUA_INVALID_LUNAME

Secondary return code; an invalid **lua_luname** was specified.

LUA_BAD_SESSION_ID

Secondary return code; an invalid value for **lua_sid** was specified in the VCB.

LUA_BAD_DATA_PTR

Secondary return code; the **lua_data_ptr** parameter either does not contain a valid pointer or does not point to a read/write segment and supplied data is required.

LUA_RESERVED_FIELD_NOT_ZERO

Secondary return code; a reserved parameter for the verb just issued is not set to zero.

LUA_INVALID_POST_HANDLE

Secondary return code; for a Microsoft Windows Server 2003 or Windows 2000 system using events as the asynchronous posting method, the Windows LUA VCB does not contain a valid event handle.

LUA_INVALID_FLOW

Secondary return code; the **lua_flag1** flow flags were set incorrectly when a verb was issued:

When issuing **SLI_SEND** to send an SNA response, set only one **lua_flag1** flow flag.

When issuing SLI_RECEIVE, set at least one lua_flag1 flow flag.

LUA_VERB_LENGTH_INVALID

Secondary return code; an LUA verb was issued with a value for **lua_verb_length** unexpected by LUA.

LUA_REQUIRED_FIELD_MISSING

Secondary return code; the verb that was issued either did not include a data pointer (if the data count was not zero) or did not include an **lua_flag1** flow flag.

LUA_INVALID_MESSAGE_TYPE

Secondary return code; the **lua_message_type** parameter is not recognized by the LUA interface.

LUA_DATA_LENGTH_ERROR

Secondary return code; the application did not provide user-supplied data required by the verb issued. Note that when **SLI_SEND** is issued for an SNA LUSTAT command, status (in four bytes) is required, and that when SLI_OPEN is issued with secondary initialization, data is required.

LUA_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

LUA_NO_SLI_SESSION

Secondary return code; a session was not open or was down due to an SLI_CLOSE or session failure when a command was issued.

LUA_MAX_NUMBER_OF_SENDS

Secondary return code; the application issued a third **SLI_SEND** before one completed.

LUA_SEND_ON_FLOW_PENDING

Secondary return code; an **SLI_SEND** was still outstanding when the application issued another **SLI_SEND** for an SNA flow.

LUA_SESSION_FAILURE

Primary return code; an error condition, specified in the secondary return code, caused the session to fail.

LUA_RECEIVED_UNBIND

Secondary return code; the primary logical unit (PLU) sent an SNA UNBIND command to the LUA interface when a session was active. As a result, the session was stopped.

LUA_SLI_LOGIC_ERROR

Secondary return code; the LUA interface found an internal error in logic.

LUA_NO_RUI_SESSION

Secondary return code; no session has been initialized for the LUA verb issued, or some verb other than SLI_OPEN was issued before the session was initialized.

LUA_LU_COMPONENT_DISCONNECTED

Secondary return code; an LU component is unavailable because it is not connected properly. Make sure that the power is on.

LUA_DATA_SEGMENT_LENGTH_ERROR

Secondary return code; one of the following has occurred:

The supplied data segment for SLI_RECEIVE or **SLI_SEND** is not a read/write data segment as required.

The supplied data segment for SLI_RECEIVE is not as long as that provided in lua_max_length.

The supplied data segment for SLI_SEND is not as long as that provided in lua_data_length.

LUA_VERB_RECORD_SPANS_SEGMENTS

Secondary return code; the LUA VCB length parameter plus the segment offset is beyond the segment end.

LUA_NOT_ACTIVE

Secondary return code; LUA was not active within Microsoft Host Integration Server or SNA Server when an LUA verb was issued.

LUA_SLI_LOGIC_ERROR

Secondary return code; the LUA interface found an internal error in logic.

LUA_INVALID_PROCESS

Secondary return code; the session for which an LUA verb was issued is unavailable because another OS/2 process owns the session.

LUA_LU_INOPERATIVE

Secondary return code; a severe error occurred while the LUA was attempting to stop the session. This LU is unavailable for any LUA requests until an activate logical unit (ACTLU) is received from the host.

LUA_MODE_INCONSISTENCY

Secondary return code; performing this function is not allowed by the current status. The request sent to the half-session component was not executed even though it was understood and supported. This SNA sense code is also an exception request sense code.

LUA_INSUFFICIENT_RESOURCES

Secondary return code; a temporary condition of insufficient resources caused the request receiver to be unable to perform. The request sent to the half-session component was not executed, even though it was understood and supported.

LUA_SEND_CORRELATION_TABLE_FULL

Secondary return code; the session send correlation table for the flow requested reached its capacity.

LUA_RU_LENGTH_ERROR

Secondary return code; the request/response unit (RU) request was an incorrect length (either too short or too long). The request unit was not interpreted or processed even though it was delivered to the half-session component. The half-session capabilities do not match. This SNA sense code is also an exception request sense code.

LUA_FUNCTION_NOT_SUPPORTED

Secondary return code; LUA does not support the requested function. A control character, an RU parameter, or a formatted request code may have specified the function. Specific sense code information is in bytes 2 and 3.

LUA_HDX_BRACKET_STATE_ERROR

Secondary return code; the existing state error prevented the current request from being sent. The determination was made by a protocol computer.

LUA_RESPONSE_ALREADY_SENT

Secondary return code; a response for the chain was already sent so that the current request was not sent. The determination was made by a protocol computer.

LUA_EXR_SENSE_INCORRECT

Secondary return code; the application responded negatively to an exception request. The sense code was unacceptable.

LUA_RESPONSE_OUT_OF_ORDER

Secondary return code; the current response was not for the oldest request. The determination was made by a protocol computer.

LUA_CHAIN_RESPONSE_REQUIRED

Secondary return code; a CHASE response was still outstanding when a more recent request was attempted. The determination was made by a protocol computer.

LUA_BRACKET

Secondary return code; the sender failed to enforce the session bracket rules. Note that contention and race conditions are exempt from this error. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DIRECTION

Secondary return code; while the half-duplex flip-flop state was NOT_RECEIVE, a request for normal flow was received. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DATA_TRAFFIC_RESET

Secondary return code; a half-session of an active session but with inactive data traffic received a normal flow data flow control (DFC) or function management data (FMD) request. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DATA_TRAFFIC_QUIESCED

Secondary return code; a DFC or FMD request was received from a half-session that sent either a SHUTC command or QC command, and the DFC or FMD request has not responded to a RELQ command. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DATA_TRAFFIC_NOT_RESET

Secondary return code; while the data traffic state was not reset, the session control request was received. An invalid request header or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_NO_BEGIN_BRACKET

Secondary return code; the receiver has already sent a positive response to a BIS command when a BID or an FMD request specifying BBI=BB was received. An invalid request header or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_SC_PROTOCOL_VIOLATION

Secondary return code; a violation of SC protocol occurred. A request (that is permitted only after an SC request and a positive response to that request have been successfully exchanged) was received before the required exchange. Byte 4 of the sense data contains the request code. No user data exists for this sense code. An invalid header request or data flow control state was found. Delivery to the half-session component was prevented.

LUA_IMMEDIATE_REQUEST_MODE_ERROR

Secondary return code; the request violated the immediate request mode protocol. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_QUEUED_RESPONSE_ERROR

Secondary return code; the request violated the queued response protocol. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_ERP_SYNC_EVENT_ERROR

Secondary return code; a violation of the ERP synchronous event protocol occurred. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_RSP_BEFORE_SENDING_REQ

Secondary return code; a previously received request has not been responded to yet and an attempt was made in half-duplex send/receive mode to send a normal flow request. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_RSP_CORRELATION_ERROR

Secondary return code; a response was sent that does not correspond to a previously received request or a response was received that does not correspond to a previously sent request.

LUA_BB_NOT_ALLOWED

Secondary return code; the begin bracket indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_EB_NOT ALLOWED

Secondary return code; the end bracket indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_EXCEPTION_RSP_NOT_ALLOWED

Secondary return code; when an exception response was not allowed, one was requested. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_DEFINITE_RSP_NOT_ALLOWED

Secondary return code; when a definite response was not allowed, one was requested. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CD_NOT_ALLOWED

Secondary return code; the change-direction indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_NO_RESPONSE_NOT_ALLOWED

Secondary return code; a request other than an EXR contained a "no response." The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CHAINING_NOT_SUPPORTED

Secondary return code; the chaining indicators were incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_BRACKETS_NOT_SUPPORTED

Secondary return code; the bracket indicators were incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CD_NOT_SUPPORTED

Secondary return code; the change-direction indicator was set, but LUA does not support change-direction for this situation. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_FI

Secondary return code; the format indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_ALTERNATE_CODE_NOT_SUPPORTED

Secondary return code; the code selection indicator was set, but LUA does not support code selection for this session. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_REQUEST_CODE

Secondary return code; the request code was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_SPEC_OF_SDI_RTI

Secondary return code; the SDI and the RTI were not specified correctly on a response. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_DR1I_DR2I_ERI

Secondary return code; the DR1I, the DR2I, and the ERI were specified incorrectly. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_QRI

Secondary return code; the queued response indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_EDI

Secondary return code; the EDI was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_PDI

Secondary return code; the PDI was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_NO_SESSION

Secondary return code; a request to activate a session is required because no active half-session in the receiving end node for the origination-destination pair exists, or no active boundary function half-session component for the origination-destination pair in a node that supplies the boundary function exists. Delivery of the request could not take place for one of the following reasons:

A path information unit error

A path outage

An invalid sequence of requests for activation

If a path error is received during an active session, that usually indicates there is no longer a valid path to the session partner.

LUA_CANCELED

Primary return code; the secondary return code gives the reason for canceling the command.

LUA_TERMINATED

Secondary return code; the session was terminated when a verb was pending. The verb process has been canceled.

LUA_IN_PROGRESS

Primary return code; an asynchronous command was received but is not completed.

LUA_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

The node used by this conversation encountered an ABEND.

The connection between the transaction program (TP) and the physical unit (PU) 2.1 node has been broken (a LAN error).

The SnaBase at the TPs computer encountered an ABEND.

LUA_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

LUA_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

LUA_UNEXPECTED_DOS_ERROR

Primary return code; after issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

LUA_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

LUA_INVALID_VERB

Primary return code; either the verb code or the operation code, or both, is invalid. The verb did not execute.

Remarks

SLI_SEND sends responses, SNA commands, and data from the Windows LUA application to a host LU. A session must already be open to issue **SLI_SEND** for a particular LU-LU session flow. To send data on the SSCP normal flow prior to the completion of SLI_OPEN, the session must have been initialized as primary with SSCP access. In addition, the session status must be INIT_COMPLETE.

The settings for lua_message_type determine the type of processing that will be done by SLI_SEND. The following table indicates the parameters to set based on the value of lua_message_type.

SLI_SEND parameter	LU_DATA SSCP_DATA	BID BIS RTR	CHASE QC	LUSTAT_LU LUSTAT_SSCP	QEC RELQ SBI SIGNAL	RQR	RSP
lua_data _length	Req.	0	0	Req.	0	0	Req. (0 if no data)
lua_data _ptr	Req. (0 if no data)	0	0	Req.	0	0	Req. (0 if no data)
lua_flag1 flow flags	0	0	0	0	0	0	Req. (set one)
lua_rh	FI DRL1 DRL2 RI BBI EBI CDI CSI EDI	SDI QRI	SDI QRI EBI CDI	SDI QRI DRL1 DRL2 RI BBI EBI CDI	SDI	0	RRI RI
lua_th	0	0	0	0	0	0	SNF

The location provided in **lua_data_ptr** and the length provided in **lua_data_length** determine the data that the SLI sends. The data will be chained by the SLI verbs if necessary.

When sending a response, the type of response determines the SLI_SEND information required. For all responses, you must:

- Set the selected **lua_flag1** flow flag.
- Provide the sequence number in lua_th.snf for the request to which you are responding.
- Set lua_message_type to LUA_MESSAGE_TYPE_RSP.

For multichain message responses, the sequence number of the last received chain element must be used. For a response to a multichain message ending with a CANCEL command, the CANCEL command sequence number is used.

For positive responses that only require the request code, set lua_rh.ri to zero (indicating that the response is positive) and lua_data_length to zero (indicating no data is provided). The request code is filled in by the SLI, using the sequence number provided.

For negative responses in which lua_rh.ri is set to 1, set the lua_data_ptr to the SNA sense code address and the lua_data_length to the SNA sense code length (four bytes). The sequence number is used by the SLI to fill in the request code.

SLI_SEND_EX

The **SLI_SEND_EX** verb sends responses, SNA commands, and data from a Microsoft® Windows® logical unit application (LUA) application to a host logical unit (LU).

The SLI_SEND_EX verb also supports inbound chaining. The maximum length of data that can be sent by a single verb is 4,294,967,295 bytes. This is compared to a maximum of 65,535 bytes that can be sent by the SLI_SEND verb.

The following structure describes the LUA_COMMON member of the verb control block (VCB) used by SLI_SEND_EX.

The second syntax union below describes the **LUA_SPECIFIC** member of the VCB used by **SLI_SEND_EX**. Other union members are omitted for clarity.

Syntax

```
struct LUA_COMMON {
    unsigned short    lua_verb;
    unsigned short    lua_verb_length;
    unsigned short    lua_prim_rc;
    unsigned long     lua_sec_rc;
    unsigned short    lua_opcode;
    unsigned long     lua_correlator;
    unsigned char     lua_luname[8];
    unsigned short    lua_extension_list_offset;
    unsigned short    lua_cobol_offset;
    unsigned long     lua_sid;
    unsigned short    lua_max_length;
    unsigned short    lua_data_length;
    char FAR *        lua_data_ptr;
    unsigned long     lua_post_handle;
    struct LUA_TH     lua_th;
    struct LUA_RH     lua_rh;
    struct LUA_FLAG1  lua_flag1;

    };
};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_SLI for Session Level Interface (SLI) verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the LUA VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_SLI_SEND_EX.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

SLI_SEND only requires this parameter if lua_sid is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by **SLI_SEND_EX** and should be set to zero.

lua_cobol_offset

Not used by LUA in Microsoft® Host Integration Server or SNA Server and should be set to zero.

lua_sid

Supplied and returned parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Not used by **SLI_SEND_EX** and should be set to zero.

lua_data_length

This parameter is reserved and must be set to zero.

The length of data to be sent is set in the lua_data_length_ex parameter.

lua_data_ptr

Pointer to the application-supplied buffer that contains the data to be sent to the host by **SLI_SEND_EX**.

Both SNA commands and data are placed in this buffer, and they can be in an Extended Binary Coded Decimal Interchange Code (EBCDIC) format.

lua_post_handle

Supplied parameter. Used under Microsoft Windows Server™ 2003 or Windows 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Returned parameter. Contains the SNA transmission header (TH) of the message received. Various subparameters are set for write functions and returned for read and bid functions. Its subparameters are as follows:

lua_th.flags_fid

Format identification type 2, four bits.

lua_th.flags_mpf

Segmenting mapping field, two bits. Defines the type of data segment. The following values are valid:

0x00 Middle segment**0x04** Last segment**0x08** First segment**0x0C** Only segment

lua_th.flags_odai

Originating address field–destination address field (OAF–DAF) assignor indicator, one bit.

lua_th.flags_efi

Expedited flow indicator, one bit.

lua_th.daf

Destination address field (DAF), an unsigned char.

lua_th.oaf

Originating address field (OAF), an unsigned char.

lua_th.snf

Sequence number field, an unsigned char[2].

lua_rh

Supplied parameter. Contains the SNA request/response header (RH) of the message sent or received. It is set for RUI_WRITE and **SLI_SEND**, and returned by RUI_READ and RUI_BID. For the RH for **SLI_SEND_EX**, all fields except the queued-response indicator (**lua_rh.qri**) and pacing indicator (**lua_rh.pi**) are used.

lua_rh.rri

Request-response indicator, one bit.

lua_rh.ruc

Request/response unit (RU) category, two bits.

lua_rh.fi

Format indicator, one bit.

lua_rh.sdi

Sense data included indicator, one bit.

lua_rh.bci

Begin chain indicator, one bit.

lua_rh.eci

End chain indicator, one bit.

lua_rh.dr1i

Definite response 1 indicator, one bit.

lua_rh.dr2i

Definite response 2 indicator, one bit.

lua_rh.ri

Exception response indicator (for a request), or response type indicator (for a response), one bit.

lua_rh.qri

Queued response indicator, one bit.

lua_rh.pi

Pacing indicator, one bit.

lua_rh.bbi

Begin bracket indicator, one bit.

lua_rh.ebi

End bracket indicator, one bit.

lua_rh.cdi

Change direction indicator, one bit.

lua_rh.csi

Code selection indicator, one bit.

lua_rh.edi

Enciphered data indicator, one bit.

lua_rh.pdi

Padded data indicator, one bit.

lua_flag1

Supplied parameter. Contains a data structure containing flags for messages supplied by the application. Its subparameters are as follows:

lua_flag1.bid_enable

Bid enable indicator, one bit.

lua_flag1.close_abend

Close immediate indicator, one bit.

lua_flag1.nowait

No wait for data flag, one bit.

lua_flag1.sscp_exp

System services control point (SSCP) expedited flow, one bit.

lua_flag1.sscp_norm

SSCP normal flow, one bit.

lua_flag1.lu_exp

LU expedited flow, one bit.

lua_flag1.lu_norm

LU normal flow, one bit.

Set one of the following flags to 1 to indicate on which message flow the data is to be sent:

lua_flag1.sscp_exp

lua_flag1.sscp_norm

lua_flag1.lu_exp

lua_flag1.lu_norm

lua_message_type

Specifies the type of the inbound or outbound SNA commands and data. This is a supplied parameter for **SLI_SEND_EX**.

Possible values are as follows:

LUA_MESSAGE_TYPE_LU_DATA

LUA_MESSAGE_TYPE_SSCP_DATA

LUA_MESSAGE_TYPE_RSP

LUA_MESSAGE_TYPE_BID

LUA_MESSAGE_TYPE_BIS

LUA_MESSAGE_TYPE_CANCEL

LUA_MESSAGE_TYPE_CHASE

LUA_MESSAGE_TYPE_LUSTAT_LU

LUA_MESSAGE_TYPE_LUSTAT_SSCP

LUA_MESSAGE_TYPE_QC

LUA_MESSAGE_TYPE_QEC

LUA_MESSAGE_TYPE_RELQ

LUA_MESSAGE_TYPE_RQR

LUA_MESSAGE_TYPE_RTR

LUA_MESSAGE_TYPE_SBI

LUA_MESSAGE_TYPE_SIGNAL

The SLI receives and responds to the BIND and STSN requests through the LUA interface extension routines.

LU-DATA, LUSTAT_LU, LUSTAT_SSCP, and SSCP_DATA are not SNA commands.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA. Its subparameters are as follows:

lua_flag2.bid_enable

Indicates that RUI_BID was successfully re-enabled if set to 1.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_flag2.sscp_exp

Indicates SSCP expedited flow if set to 1.

lua_flag2.sscp_norm

Indicates SSCP normal flow if set to 1.

lua_flag2.lu_exp

Indicates LU expedited flow if set to 1.

lua_flag2.lu_norm

Indicates LU normal flow if set to 1.

lua_resv56

Reserved and should be set to zero.

lua_encr_decr_option

Not used by **SLI_SEND_EX** and should be set to zero.

lua_sequence_number

The union member of **LUA_SPECIFIC** used by **SLI_SEND_EX**. Returned parameter. Contains the sequence number for either the first in the chain request unit or the only segment in the chain request unit. Note that this parameter is not byte-reversed.

lua_data_length_ex

The union member of **LUA_SPECIFIC** used by **SLI_SEND_EX**. Supplied parameter. Specifies the length of data being sent.

Return Codes

LUA_OK

Primary return code; the verb executed successfully.

LUA_SEC_OK

Secondary return code; no additional information exists for LUA_OK.

LUA_PARAMETER_CHECK

Primary return code; the verb did not execute because of a parameter error.

LUA_INVALID_LUNAME

Secondary return code; an invalid **lua_luname** was specified.

LUA_BAD_SESSION_ID

Secondary return code; an invalid value for **lua_sid** was specified in the VCB.

LUA_BAD_DATA_PTR

Secondary return code; the **lua_data_ptr** parameter either does not contain a valid pointer or does not point to a read/write segment and supplied data is required.

LUA_RESERVED_FIELD_NOT_ZERO

Secondary return code; a reserved parameter for the verb just issued is not set to zero.

LUA_INVALID_POST_HANDLE

Secondary return code; for a Microsoft Windows Server 2003 or Windows 2000 system using events as the asynchronous posting method, the Windows LUA VCB does not contain a valid event handle.

LUA_INVALID_FLOW

Secondary return code; the **lua_flag1** flow flags were set incorrectly when a verb was issued:

When issuing **SLI_SEND_EX** to send an SNA response, set only one **lua_flag1** flow flag.

When issuing SLI_RECEIVE_EX, set at least one lua_flag1 flow flag.

LUA_VERB_LENGTH_INVALID

Secondary return code; an LUA verb was issued with a value for **lua_verb_length** unexpected by LUA.

LUA_REQUIRED_FIELD_MISSING

Secondary return code; the verb that was issued either did not include a data pointer (if the data count was not zero) or did not include an **lua_flag1** flow flag.

LUA_INVALID_MESSAGE_TYPE

Secondary return code; the **lua_message_type** parameter is not recognized by the LUA interface.

LUA_DATA_LENGTH_ERROR

Secondary return code; the application did not provide user-supplied data required by the verb issued. Note that when **SLI_SEND_EX** is issued for an SNA LUSTAT command, status (in four bytes) is required, and that when SLI_OPEN is issued with secondary initialization, data is required.

LUA_STATE_CHECK

Primary return code; the verb did not execute because it was issued in an invalid state.

LUA_NO_SLI_SESSION

Secondary return code; a session was not open or was down due to an SLI_CLOSE or session failure when a command was issued.

LUA_MAX_NUMBER_OF_SENDS

Secondary return code; the application issued a third **SLI_SEND** or an **SLI_SEND_EX** before one completed.

LUA_SEND_ON_FLOW_PENDING

Secondary return code; an **SLI_SEND** or an **SLI_SEND_EX** was still outstanding when the application issued another **SLI_SEND_EX** for an SNA flow.

LUA_SESSION_FAILURE

Primary return code; an error condition, specified in the secondary return code, caused the session to fail.

LUA_RECEIVED_UNBIND

Secondary return code; the primary logical unit (PLU) sent an SNA UNBIND command to the LUA interface when a session was active. As a result, the session was stopped.

LUA_SLI_LOGIC_ERROR

Secondary return code; the LUA interface found an internal error in logic.

LUA_NO_RUI_SESSION

Secondary return code; no session has been initialized for the LUA verb issued, or some verb other than SLI_OPEN was issued before the session was initialized.

LUA_LU_COMPONENT_DISCONNECTED

Secondary return code; an LU component is unavailable because it is not connected properly. Make sure that the power is on.

LUA_DATA_SEGMENT_LENGTH_ERROR

Secondary return code; one of the following has occurred:

The supplied data segment for SLI_RECEIVE_EX or **SLI_SEND_EX** is not a read/write data segment as required.

The supplied data segment for SLI_RECEIVE_EX is not as long as that provided in lua_max_length_ex.

The supplied data segment for SLI_SEND_EX is not as long as that provided in lua_data_length_ex.

LUA_VERB_RECORD_SPANS_SEGMENTS

Secondary return code; the LUA VCB length parameter plus the segment offset is beyond the segment end.

LUA_NOT_ACTIVE

Secondary return code; LUA was not active within Microsoft Host Integration Server or SNA Server when an LUA verb was issued.

LUA_SLI_LOGIC_ERROR

Secondary return code; the LUA interface found an internal error in logic.

LUA_INVALID_PROCESS

Secondary return code; the session for which an LUA verb was issued is unavailable because another OS/2 process owns the session.

LUA_LU_INOPERATIVE

Secondary return code; a severe error occurred while the LUA was attempting to stop the session. This LU is unavailable for any LUA requests until an activate logical unit (ACTLU) is received from the host.

LUA_MODE_INCONSISTENCY

Secondary return code; performing this function is not allowed by the current status. The request sent to the half-session component was not executed even though it was understood and supported. This SNA sense code is also an exception request sense code.

LUA_INSUFFICIENT_RESOURCES

Secondary return code; a temporary condition of insufficient resources caused the request receiver to be unable to perform. The request sent to the half-session component was not executed, even though it was understood and supported.

LUA_SEND_CORRELATION_TABLE_FULL

Secondary return code; the session send correlation table for the flow requested reached its capacity.

LUA_RU_LENGTH_ERROR

Secondary return code; the RU request was an incorrect length (either too short or too long). The request unit was not interpreted or processed even though it was delivered to the half-session component. The half-session capabilities do not match. This SNA sense code is also an exception request sense code.

LUA_FUNCTION_NOT_SUPPORTED

Secondary return code; LUA does not support the requested function. A control character, an RU parameter, or a formatted request code may have specified the function. Specific sense code information is in bytes 2 and 3.

LUA_HDX_BRACKET_STATE_ERROR

Secondary return code; the existing state error prevented the current request from being sent. The determination was made by a protocol computer.

LUA_RESPONSE_ALREADY_SENT

Secondary return code; a response for the chain was already sent so that the current request was not sent. The determination was made by a protocol computer.

LUA_EXR_SENSE_INCORRECT

Secondary return code; the application responded negatively to an exception request. The sense code was unacceptable.

LUA_RESPONSE_OUT_OF_ORDER

Secondary return code; the current response was not for the oldest request. The determination was made by a protocol

computer.

LUA_CHAIN_RESPONSE_REQUIRED

Secondary return code; a CHASE response was still outstanding when a more recent request was attempted. The determination was made by a protocol computer.

LUA_BRACKET

Secondary return code; the sender failed to enforce the session bracket rules. Note that contention and race conditions are exempt from this error. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DIRECTION

Secondary return code; while the half-duplex flip-flop state was NOT_RECEIVE, a request for normal flow was received. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DATA_TRAFFIC_RESET

Secondary return code; a half-session of an active session but with inactive data traffic received a normal flow data flow control (DFC) or function management data (FMD) request. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DATA_TRAFFIC_QUIESCED

Secondary return code; a DFC or FMD request was received from a half-session that sent either a SHUTC command or QC command, and the DFC or FMD request has not responded to a RELQ command. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_DATA_TRAFFIC_NOT_RESET

Secondary return code; while the data traffic state was not reset, the session control request was received. An invalid request header or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_NO_BEGIN_BRACKET

Secondary return code; the receiver has already sent a positive response to a BIS command when a BID or an FMD request specifying BBI=BB was received. An invalid request header or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_SC_PROTOCOL_VIOLATION

Secondary return code; a violation of SC protocol occurred. A request (that is permitted only after an SC request and a positive response to that request have been successfully exchanged) was received before the required exchange. Byte 4 of the sense data contains the request code. No user data exists for this sense code. An invalid header request or data flow control state was found. Delivery to the half-session component was prevented.

LUA_IMMEDIATE_REQUEST_MODE_ERROR

Secondary return code; the request violated the immediate request mode protocol. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_QUEUED_RESPONSE_ERROR

Secondary return code; the request violated the queued response protocol. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_ERP_SYNC_EVENT_ERROR

Secondary return code; a violation of the ERP synchronous event protocol occurred. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_RSP_BEFORE_SENDING_REQ

Secondary return code; a previously received request has not been responded to yet and an attempt was made in half-duplex send/receive mode to send a normal flow request. An invalid header request or request unit for the received current session

control or data flow control state was found. Delivery to the half-session component was prevented.

LUA_RSP_CORRELATION_ERROR

Secondary return code; a response was sent that does not correspond to a previously received request or a response was received that does not correspond to a previously sent request.

LUA_BB_NOT_ALLOWED

Secondary return code; the begin bracket indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_EB_NOT ALLOWED

Secondary return code; the end bracket indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_EXCEPTION_RSP_NOT_ALLOWED

Secondary return code; when an exception response was not allowed, one was requested. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_DEFINITE_RSP_NOT_ALLOWED

Secondary return code; when a definite response was not allowed, one was requested. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CD_NOT_ALLOWED

Secondary return code; the change-direction indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_NO_RESPONSE_NOT_ALLOWED

Secondary return code; a request other than an EXR contained a "no response." The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CHAINING_NOT_SUPPORTED

Secondary return code; the chaining indicators were incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_BRACKETS_NOT_SUPPORTED

Secondary return code; the bracket indicators were incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_CD_NOT_SUPPORTED

Secondary return code; the change-direction indicator was set, but LUA does not support change-direction for this situation. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_FI

Secondary return code; the format indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_ALTERNATE_CODE_NOT_SUPPORTED

Secondary return code; the code selection indicator was set, but LUA does not support code selection for this session. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_REQUEST_CODE

Secondary return code; the request code was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_SPEC_OF_SDI_RTI

Secondary return code; the SDI and the RTI were not specified correctly on a response. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_DR1I_DR2I_ERI

Secondary return code; the DR1I, the DR2I, and the ERI were specified incorrectly. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_QRI

Secondary return code; the queued response indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_EDI

Secondary return code; the EDI was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_INCORRECT_USE_OF_PDI

Secondary return code; the PDI was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

LUA_NO_SESSION

Secondary return code; a request to activate a session is required because no active half-session in the receiving end node for the origination-destination pair exists, or no active boundary function half-session component for the origination-destination pair in a node that supplies the boundary function exists. Delivery of the request could not take place for one of the following reasons:

A path information unit error

A path outage

An invalid sequence of requests for activation

If a path error is received during an active session, that usually indicates there is no longer a valid path to the session partner.

LUA_CANCELED

Primary return code; the secondary return code gives the reason for canceling the command.

LUA_TERMINATED

Secondary return code; the session was terminated when a verb was pending. The verb process has been canceled.

LUA_IN_PROGRESS

Primary return code; an asynchronous command was received but is not completed.

LUA_COMM_SUBSYSTEM_ABENDED

Primary return code; indicates one of the following conditions:

The node used by this conversation encountered an ABEND.

The connection between the transaction program (TP) and the physical unit (PU) 2.1 node has been broken (a LAN error).

The SnaBase at the TPs computer encountered an ABEND.

LUA_COMM_SUBSYSTEM_NOT_LOADED

Primary return code; a required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

LUA_INVALID_VERB_SEGMENT

Primary return code; the VCB extended beyond the end of the data segment.

LUA_UNEXPECTED_DOS_ERROR

Primary return code; after issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

LUA_STACK_TOO_SMALL

Primary return code; the stack size of the application is too small to execute the verb. Increase the stack size of your application.

LUA_INVALID_VERB

Primary return code; either the verb code or the operation code, or both, is invalid. The verb did not execute.

Remarks

SLI_SEND_EX sends responses, SNA commands, and data from the Windows LUA application to a host LU.

The difference between SLI_SEND_EX and SLI_SEND is that the SLI_SEND_EX verb supports inbound chaining and can send up to a maximum of 4,295 kilobytes (KB) in a single verb request. In contrast, SLI_SEND is limited to sending up to 64 KB in a verb request. A single SLI_SEND_EX or SLI_SEND verb defines a chain. A single SLI_RECEIVE_EX or SLI_RECEIVE verb receives a whole chain.

A session must already be open to issue SLI_SEND_EX for a particular LU-LU session flow. To send data on the SSCP normal flow prior to the completion of SLI_OPEN, the session must have been initialized as primary with SSCP access. In addition, the session status must be INIT_COMPLETE.

The settings for lua_message_type determine the type of processing that will be done by SLI_SEND_EX. The following table indicates the parameters to set based on the value of lua_message_type.

SLI_SEND_EX parameter	**LU_DATA SSCP_DATA**	**BID BIS RTR**	**CHASE QC**	**LUSTAT_LU LUSTAT_SSCP**	**QEC RELQ SBI SIGNAL**	**RQR**	**RSP**
lua_data _length	Req.	0	0	Req.	0	0	Req. (0 if no data)
lua_data _ptr	Req. (0 if no data)	0	0	Req.	0	0	Req. (0 if no data)
lua_flag1 flow flags	0	0	0	0	0	0	Req. (set one)
lua_rh	FI DRL1 DRL2 RI BBI EBI CDI CSI EDI	SDI QRI	SDI QRI EBI CDI	SDI QRI DRL1 DRL2 RI BBI EBI CDI	SDI	0	RRI RI

lua_th	0	0	0	0	0	0	SNF

The location provided in **lua_data_ptr** and the length provided in **lua_data_length_ex** determine the data that the SLI sends. The data will be chained by the SLI verbs if necessary.

When sending a response, the type of response determines the SLI_SEND_EX information required. For all responses, you must:

- Set the selected **lua_flag1** flow flag.
- Provide the sequence number in lua_th.snf for the request to which you are responding.
- Set lua_message_type to LUA_MESSAGE_TYPE_RSP.

For multichain message responses, the sequence number of the last received chain element must be used. For a response to a multichain message ending with a CANCEL command, the CANCEL command sequence number is used.

For positive responses that only require the request code, set lua_rh.ri to zero (indicating that the response is positive) and lua_data_length to zero (indicating no data is provided). The request code is filled in by the SLI, using the sequence number provided.

For negative responses in which lua_rh.ri is set to 1, set the lua_data_ptr to the SNA sense code address and the lua_data_length to the SNA sense code length (four bytes). The sequence number is used by the SLI to fill in the request code.

SLI_BIND_ROUTINE

The **SLI_BIND_ROUTINE** verb notifies the Microsoft® Windows® logical unit application (LUA) application that a BIND request has come from the host and allows the user-supplied routine to examine the request and formulate a response.

The following structure describes the LUA_COMMON member of the verb control block (VCB) used by SLI_BIND_ROUTINE.

Syntax

```
struct LUA_COMMON {
    unsigned short    lua_verb;
    unsigned short    lua_verb_length;
    unsigned short    lua_prim_rc;
    unsigned long     lua_sec_rc;
    unsigned short    lua_opcode;
    unsigned long     lua_correlator;
    unsigned char     lua_luname[8];
    unsigned short    lua_extension_list_offset;
    unsigned short    lua_cobol_offset;
    unsigned long     lua_sid;
    unsigned short    lua_max_length;
    unsigned short    lua_data_length;
    char FAR *        lua_data_ptr;
    unsigned long     lua_post_handle;
    struct LUA_TH     lua_th;
    struct LUA_RH     lua_rh;
    struct LUA_FLAG1  lua_flag1;
    unsigned char     lua_message_type;
    struct LUA_FLAG2  lua_flag2;
    unsigned char     lua_resv56[7];
    unsigned char     lua_encr_decr_option;
};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_SLI for Session Level Interface (SLI) verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the LUA VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_SLI_BIND_ROUTINE.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

SLI_BIND_ROUTINE only requires this parameter if lua_sid is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by **SLI_BIND_ROUTINE** and should be set to zero.

lua_cobol_offset

Not used by LUA in Microsoft® Host Integration Server or SNA Server and should be zero.

lua_sid

Supplied parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Not used by **SLI_BIND_ROUTINE** and should be set to zero.

lua_data_length

Returned parameter. Specifies the length of the BIND request/response unit (RU) data returned in the data buffer.

lua_data_ptr

For the **SLI_BIND_ROUTINE** this parameter contains the address of the BIND RU.

lua_post_handle

Supplied parameter. Used under Microsoft Windows Server™ 2003 or Windows 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Supplied parameter. Contains the SNA transmission header (TH) of the message received. Various subparameters are returned for read and bid functions.

lua_rh

Supplied parameter. Contains the SNA request/response header (RH) of the message sent or received.

lua_flag1

Supplied parameter. Contains a data structure containing flags for messages supplied by the application.

lua_message_type

Supplied parameter. Specifies the type of SNA data or command sent to the host.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_flag2.sscp_exp

Indicates SSCP expedited flow if set to 1.

lua_flag2.sscp_norm

Indicates SSCP normal flow if set to 1.

lua_flag2.lu_exp

Indicates LU expedited flow if set to 1.

lua_flag2.lu_norm

Indicates LU normal flow if set to 1.

lua_resv56

Reserved and should be set to zero.

lua_encr_decr_option

Not used by **SLI_BIND_ROUTINE** and should be set to zero.

Return Codes

LUA_OK

Primary return code; the verb executed successfully.

LUA_SEC_OK

Secondary return code; no additional information exists for LUA_OK.

LUA_NEGATIVE_RSP

Primary return code; either the LUA sent a negative response to a message received from the primary logical unit (PLU) because an error was found in the message, or the application responded negatively to a chain for which the end-of-chain has arrived.

Remarks

SLI_BIND_ROUTINE provides a mechanism for the Windows LUA application to examine BIND requests that are received from the host. The Windows LUA uses a user-supplied dynamic-link library (DLL) to notify the Windows LUA application that a BIND request has been received. The user-supplied DLL routine then examines the contents of the BIND and formulates a response for the request.

The DLL name for the routine is provided as extensions of the SLI_OPEN verbs VCB. The lua_extension_list_offset parameter provides the offset from the start of the VCB to the first name in the extension list.

The Windows LUA interface assigns storage space where the VCB is structured. The VCB of SLI_BIND_ROUTINE contains lua_th and lua_rh. The address of the BIND RU is specified in lua_data_ptr and the length of the RU is specified in lua_data_length.

When SLI_BIND_ROUTINE returns to the Windows LUA, processing of SLI_BIND_ROUTINE is completed. The BIND response should overwrite the BIND RU. When the BIND is accepted, the primary return code should be set to LUA_OK. If the BIND is rejected, the primary return code should be set to LUA_NEGATIVE_RSP and the BIND buffer contains the negative sense code. The lua_data_ptr parameter should not be modified.

If a negative response is returned from SLI_BIND_ROUTINE, SLI_OPEN is canceled. The lua_prim_rc of the SLI_OPEN is set to LUA_SESSION_FAILURE, and the lua_sec_rc is set to LUA_NEG_RSP_FROM_BIND_ROUTINE.

SLI_STSN_ROUTINE

The **SLI_STSN_ROUTINE** verb notifies the Microsoft® Windows® logical unit application (LUA) application that an STSN command has come from the host and allows the user-supplied routine to examine the request and formulate a response.

The following structure describes the LUA_COMMON member of the verb control block (VCB) used by SLI_STSN_ROUTINE.

Syntax

```
struct LUA_COMMON {
    unsigned short    lua_verb;
    unsigned short    lua_verb_length;
    unsigned short    lua_prim_rc;
    unsigned long     lua_sec_rc;
    unsigned short    lua_opcode;
    unsigned long     lua_correlator;
    unsigned char     lua_luname[8];
    unsigned short    lua_extension_list_offset;
    unsigned short    lua_cobol_offset;
    unsigned long     lua_sid;
    unsigned short    lua_max_length;
    unsigned short    lua_data_length;
    char FAR *        lua_data_ptr;
    unsigned long     lua_post_handle;
    struct LUA_TH     lua_th;
    struct LUA_RH     lua_rh;
    struct LUA_FLAG1  lua_flag1;
    unsigned char     lua_message_type;
    struct LUA_FLAG2  lua_flag2;
    unsigned char     lua_resv56[7];
    unsigned char     lua_encr_decr_option;
};
```

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_SLI for Session Level Interface (SLI) verbs.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the LUA VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, LUA_OPCODE_SLI_STSN_ROUTINE.

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

SLI_STSN_ROUTINE only requires this parameter if lua_sid is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Not used by **SLI_STSN_ROUTINE** and should be set to zero.

lua_cobol_offset

Not used by LUA in Microsoft® Host Integration Server or SNA Server and should be zero.

lua_sid

Supplied parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Not used by **SLI_STSN_ROUTINE** and should be set to zero.

lua_data_length

Returned parameter. Specifies the length of the STSN request/response unit (RU) data returned in the data buffer.

lua_data_ptr

For the **SLI_STSN_ROUTINE** this parameter contains the address of the STSN RU.

lua_post_handle

Supplied parameter. Used under Microsoft Windows Server™ 2003 or Windows 2000 Server if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

For all other environments, this parameter is reserved and should be set to zero.

lua_th

Returned parameter. Contains the SNA transmission header (TH) of the message received. Various subparameters are returned for read and bid functions.

lua_rh

Returned parameter. Contains the SNA request/response header (RH) of the message sent or received.

lua_flag1

Supplied parameter. Contains a data structure containing flags for messages supplied by the application.

lua_message_type

Supplied parameter. Specifies the type of SNA data or command sent to the host.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_flag2.sscp_exp

Indicates system services control point (SSCP) expedited flow if set to 1.

lua_flag2.sscp_norm

Indicates SSCP normal flow if set to 1.

lua_flag2.lu_exp

Indicates LU expedited flow if set to 1.

lua_flag2.lu_norm

Indicates LU normal flow if set to 1.

lua_resv56

Reserved and should be set to zero.

lua_encr_decr_option

Not used by **SLI_STSN_ROUTINE** and should be set to zero.

Return Codes

LUA_OK

Primary return code; the verb executed successfully.

LUA_SEC_OK

Secondary return code; no additional information exists for LUA_OK.

LUA_NEGATIVE_RSP

Primary return code; either the LUA sent a negative response to a message received from the primary logical unit (PLU) because an error was found in the message, or the application responded negatively to a chain for which the end-of-chain has arrived.

Remarks

SLI_STSN_ROUTINE provides a mechanism for the Windows LUA application to examine and respond to STSN commands. The Windows LUA notifies the Windows LUA application that an STSN command has been received from the host. This is done through a user-supplied dynamic-link library (DLL). The users DLL examines the STSN request and formulates a response to the request.

The DLL name for the routine is provided as extensions of the SLI_OPEN verbs VCB. The lua_extension_list_offset parameter provides the offset from the start of the VCB to the first name in the extension list.

The Windows LUA interface assigns storage space where the VCB is structured. The VCB of the SLI_STSN_ROUTINE contains lua_th and lua_rh. The address of the STSN RU is specified in lua_data_ptr and the length of the RU is specified in lua_data_length.

When SLI_STSN_ROUTINE returns to the Windows LUA, processing of the SLI_STSN_ROUTINE is completed. The STSN response should overwrite the STSN RU. When the STSN is accepted, the primary return code should be set to LUA_OK. If the STSN is rejected, the primary return code should be set to LUA_NEGATIVE_RSP and the STSN buffer contains the negative sense code. The lua_data_ptr parameter should not be modified.

If a negative response is returned from SLI_STSN_ROUTINE, SLI_OPEN is canceled. The lua_prim_rc of the SLI_OPEN is set to LUA_SESSION_FAILURE, and the lua_sec_rc is set to LUA_NEG_RSP_FROM_STSN_ROUTINE.

LUA Extensions for the Windows Environment

The extensions described in this section are designed for Microsoft® Windows®. They provide support for programming compatibility and optimum application performance in 32-bit operating environments. These extensions are supported on Microsoft Windows Server™ 2003, Windows XP Professional, and Windows 2000 Server.

The Windows logical unit application (LUA) programming interface enables multithreaded Windows-based processes. A process contains one or more threads of execution. For each extension, this section provides a definition of the function with syntax, return codes, and remarks for using the extension.

These functions can be grouped into two categories depending on whether Request Unit Interface (RUI) or Session Level Interface (SLI) verbs are used.

In This Section

RUI

The **RUI** function provides event notification for all Request Unit Interface (RUI) verbs.

Syntax

```
            void WINAPI RUI(
    LUA_VERB_RECORD FAR *lpVCB  );
```

Parameters

lpVCB

Pointer to the logical unit application (LUA) verb control block (VCB), **LUA_VERB_RECORD**.

Return Value

The code returned in **lua_prim_rc** indicates whether asynchronous notification will occur. If the field is set to LUA_IN_PROGRESS, asynchronous notification will occur through event signaling. If the flag is not LUA_IN_PROGRESS, the request completed synchronously. Examine the primary return code and secondary return code for any errors.

Remarks

The application must provide a handle to an event in the **lua_post_handle** parameter of the VCB. The event must be in the not-signaled state.

When the asynchronous operation is complete, the application is notified through the signaling of the event. Upon signaling of the event, examine the primary return code and secondary return code for any error conditions.

Reference

WinRUI

SLI

The **SLI** function provides event notification for all Session Level Interface (SLI) verbs.

Syntax

```
            void WINAPI SLI(
    LUA_VERB_RECORD FAR *lpVCB  );
```

Parameters

lpVCB

Pointer to the logical unit application (LUA) verb control block (VCB), **LUA_VERB_RECORD**.

Return Value

The code returned in **lua_prim_rc** indicates whether asynchronous notification will occur. If the field is set to LUA_IN_PROGRESS, asynchronous notification will occur through event signaling. If the flag is not LUA_IN_PROGRESS, the request completed synchronously. Examine the primary return code and secondary return code for any errors.

Remarks

The application must provide a handle to an event in the **lua_post_handle** parameter of the VCB. The event must be in the not-signaled state.

When the asynchronous operation is complete, the application is notified through the signaling of the event. Upon signaling of the event, examine the primary return code and secondary return code for any error conditions.

WinSLI

WinRUI

The **WinRUI** function provides asynchronous message notification for all Microsoft® Windows®-based Request Unit Interface (RUI) verbs.

Syntax

```
int WINAPI WinRUI(
HWND hWnd,
LUA_VERB_RECORD FAR *lpVCB
);
```

Parameters

hWnd

Handle of window to receive message.

lpVCB

Pointer to the logical unit application (LUA) verb control block (VCB), **LUA_VERB_RECORD**.

Return Value

The function returns a value indicating whether the request was accepted by the Windows-based RUI for processing. A returned value of zero indicates that the request was accepted and will be processed. A value other than zero indicates an error. Possible error codes are as follows:

WLUAINVALIDHANDLE

The window handle provided is invalid.

WLUASTARTUPNOTCALLED

The application has not initiated a session using WinRUIStartup.

The value returned in **lua_flag2.async** indicates whether asynchronous notification will occur. If the flag is set (nonzero), asynchronous notification will occur through a message posted to the applications message queue. If the flag is not set, the request completed synchronously. Examine the primary return code and secondary return code for any error conditions.

Remarks

When the asynchronous operation is complete, the applications window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinRUI" as the input string. The *lParam* argument contains the address of the VCB being posted as complete. The *wParam* argument is undefined.

Note

It is possible for the request to be accepted for processing (the function call returns zero) but rejected later with a primary return code and secondary return code set in the VCB. Examine the primary return code and secondary return code for any error conditions.

If the application calls **WinRUI** without first initializing the session using **WinRUIStartup**, an error is returned.

RUI

WinRUIStartup

WinRUICleanup

The **WinRUICleanup** function terminates and deregisters an application using Request Unit Interface (RUI) verbs from a Microsoft® Windows® logical unit application (LUA) implementation.

Syntax

```
BOOL WINAPI WinRUICleanup(void);
```

Return Value

The return code specifies whether the deregistration was successful. If the value is not zero, the application was successfully deregistered. If the value is zero, the application was not deregistered.

Remarks

Use **WinRUICleanup** to indicate deregistration of a Windows LUA application from a Windows LUA implementation. This function can be used, for example, to free up resources allocated to the specific application.

If **WinRUICleanup** is called while LUs are in session (RUI_TERM not issued), the cleanup code should issue an **RUI_TERM** close type ABEND for the application for all open sessions.

RUI_TERM

WinRUIStartup

WinRUIGetLastInitStatus

The **WinRUIGetLastInitStatus** function enables an application to determine the status of an RUI_INIT, so that the application can evaluate whether the **RUI_INIT** should be timed out. This extension can be used to initiate status reporting, terminate status reporting, or find the current status. For details, see the Remarks section.

Syntax

```
          int WINAPI WinRUIGetLastInitStatus(
    DWORD dwSid,
     HANDLE hStatusHandle,
    DWORD dwNotifyType,
    BOOL bClearPrevious    );
```

Parameters

dwSid

Specifies the RUI session identifier of the session for which status will be determined. If *dwSid* is zero, *hStatusHandle* is used to report status on all sessions. Note that the **lua_sid** parameter in the RUI_INIT verb control block (VCB) is valid as soon as the call to RUI or WinRUI for the **RUI_INIT** returns.

hStatusHandle

Specifies a handle used for signaling the application that the status for the session (specified by *dwSid*) has changed. Can be a window handle, an event handle, or NULL; *dwNotifyType* must be set accordingly:

If *hStatusHandle* is a window handle, status is sent to the application through a window message. The message is obtained from **RegisterWindowMessage** using the string "WinRUI". The parameter *wParam* contains the session status. (For more information, see Return Codes.) Depending on the value of *dwNotifyType*, *lParam* contains either the RUI session identifier of the session, or the value of **lua_correlator** from the RUI_INIT verb.

If *hStatusHandle* is an event handle, when the status for the session specified by *dwSid* changes, the event is put into the signaled state. The application must then make a further call to **WinRUIGetLastInitStatus** to find out the new status. Note that the event should not be the same as one used for signaling completion of any RUI verb.

If *hStatusHandle* is NULL, the status of the session specified by *dwSid* is returned in the return code. In this case, *dwSid* must not be zero unless *bClearPrevious* is TRUE. If *hStatusHandle* is NULL, *dwNotifyType* is ignored.

dwNotifyType

Specifies the type of indication required. This determines the contents of the *lParam* of the window message, and how **WinRUIGetLastInitStatus** interprets *hStatusHandle*. Allowed values are:

WLUA_NTFY_EVENT

The *hStatusHandle* parameter contains an event handle.

WLUA_NTFY_MSG_CORRELATOR

The *hStatusHandle* parameter contains a window handle, and the *lParam* of the returned window message should contain the value of the **lua_correlator** field on the RUI_INIT.

WLUA_NTFY_MSG_SID

The *hStatusHandle* parameter contains a window handle, and the *lParam* of the returned window message should contain the LUA session identifier.

bClearPrevious

If TRUE, status messages are no longer sent for the session identified by *dwSid*. If *dwSid* is zero, status messages are no longer sent for any session. If *bClearPrevious* is TRUE, *hStatusHandle* and *dwNotifyType* are ignored.

Return Value

WLUASYSNOTREADY

SNABASE is not running.

WLUANTFYINVALID

The *dwNotifyType* parameter is invalid.

WLUAINVALIDHANDLE

The *hStatusHandle* parameter does not contain a valid handle.

WLUASTARTUPNOTCALLED

WinRUIStartup has not been called.

WLUALINKINACTIVE

The link to the host is not yet active.

WLUALINKACTIVATING

The link to the host is being activated.

WLUAPUINACTIVE

The link to the host is active, but no ACTPU has yet been received.

WLUAPUACTIVE

An ACTPU has been received.

WLUAPUREACTIVATED

The physical unit (PU) has been reactivated.

WLUALUINACTIVE

The link to the host is active, and an ACTPU has been received, but no ACTLU has been received.

WLUALUACTIVE

The LU is active.

WLUALUREACTIVATED

The LU has been reactivated.

WLUAUNKNOWN

The session is in an unknown status. (This is an internal error.)

WLUAGETLU

The session is waiting for an Open(SSCP) response from the node.

WLUASIDINVALID

The security ID (SID) specified does not match any known by the RUI.

WLUASIDZERO

The *hStatusHandle* parameter is NULL and *bClearPrevious* is FALSE, but *dwSid* is zero.

WLUAGLOBALHANDLER

The *dwSid* parameter is zero, and messages from all sessions will be notified. (This is a normal return code, not an error.)

Remarks

This extension is intended to be used with either a window handle or an event handle to enable asynchronous notification of status changes. It can also be used alone to find the current status of a session.

With a window handle

There are two ways to use this extension with a window handle:

```
WinRUIGetLastInitStatus(Sid,Handle,WLUA_NTFY_MSG_CORRELATOR,FALSE);
```

—or—

```
WinRUIGetLastInitStatus(Sid,Handle,WLUA_NTFY_MSG_SID,FALSE);
```

With this implementation, changes in status are reported by a window message sent to the window handle specified. If WLUA_NTFY_MSG_CORRELATOR is specified, the *lParam* field in the window message contains the **lua_correlator** field for the session. If WLUA_NTFY_MSG_SID is specified, the *lParam* field in the window message contains the LUA session identifier for the session.

When the extension has been used with a window handle, use the following to cancel status reporting:

```
WinRUIGetLastInitStatus(Sid,NULL,0,TRUE);
```

For this implementation, note that if *Sid* is nonzero, status is only reported for that session. If *Sid* is zero, status is reported for all sessions.

With an event handle

To use this extension with an event handle, implement it as follows:

```
WinRUIGetLastInitStatus(Sid,Handle,WLUA_NOTIFY_EVENT,FALSE);
```

The event whose handle is given will be signaled when a change in state occurs. Because no information is returned when an event is signaled, a further call must be issued to find out the status.

```
Status = WinRUIGetLastInitStatus(Sid,NULL,0,0,FALSE);
```

Note that in this case, a *Sid* must be specified.

When the extension has been used with an event handle, use the following to cancel the reporting of status:

```
WinRUIGetLastInitStatus(Sid,NULL,0,TRUE);
```

Query current status

To use this extension to query the current status of a session, it is not necessary to use an event or window handle. Instead, use the following:

```
Status = WinRUIGetLastInitStatus(Sid,NULL,0,0,FALSE);
```

WinRUI
WinRUIStartup

WinRUIStartup

The **WinRUIStartup** function enables an application using Request Unit Interface (RUI) verbs to specify the version of Windows logical unit application (LUA) required and to retrieve details of the specific Microsoft Windows LUA implementation. This function must be called by an application to register itself with a Windows LUA implementation before issuing any further Windows LUA calls.

Syntax

```
            int WINAPI WinRUIStartup(
    WORD wVersionRequired,
      LUADATA FAR *lpLuaData  );
```

Parameters

wVersionRequired

Specifies the version of Windows LUA support required. The high-order byte specifies the minor version (revision) number. The low-order byte specifies the major version number.

lpLuaData

Pointer to the **LUADATA** structure containing the returned version number information.

Return Value

The return code specifies whether the application was registered successfully and whether the Windows LUA implementation can support the specified version number. If the value is zero, it was registered successfully and the specified version can be supported. Otherwise, the return code is one of the following:

WLUASYSNOTREADY

The underlying network system is not ready for network communication.

WLUAVERNOTSUPPORTED

The version of Windows LUA support requested is not provided by this particular Windows LUA implementation.

WLUAINVALID

The Windows LUA version specified by the application is not supported by this dynamic-link library (DLL).

WLUAFAILURE

A failure occurred while the Windows LUA DLL was initializing. This usually occurs because an operating system call failed.

WLUAINITREJECT

WinRUIStartup was called multiple times.

Remarks

To support future Windows LUA implementations and applications that may have functionality differences, a negotiation takes place in **WinRUIStartup**. An application passes to **WinRUIStartup** the Windows LUA version that it can use. If this version is lower than the lowest version supported by the Windows LUA DLL, the DLL cannot support the application and **WinRUIStartup** fails. If the version is not lower, however, the call succeeds and returns the highest version of Windows LUA supported by the DLL. If this version is lower than the lowest version supported by the application, the application either fails its initialization or attempts to find another Windows LUA DLL on the system.

This negotiation allows both a Windows LUA DLL and a Windows LUA application to support a range of Windows LUA versions. An application can successfully use a DLL if there is any overlap in the versions. The following table illustrates how **WinRUIStartup** works in conjunction with different application and DLL versions.

LUA App versions	LUA DLL versions	To WinRUIStartup	From WinRUIStartup	Result
1.0	1.0	1.0	1.0	Use 1.0

1.0, 2.0	1.0	2.0	1.0	Use 1.0
1.0	1.0, 2.0	1.0	2.0	Use 1.0
1.0	2.0, 3.0	1.0	WLUAINVALID	Fail
2.0, 3.0	1.0	3.0	1.0	App fails
1.0, 2.0, 3.0	1.0, 2.0, 3.0	3.0	3.0	Use 3.0

Note

The application that uses RUI verbs must call **WinRUIStartup** prior to issuing any other LUA commands. However, **WinRUIStartup** needs to be called only once per application. If it is called multiple times, the subsequent calls will be rejected.

Details of the actual LUA implementation are described in the **WLUADATA** structure, defined as follows:

```
typedef struct { WORD wVersion;
            char szDescription[WLUADESCRIPTION_LEN+1];
            } LUADATA;
```

Having made its last Windows LUA call, an application should call the **WinRUICleanup** routine.

Each LUA application that uses RUI verbs must make a **WinRUIStartup** call before issuing any other LUA calls.

Reference

WinRUICleanup

WinSLI

The **WinSLI** function provides asynchronous message notification for all Microsoft® Windows®-based Session Level Interface (SLI) verbs.

Syntax

```
            int WINAPI WinSLI(
    HWND hWnd,
      LUA_VERB_RECORD FAR *lpVCB  );
```

Parameters

hWnd

Handle of window to receive message.

lpVCB

Pointer to the logical unit application (LUA) verb control block (VCB), **LUA_VERB_RECORD**.

Return Value

The function returns a value indicating whether the request was accepted by the Windows-based SLI for processing. A returned value of zero indicates that the request was accepted and will be processed. A value other than zero indicates an error. Possible error codes are as follows:

WLUAINVALIDHANDLE

The window handle provided is invalid.

WLUASTARTUPNOTCALLED

The application has not initiated a session using WinSLIStartup.

The value returned in **lua_flag2.async** indicates whether asynchronous notification will occur. If the flag is set (nonzero), asynchronous notification will occur through a message posted to the applications message queue. If the flag is not set, the request completed synchronously. Examine the primary return code and secondary return code for any error conditions.

Remarks

When the asynchronous operation is complete, the applications window *hWnd* receives the message returned by **RegisterWindowMessage** with "WinSLI" as the input string. The *lParam* argument contains the address of the VCB being posted as complete. The *wParam* argument is undefined.

Note

It is possible for the request to be accepted for processing (the function call returns zero) but rejected later with a primary return code and secondary return code set in the VCB. Examine the primary return code and secondary return code for any error conditions.

If the application calls **WinSLI** without first initializing the session using **WinSLIStartup**, an error is returned.

Reference

SLI

WinSLIStartup

WinSLICleanup

The **WinSLICleanup** function terminates and deregisters an application using Session Level Interface (SLI) verbs from a Microsoft® Windows® logical unit application (LUA) implementation.

Syntax

```
BOOL WINAPI WinSLICleanup(void);
```

Return Value

The return code specifies whether the deregistration was successful. If the value is not zero, the application was successfully deregistered. If the value is zero, the application was not deregistered.

Remarks

Use **WinSLICleanup** to indicate deregistration of a Windows LUA application from a Windows LUA implementation. This function can be used, for example, to free up resources allocated to the specific application.

If **WinSLICleanup** is called while LUs are in session (SLI_CLOSE not issued), the cleanup code should issue an **SLI_CLOSE** close type ABEND for the application for all open sessions.

WinSLIStartup

WinSLIStartup

The **WinSLIStartup** function allows an application using the Session Level Interface (SLI) verbs to specify the version of Microsoft Windows logical unit application (LUA) required and to retrieve details of the specific Windows LUA implementation. This function must be called by an application to register itself with a Windows LUA implementation before issuing any further Windows LUA calls.

Syntax

```
int WINAPI WinSLIStartup(
WORD wVersionRequired,
LUADATA FAR *lpLuaData
);
```

Parameters

wVersionRequired

Specifies the version of Windows LUA support required. The high-order byte specifies the minor version (revision) number. The low-order byte specifies the major version number.

lpLuaData

Pointer to the **LUADATA** structure containing the returned version number information.

Return Value

The return code specifies whether the application was registered successfully and whether the Windows LUA implementation can support the specified version number. If the value is zero, it was registered successfully and the specified version can be supported. Otherwise, the return code is one of the following:

WLUASYSNOTREADY

The underlying network system is not ready for network communication.

WLUAVERNOTSUPPORTED

The version of Windows LUA support requested is not provided by this particular Windows LUA implementation.

WLUAINVALID

The Windows LUA version specified by the application is not supported by this dynamic-link library (DLL).

WLUAFAILURE

A failure occurred while the Windows LUA DLL was initializing. This usually occurs because an operating system call failed.

WLUAINITREJECT

WinSLIStartup was called multiple times.

Remarks

To support future Windows LUA implementations and applications that may have functionality differences, a negotiation takes place in **WinSLIStartup**. An application passes to **WinSLIStartup** the Windows LUA version that it can use. If this version is lower than the lowest version supported by the Windows LUA DLL, the DLL cannot support the application and **WinSLIStartup** fails. If the version is not lower, however, the call succeeds and returns the highest version of Windows LUA supported by the DLL. If this version is lower than the lowest version supported by the application, the application either fails its initialization or attempts to find another Windows LUA DLL on the system.

This negotiation allows both a Windows LUA DLL and a Windows LUA application to support a range of Windows LUA versions. An application can successfully use a DLL if there is any overlap in the versions. The following table illustrates how **WinSLIStartup** works in conjunction with different application and DLL versions.

App versions	LUA DLL versions	To WinSLIStartup	From WinSLIStartup	Result
1.0	1.0	1.0	1.0	Use 1.0

1.0, 2.0	1.0	2.0	1.0	Use 1.0
1.0	1.0, 2.0	1.0	2.0	Use 1.0
1.0	2.0, 3.0	1.0	WLUAINVALID	Fail
2.0, 3.0	1.0	3.0	1.0	App fails
1.0, 2.0, 3.0	1.0, 2.0, 3.0	3.0	3.0	Use 3.0

Note

The application that uses SLI verbs must call **WinSLIStartup** prior to issuing any other LUA commands. However, **WinSLISt artup** needs to be called only once per application. If it is called multiple times, the subsequent calls will be rejected.

Details of the actual LUA implementation are described in the **WLUADATA** structure, defined as follows:

```
typedef struct { WORD wVersion;
            char szDescription[WLUADESCRIPTION_LEN+1];
            } LUADATA;
```

Having made its last Windows LUA call, an application should call the **WinSLICleanup** routine.

Each LUA application that uses SLI verbs must make a **WinSLIStartup** call before issuing any other LUA calls.

WinSLICleanup

SNA Services Enhancement to the Windows LUA Environment

This section describes the Microsoft® Host Integration Server extension to Microsoft Windows® logical unit application (LUA) that converts primary and secondary return codes in the verb control block (VCB) to a printable string.

This section contains:

- GetLuaReturnCode

GetLuaReturnCode

The **GetLuaReturnCode** function converts the primary and secondary return codes in the verb control block (VCB) to a printable string. This function provides a standard set of error strings for use by logical unit application (LUA) applications.

Syntax

```
            int WINAPI GetLuaReturnCode(
    struct LUA_COMMON FAR *vpb,
        UINT buffer_length,
        unsigned char FAR *buffer_addr );
```

Parameters

vpb

Supplied parameter. Specifies the address of the verb control block.

buffer_length

Supplied parameter. Specifies the length of the buffer pointed to by *buffer_addr*. The recommended length is 256.

buffer_addr

Supplied/returned parameter. Specifies the address of the buffer that will hold the formatted, null-terminated string.

Remarks

Return Codes

0x20000001

The parameters are invalid; the function could not read from the specified verb control block or could not write to the specified buffer.

0x20000002

The specified buffer is too small.

0x20000003

The LUA string library LUAST32.DLL could not be loaded.

Remarks

The descriptive error string returned in *buffer_addr* does not terminate with a newline character (**\n**).

The descriptive error strings are contained in LUAST32.DLL and can be customized for different languages.

LUA Verb Control Blocks

When an application issues a Microsoft® Windows® logical unit application (LUA) verb, the verb is coded within the application as a precisely defined verb control block (VCB). The total length of this VCB is variable and is defined by **lua_verb_length**.

This section defines the structure of individual Windows LUA VCBs.

This section contains:

Common Structure of LUA VCBs

The following data structure shows the parameters that are common to all Microsoft® Windows® logical unit application (LUA) verbs.

Syntax

```
struct LUA_COMMON {
    unsigned short lua_verb;
    unsigned short lua_verb_length;
    unsigned short lua_prim_rc;
    unsigned long  lua_sec_rc;
    unsigned short lua_opcode;
    unsigned long  lua_correlator;
    unsigned char  lua_luname[8];
    unsigned short lua_extension_list_offset;
    unsigned short lua_cobol_offset;
    unsigned long  lua_sid;
    unsigned short lua_max_length;
    unsigned short lua_data_length;
    char FAR *     lua_data_ptr;
    unsigned long  lua_post_handle;
    struct LUA_TH  lua_th;
    struct LUA_RH  lua_rh;
    struct LUA_FLAG1 lua_flag1;
    unsigned char  lua_message_type;
    struct LUA_FLAG2 lua_flag2;
    unsigned char  lua_resv56[7];
    unsigned char  lua_encr_decr_option;
} LUA_COMMON;
```

Remarks

Members

lua_verb

Supplied parameter. Contains the verb code, LUA_VERB_RUI for Request Unit Interface (RUI) verbs or LUA_VERB_SLI for SLI verbs. For both of these macros the value is 0x5200.

lua_verb_length

Supplied parameter. Specifies the length in bytes of the LUA VCB. It must contain the length of the verb record being issued.

lua_prim_rc

Primary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_sec_rc

Secondary return code set by LUA at the completion of the verb. The valid return codes vary depending on the LUA verb issued.

lua_opcode

Supplied parameter. Contains the LUA command code (verb operation code) for the verb to be issued, for example, LUA_OPCODE_RUI_BID for the RUI_BID verb. Valid values are as follows:

LUA_OPCODE_SLI_OPEN

LUA_OPCODE_SLI_CLOSE

LUA_OPCODE_SLI_RECEIVE

LUA_OPCODE_SLI_SEND

LUA_OPCODE_SLI_PURGE

LUA_OPCODE_SLI_BID

LUA_OPCODE_SLI_BIND_ROUTINE

LUA_OPCODE_SLI_STSN_ROUTINE

LUA_OPCODE_SLI_CRV_ROUTINE

LUA_OPCODE_RUI_INIT

LUA_OPCODE_RUI_TERM

LUA_OPCODE_RUI_READ

LUA_OPCODE_RUI_WRITE

LUA_OPCODE_RUI_PURGE

LUA_OPCODE_RUI_BID

lua_correlator

Supplied parameter. Contains a user-supplied value that links the verb with other user-supplied information. LUA does not use or change this information. This parameter is optional.

lua_luname

Supplied parameter. Specifies the ASCII name of the local LU used by the Windows LUA session.

SLI_OPEN and RUI_INIT require this parameter. Other Windows LUA verbs only require this parameter if **lua_sid** is zero.

This parameter is eight bytes long, padded on the right with spaces (0x20) if the name is shorter than eight characters.

lua_extension_list_offset

Specifies the offset from the start of the VCB to the extension list of user-supplied dynamic-link libraries (DLLs). This parameter is not used by RUI in Microsoft® Host Integration Server and should be set to zero. The value must be the beginning of a word boundary unless there is no extension list.

lua_cobol_offset

Offset of the COBOL extension. Not used by LUA in Host Integration Server and should be zero.

lua_sid

Supplied and returned parameter. Specifies the session identifier and is returned by SLI_OPEN and RUI_INIT. Other verbs use this parameter to identify the session used for the command. If other verbs use the **lua_luname** parameter to identify sessions, set the **lua_sid** parameter to zero.

lua_max_length

Specifies the length of received buffer for RUI_READand SLI_RECEIVE. For other RUI and SLI verbs, it is not used and should be set to zero.

lua_data_length

Specifies the length of the data being sent or received. It specifies the length of data returned in **lua_peek_data** for the RUI_BID verb.

lua_data_ptr

Pointer to an application-supplied buffer.

When SLI_RECEIVE or RUI_READ is issued, this parameter points to the location to receive the data from the host.

When SLI_SEND or RUI_WRITE is issued, this parameter points to the location of the application's data to be sent to the host.

When SLI_PURGE or RUI_PURGE is issued, this parameter points to the location of the **SLI_RECEIVE** or **RUI_READ** verb's VCB that is to be canceled.

When SLI_OPEN is issued, this parameter can be one of the following:

- The logon message for the SSCP normal flow when the initialization type is secondary with an unformatted logon message.

- The request/response unit (RU) for INITSELF. When the initialization type is secondary with INITSELF, the necessary data for the application is provided.

- For all other open types, this field should be set to zero.

For other RUI and Session Level Interface (SLI) verbs, this parameter is not used and should be set to zero. Both SNA commands and data are placed in this buffer, and they can be in an EBCDIC format.

This information is provided by the Windows LUA application.

lua_post_handle

Supplied parameter. Used under Microsoft Windows® 2000 and Windows Server™ 2003 if asynchronous notification is to be accomplished by events. This variable contains the handle of the event to be signaled or a window handle.

lua_th

Returned parameter. Contains the SNA transmission header (TH) of the message sent or received. Various subparameters are set for write functions and returned for read and bid functions. The subparameters are as follows:

lua_th.flags_fid

Format identification type 2, four bits.

lua_th.flags_mpf

Segmenting mapping field, two bits. Defines the type of data segment. The following values are valid:

0x00 Middle segment**0x04** Last segment**0x08** First segment**0x0C** Only segment

lua_th.flags_odai

Originating address field–destination address field (OAF–DAF) assignor indicator, one bit.

lua_th.flags_efi

Expedited flow indicator, one bit.

lua_th.daf

Destination address field (DAF), an unsigned char.

lua_th.oaf

Originating address field (OAF), an unsigned char.

lua_th.snf

Sequence number field, an unsigned char[2].

lua_rh

Returned parameter. Contains the SNA request/response header (RH) of the message sent or received. It is set for the write function and returned by the read and bid functions. Its sub parameters are as follows:

lua_rh.rri

Request-response indicator, one bit.

lua_rh.ruc

RU category, two bits. The following values are valid:

LUA_RH_FMD (**0x00**) FM data segment**LUA_RH_NC** (**0x20**) Network control**LUA_RH_DFC** (**0x40**) Data flow control**LUA_RH_SC** (**0x60**) Session control

lua_rh.fi

Format indicator, one bit.

lua_rh.sdi

Sense data included indicator, one bit.

lua_rh.bci

Begin chain indicator, one bit.

lua_rh.eci

End chain indicator, one bit.

lua_rh.dr1i

Definite response 1 indicator, one bit.

lua_rh.dr2i

Definite response 2 indicator, one bit.

lua_rh.ri

Exception response indicator (for a request), or response type indicator (for a response), one bit.

lua_rh.qri

Queued response indicator, one bit.

lua_rh.pi

Pacing indicator, one bit.

lua_rh.bbi

Begin bracket indicator, one bit.

lua_rh.ebi

End bracket indicator, one bit.

lua_rh.cdi

Change direction indicator, one bit.

lua_rh.csi

Code selection indicator, one bit.

lua_rh.edi

Enciphered data indicator, one bit.

lua_rh.pdi

Padded data indicator, one bit.

lua_flag1

Supplied parameter. Contains a data structure containing flags for messages supplied by the application. This parameter is used by RUI_BID, RUI_READ, RUI_WRITE, SLI_BID, SLI_RECEIVE, and SLI_SEND. For other LUA verbs this parameter is not used and should be set to zero. Its subparameters are as follows:

lua_flag1.bid_enable

Bid enable indicator, one bit.

lua_flag1.close_abend

Close immediate indicator, one bit.

lua_flag1.nowait

No wait for data flag, one bit.

lua_flag1.sscp_exp

SSCP expedited flow, one bit.

lua_flag1.sscp_norm

SSCP normal flow, one bit.

lua_flag1.lu_exp

LU expedited flow, one bit.

lua_flag1.lu_norm

LU normal flow, one bit.

lua_message_type

Specifies the type of the inbound or outbound SNA commands and data. This is a returned parameter for RUI_INIT and SLI_OPEN and a supplied parameter for SLI_SEND. For other LUA verbs this variable is not used and should be set to zero.

Possible values are:

LUA_MESSAGE_TYPE_LU_DATA

LUA_MESSAGE_TYPE_SSCP_DATA

LUA_MESSAGE_TYPE_BID

LUA_MESSAGE_TYPE_BIND

LUA_MESSAGE_TYPE_BIS

LUA_MESSAGE_TYPE_CANCEL

LUA_MESSAGE_TYPE_CHASE

LUA_MESSAGE_TYPE_CLEAR

LUA_MESSAGE_TYPE_CRV

LUA_MESSAGE_TYPE_LUSTAT_LU

LUA_MESSAGE_TYPE_LUSTAT_SSCP

LUA_MESSAGE_TYPE_QC

LUA_MESSAGE_TYPE_QEC

LUA_MESSAGE_TYPE_RELQ

LUA_MESSAGE_TYPE_RQR

LUA_MESSAGE_TYPE_RTR

LUA_MESSAGE_TYPE_SBI

LUA_MESSAGE_TYPE_SHUTD

LUA_MESSAGE_TYPE_SIGNAL

LUA_MESSAGE_TYPE_SDT

LUA_MESSAGE_TYPE_STSN

LUA_MESSAGE_TYPE_UNBIND

The SLI receives and responds to the BIND, CRV, and STSN requests through the LUA interface extension routines.

LU_DATA, LUSTAT_LU, LUSTAT_SSCP, and SSCP_DATA are not SNA commands.

lua_flag2

Returned parameter. Contains flags for messages returned by LUA. This parameter is returned by RUI_BID, RUI_READ, RUI_WRITE, SLI_BID, SLI_RECEIVE, and SLI_SEND. For other LUA verbs this parameter is not used and should be set to zero. Its subparameters are as follows:

lua_flag2.bid_enable

Indicates that **RUI_BID** was successfully re-enabled if set to 1.

lua_flag2.async

Indicates that the LUA interface verb completed asynchronously if set to 1.

lua_flag2.sscp_exp

Indicates SSCP expedited flow if set to 1.

lua_flag2.sscp_norm

Indicates SSCP normal flow if set to 1.

lua_flag2.lu_exp

Indicates LU expedited flow if set to 1.

lua_flag2.lu_norm

Indicates LU normal flow if set to 1.

lua_resv56

This supplied parameter is a reserved field used by SLI_OPEN and RUI_INIT. For all other LUA verbs, this parameter is reserved and should be set to zero.

lua_encr_decr_option

This parameter is a field for cryptography options. On **RUI_INIT**, only the following are supported:

- **lua_encr_decr_option** = 0
- **lua_encr_decr_option** = 128

For all other LUA verbs, this parameter is reserved and should be set to zero.

Values for lua_message_type

The following table describes the possible values for **lua_message_type**.

Message type	SNA data	SLI_SEND	SLI_BID SLI_RECEIVE	RUI_BID RUI_READ
0xC8	BID	X	X	X
0x31	BIND		Extension*	X
0x70	BIS	X	X	X
0x83	CANCEL	X	X	X
0x84	CHASE	X	X	X
0xA1	CLEAR			X
0xD0	CRV			X
0x01	LU_DATA**	X	X	X
0x04	LUSTAT_LU**	X	X	X
0x14	LUSTAT_SSCP**	X	X	X
0x81	QC	X	X	X
0x80	QEC	X	X	X
0x82	RELQ	X	X	X
0xA3	RQR	X		X
0x02	RSP	X	X	
0x05	RTR	X	X	X
0x71	SBI	X	X	X
0xC0	SHUTD			X
0xC9	SIGNAL	X	X	X
0xA0	SDT			X
0x11	SSCP_DATA**	X	X	X
0xA2	STSN		Extension*	X
0x32	UNBIND			X

*The SLI receives and responds to the BIND, CRV, and STSN requests through the LUA interface extension routines.

**Not an SNA command.

Command-Specific Structure of LUA VCBs

The following union shows the specific data structure that is included for functions that use the **LUA_SPECIFIC** part of a verb control block. The only logical unit application (LUA) verbs that use this union are RUI_BID,SLI_BID,SLI_OPEN, and SLI_SEND.

Syntax

```
union LUA_SPECIFIC {
    struct SLI_OPEN open;
    unsigned char lua_sequence_number[2];
    unsigned char lua_peek_data[12];
} LUA_SPECIFIC;
```

Remarks

Members

open

The union member of **LUA_SPECIFIC** used by the **SLI_OPEN** verb.

lua_sequence_number

The union member of **LUA_SPECIFIC** used by the **SLI_SEND** verb. Returned parameter. Sequence number of the RU to the host. It contains the sequence number for either the first in the chain request unit or the only segment in the chain request unit. Note that this parameter is not byte-reversed.

lua_peek_data

The union member of **LUA_SPECIFIC** used by the **RUI_BID** and **SLI_BID** verbs. Returned parameter. Contains up to 12 bytes of the data waiting to be read. It is a preview (up to 12 bytes) of the request/response unit (RU) data waiting to be read. The **lua_data_length** parameter contains the exact length of the data peeked at.

The following topic describes command-specific parameters for **SLI_OPEN**.

This section contains:

- SLI_OPEN VCB Structure

SLI_OPEN VCB Structure

The following structure shows the **SLI_OPEN** fields of the **LUA SPECIFIC** union member for the SLI_OPEN verb.

Syntax

```
struct SLI_OPEN {
    unsigned char lua_init_type;
    unsigned char lua_resv65;
    unsigned short lua_wait;
    struct LUA_EXT_ENTRY lua_open_extension[3];
    unsigned char lua_ending_delim;
} SLI_OPEN;
```

Remarks

Members

lua_init_type

Type of session initiation, which determines how the LU-LU session is initialized by the Windows LUA interface. The following values are valid:

lua_init_type_sec_is

Secondary-initiated and sends the INITSELF command supplied in the OPEN data buffer.

lua_init_type_sec_log

Secondary-initiated with an unformatted LOGON message in the OPEN data buffer.

lua_init_type_prim

Primary-initiated and waits on the BIND command.

lua_init_type_prim_sscp

Primary-initiated with SSCP access.

lua_resv65

Reserved field.

lua_wait

Secondary retry wait time. Specifies how many seconds the Windows LUA interface is to wait before retransmitting the INITSELF or the LOGON message after receiving one of the following:

- A NOTIFY command (indicating a procedure error)
- A network services procedure error message
- A negative response with one of the following secondary return codes:

  RESOURCE_NOT_AVAILABLE SESSION_LIMIT_EXCEEDED SESSION_SERVICE_PATH_ERROR

lua_open_extension

Supplied parameter. Specifies any user-supplied dynamic-link libraries (DLLs) used to process specific LUA messages.

lua_ending_delim

Extension list delimiter.

LUA Common Return Codes

This section describes the primary and, if applicable, secondary return codes that are common to the logical unit application (LUA) verbs. The return codes are listed in hexadecimal order.

Verb-specific return codes are described for the individual verbs in LUA RUI Verbs and LUA SLI Verbs.

This section contains:

LUA Primary Return Codes

0x0000
LUA_OK

The verb executed successfully.

0x0001
LUA_PARAMETER_CHECK

The verb did not execute because of a parameter error.

0x0002
LUA_STATE_CHECK

The verb did not execute because it was issued in an invalid state.

0x000F
LUA_SESSION_FAILURE

A required Microsoft® Host Integration Server component (such as the local node) has terminated.

0x0014
LUA_UNSUCCESSFUL

The verb record supplied was valid, but the verb did not complete successfully.

0x0018
LUA_NEGATIVE_RESPONSE

Either the logical unit application (LUA) sent a negative response to a message received from the primary logical unit (PLU) because an error was found in the message, or the application responded negatively to a chain for which the end-of-chain has arrived.

0x0021
LUA_CANCELED

The secondary return code gives the reason for canceling the command.

0x0030
LUA_IN_PROGRESS

An asynchronous command was received but is not completed.

0x0040
LUA_STATUS

The secondary return code contains Session Level Interface (SLI) status information for the application.

0xF003
LUA_COMM_SUBSYSTEM_ABENDED

Indicates one of the following conditions:

- The node used by this conversation encountered an ABEND.
- The connection between the transaction program (TP) and the physical unit (PU) 2.1 node was broken (a LAN error).
- The SnaBase at the TPs computer encountered an ABEND.

0xF004
LUA_COMM_SUBSYSTEM_NOT_LOADED

A required component could not be loaded or terminated while processing the verb. Thus, communication could not take place. Contact the system administrator for corrective action.

0xF008

LUA_INVALID_VERB_SEGMENT

The verb control block (VCB) extended beyond the end of the data segment.

0xF011
LUA_UNEXPECTED_DOS_ERROR

After issuing an operating system call, an unexpected operating system return code was received and is specified in the secondary return code.

0xF015
LUA_STACK_TOO_SMALL

The stack size of the application is too small to execute the verb. Increase the stack size of your application.

0xFFFF
LUA_INVALID_VERB

Either the verb code or the operation code, or both, is invalid. The verb did not execute.

LUA Secondary Return Codes

0x00000000
LUA_SEC_RC_OK

No additional information exists for LUA_OK.

0x00000001
LUA_INVALID_LUNAME

An invalid **lua_luname** name was specified.

0x00000002
LUA_BAD_SESSION_ID

An invalid value for **lua_sid** was specified in the verb control block (VCB).

0x00000003
LUA_DATA_TRUNCATED

The data was truncated because the data received was longer than the buffer length specified in **lua_max_length**.

0x00000004
LUA_BAD_DATA_PTR

The **lua_data_ptr** parameter either does not contain a valid pointer or does not point to a read/write segment, and supplied data is required.

0x00000005
LUA_DATA_LENGTH_ERROR

One of the following occurred:

- The supplied data segment for **SLI_RECEIVE** or **SLI_SEND** is not a read/write data segment as required.
- The supplied data segment for **SLI_RECEIVE** is not as long as that provided in **lua_max_length**.
- The supplied data segment for **SLI_SEND** is not as long as that provided in **lua_data_length**.

0x00000006
LUA_RESERVED_FIELD_NOT_ZERO

A reserved parameter for the verb just issued is not set to zero.

0x00000007
LUA_INVALID_POST_HANDLE

For a Microsoft Windows Server 2003 or Windows 2000 system using events as the asynchronous posting method, the Windows-based logical unit application (LUA) VCB does not contain a valid event handle.

0x0000000C
LUA_PURGED

SLI_PURGE was issued and canceled **SLI_RECEIVE**.

0x0000000F
LUA_BID_VERB_ERROR

The buffer with the **SLI_BID** VCB was released before the **SLI_RECEIVE** with **lua_flag1.bid_enable** set to 1 was issued.

0x00000010
LUA_NO_PREVIOUS_BID_ENABLED

SLI_BID was not issued prior to issuing **SLI_RECEIVE** with **bid_enable**.

0x00000011
LUA_NO_DATA

No data was available to read when **SLI_RECEIVE** containing a no-wait parameter was issued.

0x00000012
LUA_BID_ALREADY_ENABLED

SLI_RECEIVE was issued with **bid_enable** when **SLI_BID** was already active.

0x00000013
LUA_VERB_RECORD_SPANS_SEGMENTS

The LUA VCB length parameter plus the segment offset is beyond the segment end.

0x00000014
LUA_INVALID_FLOW

The **lua_flag1** flow flags were set incorrectly when a verb was issued as follows:

- When issuing **SLI_SEND** to send an SNA response, set only one **lua_flag1** flow flag.
- When issuing **SLI_RECEIVE**, set at least one **lua_flag1** flow flag.

0x00000015
LUA_NOT_ACTIVE

LUA was not active within Microsoft Host Integration Server when an LUA verb was issued.

0x00000016
LUA_VERB_LENGTH_INVALID

An LUA verb was issued with the value of **lua_verb_length** unexpected by the LUA.

0x00000019
LUA_REQUIRED_FIELD_MISSING

The verb that was issued either did not include a data pointer (if the data count was not zero) or did not include an **lua_flag1** flow flag.

0x00000030
LUA_READY

Following a NOT_READY status, this status is issued to notify you that the Session Level Interface (SLI) is ready to process commands.

0x00000031
LUA_NOT_READY

One of the following caused the SLI session to be temporarily suspended:

- An SNA UNBIND type 0x02 command was received, indicating a new BIND is coming.

  If the UNBIND type 0x02 is received after the beginning **SLI_OPEN** is complete, the session is suspended until a BIND, optional CRV and STSN, and SDT flows are received. These routines are re-entrant because they must be called again. The session resumes after the SLI processes the SDT command. If the UNBIND type 0x02 is received while **SLI_OPEN** is still processing, the primary return code is session-failure, not status.

- The receipt of an SNA CLEAR caused the suspension.

  Receipt of an SNA SDT will cause the session to resume.

0x00000032
LUA_INIT_COMPLETE

The LUA interface initialized the session while **SLI_OPEN** was processing. LUA applications that issue **SLI_OPEN** with **lua_open_type_prim_sscp** receive this status on **SLI_RECEIVE** or **SLI_BID**.

0x00000033
LUA_SESSION_END_REQUESTED

The LUA interface received an SNA shutdown command (SHUTD) from the host, indicating the host is ready to shut down the session.

0x00000034
LUA_NO_SLI_SESSION

A session was not open or was down due to an **SLI_CLOSE** or session failure when a command was issued.

0x00000035
LUA_SESSION_ALREADY_OPEN

A session is already open for the logical unit (LU) name specified in **SLI_OPEN**.

0x00000036
LUA_INVALID_OPEN_INIT_TYPE

The value in the **lua_init_type** contained in **SLI_OPEN** is invalid.

0x00000037
LUA_INVALID_OPEN_DATA

The **lua_init_type** for the **SLI_OPEN** issued is set to LUA_INIT_TYPE_SEC_IS when the buffer for data does not have a valid INITSELF command.

0x00000038
LUA_UNEXPECTED_SNA_SEQUENCE

Unexpected data or commands were received from the host while **SLI_OPEN** was processing.

0x00000039
LUA_NEG_RSP_FROM_BIND_ROUTINE

The user-supplied SLI_BIND routine responded negatively to the BIND. **SLI_OPEN** ended unsuccessfully.

0x0000003B
LUA_NEG_RSP_FROM_STSN_ROUTINE

The user-supplied SLI STSN routine responded negatively to the STSN. **SLI_OPEN** ended unsuccessfully.

0x0000003E
LUA_INVALID_OPEN_ROUTINE_TYPE

The **lua_open_routine_type** for the **SLI_OPEN** list of extension routines is invalid.

0x0000003F
LUA_MAX_NUMBER_OF_SENDS

The application issued a third **SLI_SEND** before one completed.

0x00000040
LUA_SEND_ON_FLOW_PENDING

An **SLI_SEND** was still outstanding when the application issued another **SLI_SEND** for an SNA flow.

0x00000041
LUA_INVALID_MESSAGE_TYPE

The **lua_message_type** parameter is not recognized by the LUA interface.

0x00000042
LUA_RECEIVE_ON_FLOW_PENDING

An **SLI_RECEIVE** was still outstanding when this application issued another **SLI_RECEIVE** for an SNA flow.

0x00000043
LUA_DATA_LENGTH_ERROR

The application did not provide user-supplied data required by the verb issued. Note that when **SLI_SEND** is issued for an SNA LUSTAT command, status (in four bytes) is required, and that when **SLI_OPEN** is issued with secondary initialization, data is required.

0x00000044
LUA_CLOSE_PENDING

One of the following occurred:

- A CLOSE_ABEND was still pending when another CLOSE_ABEND was issued. You can issue a CLOSE_ABEND if a CLOSE_NORMAL is pending.
- Either a CLOSE_ABEND or a CLOSE_NORMAL was still pending when a CLOSE_NORMAL was issued.

0x00000046
LUA_NEGATIVE_RSP_CHASE

A negative response to an SNA CHASE command from the host was received by the LUA interface while **SLI_CLOSE** was being processed. **SLI_CLOSE** continued processing to stop the session.

0x00000047
LUA_NEGATIVE_RSP_SHUTC

A negative response to an SNA SHUTC command from the host was received by the SLI while **SLI_CLOSE** was still being processed. **SLI_CLOSE** continued processing to stop the session.

0x00000048
LUA_NEGATIVE_RSP_RSHUTD

A negative response to an SNA RSHUTD command from the host was received by the LUA interface while **SLI_CLOSE** was being processed. **SLI_CLOSE** continued processing to stop the session.

0x0000004A
LUA_NO_RECEIVE_TO_PURGE

No **SLI_RECEIVE** was outstanding when you issued **SLI_PURGE**. One of two situations caused the problem:

- **SLI_RECEIVE** completed before **SLI_PURGE** finished processing.

  You can change the application to take care of this problem because it is not an error condition.

- The **lua_data_ptr** parameter does not correctly point to the **SLI_RECEIVE** you want to purge.

0x0000004D
LUA_CANCEL_COMMAND_RECEIVED

The host sent an SNA CANCEL command to cancel the data chain currently being received by **SLI_RECEIVE**.

0x0000004E
LUA_RUI_WRITE_FAILURE

An unexpected error was posted to the SLI by **RUI_WRITE**.

0x00000051
LUA_SLI_BID_PENDING

An SLI verb was still active when another **SLI_BID** was issued. Only one **SLI_BID** can be active at a time.

0x00000052
LUA_SLI_PURGE_PENDING

An **SLI_PURGE** was still active when another **SLI_PURGE** was issued. Only one **SLI_PURGE** can be active at a time.

0x00000053
LUA_PROCEDURE_ERROR

A host procedure error is indicated by the receipt of an NSPE or NOTIFY message. The return code is posted to **SLI_OPEN** when the retry option is not used. To use the reset option, set **lua_wait** to a value other than zero. The LOGON or INITSELF command will be retried until the host is ready or until you issue **SLI_CLOSE**.

0x00000054
LUA_INVALID_SLI_ENCR_OPTION

The **lua_encr_decr_option** parameter was set to 128 in **SLI_OPEN**, which is not supported for the encryption/decryption processing option.

0x00000055
LUA_RECEIVED_UNBIND

The primary LU sent an SNA UNBIND command to the LUA interface when a session was active. As a result, the session was stopped.

0x0000007F
LUA_SLI_LOGIC_ERROR

The LUA interface found an internal error in logic.

0x00000080
LUA_TERMINATED

The session was terminated when a verb was pending. The verb process has been canceled.

0x00000081
LUA_NO_RUI_SESSION

No session has been initialized for the LUA verb issued, or some verb other than **SLI_OPEN** was issued before the session was initialized.

0x00000083
LUA_INVALID_PROCESS

The session for which a Request Unit Interface (RUI) verb was issued is unavailable because another process owns the session.

0x0000008C
LUA_LINK_NOT_STARTED

The LUA was not able to activate the data link during initialization of the session.

0x0000008D
LUA_INVALID_ADAPTER

The configuration for the data link control (DLC) is in error, or the configuration file is corrupted.

0x0000008E
LUA_ENCR_DECR_LOAD_ERROR

An unexpected return code was received from the OS/2 **DosLoadModule** function while attempting to load the user-provided encryption or decryption dynamic link module.

0x0000008F
LUA_ENCR_DECR_LOAD_ERROR

An unexpected return code was received from the OS/2 **DosGetProcAddr** function while attempting to get the procedure address within the user-provided encryption or decryption dynamic link module.

0x000000BE
LUA_NEG_NOTIFY_RSP

The system services control point (SSCP) responded negatively to a NOTIFY request issued indicating that the secondary LU was capable of a session. The half-session component that received the request understood and supported the request but could not execute it.

0x000000FF
LUA_LU_INOPERATIVE

A severe error occurred while the RUI was attempting to stop the session. This LU is unavailable for any LUA requests until an ACTLU is received from the host.

0x08010000
LUA_RESOURCE_NOT_AVAILABLE

The logical unit, physical unit, link, or link station specified in the request unit is unavailable. This return code is posted to **SLI_OPEN** when a resource is unavailable unless you use the retry option.

To use the retry option, set **lua_wait** to a value other than zero. The LOGON or INITSELF command will be retried until the host is ready or until you issue **SLI_CLOSE**.

0x08050000

LUA_SESSION_LIMIT_EXCEEDED

The session requested was not activated because a network addressable unit (NAU) is at its session limit.

This SNA sense code applies to the following requests: BID, CINIT, INIT, and ACTDRM. The code will be posted to **SLI_OPEN** when an NAU is at its limit, unless you use the retry option.

To use the retry option, set **lua_wait** to a value other than zero. The LOGON or INITSELF command will be retried until the host is ready or until you issue **SLI_CLOSE**.

0x08090000
LUA_MODE_INCONSISTENCY

Performing this function is not allowed by the current status. The request sent to the half-session component was not executed even though it was understood and supported. This SNA sense code is also an exception request sense code.

0x08120000
LUA_INSUFFICIENT_RESOURCES

A temporary condition of insufficient resources caused the request receiver to be unable to perform. The request sent to the half-session component was not executed, even though it was understood and supported.

0x081B0000
LUA_RECEIVER_IN_TRANSMIT_MODE

Either resources needed to handle normal flow data were not available or the state of the half-duplex contention was not received when a normal-flow request was received. The result is a race condition. This SNA sense code is also an exception request sense code.

0x08310000
LUA_LU_COMPONENT_DISCONNECTED

An LU component is unavailable because it is not connected properly. Make sure that the power is on.

0x08350001
LUA_NEGOTIABLE_BIND_ERROR

A negotiable BIND was received, which is only allowed by the SLI when a user-supplied SLI_BIND routine is provided with **SLI_OPEN**.

0x08350002
LUA_BIND_FM_PROFILE_ERROR

Only file management header profiles 3 and 4 are supported by the LUA interface. A file management profile other than 3 or 4 was found on the BIND.

0x08350003
LUA_BIND_TS_PROFILE_ERROR

Only Transmission Service (TS) profiles 3 and 4 are supported by the LUA interface. A TS profile other than 3 or 4 was found on the BIND.

0x0835000E
LUA_BIND_LU_TYPE_ERROR

Only LU 0, LU 1, LU 2, and LU 3 are supported by LUA. An LU other than 0, 1, 2, or 3 was found.

0x08570000
LUA_SSCP_LU_SESSION_NOT_ACTIVE

The required SSCP-LU is inactive. Specific sense code information is in bytes 2 and 3. Valid settings are 0x0000, 0x0001, 0x0002, 0x0003, and 0x0004.

0x08780001
LUA_RECEIVE_CORRELATION_TABLE_FULL

The session receive correlation table for the flow requested reached its capacity.

0x08780002
LUA_SEND_CORR_TABLE_FULL

The session send correlation table for the flow requested reached its capacity.

0x087D0000
LUA_SESSION_SERVICE_PATH_ERROR

A request for session services cannot be rerouted to an SSCP-SSCP session path. Specific sense code information in bytes 2 and 3 gives more information about why the request cannot be rerouted.

0x10020000
LUA_RU_LENGTH_ERROR

The request/response unit (RU) request was an incorrect length (either too short or too long). The RU was not interpreted or processed even though it was delivered to the half-session component. The half-session capabilities do not match. This SNA sense code is also an exception request sense code.

0x10030000
LUA_FUNCTION_NOT_SUPPORTED

The LUA does not support the requested function. A control character, an RU parameter, or a formatted request code may have specified the function. Specific sense code information is in bytes 2 and 3.

0x10050121
LUA_HDX_BRACKET_STATE_ERROR

The existing state error prevented the current request from being sent. The determination was made by a protocol computer.

0x10050122
LUA_RESPONSE_ALREADY_SENT

A response for the chain was already sent so that the current request was not sent. The determination was made by a protocol computer.

0x10050123
LUA_EXR_SENSE_INCORRECT

The application responded negatively to an exception request. The sense code was unacceptable.

0x10050124
LUA_RESPONSE_OUT_OF_ORDER

The current response was not for the oldest request. The determination was made by a protocol computer.

0x10050125
LUA_CHASE_RESPONSE_REQUIRED

A CHASE response was still outstanding when a more recent request was attempted. The determination was made by a protocol computer.

0x20020000
LUA_CHAINING_ERROR

The sequence of the chain indicator settings is in error. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

0x20030000
LUA_BRACKET

The sender failed to enforce the session bracket rules. Note that contention and race conditions are exempt from this error. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

0x20040000
LUA_DIRECTION

While the half-duplex flip-flop state was NOT_RECEIVE, a request for normal flow was received. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

0x20050000
LUA_DATA_TRAFFIC_RESET

A half-session of an active session with inactive data traffic received a normal flow DFC or FMD request. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

0x20060000
LUA_DATA_TRAFFIC_QUIESCED

A data flow control (DFC) or function management data (FMD) request was received from a half-session that sent either a SHUTC command or QC command, and the DFC or FMD request has not responded to a RELQ command. An invalid request header or request unit for the receivers current session control or data flow control state was found. Delivery to the half-session component was prevented.

0x20070000
LUA_DATA_TRAFFIC_NOT_RESET

While the data traffic state was not reset, the session control request was received. An invalid request header or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

0x20080000
LUA_NO_BEGIN_BRACKET

The receiver has already sent a positive response to a Bracket Initiation Stopped (BIS) command when a BID or an FMD request specifying BBI=BB was received. An invalid request header or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

0x20090000
LUA_SC_PROTOCOL_VIOLATION

A violation of the session control (SC) protocol occurred. A request (that is permitted only after an SC request and a positive response to that request have been successfully exchanged) was received before the required exchange. Byte 4 of the sense data contains the request code. No user data exists for this sense code. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

0x200A0000
LUA_IMMEDIATE_REQUEST_MODE_ERROR

The request violated the immediate request mode protocol. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

0x200B0000
LUA_QUEUED_RESPONSE_ERROR

The request violated the queued response protocol. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

0x200C0000
LUA_ERP_SYNC_EVENT_ERROR

A violation of the ERP synchronous event protocol occurred. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

0x200D0000
LUA_RSP_BEFORE_SENDING_REQ

A previously received request has not yet been responded to and an attempt was made in half-duplex send/receive mode to send a normal flow request. An invalid header request or request unit for the received current session control or data flow control state was found. Delivery to the half-session component was prevented.

0x200E0000
LUA_RSP_CORRELATION_ERROR

A response was sent that does not correspond to a previously received request or a response was received that does not correspond to a request sent previously.

0x200F0000
LUA_RSP_PROTOCOL_ERROR

A violation of the response protocol was found in the response received from the primary half-session.

0x40010000
LUA_INVALID_SC_OR_NC_RH

The request/response header (RH) of a session control (SC) or network control (NC) request was invalid.

0x40030000
LUA_BB_NOT_ALLOWED

The begin bracket indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x40040000
LUA_EB_NOT_ALLOWED

The end bracket indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x40060000
LUA_EXCEPTION_RSP_NOT_ALLOWED

When an exception response was not allowed, one was requested. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x40070000
LUA_DEFINITE_RSP_NOT_ALLOWED

When a definite response was not allowed, one was requested. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x40080000
LUA_PACING_NOT_SUPPORTED

The request contained a pacing indicator when support of pacing for this session does not exist for the receiving half-session or boundary function half-session. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x40090000
LUA_CD_NOT_ALLOWED

The change-direction indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x400A0000
LUA_NO_RESPONSE_NOT_ALLOWED

A request other than an EXR contained a NO RESPONSE. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x400B0000
LUA_CHAINING_NOT_SUPPORTED

The chaining indicators were incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x400C0000
LUA_BRACKETS_NOT_SUPPORTED

The bracket indicators were incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x400D0000
LUA_CD_NOT_SUPPORTED

The change-direction indicator was set, but LUA does not support change-direction for this situation. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-

session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x400F0000
LUA_INCORRECT_USE_OF_FI

The format indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x40100000
LUA_ALTERNATE_CODE_NOT_SUPPORTED

The code selection indicator was set, but LUA does not support code selection for this session. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x40110000
LUA_INCORRECT_RU_CATEGORY

The request unit category indicator was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x40120000
LUA_INCORRECT_REQUEST_CODE

The request code was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x40130000
LUA_INCORRECT_SPEC_OF_SDI_RTI

The sense-data-included indicator (SDI) and the response-type indicator (RTI) were not specified correctly on a response. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x40140000
LUA_INCORRECT_DR1I_DR2I_ERI

The DR1I, the DR2I, and the exception response indicator (ERI) were specified incorrectly. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x40150000
LUA_INCORRECT_USE_OF QRI

The queued response indicator (QRI) was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x40160000
LUA_INCORRECT_USE_OF_EDI

The EDI was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x40170000
LUA_INCORRECT_USE_OF_PDI

The padded data indicator (PDI) was incorrectly specified. The BIND options chosen previously or the architectural rules were violated by the request header parameter values. Delivery to the half-session component was prevented. The errors are not dependent on the current session state. The senders failure to enforce session rules may have caused the errors.

0x80030000

LUA_NAU_INOPERATIVE

The network addressable unit (NAU) is not able to process responses or requests. Delivery to the receiver could not take place for one of the following reasons:

- A path information unit error
- A path outage
- An invalid sequence of requests for activation

If a path error is received during an active session that usually means there is no longer a valid path to the session partner.

0x80050000
LUA_NO_SESSION

A request to activate a session is required because no active half-session in the receiving end node for the origination-destination pair exists, or no active boundary function half-session component for the origination-destination pair in a node that supplies the boundary function exists. Delivery of the request could not take place for one of the following reasons:

- A path information unit error
- A path outage
- An invalid sequence of requests for activation

If a path error is received during an active session that usually indicates there is no longer a valid path to the session partner.

3270 Emulation Programmer's Reference

This section contains reference material for the 3270 Emulator.

For general information about programming for the 3270 Emulator, see the 3270 Emulation Programmer's Guide section of the SDK.

In This Section

DL-BASE/DMOD Entry Points

FMI Message Formats

FMI Extension for the Windows Environment

DL-BASE/DMOD Entry Points

This section provides definitions for the entry points to the DL-BASE and the Dynamic Access Module (DMOD).

CMDGoTSR

The **CMDGoTSR** function initiates a background thread for the emulator, and then executes an MS-DOS® terminate-and-stay-resident (TSR) interrupt.

MS-DOS

Syntax

```
SHORT APIENTRY CMDGoTSR(
ULONG
            entryPoint,
            UCHAR FAR
            *stack,
            UCHAR FAR
            *topOfRam
);
```

Parameters

entryPoint

Pointer to the function where the background thread will start execution.

stack

Pointer to the stack of the background thread.

topOfRam

Top of RAM; all memory above this address will be released by the Network Access Program (NAP) for LAN Manager or the NAP for NetWare (LMBASE and NWBASE, respectively).

Remarks

An emulator should complete its initialization, and then execute this call to go resident. A thread of execution will be created at the entry point specified.

This call will never return control to the calling program.

CMDSemClear

The **CMDSemClear** function clears a RAM semaphore.

MS-DOS

Syntax

```
USHORT FAR CMDSemClear(
ULONG FAR *ramSem
);
```

Parameters

ramSem

Address of the semaphore.

CMDSemRequest

The **CMDSemRequest** function requests a RAM semaphore.

Syntax

```
USHORT FAR CMDSemRequest(
ULONG FAR
*ramSem,
ULONG timeOut
);
```

Parameters

ramSem

Address of the semaphore.

timeOut

Length of time in milliseconds to wait before returning.

Return Value

0

OK.

ERROR_SEM_TIMEOUT

Time-out expired before semaphore operation completed.

ERROR_SEM_OWNED

This thread or another thread owns the semaphore, and the calling thread specified zero time-out.

CMDSemSet

The **CMDSemSet** function sets a RAM semaphore.

Syntax

```
USHORT FAR CMDSemSet(
ULONG FAR *ramSem
);
```

Parameters

ramSem

Address of the semaphore.

CMDSemWait

The **CMDSemWait** function waits until a RAM semaphore is cleared.

Syntax

```
USHORT FAR CMDSemWait(
ULONG FAR *ramSem,
ULONG timeOut
);
```

Parameters

ramSem

Address of the semaphore.

timeOut

Length of time in milliseconds to wait before returning.

Return Value

0

OK.

ERROR_SEM_TIMEOUT

Time-out expired before semaphore operation completed.

ERROR_SEM_OWNED

This thread or another thread owns the semaphore, and the calling thread specified zero time-out.

CMDStartFG

The **CMDStartFG** function requests that scheduling of the foreground thread be resumed.

Syntax

```
USHORT FAR CMDStartFG();
```

Return Value

0

The foreground thread was successfully resumed.

nonzero

The foreground thread could not be resumed.

Remarks

The emulator should issue this call after restoring the screen contents when returning to background operation.

CMDStopFG

The **CMDStopFG** function requests that the foreground thread be suspended.

Syntax

```
USHORT FAR CMDStopFG(
USHORT timeOut
);
```

Parameters

timeOut

Maximum time to wait for the foreground thread to return before stopping it.

Return Value

0

The foreground thread was successfully stopped.

nonzero

The foreground thread was stopped within MS-DOS.

Remarks

The emulator should issue this call when it wishes to enter the foreground. If the return value is nonzero, the foreground thread has been stopped within MS-DOS and it is not safe for the emulator to come to the foreground. Under these circumstances, the emulator should restart the foreground thread by calling CMDStartFG.

If the call was successful, the emulator should save the contents of the screen before writing to it. When returning to background operation, the emulator must restore the screen and call **CMDStartFG** to allow the previous foreground application to continue.

RegisterSwitchProc

The **RegisterSwitchProc** function registers an application procedure that will be called whenever the 3270 emulator is about to be switched in or out of memory by the MS-DOS version 5, MS-DOS version 6, or Windows 3.*x* task-switching code.

MS-DOS

Syntax

```
USHORT FAR RegisterSwitchProc(
ULONG switchProc
);
```

```
VOID FAR PASCAL SwitchProc(
USHORT inOut
);
```

Parameters

inOut

Zero if emulator is about to be switched out of memory, 1 if emulator is about to be switched back into memory.

switchProc

A far pointer to the function where task activity will be notified. The function is defined as follows:

routproc

The **routproc** function is a sample routing procedure. It must be supplied as part of the application. It is called by the Dynamic Access Module (DMOD) with a message that may or may not be for this application The DMOD calls routing procedures in turn until one accepts the message.

Syntax

```
DWORD routproc(
BUFHDR *msgptr,
USHORT locl,
USHORT retstat
);
```

Parameters

msgptr

Pointer to the message passed by the DMOD to the routing procedure.

locl

Locality from which message was received (if *retstat* indicates message returned), or locality to which path was lost (if *retstat* indicates path error).

retstat

Reason for call:

CEDINMSG (1)—message returned.

CEDINLLN (2)—path error (see Remarks below).

Return Value

TRUE

The routing procedure has accepted the message.

FALSE

The message is not for this routing procedure.

Remarks

The routing procedure should first call sbpurcvx, which handles any Open response messages, as follows:

sbpurcvx(&*msgptr*, *locl*, *retstat***)**

A return code of TRUE from **sbpurcvx** indicates that **sbpurcvx** has accepted the message; an Open error response has been received for this application, and resource location is continuing. The routing procedure should not process the message any further and should return **TRUE** to prevent the DMOD from calling further routing procedures.

A return code of **FALSE** from **sbpurcvx** indicates that the routing procedure should:

- If the message is for this application, take responsibility for the message and return **TRUE** to prevent the DMOD from calling further routing procedures.
- If the message is not for this application, return **FALSE** so that the DMOD tries further routing procedures.

If a path error is returned, *msgptr* will not point to a valid message, and no more function management interface (FMI) messages will be returned for the locality value indicated. The application is responsible for ending all sessions using this locality. The routing procedure must return **FALSE**. This ensures that the lost locality is reported to all other routing procedures.

If the message is for this application, the routing procedure can either process the message immediately or put the message on an application queue, and then post the application using a semaphore. For more information, see Receiving Messages.

sbpibegt

The application calls the **sbpibegt** function to get a buffer element to append to an existing buffer.

Syntax

```
VOID sbpibegt(
PTRBFELT *eltptr
);
```

Parameters

eltptr

Pointer to a pointer to an element. On return, this points to a pointer to the element obtained, or to NULL if an element was not obtained (an internal error).

Remarks

This function should only be used to get extra elements for an existing buffer. The sepdbubl function should be used to get a new buffer.

The new element should be added to the chain of elements from the existing buffer header and the count of the number of elements updated.

This function is typically used when a received buffer is being reused to transmit a message that is longer than the incoming message.

sbpiberl

The application calls the **sbpiberl** function to release a buffer element from an existing buffer.

Syntax

```
VOID sbpiberl(
PTRBFELT *eltptr
);
```

Parameters

eltptr

Pointer to a pointer to the element to be released.

Remarks

This function should only be used to release surplus elements from a buffer. The sepdburl function should be called to release the entire buffer.

The released element should first be removed from the element chain and the count of the number of elements updated.

This function is typically used when a received buffer is being reused to transmit a message that is shorter than the incoming message.

sbpuinit

The **sbpuinit** function initializes the DL-BASE.

Syntax

```
USHORT sbpuinit(
HANDLE *sema4ptr,
USHORT proctype,
USHORT servtype,
UCHAR *uname
);
```

Parameters

sema4ptr

Semaphore, created by Dynamic Access Module (DMOD), cleared by DMOD when a message is available. For MS-DOS, the application should supply the address of a 4-byte (long) integer. This address is for internal use by Microsoft Host Integration Server 2009—the application should not subsequently attempt to reference the address.

proctype

Type of process: CLIENT–2.

servtype

Type of service/client: CES3270–2.

uname

Pointer to a character buffer of length at least 21 characters; the LAN Manager user name, or other identifying name appropriate to the network operating system, is returned to the application in this buffer. The application does not need to use this parameter, but can use it for display or logging.

Return Value

NO_ERROR

Initialization successful.

Any other return value indicates that the initialization failed. This is usually an operating system return code. The following values are also used:

DMLTABF (555)

L table is full.

DMMNWGI (562)

Failed to get network operating system information.

DMDSTFL (563)

Service table is full.

DMMPIPF (567)

Failed to make a named pipe.

DMCOMNM (582)

No name registered for this application.

DMCOMDUP (596)

A service is already running with the same name.

DMNOTLOG (598)

User is not logged on to network operating system.

DMCFGOPN (616)

Failed to open configuration file.

DMCFGREAD (618)

Failed to read from configuration file.

DMNONAP (625)

The Network Access Program (NAP) is not started.

DMMAXAPP (953)

Windows only: Maximum number of concurrent applications exceeded.

Remarks

The **sbpuinit** entry point should always be called before any other DL-BASE or DMOD entry points except SNAGetVersion. For new emulators, sepdcrec should be called after **sbpuinit**. (Because of the order of calls used in older emulators, a call to **sepdcrec** before **sbpuinit** is still supported, but this order is not recommended.)

sbpurcvx

The **sbpurcvx** function processes Open responses from a routing procedure. An application can define a routing procedure that is called by the Dynamic Access Module (DMOD) when a message is received. This routing procedure should first call **sbpurcvx** to handle any Open response messages received. This ensures that Open responses intended for the Resource Locator are handled correctly.

Syntax

```
USHORT sbpurcvx(
BUFHDR * *msgptr,
INTEGER locl,
INTEGER retstat
);
```

Parameters

msgptr

Pointer to the message returned by the DMOD to the routing procedure.

locl

Locality from which message was received (if *retstat* indicates message returned), or locality to which path was lost (if *retstat* indicates path error).

retstat

Reason for call:

CEDINMSG (1—message returned.

CEDINLLN (2)—path error.

Return Value

TRUE

The Resource Locator has accepted the message; the application should not process it any further.

FALSE

The message should be processed by the application.

Remarks

This function is called by a routing procedure that is called by the DMOD. It is not called directly by the application.

The parameters for **sbpurcvx** should be taken from the parameters for routproc. Note, however, that the first parameter to **sbpurcvx** is a pointer to a pointer to a buffer header (that is, a pointer to the corresponding parameter for the routing procedure, not the parameter itself).

sbpusend

The **sbpusend** function sends a message from an application to a partner on an LPI connection.

Syntax

```
VOID sbpusend(
PTRBFHDR msgptr
);
```

Parameters

msgptr

Pointer to the message to be sent.

Remarks

The message buffer is released after transmission by the Dynamic Access Module (DMOD). It cannot be accessed by the application again.

For an Open request message, the **destl** parameter can be zero. In this case, the Resource Locator will attempt to find a suitable destination for the Open message.

sbputerm

The **sbputerm** function must be called when the application terminates. It frees the DL-BASE and Dynamic Access Module (DMOD) resources used by the application.

For Win32®, do not call **sbputerm** from an entry point in a detached DLL process because it may cause a deadlock inside the SNADMOD.DLL.

Syntax

```
VOID sbputerm(
void
);
```

sepdbubl

The application calls the **sepdbubl** function to get a buffer with a requested number of elements.

Syntax

```
PTRBFHDR sepdbubl(
USHORT noelts
);
```

Parameters

noelts

Number of elements required.

Return Value

A pointer to the buffer obtained. NULL if a buffer could not be obtained.

Remarks

Each element has a size of 268—the constant SNANBEDA in the header file FMI.H.

The returned buffer consists of a header and the required number of elements. The header points to the first element, which points to the next element, and so on to make an element chain.

It is possible to add an element to an existing buffer by calling sbpibegt to get the extra element. The new element should be added to the element chain of the buffer, and the "number of elements" count should be updated.

The application must release any buffers that are not transmitted.

sepdburl

The application calls the **sepdburl** function to release a buffer.

Syntax

```
VOID sepdburl(
PTRBFHDR msgptr
);
```

Parameters

msgptr

Pointer to the buffer to be released.

Remarks

It is important that buffers are released after use. This is done automatically when a message is transmitted. For messages received, it is the responsibility of the application to either release or reuse the buffer.

This function releases both the buffer header and any associated buffer elements. It is possible to release single elements from a buffer by using the function sbpiberl.

sepdchnk

The **sepdchnk** function gets the function management interface (FMI) chunk size. The application calls this function to obtain the chunk size that should be used on the FMI. For more information on FMI chunking, see Pacing and Chunking.

Syntax

```
VOID sepdchnk(
USHORT *pipesizeptr,
USHORT *chunksizeptr
);
```

Parameters

pipesizeptr

Size in bytes of the pipe between the application and the local node.

chunksizeptr

Dynamic Access Module (DMOD) chunk size in bytes.

Remarks

The application does not need to use the pipe size returned by this call. (It is included on this call because the local node uses the same call to obtain both the pipe size and the chunk size.)

sepdcrec

The **sepdcrec** function gets configuration information. The application calls this function to obtain the 3270 configuration information for the name with which the user logged on to the network operating system. The call also registers this user name in the service table.

Syntax

```
USHORT sepdcrec(
UCHAR *pBuffer,
USHORT length,
USHORT *numbytes
);
```

Parameters

pBuffer

Pointer to a buffer supplied by the application, in which configuration information is returned.

length

Size of the supplied buffer.

numbytes

Used by Host Integration Server 2009 to return the number of bytes of information returned in the buffer.

Return Value

NO_ERROR (0)

OK.

NOCSSRVR (1)

No configuration file server available.

NODGNREC (2)

No diagnostics record found in configuration file.

NOUSRREC (3)

No user record found in configuration file for this user.

BUF2SMAL (4)

Supplied buffer was too small.

NONOS (5)

Network operating system is not started.

NOTLOGON (6)

User is not logged on to the network operating system.

READERR (7)

Failed to read from configuration file.

NONAP (8)

The Network Access Program (NAP) is not started.

MAXAPP (9)

Windows only: Maximum number of concurrent applications exceeded.

ERROR_SERVER (14)

Error on the server end of the remote procedure call (RPC).

ERROR_LOCAL_FAILURE (15)

Error on the local end of the RPC.

Remarks

The sbpuinit function should always be called before any other DL-BASE or Dynamic Access Module (DMOD) entry points except SNAGetVersion. For new emulators, **sepdcrec** should be called after **sbpuinit**. (Because of the order of calls used in older emulators, a call to **sepdcrec** before **sbpuinit** is still supported, but this order is not recommended.)

On successful return, the buffer contains pointers to the appropriate 3270 user record and the diagnostics record, followed by the records themselves. It is formatted as follows:

```
TECWRKUS *pUserRecord,
TEDIAGNS *pDiagRecord
);
```

(UserRecord—variable length)

(DiagRecord)

The two records should be accessed using the supplied pointers.

See Configuration Information for details of the format of these records and of how the application uses the configuration file information.

If there is no 3270 user record for this user in the configuration file, or if no diagnostics record is found in the configuration file (an internal error), the application should terminate and not allow the user to use 3270 emulation. The Host Integration Server error log messages COM0438 and COM0437 can be used to report these failures.

If the supplied buffer is too small for the returned information, the contents of the buffer are undefined and should not be examined, but the *numbytes* parameter will contain the total number of bytes of information available (that is, the size of the two pointers plus the two configuration records). The application should retry with a buffer of at least this size.

sepdgetinfo

The **sepdgetinfo** function returns a structure containing the version number of Host Integration Server 2009, the path of the current configuration file, and the network operating system over which Host Integration Server is running.

Syntax

```
USHORT sepdgetinfo(
struct cs_info *pCSInfo
);
```

Parameters

pCSInfo

Pointer to a buffer supplied by the application, containing a **cs_info** data structure in which system information is returned. The application must set the **length** member in this data structure (for more information, see Remarks later in this topic); the other members should be set to nulls or blanks.

The cs_info structure

The returned **cs_info** structure and its members are as follows:

```
struct cs_info {
    unsigned short length;
    unsigned char  major_ver;
    unsigned char  minor_ver;
    unsigned char  config_share[80];
    unsigned short nos;
 } cs_info;
```

Members

length

Length of the data structure supplied by the application.

major_ver

Major version number:

1 for Host Integration Server 1.1 (Connection Server 1.1) 2 for Host Integration Server 2.0 (Connection Server 2.0)

minor_ver

Minor version number (decimal):

10 for Connection Server 1.1 (indicates 1.10)00 for Connection Server 2.0 (indicates 2.00)

config_share[80]

Path of the running configuration file：\\server\share\ (null terminated).

nos

Network operating system in use

1: LAN Manager / LAN Server2: NetWare

Return Value

NO_ERROR (0)

OK.

NOCSSRVR (1)

No configuration file server available.

BADLNGTH (2)

Supplied buffer was too small.

Remarks

The application must set the **length** member to the length of the **cs_info** structure (86 bytes in the current version). Any other value will be rejected. This parameter is used to ensure compatibility with future versions; an application supplying this length will always obtain the information shown here, but in future versions it may be possible to specify larger values and obtain further information.

On successful return, the data structure **cs_info** contains the version number of Host Integration Server 2009, the path of the current configuration file, and the network operating system over which Host Integration Server is running.

Do not use the configuration file path returned by **sepdgetinfo** because NetWare clients will not be able to access this path.

If there is no configuration file server available, only the version number fields are valid; the other fields should not be checked.

sepdrout

The **sepdrout** function for Win32® allows an application to perform its own routing of received messages by setting up a procedure that is called by the Dynamic Access Module (DMOD) when a message is received.

Syntax

```
DWORD sepdrout(
DWORD ( *proc_addr,)
(BUFHDR *, USHORT, USHORT
);

DWORD sepdrout(
    DWORD *proc_addr,
    (BUFHDR *, USHORT, USHORT
   );
```

Parameters

proc_addr

The routing procedure.

Return Value

NO_ERROR (0)

Successful.

Anything else

Unsuccessful.

Remarks

This facility is only available to clients, as defined in the call to sbpuinit.

An application can have up to four routing procedures. Note that the Advanced Program-to-Program Communications (APPC) and Common Service Verb (CSV) libraries each use a routing procedure. When the DMOD receives a message, each routing procedure is called, until one accepts the message.

For an example of a routing procedure, see routproc.

sepwrout

The **sepwrout** function is the Windows version of sepdrout. It has the same parameters and is used in exactly the same way.

FMI Message Formats

This section describes the message formats for the function management interface (FMI). The message formats are presented in a language-independent notation. Details of the message format notation and key assumptions about the contents of the message formats are as follows:

- Reserved indicates that the field is set to zero (for a numeric field) or all nulls (for names) by the sender of the message.
- Undefined indicates that the value of the field is indeterminate. The field is not set by the sender and should not be examined by the receiver of the message.
- Fields that occupy two bytes, such as **opresid** in the Open(PLU) Request, are represented with the most arithmetically significant byte in the lowest byte address, irrespective of the normal orientation used by the processor on which the software executes. That is, the 2-byte value 0x1234 has the byte 0x12 in the lowest byte address. However, the following fields are exceptions:
    - The **srci** and **desti** fields in buffer headers are stored in the local format of the application that assigns them, because only the assigning application needs to interpret these values.
    - The **startd** and **endd** fields in elements are always stored in low-byte, high-byte orientation (the normal orientation of an Intel processor).
- Messages are composed of buffers consisting of a buffer header and zero or more buffer elements. For more information about buffer formats, see Messages.
- Applications must assign unique index (I) values for every active LPI connection within the node. In particular, the Open(SSCP) Request must be different from the source index it sends in response to the Open(PLU). Additionally, zero should not be used as an I value. An I value of zero means that the sender of the message is inviting the recipient of the message to assign an I value.
- The **startd** field in each element gives the offset of the first byte of data in the element after the **trpad** field.

  For non-logical unit application (LUA) applications, **startd** will either be 1 (data starts in the byte after the **trpad** field), 10 (nine bytes of padding are included between the **trpad** field and the start of the data), or 13 (12 bytes of padding are included between the **trpad** field and the start of the data).

  For LUA applications, **startd** is 4 (three bytes of padding between the **trpad** field and the start of the data) in the first element of a message and 13 (12 bytes of padding) in subsequent elements.

  The local node uses extra bytes for additional header information. This avoids having to copy data into a new buffer when adding this information.
- Because **startd** indicates the index into **dataru** starting from 1, not 0, the first byte of valid data is always at **dataru[startd–1]**.
- If **startd** is greater than **endd**, there is no valid data in the message.
- All fields within **dataru** are of type **CHAR**, except where the remarks indicate otherwise.
- Note that where a buffer element has a **startd** of 1, 10, or 13, this only applies to the initial element in the chain of elements, and subsequent elements in the chain have a **startd** of 1. Messages with two distinct linked element chains in the message formats (for example Open(PLU) Request and Open(PLU) OK Response) have the **startd** field in the elements at the start of the chains as the value (1, 10, or 13) given in the message format, and the **startd** fields in all other elements as 1.

Open(SSCP)

The **Open(SSCP)** message is used by the application to open the system services control point (SSCP) connection. The Open request is sent by the application to the node, and the Open response comes from the node to the application.

Open(SSCP) Request

The **Open(SSCP) Request** message flows from the application to the node. It is used with a system services control point (SSCP) connection.

Syntax

```
  struct Open(SSCP) Request {
      PTRBFHDR  nxtqptr;
      PTRBFELT  hdrept;
      CHAR      numelts;
      CHAR      msgtype;
      CHAR      srcl;
      CHAR      srcp;
      INTEGER   srci;
      CHAR      destl;
      CHAR      destp;
      INTEGER   desti;
      CHAR      ophdr.openqual;
      CHAR      ophdr.opentype;
      CHAR      ophdr.appltype;
      CHAR      ophdr.opluno;
      INTEGER   ophdr.opresid;
      INTEGER   ophdr.icreditr;
      INTEGER   ophdr.icredits;
      CHAR      ophdr.opninfo1;
      CHAR      ophdr.opnpad1;
  };
  struct Open(SSCP) Request {
      PTRBFELT   hdreptr->elteptr;
      INTEGER    hdreptr->startd;
      INTEGER    hdreptr->endd;
      CHAR       hdreptr->trpad;
      CHAR[268]  hdreptr->dataru;
  };
  struct Open(SSCP) Request {
      PTRBFELT  hdreptr->elteptr->elteptr;
      INTEGER   hdreptr->elteptr->startd;
      INTEGER   hdreptr->elteptr->endd;
      CHAR      hdreptr->elteptr->trpad;
      CHAR[268] hdreptr->elteptr->dataru;
  };
```

Members

nxtqptr

Pointer to next buffer header.

hdrept

Pointer to first buffer element.

numelts

Number of buffer elements (0x02).

msgtype

Message type OPENMSG (0x01).

srcl

Source locality.

srcp

Source partner. (For more information, see Remarks.)

srci

Source index.

destl

Destination locality.

destp

Destination partner.

desti

Destination index.

ophdr.openqual

Open qualifier REQU (0x01).

ophdr.opentype

Open type SSCPSEC (0x01).

ophdr.appltype

Application program interface type.

Function management interface (FMI) without chunking (0x02).

FMI with chunking (0x82). (For more information, see Remarks.)

ophdr.opluno

Logical Unit number. (For more information, see Remarks.)

ophdr.opresid

Resource identifier.

ophdr.icreditr

Reserved.

ophdr.icredits

Reserved.

ophdr.opninfo1

Reserved.

ophdr.opnpad1

Open force type. (For more information, see Remarks.)

OPEN_TEST (0x00)

OPEN_FORCE (0x01)

Element 1

hdreptr−>elteptr

Pointer to next buffer element.

hdreptr−>startd

Start of data in this buffer element (1).

hdreptr−>endd

End of data in this buffer element.

hdreptr−>trpad

Reserved (1 byte).

hdreptr−>dataru

Data request/response unit (RU), as follows:

dataru[0–9]

Source name. Should be filled with blanks.

dataru[10–19]

Destination name. Set to the logical unit (LU) with which you want to communicate.

dataru[20]

Sense 4003 flag.

dataru[21]

Sense 4004 flag.

dataru[22]

Sense 4006 flag.

dataru[23]

Sense 4007 flag.

dataru[24]

Sense 4009 flag.

dataru[25]

Sense 400A flag.

dataru[26]

Sense 400B flag.

dataru[27]

Sense 400C flag.

dataru[28]

Sense 400D flag.

dataru[29]

Sense 400F flag.

dataru[30]

Sense 4011 flag.

dataru[31]

Sense 4012 flag.

dataru[32]

Sense 4014 flag.

dataru[33]

High priority indicator.

HIGH (0x01)

LOW (0x02)

dataru[34]

Logical unit application (LUA) supported indicator.

Supported (0x01)

Not supported (0x00)

dataru[35–36]

Chunk size obtained from Dynamic Access Module (DMOD). (For more information, see Remarks.)

dataru[37]

Segment delivery option.

Do not deliver request/response unit (RU) segments (0x00)

Deliver RU segments (0x01)

dataru[38]

High-level language application programming interface (HLLAPI) session identifier. (For more information, see Remarks.)

Element 2

hdreptr–>elteptr–>elteptr

Pointer to next buffer element (NIL).

hdreptr–>elteptr–>startd

Start of data in this buffer element (1).

hdreptr–>elteptr–>endd

End of data in this buffer element.

hdreptr–>elteptr–>trpad

Reserved.

hdreptr–>elteptr–>dataru

Data RU, as follows:

dataru[0]

ASCII string identifying the 3270 emulator. (For more information, see Remarks.)

Remarks

- The **Open(SSCP) Request** message consists of a buffer header and two buffer elements.
- The source L value, the destination Locality Partner Index (LPI) values, and the source name are reserved.
- For a 3270 emulator, the source P value must be set to S3PROD (0x12), which identifies the application as a 3270 emulator. The destination name should be set to the LU name or pool name taken from the 3270 user record (right-filled with ASCII spaces if fewer than 10 characters).
- An LUA application uses the source P value LUAPROD (0x1D). This is independent of the value of the LUA supported indicator, which selects the LUA variant of the FMI.
- The SNS4003 to SNS4014 fields, together with the high priority indicator, are referred to in the text as the SSCP connection information control block (CICB). (For more information, see Opening the SSCP Connection.) A value of 0x00 indicates that the data flow control (DFC) receive check corresponding to the sense code is not supported for this LU. A value of 0x01 indicates that it is supported. Note that the corresponding send checks are always performed regardless of these values.
- The LU number is only used internally in the local node on the **Open(SSCP) Request**. It is generated from the destination name in the first element.
- The open force type field is used when locating resources across more than one server and for automatic activation of connections when the application wishes to use an LU for which the connection is inactive. The application does not need to set this flag. It is used by the DL-BASE. For details, see Opening the SSCP Connection.
- The application program interface type field defines whether RU chunking is used from the local node to the application. This may be necessary if large RUs are being used. For more information about FMI chunking, see Pacing and Chunking.
- The chunk size field (at **dataru[35]**) is an integer value.

- The segment delivery option specifies whether the local node should deliver segments of RUs to the application as soon as they are received or should assemble whole RUs before delivering them to the application. Segment delivery allows the application to update the user's screen as soon as data is received, known as window shading, which can result in a faster perceived response. For more information, see Segment Delivery. This option is required only when chunking is being used. It is included on this message so that the local node can calculate the initial chunk credit values on the corresponding primary logical unit (PLU) connection. The option must still be set on the **Open(PLU) Response**. The setting specified on that message will override the one specified here if there is a conflict. If this happens, the initial credit values may not be suitable.

- The LUA supported indicator specifies whether the application uses the LUA variant of the FMI.

- If the element is shorter than (s+34) bytes, Microsoft® Host Integration Server assumes no LUA and no chunking. This ensures backward compatibility with previous versions of the local node software in which these options were not available.

- The HLLAPI session identifier is a single ASCII character that identifies the 3270 display session to which the **Open(SSCP)** applies. HLLAPI uses this to identify a particular 3270 presentation space to which an HLLAPI function refers. It is also referred to by 3270 as the session's short name, or by HLLAPI as the presentation space identifier (PS identifier). If the 3270 emulator does not support session identifiers, this field should be set to zero.

- The second element contains an ASCII string that you can use to identify the type of 3270 emulator. This string will be logged in the audit log file by the client's DL-BASE and can also be seen in traces. The **startd** and **endd** fields must be set up to define the limits of this string.

Open(SSCP) Response

The **Open(SSCP) Response** message flows from the node to the application. It is used with an system services control point (SSCP) connection.

Syntax

```
  struct Open(SSCP) Response {
      PTRBFHDR  nxtqptr;
      PTRBFELT hdreptr;
      CHAR     numelts;
      CHAR     msgtype;
      CHAR     srcl;
      CHAR     srcp;
      INTEGER  srci;
      CHAR     destl;
      CHAR     destp;
      INTEGER  desti;
      CHAR     ophdr.openqual;
      CHAR     ophdr.opentype;
      CHAR     ophdr.appltype;
      CHAR     ophdr.opluno;
      INTEGER  ophdr.opresid;
      INTEGER  ophdr.operr1;
      INTEGER  ophdr.operr2;
  };
  struct Open(SSCP) Response {
      PTRBFELT  hdreptr->elteptr;
      INTEGER   hdreptr->startd;
      INTEGER   hdreptr->endd;
      CHAR      hdreptr->trpad;
      CHAR[256] dataru;
  };
```

Members

nxtqptr

destp

Destination partner.

desti

Destination index.

ophdr.openqual

Open qualifier.

RSPOK (0x02) RSPERR (0x03)

ophdr.opentype

Open type SSCPSEC (0x01).

ophdr.appltype

Application program interface type.

0x02 (function management interface (FMI) application)

ophdr.opluno

Logical unit number.

ophdr.opresid

Resource identifier.

ophdr.operr1

Error code 1.

ophdr.operr2

Error code 2.

Element 1

hdreptr–>elteptr

Pointer to buffer element (NIL).

hdreptr–>startd

Start of data in this buffer element (1).

hdreptr–>endd

End of data in this buffer element.

hdreptr–>trpad

Reserved (1 byte).

hdreptr–>dataru

Data RU, as follows:

dataru[0–9]

Source name.

dataru[10–19]

Destination name.

dataru[20–27]

Name of the local node that accepted the Open.

dataru[28–35]

Name of the connection used by the logical unit (LU).

dataru[36–37]

The internal identifier of the local node for the connection. (For more information, see Remarks.)

dataru[38]

The type of link service used by the connection, as shown in the following table.

Link service	Connection
CESLINK	(03) - SDLC
CESX25	(04) - X.25
CESTR	(11) - Token Ring
CESTCPIP	(30) - TCP/IP
CESRELAY	(31) - Frame Relay
CESCHANL	(32) - Channel
CESISDN	(33) – ISDN
CESETHER	(34) - Ethernet 802.2

Remarks

- The **Open(SSCP) Response** message consists of a buffer header and a single buffer element.
- If the open qualifier is RSPERR, the error code is valid and the Locality Partner Index (LPIs) and names are undefined. (For more information, see Error and Sense Codes.)
- The LU number indicates the LU selected by the local node from the configuration data. (For more information, see Opening the SSCP Connection.)
- When the **Open(SSCP)** is for an LU group, the source name contains the name of the selected LU.
- The connection identifier is an integer value. It uniquely identifies a particular connection on this local node. All sessions using the same connection will return the same identifier. This value is typically used when a link error is received on one session to determine which other sessions will be affected.

Open(PLU)

The **Open(PLU)** message is used by the local node to open the primary logical unit (PLU) connection with the application on receipt of a **BIND** command from the host.

Open(PLU) Request

The **Open(PLU) Request** message flows from the node to the application. It is used with a primary logical unit (PLU) connection.

```
struct Open(PLU) Request {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      ophdr.openqual;
    CHAR      ophdr.opentype;
    CHAR      ophdr.appltype;
    CHAR      ophdr.opluno;
    INTEGER   ophdr.opresid;
    INTEGER   ophdr.icreditr;
    INTEGER   ophdr.icredits;
    CHAR      ophdr.opninfo1;
};
struct Open(PLU) Request {
    PTRBFELT   hdreptr->elteptr;
    INTEGER    hdreptr->startd;
    INTEGER    hdreptr->endd;
    CHAR       hdreptr->trpad;
    CHAR[268]  hdreptr->dataru;
};
struct Open(PLU) Request {
    PTRBFELT  hdreptr->elteptr->elteptr;
    INTEGER   hdreptr->elteptr->startd;
    INTEGER   hdreptr->elteptr->endd;
    CHAR      hdreptr->elteptr->trpad;
    CHAR[ ]   hdreptr->elteptr->dataru;
};
```

Bind is not negotiable (0x00)

Bind is negotiable (0x01)

Element 1

hdreptr–>elteptr

Pointer to buffer element.

hdreptr–>startd

Start of data in this buffer element (1).

hdreptr–>endd

End of data in this buffer element.

hdreptr–>trpad

Reserved.

hdreptr–>dataru

Data RU, as follows:

dataru[0–9]

Source name.

dataru[10–19]

Destination name.

dataru[20]

Secondary pacing send window.

dataru[21]

Secondary pacing receive window.

dataru[22–23]

Secondary send maximum request/response unit (RU) size. (For more information, see Remarks.)

dataru[24–25]

Primary send maximum RU size. (For more information, see Remarks.)

dataru[26]

Secondary send chunk size (in units of elements).

dataru[27]

Primary send chunk size (in units of elements).

Element 2

hdreptr–>elteptr–>elteptr

Pointer to buffer element (NIL).

hdreptr–>elteptr–>startd

Start of data in this buffer element (13).

hdreptr–>elteptr–>endd

End of data in this buffer element.

hdreptr–>elteptr–>trpad

Reserved.

hdreptr–>elteptr–>dataru

Data RU, as follows:

dataru[13]

The **BIND** RU received from the host.

Remarks

- The **Open(PLU) Request** message consists of a buffer header, an initial element containing the source and destination names, RU sizes, and so on, followed by a second element containing the **BIND** RU received from the host.
- The source Locality Partner Index (LPI) and the L and P parts of the destination LPI are valid, but the I part of the destination LPI is reserved.
- The two send maximum RU size fields (in **dataru[22–25]**) are both integer values.
- The **BIND** RU can be up to 256 bytes in length.
- If the application is using the logical unit application (LUA) variant of the function management interface (FMI), the **BIND** RU is preceded by its transmission header (TH) and response header (RH). The **startd** field of the second element points to the TH. (For more information about FMI, see FMI Concepts.)
- The LU number matches that allocated to the named application on the Open(SSCP) Response.
- The resource identifier matches the value used by the application on the Open(SSCP) Request.
- If chunking was specified on the **Open(SSCP) Request**, the **icredits** (initial credit from local node to application) field

specifies the number of chunks, rather than RUs, that can be transmitted. The two send chunk size parameters are specified in units of elements. (Each element contains up to 256 bytes of RU data.) A value of zero indicates that the chunk size is not the limiting factor in determining the size of messages. The limiting factor is the RU size or the segment size, so chunking is not required. In this case, credit will still be used, with the unit of credit being a message.

- The **icreditr** (initial credit from application to local node) field is not used and must be set to zero.

Open(PLU) OResponse

The **Open(PLU) OK Response** message flows from the application to the node. It is used with a primary logical unit (PLU) connection.

Syntax

```
struct Open(PLU) OK Response {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      ophdr.openqual;
    CHAR      ophdr.opentype;
    CHAR      ophdr.appltype;
    CHAR      ophdr.opluno;
    INTEGER   ophdr.opresid;
    INTEGER   ophdr.icreditr;
    INTEGER   ophdr.icredits;
    CHAR      ophdr.opninfo1;
};
struct Open(PLU) OK Response {
    PTRBFELT hdreptr->elteptr;
    INTEGER hdreptr->startd;
    INTEGER hdreptr->endd;
    CHAR hdreptr->trpad;
    CHAR[268] hdreptr->dataru;
};
struct Open(PLU) OK Response {
    PTRBFELT   hdreptr->elteptr->elteptr;
    INTEGER    hdreptr->elteptr->startd;
    INTEGER    hdreptr->elteptr->endd;
    CHAR       hdreptr->elteptr->trpad;
    CHAR[268]  hdreptr->elteptr->dataru;
};
```

Negotiable bind indicator.

Bind is not negotiable (0x00)

Bind is negotiable (0x01)

Element 1

hdreptr–>elteptr

Pointer to buffer element.

hdreptr–>startd

Start of data in this buffer element (1).

hdreptr–>endd

End of data in this buffer element.

hdreptr–>trpad

Reserved.

hdreptr–>dataru

Data RU, as follows:

dataru[0–9]

Source name.

dataru[10–19]

Destination name.

dataru[20]

Segment delivery option.

Do not deliver request/response unit (RU) segments (0x00)

Deliver RU segments (0x01)

dataru[21]

Application pacing option.

No application pacing (0x00)

Application pacing (0x01)

dataru[22]

Application cancel option: Cancel is generated by:

local node (0x00)

application (0x01)

dataru[23]

Application transaction numbers option: transaction numbers are:

not supported by application (0x00)

supported by application (0x01)

dataru[24]

BIND table index

BIND_TABLE_INDEX_PRT (1) (printer session)

BIND_TABLE_INDEX_CRT (2) (display session)

Element 2

hdreptr–>elteptr–>elteptr

Pointer to buffer element (NIL).

hdreptr–>elteptr–>startd

Start of data in this buffer element (13).

hdreptr–>elteptr–>endd

End of data in this buffer element.

hdreptr–>elteptr–>trpad

Reserved.

hdreptr–>elteptr–>dataru

Data RU, as follows:

dataru[13]

The **BIND** RU.

Remarks

- The **Open(PLU) OK Response** message consists of a buffer header, an initial element containing the source and destination names and connection information control block (CICB), followed by elements containing the **BIND** RU received from the host.

- The application should reflect the source and destination Locality Partner Index (LPIs) and the source and destination names from the Open(PLU) Request and must supply the I part of the source LPI.

- The fields from segment delivery option to bind table index (in the first element) are referred to in the text as the PLU CICB. For more information about the contents of the CICB, see Opening the PLU Connection.

- The **BIND** RU can be up to 256 bytes in length.

- For LUA, the **BIND** RU is not preceded by its transmission header (TH) and response header (RH). This is in contrast with the Open(PLU) Request, where the TH and RH are included.

- As in the **Open(PLU) Request**, the **icredits** value is in units of chunks if chunking is being used.

Open(PLU) Error Response

The **Open(PLU) Error Response** message flows from the application to the node. It is used with a primary logical unit (PLU) connection.

Syntax

```
struct Open(PLU) Error Response {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      ophdr.openqual;
    CHAR      ophdr.opentype;
    CHAR      ophdr.appltype;
    CHAR      ophdr.opluno;
    INTEGER  ophdr.opresid;
    INTEGER  ophdr.operr1;
    INTEGER  ophdr.operr2;
};
```

Members

nxtqptr

Pointer to next buffer header.

hdreptr

Pointer to first buffer element (NIL).

numelts

Number of buffer elements (0x00).

msgtype

Message type OPENMSG (0x01).

srcl

Source locality.

srcp

Source partner.

srci

Source index.

destl

Destination locality.

destp

Destination partner.

desti

Destination index.

ophdr.openqual

Open qualifier RSPERR (0x03).

ophdr.opentype

Open type LUSEC (0x02).

ophdr.appltype

Application program interface type.

0x02 (FMI application)

ophdr.opluno

Logical unit number.

ophdr.opresid

Resource identifier.

ophdr.operr1

Error code 1.

ophdr.operr2

Error code 2.

Remarks

- The **Open(PLU) Error Response** message consists of a buffer header only.
- The application should reflect the source and destination Locality Partner Index (LPIs).

Open(PLU) OConfirm

The **Open(PLU) OK Confirm** message flows from the node to the application. It is used with a primary logical unit (PLU) connection.

Syntax

```
struct Open(PLU) OK Confirm {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   dsti;
    CHAR      ophdr.openqual;
    CHAR      ophdr.opentype;
    CHAR      ophdr.appltype;
    CHAR      ophdr.opluno;
    INTEGER   ophdr.opresid;
    INTEGER   ophdr.icreditr;
    INTEGER   ophdr.icredits;
    CHAR      ophdr.opninfo1;
};
struct Open(PLU) OK Confirm {
    PTRBFELT   hdreptr->elteptr;
    INTEGER    hdreptr->startd;
    INTEGER    hdreptr->endd;
    CHAR       hdreptr->trpad;
    CHAR[268]  hdreptr->dataru;
};
```

Members

nxtqptr

Pointer to next buffer header.

Destination index.

ophdr.openqual

Open qualifier CONFOK (0x04).

ophdr.opentype

Open type LUSEC (0x02).

ophdr.appltype

Application program interface type.

0x02 (FMI application)

ophdr.opluno

Logical unit number.

ophdr.opresid

Resource identifier.

ophdr.icreditr

Reserved.

ophdr.icredits

Reserved.

ophdr.opninfo1

PLU address.

Element

hdreptr−>elteptr

Pointer to buffer element (NIL).

hdreptr−>startd

Start of data in this buffer element (1).

hdreptr−>endd

End of data in this buffer element.

hdreptr−>trpad

Reserved.

hdreptr−>dataru

Data request/response unit (RU), as follows:

dataru[0]

Function management (FM) profile.

dataru[1]

Transmission Service profile (TS profile).

dataru[2]

Primary chaining use.

dataru[3]

Primary request control mode.

dataru[4]

Primary chain response protocol.

dataru[5]

Primary two-phase commit.

dataru[6]

Primary compression indicator.

dataru[7]

Primary send end bracket (EB) indicator.

dataru[8]

Secondary chaining use.

dataru[9]

Secondary request control mode.

dataru[10]

Secondary chain response protocol.

dataru[11]

Secondary two-phase commit.

dataru[12]

Secondary compression indicator.

dataru[13]

Secondary send EB indicator.

dataru[14]

Function Management Header (FMH) usage.

dataru[15]

Bracket usage.

Brackets not used (0x00)

Brackets used (0x01)

dataru[16]

Bracket reset state.

Bracket reset state between-brackets (BETB) (0x01)

Bracket reset state in-bracket (INB) (0x02)

dataru[17]

Bracket termination rule.

dataru[18]

Alternate code set indicator.

dataru[19]

Sequence number availability.

dataru[20]

Normal-flow send/receive mode.

dataru[21]

Half-duplex flip-flop reset.

dataru[22]

Secondary pacing send window.

dataru[23]

Secondary pacing receive window.

dataru[24–25]

Secondary send maximum RU size (INTEGER value).

dataru[26–27]

Primary send maximum RU size (INTEGER value).

dataru[28]

LU-LU session type.

dataru[29]

PLU name size.

dataru[30–37]

PLU name (Extended Binary Coded Decimal Interchange Code or EBCDIC).

dataru[38]

Session type 1: PS Function Management Header (FMH) type.

dataru[39]

PS data stream profile.

dataru[40]

Number of outstanding destinations.

dataru[41]

Compacted data indicator.

dataru[42]

Peripheral Data Interchange Record (PDIR) allowed indicator.

dataru[43]

Session type 2 or 3: query support.

dataru[44]

Dynamic screen size.

dataru[45]

Basic row size.

dataru[46]

Basic column size.

dataru[47]

Alternate row size.

dataru[48]

Alternate column size.

Remarks

- The **Open(PLU) OK Confirm** message consists of a buffer header and one element.
- The message does not carry source and destination names. Both LPIs are valid.
- The contents of **dataru** are referred to in the text as the PLU bind information control block (BICB). The BICB is only valid

for an open-qualifier of CONFOK. For further information about the contents of the BICB, see Opening the PLU Connection.

Open(PLU) Error Confirm

The **Open(PLU) Error Confirm** message flows from the node to the application. It is used with a primary logical unit (PLU) connection.

Syntax

```
struct Open(PLU) Error Confirm {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      ophdr.openqual;
    CHAR      ophdr.opentype;
    CHAR      ophdr.appltype;
    CHAR      ophdr.opluno;
    INTEGER   ophdr.opresid;
    INTEGER   ophdr.operr1;
    INTEGER   ophdr.operr2;
};
```

Members

nxtqptr

Pointer to next buffer header.

hdreptr

Pointer to first buffer element (NIL).

numelts

Number of buffer elements (0x00).

msgtype

Message type OPENMSG (0x01).

desti

Destination index.

ophdr.openqual

Open qualifier CONFERR (0x05).

ophdr.opentype

Open type LUSEC (0x02).

ophdr.appltype

Application program interface type.

0x02 (function management interface (FMI) application)

ophdr.opluno

Logical unit number.

ophdr.opresid

Resource identifier.

ophdr.operr1

Error code 1.

ophdr.operr2

Error code 2.

Remarks

- The **Open(PLU) Error Confirm** message consists of a buffer header only.
- The error codes are valid. (For more information, see Error and Sense Codes.) An **Open(PLU) Error Confirm** closes the connection.

Close(SSCP)

The **Close(SSCP)** message closes an open system services control point (SSCP) connection.

Close(SSCP) Request

The **Close(SSCP) Request** message flows from the application to the node. It is used with a system services control point (SSCP) connection.

Syntax

```
struct Close(SSCP) Request {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      clhdr.closqual;
    CHAR      clhdr.clstype;
};
```

Members

nxtqptr

Pointer to next buffer header.

hdreptr

Pointer to buffer element (NIL).

numelts

Number of buffer elements (0x00).

msgtype

Message type CLOSEMSG (0x02).

srcl

Source locality.

srcp

Source partner.

srci

Source index.

destl

Destination locality.

destp

Destination partner.

desti

Destination index.

clhdr.closqual

Close qualifier REQU (0x01).

clhdr.clstype

Close subtype SSCPSEC (0x01).

Remarks

- The **Close(SSCP) Request** message consists of a buffer header only. There is no buffer element.

Close(SSCP) Response

The **Close(SSCP) Response** message flows from the node to the application. It is used with a system services control point (SSCP) connection.

Syntax

```
struct Close(SSCP) Response {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      clhdr.closqual;
    CHAR      clhdr.clstype;
};
```

Members

nxtqptr

Pointer to next buffer header.

hdreptr

Pointer to buffer element (NIL).

numelts

Number of buffer elements (0x00).

msgtype

Message type CLOSEMSG (0x02).

srcl

Source locality.

srcp

Source partner.

srci

Source index.

destl

Destination locality.

destp

Destination partner.

desti

Destination index.

clhdr.closqual

Close qualifier RSPOK (0x02).

clhdr.clstype

Close subtype SSCPSEC (0x01).

Remarks

- The **Close(SSCP) Response** message consists of a buffer header only. There is no buffer element.
- The **Close(SSCP)** protocol is unconditional. It is not possible for the local node to keep the SSCP connection open after the application sends **Close(SSCP)**.

Close(PLU)

The **Close(PLU)** message closes an open primary logical unit (PLU) connection.

Close(PLU) Request

The **Close(PLU) Request** message flows from the node to the application and from the application to the node. It is used with a primary logical unit (PLU) connection.

```
struct Close (PLU) Request {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      clhdr.closqual;
    CHAR      clhdr.clstype;
    CHAR      clhdr.clsctl;
    CHAR      clhdr.clspad1;
    INTEGER   clhdr.clspad2;
    INTEGER   clhdr.clserr1;
};
struct Close (PLU) Request {
    PTRBFELT hdreptr->elteptr;
    INTEGER hdreptr->startd;
    INTEGER hdreptr->endd;
    CHAR hdreptr->trpad;
    CHAR[268] hdreptr->dataru;
};
```

Members

nxtqptr

Pointer to next buffer header.

hdreptr

Pointer to buffer element (NIL if not using LUA).

numelts

Number of buffer elements (0x00 if not using LUA).

msgtype

Message type CLOSEMSG (0x02).

srcl

Source locality.

srcp

Source partner.

srci

Source index.

destl

Destination locality.

destp

Destination partner.

desti

Destination index.

clhdr.closqual

Close qualifier REQU (0x01).

clhdr.clstype

Close subtype LUSEC (0x02).

clhdr.clsctl

Close control

CLNORMAL	(0x01)	normal
CLBIND	(0x02)	bind forthcoming
CLCFAERR	(0x03)	CFA error
CLPUINAC	(0x04)	PU inactive
CLLUINAC	(0x05)	LU inactive
CLLNKERR	(0x06)	link error
CLBFSHRT	(0x07)	node buffer shortage
CLRCVCHK	(0x08)	DFC receive check
CLSLUTRM	(0x09)	SLU termination

clhdr.clspad1

Reserved.

clhdr.clspad2

Reserved.

clhdr.clserr1

Error code (only valid for close control = link error).

LUA only (see Remarks): Element

hdreptr−>elteptr

Pointer to buffer element (NIL).

hdreptr−>startd

Start of data in this buffer element (13).

hdreptr−>endd

End of data in this buffer element.

hdreptr−>trpad

Reserved.

hdreptr−>dataru

The **UNBIND** request/response unit (RU) received from the host, with its transmission header (TH) and response header (RH).

Remarks

- If the application is using the LUA variant of the function management interface (FMI), and the **Close(PLU) Request** was generated by receipt of an **UNBIND** from the host, the element is included, and **startd** points to the TH of the **UNBIND** message. (For more information about FMI, see FMI Concepts.)

- In all other cases (for example, if the **Close(PLU) Request** was generated by the local node as a result of a link outage), the message consists of a buffer header only. There is no buffer element.

- The close control field is only valid on messages from the local node to the application.

- If the close control field specifies link error, the error code field gives the link outage code.

Close(PLU) Response

The **Close(PLU) Response** message flows from the node to the application and from the application to the node. It is used with a primary logical unit (PLU) connection.

Syntax

```
struct Close(PLU) Response {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      clhdr.closqual;
    CHAR      clhdr.clstype;
};
```

Members

nxtqptr

Pointer to next buffer header.

hdreptr

Pointer to buffer element (NIL).

numelts

Number of buffer elements (0x00).

msgtype

Message type CLOSEMSG (0x02).

srcl

Source locality.

srcp

Source partner.

srci

Source index.

destl

Destination locality.

destp

Destination partner.

desti

Destination index.

clhdr.closqual

Close qualifier RSPOK (0x02).

clhdr.clstype

Close subtype LUSEC (0x02).

Remarks

- The **Close(PLU) Response** message consists of a buffer header only. There is no buffer element.

- The **Close(PLU)** protocol is unconditional. It is not possible for the recipient of a Close(PLU) Request (either the local node or an application) to keep the PLU connection open. The only valid response is **Close(PLU) Response** with the close qualifier as RSPOK.

Data

Data messages carry both inbound and outbound data between the application and the local node on all connections. For a detailed description of outbound and inbound data flows, see Data Flow.

The **Data** message flows from the node to the application and from the application to the node. It is used with both the system services control point (SSCP) and the primary logical unit (PLU) connections.

Syntax

```
struct Data {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      dfhdr.fhackrqd;
    CHAR      dfhdr.fhpad1;
    INTEGER   dfhdr.fhmsgkey;
    CHAR      dfhdr.fhflags1;
    CHAR      dfhdr.fhflags2;
    INTEGER   dfhdr.fhpad2;
    INTEGER   dfhdr.fhpad3;
    INTEGER   dfhdr.fhseqno;
};
struct Data {
    PTRBFELT   hdreptr->elteptr
    INTEGER    hdreptr->startd
    INTEGER    hdreptr->endd
    CHAR       hdreptr->trpad;
    CHAR[268]  hdreptr->dataru;
};
```

Members

nxtqptr

Pointer to next buffer header.

hdreptr

Pointer to buffer element.

numelts

Number of buffer elements.

msgtype

Message type DATAFMI (0x20).

srcl

Source locality.

srcp

Source partner.

srci

Source index.

destl

Destination locality.

destp

Destination partner.

desti

Destination index.

dfhdr.fhackrqd

Acknowledgment required indicator.

NOACKREQ (0x00) ACKREQ (0x01)

dfhdr.fhpad1

Reserved.

dfhdr.fhmsgkey

Message key.

dfhdr.fhflags1

Application flag 1.

dfhdr.fhflags2

Application flag 2.

dfhdr.fhpad2

Reserved.

dfhdr.fhpad3

Reserved.

dfhdr.fhseqno

Sequence number.

Element

hdreptr–>elteptr

Pointer to buffer element.

hdreptr–>startd

Start of data in this buffer element:

Non-logical unit application (LUA): 13, or 10 for second and subsequent segments of outbound segmented request/response units (RUs). LUA, inbound data: 4 in first element, 13 in subsequent elements.

hdreptr–>endd

End of data in this buffer element.

hdreptr–>trpad

Reserved.

hdreptr–>dataru

Data RU.

Remarks

- The use of the acknowledgment required indicator in both inbound and outbound data acknowledgment protocols is described in Data Flow.
- The use of the application flag fields is described in Application Flags (For more information, see the note that follows for LUA.)
- The sequence number is undefined for inbound data but contains the corresponding SNA sequence number for

outbound data.

- If the application is using the LUA variant of the function management interface (FMI), the transmission header (TH) and (if appropriate) response header (RH) are included in the data, and the **startd** field points to the TH. The **fhmsgkey**, **fhflags1**, **fhflags2**, and **fhseqno** fields are undefined and should not be used. The corresponding data from the element should be used instead. (For more information about FMI, see FMI Concepts.)

Status-Acknowledge

Status-Acknowledge messages flow between the application and the local node as part of the outbound and inbound data acknowledgment protocols. For a detailed description of outbound and inbound acknowledgment protocols, see Data Flow.

Note
The format of this message is slightly different for messages from the application to the local node on the primary logical unit (PLU) connection, as is explained in the following topic Status-Acknowledge(Ack)

Status-Acknowledge(Ack)

The **Status-Acknowledge(Ack)** message flows from the node to the application and from the application to the node, and is used with both system services control point (SSCP) and primary logical unit (PLU) connections.

The following structure shows the message format for all SSCP messages and for PLU messages flowing from the node to the application.

Syntax

```
struct Status-Acknowledge(Ack) {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      sfhdr.stackhdr.akstat;
    CHAR      sfhdr.stackhdr.akqual;
    INTEGER   sfhdr.stackhdr.akmsgkey;
    CHAR      sfhdr.stackhdr.akflags1;
    CHAR      sfhdr.stackhdr.akflags2;
    INTEGER   sfhdr.stackhdr.aknumb1;
    INTEGER   sfhdr.stackhdr.aknumb2;
    INTEGER   sfhdr.stackhdr.akseqno;
};
struct Status-Acknowledge(Ack) {
    PTRBFELT   hdreptr->elteptr;
    INTEGER    hdreptr->startd;
    INTEGER    hdreptr->endd;
    CHAR       hdreptr->trpad;
    CHAR[268]  hdreptr->dataru;
};
```

Members

nxtqptr

Pointer to next buffer header.

hdreptr

Pointer to buffer element (NIL if not using LUA).

numelts

Number of buffer elements (0x00 if not using LUA).

msgtype

Message type STATFMI (0x21).

srcl

Destination locality.

destp

Destination partner.

desti

Destination index.

sfhdr.stackhdr.akstat

Status type ACK (0x01).

sfhdr.stackhdr.akqual

Acknowledgment type ACKPOS (0x02).

sfhdr.stackhdr.akmsgkey

Message key.

sfhdr.stackhdr.akflags1

Application flag 1.

sfhdr.stackhdr.akflags2

Application flag 2.

sfhdr.stackhdr.aknumb1

Undefined.

sfhdr.stackhdr.aknumb2

Reserved.

sfhdr.stackhdr.akseqno

SNA sequence number.

LUA only (see Remarks): Element

hdreptr−>elteptr

Pointer to buffer element (NIL).

hdreptr−>startd

Start of data in this buffer element.

13 or 10 for second and subsequent segments of outbound segmented request/response units (RUs)

hdreptr−>endd

End of data in this buffer element.

hdreptr−>trpad

Reserved.

hdreptr−>dataru

Data RU.

The message format for PLU messages flowing from the application to the node is identical to the preceding format, except that the application flag 1 and application flag 2 fields are not used. They are replaced by the following INTEGER field:

sfhdr.stackhdr.akmsgtim

Last host response time

0xFFFF - no response time measured 0x*nnnn* - last response time measured, in units of 0.1 second

INTEGER	*sfhdr.stackhdr.akmsgtim*	Last host response time 0xFFFF - no response time measured 0x*nnnn* - last response time measured, in units of 0.1 second

Remarks

- The message key and application flags reflect the message key and application flags of the data message to which this is an acknowledgment. (For more information, see the note about LUA that follows.)

- For outbound **Status-Acknowledge(Ack)** messages from the local node to the application, the SNA sequence number gives the sequence number of the inbound data message to which this is an acknowledgment. (For more information, see the note about LUA that follows.) It is normally used only by Transmission Service profile (TS profile) 4 applications.

- For inbound **Status-Acknowledge(Ack)** messages from the application to the local node, the SNA sequence number reflects the sequence number of the outbound data message to which this is an acknowledgment.

- If the host specified that response time statistics are to be maintained, the application is responsible for measuring and reporting response times to the local node, using the **akmsgtim** field of this message. (For details, see RTM Parameters and Response Time Monitor Data.)

- If the application is using the LUA variant of the function management interface (FMI), the transmission header (TH) and (if appropriate) response header (RH) are included in the data, and the **startd** field points to the TH. The **akmsgkey**, **akflags1**, and **akflags2** fields are undefined and should not be used. The corresponding data from the element should be used instead. The **akseqno** field is similarly undefined on messages from the local node to the application. It must be set on messages from the application to the local node. The **akseqno** field is used to hold the sequence number of the request being acknowledged. (For more information about FMI, see FMI Concepts.)

- If the application is not using the LUA variant of the FMI, the message consists of a buffer header only. There is no buffer element.

Status-Acknowledge(Nack-1)

The **Status-Acknowledge(Nack-1)** message flows from the node to the application and from the application to the node. It is used with both system services control point (SSCP) and primary logical unit (PLU) connections.

Syntax

```
struct Status-Acknowledge(Nack-1) {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      sfhdr.stackhdr.akstat;
    CHAR      sfhdr.stackhdr.akqual;
    INTEGER   sfhdr.stackhdr.akmsgkey;
    CHAR      sfhdr.stackhdr.akflags1;
    CHAR      sfhdr.stackhdr.akflags2;
    INTEGER   sfhdr.stackhdr.aknumb1;
    INTEGER   sfhdr.stackhdr.aknumb2;
    INTEGER   sfhdr.stackhdr.akseqno;
};
struct Status-Acknowledge(Nack-1) {
    PTRBFELT   hdreptr->elteptr;
    INTEGER    hdreptr->startd;
    INTEGER    hdreptr->endd;
    CHAR       hdreptr->trpad;
    CHAR[268]  hdreptr->dataru;
};
```

Members

nxtqptr

Pointer to next buffer header.

hdreptr

Pointer to buffer element (NIL if not using LUA).

numelts

Number of buffer elements (0x00 if not using LUA).

msgtype

Message type STATFMI (0x21).

srcl

Source locality.

srcp

Source partner.

srci

Source index.

destl

Destination locality.

destp

Destination partner.

desti

Destination index.

sfhdr.stackhdr.akstat

Status type ACK (0x01).

sfhdr.stackhdr.akqual

Acknowledgment type ACKNEG1 (0x03).

sfhdr.stackhdr.akmsgkey

Message key.

sfhdr.stackhdr.akflags1

Application flag 1.

sfhdr.stackhdr.akflags2

Application flag 2.

sfhdr.stackhdr.aknumb1

Sense data 1.

sfhdr.stackhdr.aknumb2

Sense data 2.

sfhdr.stackhdr.akseqno

SNA sequence number.

LUA only (see Remarks): Element

hdreptr−>elteptr

Pointer to buffer element (NIL).

hdreptr−>startd

Start of data in this buffer element.

13 or 10 for second and subsequent segments of outbound segmented request/response units (RUs)

hdreptr−>endd

End of data in this buffer element.

hdreptr−>trpad

Reserved.

hdreptr−>dataru

Data RU.

Remarks

- The message key and application flags reflect the message key and application flags of the data message to which this is a negative acknowledgment. (For more information, see the note about LUA that follows.)
- For **Status-Acknowledge(Nack-1)** messages from the local node to the application, the sense data reflects the sense data in the SNA negative response.
- For **Status-Acknowledge(Nack-1)** messages from the application to the local node, the sense data fields are those intended for the SNA negative response to the host.

- For outbound **Status-Acknowledge(Nack-1)** messages from the local node to the application, the SNA sequence number gives the sequence number of the inbound data message to which this is a negative acknowledgment. (For more information, see the note about LUA that follows.)

- For inbound **Status-Acknowledge(Nack-1)** messages from the application to the local node, the SNA sequence number reflects the sequence number of the outbound data message to which this is a negative acknowledgment.

- If the application is using the LUA variant of the function management interface (FMI), the transmission header (TH) and (if appropriate) response header (RH) are included in the data, and the **startd** field points to the TH. The **akmsgkey**, **akflags1**, and **akflags2** fields are undefined and should not be used. The corresponding data from the element should be used instead. The **akseqno** field is similarly undefined on messages from the local node to the application. It must be set on messages from the application to the local node. (For more information about FMI, see FMI Concepts.)

- If the application is not using the LUA variant of the FMI, the message consists of a buffer header only. There is no buffer element.

Status-Acknowledge(Nack-2)

The **Status-Acknowledge(Nack-2)** message flows from the node to the application. It is used with both system services control point (SSCP) and primary logical unit (PLU) connections.

Syntax

```
struct Status-Acknowledge(Nack-2) {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      sfhdr.stackhdr.akstat;
    CHAR      sfhdr.stackhdr.akqual;
    INTEGER   sfhdr.stackhdr.akmsgkey;
    CHAR      sfhdr.stackhdr.akflags1;
    CHAR sfhdr.stackhdr.akflags2;
    INTEGER sfhdr.stackhdr.aknumb1;
    INTEGER sfhdr.stackhdr.aknumb2;
};
```

Members

nxtqptr

Pointer to next buffer header.

sfhdr.stackhdr.akstat

Status type ACK (0x01).

sfhdr.stackhdr.akqual

Acknowledgment type ACKNEG2 (0x04).

sfhdr.stackhdr.akmsgkey

Message key.

sfhdr.stackhdr.akflags1

Reserved.

sfhdr.stackhdr.akflags2

Critical failure indicator.

Noncritical failure (0x00) Critical failure (0x01)

sfhdr.stackhdr.aknumb1

Error code 1.

sfhdr.stackhdr.aknumb2

Error code 2.

Remarks

- The **Status-Acknowledge(Nack-2)** message consists of a buffer header only. There is no buffer element.
- The message key refers to the message key in the inbound data message to which this is a negative acknowledgment.
- For more information about error codes, see Error and Sense Codes.

Status-Acknowledge(ACKLUA)

The **Status-Acknowledge(ACKLUA)** message is for logical unit application (LUA) applications only. It flows from the node to the application, and is used with both the system services control point (SSCP) and primary logical unit (PLU) connections.

Syntax

```
struct Status-Acknowledge(ACKLUA) {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      sfhdr.stackhdr.akstat;
    CHAR      sfhdr.stackhdr.akqual;
    INTEGER   sfhdr.stackhdr.akmsgkey;
    CHAR      sfhdr.stackhdr.akflags1;
    CHAR      sfhdr.stackhdr.akflags2;
    INTEGER   sfhdr.stackhdr.aknumb1;
    INTEGER   sfhdr.stackhdr.aknumb2;
    INTEGER   sfhdr.stackhdr.akseqno;
};
```

Members

nxtqptr

Pointer to next buffer header.

hdreptr

Pointer to buffer element (NIL).

numelts

Number of buffer elements (0x00).

msgtype

Message type STATFMI (0x21).

sfhdr.stackhdr.akstat

Status type ACK (0x01).

sfhdr.stackhdr.akqual

Acknowledgment type.

sfhdr.stackhdr.akmsgkey

Message key.

sfhdr.stackhdr.akflags1

Application flag 1.

sfhdr.stackhdr.akflags2

Application flag 2.

sfhdr.stackhdr.aknumb1

Number of replies.

sfhdr.stackhdr.aknumb2

Reserved.

sfhdr.stackhdr.akseqno

SNA sequence number.

Remarks

- The message key and application flags are undefined and should not be checked.
- The SNA sequence number gives the sequence number of the inbound data message to which this is an acknowledgment.

Status-Control

For details about **Status-Control** message usage and for a summary of control type codes, see Status-Control Message.

Status-Control(...) Request

The **Status-Control(...) Request** message flows from the node to the application and from the application to the node. It is used with a primary logical unit (PLU) connection.

Syntax

```
struct Status-Control(...) Request {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      sfhdr.stctlhdr.ctlstat;
    CHAR      sfhdr.stctlhdr.ctlqual;
    CHAR      sfhdr.stctlhdr.ctltype;
    CHAR      sfhdr.stctlhdr.ctlack;
    CHAR      sfhdr.stctlhdr.ctlflag1;
    CHAR      sfhdr.stctlhdr.ctlflag2;
    INTEGER   sfhdr.stctlhdr.ctlnumb1;
    INTEGER   sfhdr.stctlhdr.ctlnumb2;
    INTEGER   sfhdr.stctlhdr.ctlmsgk;
};
struct Status-Control(...) Request {
    PTRBFELT   hdreptr->elteptr;
    INTEGER    hdreptr->startd;
    INTEGER    hdreptr->endd;
    CHAR       hdreptr->trpad;
    CHAR[268]  hdreptr->dataru;
};
```

Members

nxtqptr

Pointer to next buffer header.

hdreptr

Pointer to buffer element (NIL if not using LUA).

numelts

sfhdr.stctlhdr.ctlstat

Status type STCNTRL (0x02).

sfhdr.stctlhdr.ctlqual

Control qualifier (0x01).

sfhdr.stctlhdr.ctltype

Control type.

sfhdr.stctlhdr.ctlack

Acknowledgment required indicator.

No acknowledgment required (0x00) Acknowledgment required (0x01)

sfhdr.stctlhdr.ctlflag1

Application flag 1.

sfhdr.stctlhdr.ctlflag2

Application flag 2. (For more information, see STSN.)

sfhdr.stctlhdr.ctlnumb1

Code 1.

sfhdr.stctlhdr.ctlnumb2

Code 2.

sfhdr.stctlhdr.ctlmsgk

Message key.

LUA only (see Remarks): Element

hdreptr−>elteptr

Pointer to buffer element (NIL).

hdreptr−>startd

Start of data in this buffer element.

13 or 10 for second and subsequent segments of outbound segmented request/response units (RUs)

hdreptr−>endd

End of data in this buffer element.

hdreptr−>trpad

Reserved.

hdreptr−>dataru

Data RU.

Remarks

- If the application is using the LUA variant of the function management interface (FMI), the transmission header (TH), response header (RH), and RU are included in the data element, and the **startd** field points to the TH. The **ctlflag1** and **ctlflag2** bytes are not defined and should not be used. The appropriate values from the data should be used instead. (For more information about FMI, see FMI Concepts.)

- If the application is not using the LUA variant of the function management interface (FMI), the message consists of a

buffer header only. There is no buffer element.

- For a summary of **Status-Control** control type codes, see the table in Status-Control Message
- The code 1 and code 2 fields apply only for **Status-Control** LUSTAT, SIGNAL, and STSN messages.
- The application flag byte 2 is used for the **Status-Control** STSN control byte. (For more information, see Recovery.)

Status-Control(...) Acknowledge

The **Status-Control(...) Acknowledge** message flows from the node to the application and from the application to the node. It is used with a primary logical unit (PLU) connection.

Syntax

```
struct Status-Control(...) Acknowledge {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      sfhdr.stctlhdr.ctlstat;
    CHAR      sfhdr.stctlhdr.ctlqual;
    CHAR      sfhdr.stctlhdr.ctltype;
    CHAR      sfhdr.stctlhdr.ctlack;
    CHAR      sfhdr.stctlhdr.ctlflag1;
    CHAR      sfhdr.stctlhdr.ctlflag2;
    INTEGER   sfhdr.stctlhdr.ctlnumb1;
    INTEGER   sfhdr.stctlhdr.ctlnumb2;
    INTEGER   sfhdr.stctlhdr.ctlmsgk;
};
struct Status-Control(...) Acknowledge {
    PTRBFELT   hdreptr->elteptr;
    INTEGER    hdreptr->startd;
    INTEGER    hdreptr->endd;
    CHAR       hdreptr->trpad;
    CHAR[268]  hdreptr->dataru;
};
```

sfhdr.stctlhdr.ctlflag2

Application flag 2. (For more information, see STSN.)

sfhdr.stctlhdr.ctlnumb1

Code 1.

sfhdr.stctlhdr.ctlnumb2

Code 2.

sfhdr.stctlhdr.ctlmsgk

Message key.

LUA only (see Remarks): Element

hdreptr–>elteptr

Pointer to buffer element (NIL).

hdreptr–>startd

Start of data in this buffer element.

13 or 10 for second and subsequent segments of outbound segmented request/response units (RUs)

hdreptr–>endd

End of data in this buffer element.

hdreptr–>trpad

Reserved.

hdreptr–>dataru

Data RU.

Remarks

- If the application is using the LUA variant of the function management interface (FMI), the transmission header (TH), response header (RH), and RU are included in the data element, and the **startd** field points to the TH. The **ctlflag1** and **ctlflag2** bytes are not defined and should not be used. The appropriate values from the data should be used instead. (For more information about FMI, see FMI Concepts.)

- If the application is not using the LUA variant of the FMI, the message consists of a buffer header only. There is no buffer element.

- For a summary of **Status-Control** control type codes, see the table in Status-Control Message.
- The code 1 and code 2 fields apply only for **Status-Control(STSN) Acknowledge** messages, where they are the application's secondary-to-primary and primary-to-secondary sequence numbers respectively.
- For messages from the application to the local node, the message key field must match the message key in the corresponding **Status-Control Request**.

Status-Control(...) Negative-Acknowledge-1

The **Status-Control(...) Negative-Acknowledge-1** message flows from the node to the application and from the application to the node. It is used with a primary logical unit (PLU) connection.

Syntax

```
struct Status-Control(...) Negative-Acknowledge-1 {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;

sfhdr.stctlhdr.ctlnumb1

Code 1.

sfhdr.stctlhdr.ctlnumb2

Code 2.

sfhdr.stctlhdr.ctlmsgk

Message key used for the SNA sequence number. (For more information, see Remarks.)

Remarks

- The **Status-Control() ACKLUA** message consists of a buffer header only. There is no buffer element.
- The application flags and the code 1 and code 2 fields are undefined and should not be used.
- The message key field gives the sequence number from the transmission header of the inbound data message to which this is an acknowledgment.
- For a summary of **Status-Control** control type codes, see the table in Status-Control Message.

Status-Error

The **Status-Error** message is used to report request reject and response header (RH) usage error conditions in outbound SNA request/response units (RUs) to the application. It flows from the node to the application and is used with both system services control point (SSCP) and primary logical unit (PLU) connections.

For more information, see Status-Error Message.

Syntax

```
struct Status-Error {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;

sfhdr.sterrhdr.errstat

Status type STERROR (0x03).

sfhdr.sterrhdr.errpad1

Reserved.

sfhdr.sterrhdr.errpad2

Reserved.

sfhdr.sterrhdr.errpad3

Reserved.

sfhdr.sterrhdr.errcode1

Error code 1.

sfhdr.sterrhdr.errcode2

Error code 2.

Remarks

- The **Status-Error** message consists of a buffer header only. There is no buffer element.
- The error codes are listed in Error and Sense Codes.

Status-Resource

The **Status-Resource** message is used to provide a simple flow control mechanism between the local node and the application to prevent the application from exhausting its resources. It flows from the application to the node, and is used with a primary logical unit (PLU) connection.

It is only used on the PLU connection where the application specifies in the PLU connection information control block (CICB) that pacing requires application participation. For further details, see Pacing and Chunking.

Syntax

```
struct Status-Resource {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      sfhdr.streshdr.resstat;
    CHAR      sfhdr.streshdr.respad;
    CHAR      sfhdr.streshdr.rescred;
};
```

sfhdr.streshdr.resstat

Status type STRESRCE (0x04).

sfhdr.streshdr.respad

Reserved.

sfhdr.streshdr.rescred

Application credit.

Remarks

- The **Status-Resource** message consists of a buffer header only. There is no buffer element.
- The **rescred** (application credit) field indicates that the application can receive further credit request/response units (RUs) of the maximum RU size, or further credit chunks if chunking is being used.

Status-RTM

The **Status-RTM** message provides the application with information about the Response Time Monitor (RTM) measurement parameters used by the host. This allows the application to match its local display of RTM statistics, if it provides such a display, with the statistics used by the host. It flows from the node to the application and is used with an system services control point (SSCP) connection.

For further details, see Response Time Monitor Data.

Syntax

```
struct Status-RTM {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      sfhdr.strtmhdr.rtmstat;
    CHAR      sfhdr.strtmhdr.strbndry;
    CHAR      sfhdr.strtmhdr.strcount;
    CHAR      sfhdr.strtmhdr.strtmdef;
    CHAR      sfhdr.strtmhdr.strtmact;
    CHAR      sfhdr.strtmhdr.strtmdsp;
};
struct Status-RTM {
    PTRBFELT   hdreptr->elteptr;
    INTEGER    hdreptr->startd;
    INTEGER    hdreptr->endd;
    CHAR       hdreptr->trpad;
    CHAR[268]  hdreptr->dataru;
};
```

sfhdr.strtmhdr.rtmstat

Status type STRTM (0x06).

sfhdr.strtmhdr.strbndry

RTM boundaries.

0x00 - No RTM boundaries follow in element. 0x01 - RTM boundaries follow in element.

sfhdr.strtmhdr.strcount

RTM counters.

0x00 - No RTM counters follow in element. 0x01 - RTM counters follow in element.

sfhdr.strtmhdr.strtmdef

RTM definition.

0x00 - No change: use last received definition. 0x01 - Timers run until first data is written to screen. 0x02 - Timers run until keyboard is unlocked. 0x03 - Timers run until application can send (change direction (CD) or end bracket (EB) received).

sfhdr.strtmhdr.strtmact

RTM measurement.

0x00 - not active 0x01 - active

sfhdr.strtmhdr.strtmdsp

Local RTM display.

0x00 - disabled 0x01 - enabled

Element

hdreptr–>elteptr

Pointer to buffer element (NIL).

hdreptr–>startd

Start of data in this element.

hdreptr–>endd

End of data in this element.

hdreptr–>trpad

Reserved.

hdreptr–>dataru

Data RU, as follows:

dataru[0–1]

Number of boundaries in element

0x0000 - no boundaries included

m - number of boundaries included

dataru[2–3]

Number of counters in element

0x0000 - no counters included

n - number of counters included

dataru[4–(2m+3)]

m boundary values.

dataru[(2m+4)–(2m+2n+3)]

*n*counter values.

dataru[(2m+2n+4)

RTM total time.

Remarks

- A **Status-RTM** message is sent after the **Open(SSCP) OK Response** to give the initial RTM parameters. It is sent again when the RTM counters are reset (either on request from the host or when the local node sends unsolicited RTM data to the host), or when the host changes any of the RTM parameters.

- The message is sent only for applications that use LUs with type video display unit (VDU) or logical units (LUs) in a VDU pool, because the RTM feature applies only to 3270 display sessions.

- All the values in the data RU are integer values.

- The RTM counter values in this message can be nonzero at startup, because RTM statistics are maintained for a specific LU and not for a specific application's use of that LU. If zero counter values are included, this indicates that the counters are to be reset.

- The RTM total time field is present only if the number of counters in the element is nonzero.

Status-Session

The **Status-Session** message provides the application with information about changes in the state of a session between the local node and the host. It flows from the node to the application and is used with both system services control point (SSCP) and primary logical unit (PLU) connections.

For further details, see Status-Session Message.

Syntax

```
struct Status-Session {
    PTRBFHDR  nxtqptr;
    PTRBFELT  hdreptr;
    CHAR      numelts;
    CHAR      msgtype;
    CHAR      srcl;
    CHAR      srcp;
    INTEGER   srci;
    CHAR      destl;
    CHAR      destp;
    INTEGER   desti;
    CHAR      sfhdr.stseshdr.sesstat;
    CHAR      sfhdr.stseshdr.sesspad;
    CHAR      sfhdr.steeshdr.sesscode;
    CHAR      sfhdr.stseshdr.sessqual;
};
```

Members

nxtqptr

Status type STSESSN (0x05).

sfhdr.stseshdr.sesspad

Reserved.

sfhdr.steeshdr.sesscode

Session code.

sfhdr.stseshdr.sessqual

Session code qualifier.

Remarks

- The **Status-Session** message consists of a buffer header only. There is no buffer element.
- The session codes are listed in Status-Session Codes.

FMI Extension for the Windows Environment

This section describes the application programming interface (API) extension to the Microsoft® Windows® 3270 Emulator Interface that converts link status and error codes to a printable string.

Following is a definition of the function, syntax, returns, and remarks for using the extension. For more information, see FMI Status, Error, and Sense Codes.

This section contains:

- GetFmiReturnCode

GetFmiReturnCode

The **GetFmiReturnCode** function converts link status and error codes to a printable string. This function provides a standard set of error strings for use by Function Management Interface (FMI) applications.

Syntax

```
int WINAPI GetFmiReturnCode (
    UINT errcode1,
    UINT errcode2,
    UINT buffer_length,
    unsigned char FAR *buffer_addr
);
```

Parameters

errcode1

Supplied parameter; see Remarks.

errcode2

Supplied parameter; see Remarks.

buffer_length

Supplied parameter; specifies the length of the buffer pointed to by *buffer_addr*. The recommended length is 256 characters.

buffer_addr

Supplied/returned parameter; specifies the address of the buffer that will hold the formatted, null-terminated string.

Return Values

0x20000001

The parameters are invalid; the function could not read the specified error codes or could not write to the specified buffer.

0x20000002

The specified buffer is too small.

Remarks

The *errcode1* and *errcode2* parameters are set according to the way that **GetFmiReturnCode** is used, as shown in the following table.

Codes to be translated	**Value for *errcode1***	**Value for *errcode2***
The *errcode1* and *errcode2* values specified in Error and Sense Codes includes messages for**Open(SSCP) Response**, **Open(PLU) Confirm**, **Status-Acknowledge(Nack-2)**, **Status-Control(...) Nack2**, **Status-Error**, and **Appl-Data** messages with the system detected error indicator (SDI) set	Unchanged from message	Unchanged from message
The status and qualifier codes returned from a Status-Session message	*status**256 + *qualifier*	0xFFFF
The return code from **WinLUAGetLastInitStatus**	The return code	0xFFFF

SNA Internationalization Programmer's Reference

This section describes the features available in Host Integration Server 2009 for programming support for international languages and different national language character sets.

The SNANLS API uses the language support features provided with Microsoft Windows Server 2003, Windows XP, and Windows 2000. SNANLS supports European languages that use single-byte encoding, as well as East Asian languages that use double-byte or Unicode encoding.

For general information about programming for SNA internationalization, see SNA Internationalization Programmer's Guide.

In This Section

SNANLS Code Page Support

The SNA National Language Support (SNANLS) API provides functions for converting single-byte character stream (SBCS) EBCDIC-to-Unicode-to-ANSI and SBCS ANSI-to-Unicode-to-EBCDIC by leveraging the Win32 National Language Support (NLS) API. The Win32 NLS API uses resource files containing NLS conversion tables that are installed on the target computer when Windows is installed or installed by the Setup program for Host Integration Server 2009 (the Setup program also adds the required registry entries). The SNANLS DLL is supplied with Host Integration Server.

SNANLS supports conversions for the following groups of code pages:

- ANSI code pages
- ANSI/OEM code pages
- EBCDIC code pages
- OEM PC code pages
- Open Systems code pages
- ISO code pages

In This Section

ANSI Code Page Support Using SNANLS

The following table shows the ANSI code pages and character code set identifiers (CCSIDs) supported by SNA National Language Support (SNANLS) in Host Integration Server 2009.

SNANLS display name	NLS code page	HOST CCSID	Type	NLS file name
ANSI - Arabic	1256	1256	SBCS	c_1256.nls
ANSI - Baltic	1257	1257	SBCS	c_1257.nls
ANSI - Cyrillic	1251	1251	SBCS	c_1251.nls
ANSI - Central Europe	1250	1250	SBCS	c_1250.nls
ANSI - Greek	1253	1253	SBCS	c_1253.nls
ANSI - Hebrew	1255	1255	SBCS	c_1258.nls
ANSI - Latin I	1252	1252	SBCS	c_1252.nls
ANSI - Turkish	1254	1254	SBCS	c_1254.nls

Note

All of these ANSI code pages support the euro.

ANSI/OEM Code Page Support Using SNANLS

The following table shows the ANSI/OEM code pages and character code set identifiers (CCSIDs) supported by SNA National Language Support (SNANLS) in Host Integration Server 2009.

SNANLS display name	NLS code page	Host CCSID	Type	NLS file name	Comments
ANSI/OEM - Japanese Shift-JIS	932	932	SBCS	c_932.nls	Japanese JIS-8 Bit + Shift-JIS
ANSI/OEM - Korean	949	949	DBCS	c_949.nls	Korean Hangul (Extended Wansung)
ANSI/OEM - Simplified Chinese GBK	936	936	DBCS	c_936.nls	Simplified Chinese GBK
ANSI/OEM - Thai	874	874	SBCS	c_874.nls	Thai
ANSI/OEM - Traditional Chinese Big5	950	950	DBCS	c_950.nls	Traditional Chinese Big5
ANSI/OEM - Viet Nam	1258	1258	SBCS	c_1258.nls	Viet Nam

Note

None of these code pages support the euro.

EBCDIC Code Page Support Using SNANLS

The following table shows the EBCDIC code pages and character code set identifiers (CCSIDs) supported by SNA National Language Support (SNANLS) in Host Integration Server 2009.

SNANLS Display Name	NLS Code Page	Host CCSID	euro	Supported by SNANLS
EBCDIC - Arabic	20420	420		partial (See Note)
EBCDIC - Cyrillic (Russian)	20880	880		yes
EBCDIC - Cyrillic (Serbian, Bulgarian)	21025	1025		yes
EBCDIC - Denmark/ Norway (Euro)	1142	277	yes	yes
EBCDIC - Denmark/ Norway	20277	277		yes
EBCDIC - Finland/ Sweden (Euro)	1143	278	yes	yes
EBCDIC - Finland/ Sweden	20278	278		yes
EBCDIC - France (Euro)	1147	297	yes	yes
EBCDIC - France	20297	297		yes
EBCDIC - Germany (Euro)	1141	273	yes	yes
EBCDIC - Germany	20273	273		yes
EBCDIC - Greek (Modern)	875	875		yes
EBCDIC - Greek	20423	423		yes
EBCDIC - Hebrew	20424	424		partial (See Note)
EBCDIC - Icelandic (Euro)	1149	871	yes	yes
EBCDIC - Icelandic	20871	871		yes
EBCDIC - International (Euro)	1148	500	yes	yes
EBCDIC - International	500	500		yes
EBCDIC - Italy (Euro)	1144	280	yes	yes
EBCDIC - Italy	20280	280		yes
EBCDIC - Japan English (Extended)	1027			
EBCDIC - Japan English/Kanji (Extended)	939	939		yes
EBCDIC - Japan English/Kanji (Extended)	5035			
EBCDIC - Japan Katakana (Extended)	290	290		yes

EBCDIC - Japan Katakana/Kanji (Extend Katakana)	930	930		yes
EBCDIC - Japan Katakana/Kanji (Extend Katakana)	5026			
EBCDIC - Japanese	931	931		yes
EBCDIC - Korea (Extended)	933	933		yes
EBCDIC - Latin America/ Spain (Euro)	1145	284	yes	yes
EBCDIC - Latin America/ Spain	20284	284		yes
EBCDIC - Multilingual/ ROECE (Latin-2)	870	870		yes
EBCDIC - Simplified Chinese (Extended)	935	935		yes
EBCDIC - Thai	20838	838		yes
EBCDIC - Traditional Chinese (Extended)	937	937		yes
EBCDIC - Turkish (Latin-3)	20905	905		yes
EBCDIC - Turkish (Latin-5)	1026	1026		yes
EBCDIC - U.S./ Canada (Euro)	1140	37	yes	yes
EBCDIC - U.S./ Canada	37	37		yes
EBCDIC - United Kingdom (Euro)	1146	285	yes	yes
EBCDIC - United Kingdom	20285	285		yes

Note

Support for Arabic and Hebrew code page conversions are limited to left-to-right output. Bidirectional output including the default Arabic and Hebrew right-to-left output is not supported in this release of Host Integration Server.

ISO Code Page Support Using SNANLS

The following table shows the ISO NLS code pages and host character code set identifiers (CCSIDs) supported by SNA National Language Support (SNANLS) in Host Integration Server 2009.

SNANLS display name	NLS code page	Host CCSID	euro	Supported by SNANLS
ISO 6937 Non-Spacing Accent	20269	6937		
ISO 8859-1 Latin-1	28591	819		
ISO 8859-15 Latin 9 (Euro)	20865	923	yes	
ISO 8859-2 Central Europe	28592	912		
ISO 8859-3 Latin 3	28593	913		
ISO 8859-4 Baltic	28594	914		
ISO 8859-5 Cyrillic	28595	915		
ISO 8859-6 Arabic	28596	1089		
ISO 8859-7 Greek	28597	813		
ISO 8859-8 Hebrew (Visually Ordered)	28598	916		
ISO 8859-9 Hebrew (Logically Ordered)	28599	920		

OEM PC Code Page Support Using SNANLS

The following table shows the OEM PC code pages and character code set identifiers (CCSIDs) supported by SNA National Language Support (SNANLS) in Host Integration Server 2009.

SNANLS display name	NLS code page	Host CCSID	Type	NLS file name	Comments
OEM - Arabic	864	864	SBCS	c_864.nls	
OEM - Baltic	775	775	SBCS	c_775.nls	
OEM - Canadian French	863	863	SBCS	c_863.nls	OEM - Canada (850 subset)
OEM - Cyrillic	855	855	SBCS	c_855.nls	
OEM - Cyrillic II	866	866	SBCS	c_866.nls	OEM - Russian
OEM - Greek 437G	737	737	SBCS	c_737.nls	
OEM - Hebrew	862	862	SBCS	c_862.nls	
OEM - Icelandic	861	861	SBCS	c_861.nls	OEM - Iceland
OEM - Modern Greek	869	869	SBCS	c_869.nls	
OEM - Multilingual Latin I	850	850	SBCS	c_850.nls	
OEM - Multilingual Latin II	852	852	SBCS	c_852.nls	
OEM - Nordic	865	865	SBCS	c_865.nls	OEM - Denmark, Norway, Finland, Sweden
OEM - Portuguese	860	860	SBCS	c_860.nls	OEM - Portugal (850 subset)
OEM - Turkish	857	857	SBCS	c_857.nls	
OEM - United States	437	437	SBCS	c_437.nls	

Note

None of these code pages support the euro.

Open Systems Code Page Support Using SNANLS

The following table shows the Open Systems NLS code pages and host character code set identifiers (CCSIDs) supported by SNA National Language Support (SNANLS) in Host Integration Server 2009.

SNANLS display name	NLS code page	Host CCSID	euro	Supported by SNANLS
Latin-1/Open System (Euro)	20924	924	yes	
Latin-1/Open System	1047	1047		

SNANLS Dependencies

The only file required to support the SNA National Language Support (SNANLS) API on Microsoft Windows Server 2003, Windows XP, and Windows 2000 is SNANLS.DLL. To link to this .dll, use the SNANLS.H header (located under the \SDK\INCLUDE subdirectory) and the SNANLS.LIB library file (located under the \SDK\LIB subdirectory) supplied with the Host Integration Server 2009 SDK. Note that individual Win32 NLS resource files must be installed in order to support the various languages and code pages on Windows Server 2003, Windows XP, and Windows 2000.

The Win32 NLS files needed to support various languages are normally installed when the operating system is installed during Setup for Windows Server 2003, Windows XP, and Windows 2000. If these files are not present on Windows Server 2003, Windows XP, and Windows 2000, they may be installed using Regional and Language Options. Click **Start**, then click **Control Panel**. Click **Regional and Language Options**, then click the **Advanced** tab. Select the appropriate settings from this dialog box.

The registry settings required to use specific NLS files are enabled on Windows Server 2003, Windows XP, and Windows 2000 when the operating system is installed. When you install the end-user client or Administrator clients from Host Integration Server 2009, the registry settings required to use specific NLS files are automatically created.

The registry settings required for common EBCDIC code pages are listed in the following table.

File name	SNANLS display name	NLS code page	Host CCSID	Registry setting
c_037.nls	EBCDIC - U.S./ Canada	37	37	Value Name=37 Type=REG_SZ Data=c_037.nls
c_500.nls	EBCDIC - International	500	500	Value Name=500 Type=REG_SZ Data=c_500.nls
c_870.nls	EBCDIC - Multilingual/ ROECE (Latin-2)	870	870	Value Name=870 Type=REG_SZ Data=c_870.nls
c_875.nls	EBCDIC - Greek (Modern)	875	875	Value Name=875 Type=REG_SZ Data=c_875.nls
c_1026.nls	EBCDIC - Turkish (Latin-5)	1026	1026	Value Name=1026 Type=REG_SZ Data=c_1026.nls
c_20273.nls	EBCDIC - Germany	20273	273	Value Name=20273 Type=REG_SZ Data=c_20273.nls
c_20277.nls	EBCDIC - Denmark/ Norway	20277	277	Value Name=20277 Type=REG_SZ Data=c_20277.nls
c_20278.nls	EBCDIC - Finland/ Sweden	20278	278	Value Name=20278 Type=REG_SZ Data=c_20278.nls
c_20280.nls	EBCDIC - Italy	20280	280	Value Name=20280 Type=REG_SZ Data=c_20280.nls
c_20284.nls	EBCDIC - Latin America/ Spain	20285	284	Value Name=20284 Type=REG_SZ Data=c_20284.nls
c_20285.nls	EBCDIC - United Kingdom	20285	285	Value Name=20285 Type=REG_SZ Data=c_20285.nls
c_20297.nls	EBCDIC - France	20297	297	Value Name=20297 Type=REG_SZ Data=c_20297.nls
c_20420.nls	EBCDIC - Arabic	20420	420	Value Name=28596 Type=REG_SZ Data=c_20420.nls

c_20423.nls	EBCDIC - Greek	20423	423	Value Name=20423 Type=REG_SZ Data=c_20423.nls
c_20424.nls	EBCDIC - Hebrew	20424	424	Value Name=20424 Type=REG_SZ Data=c_20424.nls
c_20838.nls	EBCDIC - Thai	20838	838	Value Name=20838 Type=REG_SZ Data=c_20838.nls
c_20871.nls	EBCDIC - Icelandic	20871	871	Value Name=20871 Type=REG_SZ Data=c_20871.nls
c_20880.nls	EBCDIC - Cyrillic (Russian)	20880	880	Value Name=20880 Type=REG_SZ Data=c_20880.nls
c_20905.nls	EBCDIC - Turkish (Latin-3)	20905	905	Value Name=20905 Type=REG_SZ Data=c_20905.nls
c_21025.nls	EBCDIC - Cyrillic (Serbian, Bulgarian)	21025	1025	Value Name=21025 Type=REG_SZ Data=c_21025.nls

Note

On Windows Server 2003, Windows XP, and Windows 2000, the registry settings are located under the **HKEY_LOCAL_MACHINE** under the following sub key: SYSTEM\CurrentControlSet\Control\Nls\CodePage.

SNANLS API Functions

The SNA National Language Support (SNANLS) API is documented in the SNANLS.H file in the software development kit (SDK) provided with Host Integration Server 2009.

SNANLS on Host Integration Server 2009 supports the following functions.

In This Section

- CloseNlsRegistry
- FindCloseCodePage
- FindFirstCodePage
- FindNextCodePage
- GetCodePage
- GetCodePageDisplayStr
- IsInstalledCodePage
- OpenNlsRegistry
- SnaNlsInit
- SnaNlsMapString

CloseNlsRegistry

The SNA National Language Support (SNANLS) **CloseNlsRegistry** function closes an open registry key on a local or remote computer.

Syntax

```
BOOL WINAPI CloseNlsRegistry(
HKEY KeyHandle
);
```

Parameters

KeyHandle

Supplied parameter. The handle to a key in the registry opened using **OpenNlsRegistry**.

Return Value

The **CloseNlsRegistry** function returns zero on success, otherwise a non-zero value is returned on failure.

Remarks

The *KeyHandle* parameter passed to this function is the handle returned from a previous call to the **OpenNlsRegistry** function. This function is primarily used by the Print service in Host Integration Server 2009 to determine what code pages are supported on a remote computer providing the print services function.

SNANLS supports this function on Microsoft Host Integration Server 2009.

FindCloseCodePage

The SNA National Language Support (SNANLS) **FindCloseCodePage** function closes the handle allocated by a call to the **FindFirstCodePage** function.

Syntax

```
BOOL WINAPI FindCloseCodePage(
        const HANDLEhInfo
);
```

Parameters

hInfo

Supplied parameter. The handle allocated and returned using **FindFirstCodePage**.

Return Value

The **FindCloseCodePage** function returns **TRUE** on success, otherwise the returned value on failure is **FALSE**.

Remarks

The *hInfo* parameter passed to this function is the handle returned from a previous call to the **FindFirstCodePage** function.

SNANLS supports this function on Host Integration Server 2009.

FindFirstCodePage

The SNA National Language Support (SNANLS) **FindFirstCodePage** function finds the first instance of a code page satisfying the condition specified, copies the code page information to a structure passed as a parameter, and opens and returns a handle used in subsequent calls to the **FindNextCodePage** function.

Syntax

```
const HANDLE WINAPI FindFirstCodePage(
        DWORDdwEnumOption,
        struct CodePage *pPage
);
```

Parameters

dwEnumOption

Supplied parameter. The set of conditions that a code page should satisfy. These conditions can be any combination of the following values defined in the SNANLS.h include file:

ENUM_CP_AVAILABLE (0x01)

The code page is installed and available for use.

ENUM_CP_HOST (0x02)

The code page is a host code page (EBCDIC, for example).

ENUM_CP_EURO (0x04)

The code page contains support for the euro character.

ENUM_CP_DBCS (0x08)

The code page is for a double-byte character set.

ENUM_CP_MBCS (0x10)

The code page is for a mixed-byte character set.

ENUM_CP_SBCS (0x20)

The code page is for a single-byte character set.

Note that some of these combinations represent cases that will not match any installed code pages used by SNANLS.

pPage

Supplied and returned parameter. A pointer to a struct CodePage where the code page information should be copied.

On a successful return, the memory location pointed to by this parameter will be filled with the information for the first code page satisfying the conditions in *dwEnumOption*. On failure, no changes will be made to the memory pointed to by this parameter.

The CodePage struct is defined in the SNANLS.H include file as follows:

```
struct CodePage {
    BYTE    CodePageKey;
    DWORD   CodePageID;
    WCHAR   szFriendlyName[CP_SIZE];
    short   eGroup;
    BOOL    bAvailable;
    BYTE    bccsid;
    BOOL    bEuro;
};
```

The members of this CodePage structure are as follows:

CodePageKey

A numeric value that represents the index into the array of CodePage structures. This value should be used as an opaque value, since this value can be changed arbitrarily by Service Packs when additional code pages are supported.

CodePageID

The NLS code page number.

szFriendlyName

The SNANLS display name for this code page.

eGroup

The group that this code page is represented by. .This value can be one of the following enumerations defined in the SNANLS.h include file for code groups:

ENUM_CP_EBCDIC

This code page is a member of the EBCDIC code page group.

ENUM_CP_ANSI

This code page is a member of the ANSI code page group.

ENUM_CP_ISO

This code page is a member of the ISO code page group.

ENUM_CP_OEMPC

This code page is a member of the OEM PC code page group.

ENUM_CP_ISO

This code page is a member of the ISO code page group.

ENUM_CP_ISO

This code page is a member of the ISO code page group.

ENUM_CP_OEM PC

This code page is a member of the OEM PC code page group.

ENUM_CP_OPEN

This code page is a member of the Open Systems code page group.

ENUM_CP_UCS

This code page is a member of the UCS code page group.

bAvailable

A Boolean used to indicate that this code page is installed on the computer. A value of **FALSE** for this member indicates that the computer will not be queried to determine if this code page is installed. A value of **TRUE** indicated the code page is installed.

bccsid

A flag used to indicate the type of code page. This flag can be one of the following:

ENUM_CP_DBCS (0x08)

The code page is for a double-byte character set.

ENUM_CP_MBCS (0x10)

The code page is for a mixed-byte character set.

ENUM_CP_SBCS (0x20)

The code page is for a single-byte character set.

bEuro

A Boolean value used to indicate if this code page supports the euro symbol. If this value is **TRUE**, then the euro symbol is

supported.

Return Value

The **FindFirstCodePage** function returns a handle used in calls to the **FindNextCodePage** or **FindCloseCodePage** on success. On failure, INVALID_HANDLE_VALUE is returned for the value of this handle.

Remarks

The handle returned by this function should not be tampered with by the user.

This function is supported by SNANLS on Host Integration Server.

FindNextCodePage

The SNA National Language Support (SNANLS) **FindNextCodePage** function finds the next instance of code page satisfying the condition specified in the initial call to the **FindFirstCodePage** function, and copies the code page information to a structure passed as a parameter.

Syntax

```
BOOL WINAPI FindNextCodePage(
        const HANDLE hInfo
struct CodePage *pPage
);
```

Parameters

hInfo

Supplied parameter. The handle allocated and returned using **FindFirstCodePage**.

pPage

Supplied and returned parameter. A pointer to struct CodePage where the code page information should be copied.

On a successful return, the memory location pointed to by this parameter will be filled with the information for the next code page satisfying the conditions in *dwEnumOption* parameter passed to the **FindFirstCodePage** function.

On failure, no changes will be made to the memory pointed to by this parameter.

The CodePage struct is defined in the SNANLS.H include file as follows:

```
struct CodePage {
    BYTE    CodePageKey;
    DWORD   CodePageID;
    WCHAR   szFriendlyName[CP_SIZE];
    short   eGroup;
    BOOL    bAvailable;
    BYTE    bccsid;
    BOOL    bEuro;
};
```

The members of this CodePage structure are as follows:

CodePageKey

A numeric value that represents the index into the array of CodePage structures. This value should be used as an opaque value, since this value can be changed arbitrarily by Service Packs when additional code pages are supported.

CodePageID

The NLS code page number.

szFriendlyName

The SNANLS display name for this code page. The character string is null terminated.

eGroup

The group that this code page is represented by. .This value can be one of the following enumerations defined in the SNANLS.h include file for code groups:

ENUM_CP_EBCDIC

This code page is a member of the EBCDIC code page group.

ENUM_CP_ANSI

This code page is a member of the ANSI code page group.

ENUM_CP_ISO

This code page is a member of the ISO code page group.

ENUM_CP_OEMPC

This code page is a member of the OEM PC code page group.

ENUM_CP_ISO

This code page is a member of the ISO code page group.

ENUM_CP_ISO

This code page is a member of the ISO code page group.

ENUM_CP_OEM PC

This code page is a member of the OEM PC code page group.

ENUM_CP_OPEN

This code page is a member of the Open Systems code page group.

ENUM_CP_UCS

This code page is a member of the UCS code page group.

bAvailable

A Boolean used to indicate that this code page is installed on the computer. A value of **FALSE** for this member indicates that the computer will not be queried to determine if this code page is installed. A value of **TRUE** indicated the code page is installed.

bccsid

A flag used to indicate the type of code page. This flag can be one of the following:

ENUM_CP_DBCS (0x08)

The code page is for a double-byte character set.

ENUM_CP_MBCS (0x10)

The code page is for a mixed-byte character set.

ENUM_CP_SBCS (0x20)

The code page is for a single-byte character set.

bEuro

A Boolean value used to indicate if this code page supports the euro symbol. If this value is **TRUE**, then the euro symbol is supported.

Return Value

The **FindNextCodePage** function returns a value of **TRUE** on success. On failure, the returned value is **FALSE**.

Remarks

This function is supported by SNANLS on Host Integration Server 2009.

GetCodePage

The SNA National Language Support (SNANLS) **GetCodePage** function copies the code page information identified by a key to a structure passed as a parameter.

Syntax

```
BOOL WINAPI GetCodePage(
        Int nKey
struct CodePage *pPage
);
```

Parameters

nKey

Supplied parameter. The numeric key to a code page. This value is an opaque index into an array containing the code pages supported by SNANLS. This value is normally the *CodePageKey* member of a CodePage structure returned from a previous call to **FindFirstCodePage** or **FindNextCodePage**.

pPage

Supplied and returned parameter. A pointer to struct CodePage where the code page information should be copied.

On a successful return, the memory location pointed to by this parameter will be filled with the information for the specific code page.

On failure, no changes will be made to the memory pointed to by this parameter.

The CodePage struct is defined in the SNANLS.H include file as follows:

```
struct CodePage {
    BYTE    CodePageKey;
    DWORD   CodePageID;
    WCHAR   szFriendlyName[CP_SIZE];
    short   eGroup;
    BOOL    bAvailable;
    BYTE    bccsid;
    BOOL    bEuro;
};
```

The members of this CodePage structure are as follows:

CodePageKey

A numeric value that represents the index into the array of CodePage structures. This value should be used as an opaque value, since this value can be changed arbitrarily by Service Packs when additional code pages are supported.

CodePageID

The NLS code page number.

szFriendlyName

The SNANLS display name for this code page. The character string is null terminated.

eGroup

The group that this code page is represented by. .This value can be one of the following enumerations defined in the SNANLS.h include file for code groups:

ENUM_CP_EBCDIC

This code page is a member of the EBCDIC code page group.

ENUM_CP_ANSI

This code page is a member of the ANSI code page group.

ENUM_CP_ISO

This code page is a member of the ISO code page group.

ENUM_CP_OEMPC

This code page is a member of the OEM PC code page group.

ENUM_CP_ISO

This code page is a member of the ISO code page group.

ENUM_CP_ISO

This code page is a member of the ISO code page group.

ENUM_CP_OEM PC

This code page is a member of the OEM PC code page group.

ENUM_CP_OPEN

This code page is a member of the Open Systems code page group.

ENUM_CP_UCS

This code page is a member of the UCS code page group.

bAvailable

A Boolean used to indicate that this code page is installed on the computer. A value of **FALSE** for this member indicates that the computer will not be queried to determine if this code page is installed. A value of **TRUE** indicated the code page is installed.

bccsid

A flag used to indicate the type of code page. This flag can be one of the following:

ENUM_CP_DBCS (0x08)

The code page is for a double-byte character set.

ENUM_CP_MBCS (0x10)

The code page is for a mixed-byte character set.

ENUM_CP_SBCS (0x20)

The code page is for a single-byte character set.

bEuro

A Boolean value used to indicate if this code page supports the Euro symbol. If this value is **TRUE**, then the euro symbol is supported.

Return Value

The **GetCodePage** function returns a value of **TRUE** on success. On failure, the returned value is **FALSE**.

Remarks

This function is supported by SNANLS on Host Integration Server 2009.

GetCodePageDisplayStr

The SNA National Language Support (SNANLS) **GetCodePageDisplayStr** function copies the SNANLS code page display name identified by a key to a character string passed as a parameter.

Syntax

```
BOOL WINAPI GetCodePageDisplayStr(
Int nKey
WCHAR *szDisplayStr
Int IDisplayStr
);
```

Parameters

nKey

Supplied parameter. The numeric key to a code page. This value is an opaque index into an array containing the code pages supported by SNANLS. This value is normally the *CodePageKey* member of a CodePage structure returned from a previous call to **FindFirstCodePage** or **FindNextCodePage**.

szDisplayStr

Supplied and returned parameter. A pointer to a wide-character array where the SNANLS display name for the specific code page should be copied.

On a successful return, the memory location pointed to by this parameter will be filled with the SNANLS display name for the specific code page. The character string is null terminated.

On failure, no changes will be made to the memory pointed to by this parameter.

IDisplayStr

Represents the number of available characters in the szDisplaystr parameter.

Return Value

The **GetCodePageDisplayStr** function returns a value of **TRUE** on success. On failure, the returned value is **FALSE**.

Remarks

This function is supported by SNANLS on Host Integration Server 2009.

IsInstalledCodePage

The SNA National Language Support (SNANLS) **IsInstalledCodePage** function determines if a code page is installed on a local or remote computer.

Syntax

```
BOOL WINAPI IsInstalledCodePage(
UINTCodePage,
HKEYKeyHandle
);
```

Parameters

CodePage

Supplied parameter. The NLS code page.

KeyHandle

Supplied parameter. The registry key returned from a call to the **OpenNlsRegistry** function.

Return Value

The **IsInstalledCodePage** function returns non-zero if a code page is installed, otherwise a zero value is returned on failure.

Remarks

This function is primarily used by the Print Service in Host Integration Server 2009 to determine if what code pages are supported on a remote computer providing the print services function.

This function is supported by SNANLS on Host Integration Server 2009.

OpenNlsRegistry

The SNA National Language Support (SNANLS) **OpenNlsRegistry** function opens a registry key on a local or remote computer pointing to the NLS Codepage registry entries.

Syntax

```
HKEY WINAPI OpenNlsRegistry(
char *MachineName,
HKEY hkey,
LPSTR Path
);
```

Parameters

MachineName

Supplied parameter. The name of the remote computer on which to open the registry. If this parameter is NULL, the registry on the local computer is opened.

hKey

Supplied parameter. The key to the registry to open. If this parameter is NULL, the **HKEY_LOCAL_MACHINE** key is used.

Path

Supplied parameter. The path to the key value in the registry hive to open. If this parameter is NULL, the following key is opened:

SYSTEM\CurrentControlSet\NLS\CodePage.

Return Value

The **OpenNlsRegistry** function returns a handle to the opened registry key on success, otherwise a NULL value is returned on failure.

Remarks

This function is primarily used by the Print Service in Host Integration Server 2009 to determine if what code pages are supported on a remote computer providing the print services function.

This function is supported by SNANLS in Host Integration Server 2009.

SnaNlsInit

The **SnaNlsInit** function is called to determine if the code page needed is supported by code page translations using SNA National Language Support (SNANLS). This enables an application to determine if the necessary NLS language files containing code page translation tables are installed on the local system.

Syntax

```
int WINAPI SnaNlsInit(
UINTCodePage
);
```

Parameters

CodePage

Supplied parameter. The number of the NLS code page for which support is requested. The *CodePage* parameter corresponds with the registry settings on Microsoft® Windows® 2000 located under the **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Nls\CodePage** subkey.

Return Value

The **SnaNlsInit** function returns non-zero if code page translations are supported; otherwise 0 is returned.

Remarks

If CP_ACP (the current ANSI code page) is passed as the *CodePage* parameter, this functions returns non-zero.

This function is supported by SNANLS on Microsoft® Host Integration Server.

SnaNlsMapString

The **SnaNlsMapString** function is called to translate a string from one code page to another.

Syntax

```
int WINAPI SnaNlsMapString(
LPCTSTR lpSrcStr,
LPTSTR lpDestStr,
UINT inCodePage,
UINT outCodePage,
Int in_length,
int out_length,
UINT in_type,
UINT out_type,
WORD *Options,
LONG*lConvRequiredLen
);
```

Parameters

lpSrcStr

Supplied parameter. The input source string to be translated.

lpDestStr

Returned parameter. The translated string which may be NULL if *out_length* was zero.

inCodePage

Supplied parameter. Specifies the code page of the incoming source string; ignored if the input is Unicode.

outCodePage

Supplied parameter. Specifies the code page of the output translated string; ignored if the output is Unicode.

in_length

Supplied parameter. Specifies the length of the input source string in characters if the input is multibyte or in wide characters if the input is Unicode.

out_length

Supplied parameter. Specifies the maximum length available for the output translated string in characters if the output is multibyte or in wide characters if the output is Unicode.

in_type

Supplied parameter. Specifies the type of the input source string. Possible values for *in_type* are SNA_MULTIBYTE for multibyte and SNA_UNICODE for Unicode.

out_type

Supplied parameter. Specifies the type of the output translated string. Possible values for *out_type* are SNA_MULTIBYTE for multibyte and SNA_UNICODE for Unicode.

Options

Supplied and returned parameter. As a supplied parameter, this specifies a set of options that may be applied to the translation process, including TrnsDT options and the default character for the translation. On return, this parameter indicates the required buffer length for the output translated string if the function call failed.

Return Value

The **SnaNlsMapString** function returns the number of characters or wide characters written to *lpDestStr* on success; otherwise 0 is returned on failure.

On failure, the Win32® **GetLastError** function should be used to return an error code indicating the cause of the failure. Possible values returned by GetLastError are as follows:

ERROR_NOT_SUPPORTED

This error is returned for two possible reasons—either the NLS language resource file is not available or the *in_type* and *out_type* of the source and destination strings are not of the same type.

ERROR_BUFFER_OVERFLOW

This error is returned if the output buffer is too small. In such cases, the *Options* parameter returns with the value needed for *out_length*.

ERROR_INVALID_PARAMETER

This error is returned if a bad value was passed in a parameter; for example, if the *in_type* or *out_type* parameters contained undefined values.

ERROR_INVALID_DATA

This error is returned if a bad value was passed in the *lpSrcStr* parameter; for example, if the input string has a lead byte at the end.

ERROR_OUTOFMEMORY

This error is returned if memory could not be allocated for use by the SNANLS DLL.

TrnsDT API

The SNA National Language Support (SNANLS) API also enables applications to convert double-byte character stream (DBCS) EBCDIC-to-ANSI and DBCS ANSI-to-EBCDIC by leveraging another Host Integration Server 2009 API called TrnsDT. The TrnsDT API has its own mechanism to translate East Asia code pages using conversion table resource files (*.tbl files) that the Setup program for Host Integration Server 2009 installs on the target computer.

In This Section

TrnsDT Code Page Support

The TrnsDT API is used to perform all DBCS EBCDIC-to- ASCII conversions throughout Host Integration Server 2009. To a degree, TrnsDT has been and continues to be a uniform translation method and cross-component resource. TrnsDT also handles mixed DBCS and SBCS, plus SBCS for Japan.

In This Section

Host EBCDIC SBCS Using TrnsDT

The following table shows the character code set identifiers (CCSIDs) for EBCDIC single byte character sets (SBCS) supported by TrnsDT in Host Integration Server 2009.

Code page display name	Type	CCSID	Character set	Comments
IBM EBCDIC - U.S./Canada	SBCS	037	697	IBM English lowercase
IBM EBCDIC - Japan Katakana (Extended)	SBCS	290	1172	IBM Extended English Katakana
IBM EBCDIC - Korean (Extended)	SBCS	833	934	Korean (Extended)
IBM EBCDIC - Simplified Chinese (Extended)	SBCS	836	935	Simplified Chinese single-byte
IBM EBCDIC - Japan English (Extended)	SBCS	1027	1172	IBM Extended lowercase English
IBM EBCDIC - Traditional Chinese (Extended)	SBCS	28709	937	Traditional Chinese (Extended)

Host EBCDIC DBCS Using TrnsDT

The following table shows the character code set identifiers (CCSIDs) for EBCDIC double byte character sets (DBCS) supported by TrnsDT in Host Integration Server 2009.

Code page display name	Type	CCSID	Character set	Comments
IBM EBCDIC - Japan	DBCS	300	1001	IBM Japanese (including 4370 user-defined characters).
IBM EBCDIC - Korea	DBCS	834	933	IBM Korean (including 1880 user-defined characters).
IBM EBCDIC - Traditional Chinese	DBCS	835	937	Traditional Chinese Host double-byte (including 6204 user-defined characters)
IBM EBCDIC - Simplified Chinese	DBCS	837	837	Simplified Chinese Host double-byte
IBM EBCDIC - Japan	DBCS	4396	930, 931, 939	IBM Japanese (including 1880 user-defined characters).

Host EBCDIC Mixed SBCS and DBCS Using TrnsDT

The following table shows the character code set identifiers (CCSIDs) for EBCDIC mixed single byte character sets (SBCS) and double byte character sets (DBCS) supported by TrnsDT in Host Integration Server 2009.

Code page display name	Type	CCSID	Comments
IBM EBCDIC - Japan Katakana/Kanji (Extended)	Mixed	930	Japanese Katakana-Kanji mixed with 4370 user-defined characters.
IBM EBCDIC - Japanese	Mixed	931	Japan (English Lower-Case & Japanese)
IBM EBCDIC - Korea (Extended)	Mixed	933	Korean Mixed with 1880 user-defined characters.
IBM EBCDIC - Simplified Chinese (Extended)	Mixed	935	Simplified Chinese Host mixed with 1880 user-defined characters.
IBM EBCDIC - Traditional Chinese (Extended)	Mixed	937	Traditional Chinese Host mixed with 4370/6204 user-defined characters.
IBM EBCDIC - Japan English/Kanji (Extended)	Mixed	939	Japanese Latin Kanji mixed with 4370 user-defined characters.
IBM EBCDIC - Japan Katakana/Kanji (Extended)	Mixed	5026	A subset of CCSID 930 Japanese Katakana-Kanji mixed.
IBM EBCDIC - Japan English/Kanji (Extended)	Mixed	5035	A subset of CCSID 939 Japanese Latin Kanji mixed.

TrnsDT Conversions Possible

The following table describes conversions possible for the TrnsDT API.

Country/Region	Conversion	From CCSID	To CCSID
Japan	Host-PC	930	932
Japan	Host-PC	931	932
Japan	Host-PC	939	932
Japan	Host-PC	290	932
Japan	Host-PC	1027	932
Japan	Host-PC	5026	932
Japan	Host-PC	5035	932
Japan	PC-Host	932	930
Japan	PC-Host	932	931
Japan	PC-Host	932	939
Japan	PC-Host	932	290
Japan	PC-Host	932	1027
Japan	PC-Host	932	5026
Japan	PC-Host	932	5035
Taiwan	PC-Host	950	937
Taiwan	Host-PC	937	950
Korea	PC-Host	949	933
Korea	Host-PC	933	949
China	PC-Host	936	935
China	Host-PC	935	936

TrnsDT Resource Files

The **TrnsDt** API uses a series of resource files that contain the necessary translation tables, which are listed in the following table.

File name	Description
TRNSDT.DLL	Core global resource used by all TrnsDT conversions
TRNSDTJ.DLL	Core Japanese resource
TRNSDTS.DLL	Core Simplified Chinese (PRC) resource
TRNSDTK.DLL	Core Korean resource
TRNSDTT.DLL	Core Traditional Chinese (Taiwanese) resource
SNADBC.TBL	Japanese double-byte translation tables
SNADBCS.TBL	Simplified Chinese (PRC) double-byte translation tables
SNADBCT.TBL	Simplified Chinese (Taiwanese) double-byte translation tables
SNADBCK.TBL	Korean double-byte translation tables
SNASBC.TBL	Japanese single-byte translation tables
SNASBCS.TBL	Simplified Chinese (PRC) single-byte translation tables
SNASBCK.TBL	Korean single-byte translation tables
SNASBCT.TBL	Traditional Chinese (Taiwanese) single-byte translation tables

TrnsDT API Functions

The TrnsDT API consists of a single function.

In This Section

- TrnsDT
- PASSSTRUCT structure

TrnsDT

The **TrnsDT** function is called to translate a string from one code page to another.

Syntax

```
WORD WINAPI TrnsDt(
PASSSTRUCT far* PassParm);
```

Parameters

PassParm

Supplied parameter. A pointer to a **PASSSTRUCT** structure containing members that must be supplied as well as members that are returned by the function.

Return Value

The **TrnsDT** function returns zero on success. On failure, possible values returned by this function are as follows:

ERR_FILE_NOT_FOUND

This error is returned if the TrnsDT table files (*.tbl) could not be found. Normally **TrnsDT** uses the conversion tables located in the Host Integration Server\System directory on Microsoft® Windows Server™ 2003, Windows® XP, and Windows 2000. If **TrnsDT** cannot find these tables, it searches for them in the current directory.

ERR_INVALID_PARAMETER

This error is returned if a bad value was passed for one or more of the members of the *PassParm* structure. Invalid parameters can include not zeroing the **exit_code** member, passing an **in_length** for the input source string of zero or less or greater than 65535 bytes, passing an **out_length** for the output string buffer of zero or less, passing **in_page** or **out_page** members containing undefined codepage values.

ERR_BUFFER_OVERFLOW

This error is returned if the output buffer is too small for the converted output string. In such cases, the **out_length** member returns with the necessary value in bytes for the output buffer. This error is also returned if the length of the output buffer needed to convert the source string would exceed 65535 bytes.

ERR_MEMORY_ALLOCATE

This error is returned if memory could not be allocated for use by the TrnsDT DLL.

PASSSTRUCT structure

The PASSSTRUCT structure is defined as follows:

Syntax

```
typedef struct tagPassParm {
    WORD    parm_length;
    WORD    exit_code;
    WORD    in_length;
    LPBYTE  in_addr;
    WORD    out_length;
    LPBYTE  out_addr;
    WORD    trns_id;
    WORD    in_page;
    WORD    out_page;
    WORD    option;
} PASSSTRUCT;
```

Members

parm_length

Supplied parameter. The length of the structure passed, normally set to 24. If the **option** member is not needed or used, then this parameter can be set to 22.

exit_code

Supplied and returned parameter. On entry this member must be set to zero. On return, this member indicates the exit status. Legal values for returned **exit_code** values are as follows:

0

Normal exit code indicating function completed successfully.

1

The requested conversion is not supported.

12

The **exit_code** field was not properly initialized to zero.

128

The last character in the source input string was a DBCS lead byte.

256

The conversion could not be successfully completed since the length of the resulting converted destination string exceeds 65535 bytes.

257

An error occurred when trying to load one and initialize one of the TrnsDTx.dll files.

in_length

Supplied parameter. Specifies the length of the input source string in bytes.

in_addr

Supplied parameter. A pointer to the buffer containing the source string to be converted.

out_length

Supplied and returned parameter. Specifies the maximum length available for the output translated string in bytes. On return, this member is set to the length of the converted output string on success or the output buffer length needed if the buffer was too small.

out_addr

Supplied parameter. A pointer to the buffer that will contain the output destination string after conversion.

trns_id

Supplied parameter. The conversion identifier, which is always zero.

in_page

Supplied parameter. Specifies the code page of the incoming source string.

out_page

Supplied parameter. Specifies the code page of the output translated string.

option

Supplied and returned parameter if **parm_length** was set to 24. As a supplied parameter, this specifies a set of options that may be applied to the translation process. Possible values for these options are as follows:

Bits 15-9

Reserved.

Bit 8

Add shift out (SO)/shift in (SI) bytes to the converted output strings.

Bits 3-7

Reserved.

Bit 2

If this bit is set, then convert the input string using the IBM-specified 1-byte code table. This option is only valid when converting from code page 932 to one of the following code pages: 037, 290, 930, or 931.

If this bit is zero, then convert the input source string using the conversion table that is created using the SYSCTBL utility.

In case of double-byte characters, always use the conversion table created by the SYSCTBL utility.

The SYSCTBL.EXE file is a utility program included with Host Integration Server 2009 that provides a tool that can be used to create custom conversion tables for use with the **TrnsDT** function.

Bit 1

If this bit is set, then it indicates that the input source string starts with a 2-byte character. Generally, the host data always includes SO/SI control characters in pairs, but when converting part of mixed data strings, it is necessary to start the conversion from a double-byte character without the SO control character. In this case, the data itself does not have adequate information to determine if it is double-byte or not, so bit 1 must be set.

Bit 0

If this bit is set, then it indicates that the input source string contains SO/SI control characters. Bit 8 and bit 0 should be set as follows:

Conversion from PC to host Bit 8=1, bit 0 =0 Conversion from host to PC Bit 8=0, bit 0=1

On return, **option** is set to 4 if the last character was a double-byte character.

Host Integration Server Components and NLS Support

The following table lists the conversion methods and types used by the various components in Microsoft Host Integration Server 2009.

Component	SNANLS	TrnsDT (DBCS)	Bidirectional layout (Arabic)	Notes
3270 Applet	No	No	No	
5250 Applet	No	No	No	
Security Integration Service	Yes	Yes	No	
Host Security	No	No	No	User identifiers and passwords are converted from computer to host. Only Latin I code pages are supported.
NetView Alert Service	No	No	No	
NetView RunCmd Service	No	No	No	
CSV Convert Verb	No	No	No	
ODBC Driver for DB2	Yes	Yes	Yes	
OLE DB Provider for DB2	Yes	Yes	Yes	
OLE DB Provider for AS/400 and VSAM	Yes	Yes	Yes	
Managed Provider for DB2	Yes	Yes	Yes	
Data Queues ActiveX Control	Yes	Yes	No	
Host File Transfer ActiveX Control	Yes	Yes	No	
Transaction Integrator	Yes	Yes	Yes	

SNA Print Server Data Filter Programmer's Reference

The Host Print Service feature of Host Integration Server 2009 provides server-based 3270 and 5250 printer emulation, enabling host applications to print to a Local Area Network (LAN) printer supported by Microsoft Windows Server 2003, Windows XP, Windows 2000 Server, and Novell NetWare. This section introduces the SNA Print Server Data Filter API (sometimes referred to as the Print Exit API) that can be used to extend the capabilities of the Host Print Service in Host Integration Server.

This print data filter DLL can do the following:

- Send data to the printer when a job starts (print a banner page, for example).
- Perform special processing on the data to be printed.
- Send data to the printer upon print job completion (print a trailer page, for example).

In This Section

SNA Print Server Data Filter API

You configure the path to the print data filter DLL. This DLL is used by all sessions actively using the Host Print service. However, the print data filter DLL can specify whether or not it wants a given session's print data passed to it.

The entry points to this DLL are listed as follows:

PrtFilterAlloc
Obtains a data buffer in which to pass print data.

PrtFilterFree
Indicates that a data buffer obtained previously from the DLL is no longer needed and the DLL can free the memory allocated for this resource.

PrtFilterJobData
Allows the DLL to manipulate print data.

PrtFilterJobEnd
Informs the DLL that a print job has ended.

PrtFilterJobStart
Informs the DLL that a new print job has started and enables the DLL to send special data to the Print Server at the start of a job.

A description of the example sequence of calls during an ordinary print job is listed below to illustrate how these functions are normally used:

- **PrtFilterStartJob** is called when a new print job is started. The DLL can return a data buffer with special data that will be sent to the printer (a special banner page or special printer initialization strings, for example) before printing data.

- **PrtFilterFree** is called if special data was sent in the **PrtFilterStartJob** function and indicates that the data buffer used to pass special data can be freed.

The next sequence of function calls is repeated until all of the print data has been sent:

- **PrtFilterAlloc** is called to allocate a data buffer used to pass print data in the subsequent call to **PrtFilterJobData**.

- **PrtFilterJobData** is called to pass print data to the DLL for possible modification. This allows the user DLL the opportunity to manipulate the printer data before it is sent to the printer. If the modified print data to be returned requires a larger data buffer or the DLL needs to use a different data buffer for returning data, the DLL may need to allocate a new data buffer to return this data. The DLL may also choose to free the data buffer used to pass the incoming print data if a different data buffer is used to return modified print data. The **PrtFilterFree** function will not be called with the pointer to the original data buffer if a different data buffer is returned by **PrtFilterJobData**.

- **PrtFilterFree** is called to indicate that the data buffer allocated by **PrtFilterAlloc** for passing incoming data to the **PrtFilterJobData** function can be freed. If a different data buffer was returned by **PrtFilterJobData**, then **PrtFilterFree** would be called to indicate that a data buffer allocated by the DLL used to return modified print data in the **PrtFilterJobData** function can be freed.

The final sequence occurs when all of the print data has been processed:

- **PrtFilterEndJob** is called to indicate the end of the print job and allows the DLL the option to return special data (a trailer page, for example) that should be sent to the printer.

- **PrtFilterFree** is called if special data was sent in the **PrtFilterEndJob** function and indicates that the data buffer used to pass special data can be freed.

PrtFilterAlloc

The **PrtFilterAlloc** function is called to obtain a data buffer from the user filter DLL in which to pass it the print data.

Syntax

```
            void * WINAPI PrtFilterAlloc(
  DWORD BufLen
);
```

Parameters

BufLen

Supplied parameter. Indicates the length of buffer required.

Return Value

The **PrtFilterAlloc** function allocates a memory block of *BufLen* size and returns a pointer to the buffer. This function should return a NULL pointer on failure.

See Also

Reference

PrtFilterFree

PrtFilterFree

The **PrtFilterFree** function is called to indicate that a data buffer obtained previously from the DLL is no longer needed and the DLL can free the memory allocated for this resource. This function is called for data buffers returned from calls to **PrtFilterAlloc** as well as buffers that were allocated by the DLL to pass data in the **PrtFilterStartJob**, **PrtFilterJobData**, and **PrtFilterEndJob** functions.

Syntax

```
            void WINAPI PrtFilterFree(
  void *pBuf
);
```

Parameters

pBuf

Supplied parameter. Points to the data buffer that can be freed.

See Also

Reference

PrtFilterAlloc

PrtFilterJobData

The **PrtFilterJobData** function is called to give the user DLL the opportunity to manipulate the printer data before it is printed. This allows the DLL to provide custom processing for print data sent to the print server.

Syntax

```
          void WINAPI PrtFilterJobData(
    void *UniqueID,
    char **pBufPtr,
    DWORD *pBufLen  );
```

Parameters

UniqueID

Supplied parameter. The *UniqueID* value returned by the **PrtFilterJobStart** function to identify a print job.

pBufPtr

The print server passes the print data received from the host to the user DLL for processing in this incoming buffer. The user DLL returns to the print server a pointer to an outgoing buffer of data to be printed. This outgoing buffer pointer can be different from the received buffer pointer because the print data filter DLL can modify the data. Note that in this case **PrtFilterFree** will only be called by the Host Print Service for the outgoing buffer pointer. If necessary, the print data filter DLL must call its own free function on the incoming buffer pointer that was supplied to the **PrtFilterJobData** function. This incoming buffer was allocated by a Host Print Service by a previous call to **PrtFilterAlloc.**

pBufLen

Indicates the length of the data passed in the buffer to the print server and the length of the buffer returned to the print server by the user-provided DLL.

Remarks

The data in the buffer is printable ASCII and/or printer control sequences if these are being sent in the print jobs. The buffer returned by the user DLL does not have to be the same as the buffer passed in. The returned buffer will always be freed by calling **PrtFilterFree** after the data has been spooled. The unique identifier parameter *UniqueID* is the identifier returned from a previous call to the **PrtFilterJobStart** function.

See Also

Reference

PrtFilterFree

PrtFilterJobStart

PrtFilterJobEnd

The **PrtFilterJobEnd** function is called to inform the print data filter DLL that a print job is about to end. This allows the DLL to provide custom processing and send special data to the print server at the end of a print job.

Syntax

```
            void * WINAPI PrtFilterJobEnd(
  void *UniqueID,
  char **pBufPtr,
  DWORD *pBufLen
);
```

Parameters

UniqueID

Supplied parameter. The *UniqueID* value returned by the **PrtFilterJobStart** function to identify a print job.

pBufPtr

Returned parameter. Specifies a pointer to a buffer pointer holding additional data to be printed by the print server.

pBufLen

Returned parameter. Pointer to the length of the data provided by the print data filter DLL in the buffer.

Remarks

No data is passed in the buffer, but the user DLL can return print data which will be sent to the printer before the print job is ended.

See Also

Reference

PrtFilterJobStart

PrtFilterJobStart

The **PrtFilterJobStart** function is called to inform the print data filter DLL that a new job has just been started. This allows the DLL to provide custom processing and send special data to the print server at the beginning of a job.

Syntax

```
          void * WINAPI PrtFilterJobStart(
    char *SessionName,
    DWORD LUType,
    char **pBufPtr,
    DWORD *pBufLen      );
```

Parameters

SessionName

Supplied parameter. The name of the print session which has just started a print job. The *SessionName* is the same as that configured in using the SNA Print Service Admin tool.

LUType

Supplied parameter. Specifies the printer type. Valid values are LU 1, LU 3, or LU 6.2 printers, represented by an *LUType* value of 1, 3, or 6.

pBufPtr

Returned parameter. Specifies a pointer to a buffer pointer holding additional data to be printed by the print server.

pBufLen

Returned parameter. Pointer to the length of the data provided by the print data filter DLL in the buffer.

Return Value

The **PrtFilterJobStart** function returns a unique identifier (cast to a pointer to a void) if it wants the opportunity to filter the data for this print job.

If the user DLL returns a NULL pointer, it is indicating that it is not interested in filtering this job. No further calls to the user DLL will be made for this print job.

Remarks

No data is passed in the data buffer to the print data filter DLL in this call, but the DLL can return data in *pBufPtr* (for example, a banner page). The data returned from this call should be printable ASCII and/or printer control sequences.

SNADIS Drivers Programmer's Reference

This section provides reference material for developers writing their own SNALink software.

In This Section

Base/DMOD and SNALink Entry Points

This section gives definitions for Base/DMOD and SNALink entry points that must be supplied in an SNALink.

In This Section

SNAGetBuffer

The **SNAGetBuffer** function is called by an application to get a buffer with a requested number of elements.

```
PTRBFHDR SNAGetBuffer(
INTEGER numelts
);
```

Parameters
numelts

Number of elements required.

Return Values

A pointer to the buffer obtained. NULL if a buffer could not be obtained.

Remarks

Each element has a size of 268, the constant SNANBEDA in the header file SNA_DLC.H.

The returned buffer consists of a header and the required number of elements. The header points to the first element, which points to the next element and so on to make an element chain.

It is possible to add an element to an existing buffer by calling SNAGetElement to get the extra element. The new element should be added to the element chain of the buffer, and the number of elements count should be updated.

The application must release any buffers that are not transmitted.

SNAGetElement

The **SNAGetElement** function is called by an application to get a buffer element to append to an existing buffer.

```
VOID SNAGetElement(
PTRBFELT *eltptr
);
```

Parameters
eltptr

Pointer to a pointer to an element. On return, this points to a pointer to the element obtained, or to NULL if an element was not obtained (an internal error).

Remarks

This function should only be used to get extra elements for an existing buffer. SNAGetBuffer should be used to get a new buffer.

The new element should be added to the chain of elements from the existing buffer header and the count of the number of elements updated.

This function is typically used when a received buffer is being reused to transmit a message that is longer than the incoming message.

SNAGetLinkName

The SNALink can call the **SNAGetLinkName** function to obtain its configured SNALink name.

```
VOID SNAGetLinkName(
VCHAR *linkname
);
```

Parameters
linkname

A pointer to a buffer where the NULL-terminated SNALink name is stored.

Remarks

The buffer should be at least nine bytes in length.

SNAGetVersion

The **SNAGetVersion** function returns the major version number in the low byte and minor version number in the high byte.

```
VSHORT FAR SNAGetVersion(void);
```

SNALinkDispatchProc

The **SNALinkDispatchProc** function is the link dispatcher function. The Base calls this function whenever one of the following events occurs:

- A message arrives for the link.
- The Base timer expires.
- Contact is lost with the local node.

```
VOID SNALinkDispatchProc(
PTRBFNDR msgptr,
INTEGER function,
INTEGER locality
);
```

Parameters

msgptr

The message to be processed, or NULL if some other event is being notified.

function

The reason for **SNALinkDispatchProc** being called.

locality

L value (only valid for function SBLOST).

Remarks

The *function* parameter can have one of three values:

- 0—Message received.
- SBLOST—Contact lost with local node; L-value of locality.
- SBTICK—Base timer has expired; occurs every five seconds.

For suggested usage of this function, see Sample Code for SNALinkDispatchProc.

SNALinkInitialize

The **SNALinkInitialize** function initializes the SNALink. The Base calls this function when the SNALink is loaded into memory.

```
VOID SNALinkInitializer(
HANDLE event
);
```

Parameters
event

A handle to the global Base event.

Remarks

This function should:

- Read in required configuration information.
- Perform any required initialization of the hardware or device driver.
- Set up control blocks and data structures required internally by the SNALink.

SNALinkTerminate

The **SNALinkTerminate** function terminates the SNALink. The Base calls this function, when present, during service shutdown. This allows the DLL to free memory, release system resources (such as events), and close drivers.

```
VOID SNALinkTerminate(void);
```

Remarks

This function must not send messages to other SNA components.

SNALinkWorkProc

The **SNALinkWorkProc** function is the work manager function. The Base calls this function whenever the global Base event is triggered by the SNALink, or at least once every five seconds.

```
VOID SNALinkWorkProc(void);
```

Remarks

This function can be used to perform any general processing required by the SNALink, in particular to process messages received from the link.

SNAReleaseBuffer

The **SNAReleaseBuffer** function is called by an application to release a buffer.

```
VOID SNAReleaseBuffer(
PTRBFHDR msgptr
);
```

Parameters
msgptr

Pointer to the buffer to be released.

Remarks

It is important that buffers are released after use. This is done automatically when a message is transmitted. For messages received, it is the responsibility of the application either to release or to reuse the buffer.

This function releases both the buffer header and any associated buffer elements. It is possible to release single elements from a buffer by using the function SNAReleaseElement.

SNAReleaseElement

The **SNAReleaseElement** function is called by an application to release a buffer element from an existing buffer.

```
VOID SNAReleaseElement(
PTRBFELT *eltptr
);
```

Parameters
eltptr

Pointer to a pointer to the element to be released.

Remarks

This function should only be used to release surplus elements from a buffer. SNAReleaseBuffer should be called to release the entire buffer.

The released element should first be removed from the element chain and the count of the number of elements updated.

This function is typically used when a received buffer is being reused to transmit a message that is shorter than the incoming message.

SNASendAlert

The SNALink calls the **SNASendAlert** function to send a complete preformatted Network Management Vector Transport (NMVT) alert to NetView.

```
VOID SNASendAlert(
PTRBFHDR msgptr,
INTEGER severity
);
```

Parameters

msgptr

Pointer to the NMVT alert to be sent.

severity

The severity of the problem that caused the alert (ranges from 0 through 16).

Remarks

The complete NMVT to be sent must be generated by the SNALink and inserted into a buffer. Only the elements are used—the buffer header need not be set up before sending. The fields **startd** and **endd** should be set to reflect the location of the NMVT within the element. Multiple elements can be used to store the NMVT, up to a maximum length of 512 bytes. The buffer will be freed by the Base after the NMVT has been sent.

Any NMVT sent refers to a particular Host Integration Server 2009 connection. It is recommended that the NMVT include at least a hierarchy resource list, giving the name of the remote physical unit (PU) that the connection is associated with. This name is supplied to the SNALink on the Open(STATION) message.

For complete details of the format of an NMVT, see the IBM manual *SNA Formats* (GA27-3136).

SNASendMessage

The **SNASendMessage** function is called by an application to send messages to other localities (in the case of an SNALink, the local 2.1 node).

```
VOID SNASendMessage(
PTRBFHDR *msgptr
);
```

Parameters
msgptr

Pointer to message to be sent.

Remarks

The locality, partner, index (LPI) values on the message should be set up to reference the correct connection for the data to be passed.

SNADIS Message Formats

This section describes the SNA Device Interface Specification interface in terms of message formats. These are presented in a language-independent notation that is described below.

The messages used between the node and the SNALinks are shown in the following table.

Message type	Direction	LPI connection
Open(LINK)Request	NODE ------> DLC	LINK
Close(LINK)Request	NODE ------> DLC	LINK
Send-XID	NODE ------> DLC	LINK
Open(STATION) Request	NODE ------> DLC	STATION
Close(STATION) Request	NODE ------> DLC	STATION
Open(LINK) Response	NODE <------ DLC	LINK
Close(LINK) Response	NODE <------ DLC	LINK
Request-Open-Station	NODE <------ DLC	LINK
Open(STATION) Response	NODE <------ DLC	STATION
Close(STATION) Response	NODE <------ DLC	STATION
Station-Contacted	NODE <------ DLC	STATION
Outage	NODE <------ DLC	LINK/STATION
DLC-Data	NODE <-----> DLC	STATION
Status-Resource	NODE <-----> DLC	STATION

Details of the message format notation and key assumptions about the contents of the message formats are as follows:

- "Reserved" indicates that the field must be set to zero (for a numeric field) or all nulls (for names) by the sender of the message.
- "Undefined" indicates that the value of the field is indeterminate. The field is not set by the sender and should not be examined by the receiver of the message.
- Fields that occupy two bytes — the **srci** field in all messages, and fields such as **opresid** in Open(LINK) Request — are represented with the arithmetically most significant byte in the lowest byte address, irrespective of the normal byte order used by the processor on which the software executes. That is, the 2-byte value 0x1234 has the byte 0x12 in the lowest byte address. The exception to this is the **startd** and **endd** fields in all elements, which are always stored in the processor's normal byte order.
- Messages are composed of buffers, consisting of a buffer header and zero or more buffer elements. For more information on buffer formats, see Messages.
- The **startd** field in each element gives the offset of the first byte of data in the element after the **trpad** field. Its value will either be 1 (data starts in the byte after the **trpad** field), 10 (nine bytes of padding are included between the **trpad** field

and the start of the data), or 13 (12 bytes of padding are included between the **trpad** field and the start of the data). Any extra bytes are used by the local node for additional header information. This avoids having to copy data into a new buffer when adding this information.

- Because **startd** indicates the index into **dataru** starting from 1, not 0, the first byte of valid data will always be at **dataru[startd–1]**.

- All fields within **dataru** are of type unsigned character (UCHAR), except where the notes indicate otherwise.

In This Section

Open(LINK)

Open(LINK) is used by the node to open the LINK LPI connection.

Open(LINK) Request

Flow : NODE ------> DLC

Header

Field	Type	Description
nxtqptr	PTRBFHDR	Pointer to next buffer header in a queue.
hdreptr	PTRBFELT	Pointer to first buffer element.
numelts	CHAR	Number of buffer elements: 1 (Number of elements can be 2 if the connection is for an X.25 SVC).
msgtype	CHAR	Message type: OPENMSG (0x01).
srcl	CHAR	Source locality.
srcp	CHAR	Source partner.
srci	INTEGER	Source index.
destl	CHAR	Destination locality.
destp	CHAR	Destination partner.
desti	INTEGER	Destination index.
ophdr.openqual	CHAR	Open qualifier: REQU (0x01).
ophdr.opentype	CHAR	Open type: LINK (0x10).
ophdr.opresid	INTEGER	Resource identifier.

Element 1

Field	Type	Description
hdreptr–>elteptr	PTRBFELT	Pointer to optional second buffer element (NULL if only one element).
hdreptr–>startd	INTEGER	Index to start of data in this buffer element's data array.
hdreptr–>endd	INTEGER	Index to last byte of data in this buffer element's data array.
hdreptr–>dataru	CHAR[SNANBEDA]	Defined as follows, where s = startd–1
dataru[s..s+9]	Not applicable	Source name — name of local node.
dataru[s+10..s+19]	Not applicable	Destination name—name of remote PU (blank for incoming calls).
dataru[s+20..s+21]	Not applicable	Link index.

Link Data (depends on DLC type)

Unless otherwise stated, these fields are valid for outgoing calls only.

SDLC link data field	Description
dataru[s+22]	XID supplied 0x00 Do not send initial XID 0x01 Send initial XID from this message (may be a NULL XID)
dataru[s+23]	Link operational role 0x00 Primary 0x01 Secondary 0x02 Negotiable
dataru[s+24]	Use Reject_Command indicator 0x00 Do use it 0x01 Do not use it
dataru[s+25]	Address match byte 0x00 Primary/Negotiable SDLC 0x01 to 0xFE Secondary SDLC
dataru[s+26]	Second SDLC address match byte 0x00 Primary SDLC 0xFF Secondary/Negotiable SDLC
dataru[s+27]	Reserved

Channel adapter link data	Description
dataru[s+22]	XID supplied. 0x00 Do not send initial XID. 0x01 Send initial XID from this message (may be a NULL XID).
dataru[s+23]	PU emulation type. 0x00 Unknown. 0x20 PU 2.0 (format 0 XID). 0x21 PU 2.1 (format 3 XID).
dataru[s+24]	Control Unit Image number (0 to 15) on the Channel address configured in SNA Manager.
dataru[s+25]	Channel subaddress.
dataru[s+26..s+67]	Reserved (may not be zero).

Station timers	Description
dataru[s+28..s+29]	Contact time-out.
dataru[s+30..s+31]	Contact retry limit.
dataru[s+32..s+33]	Discontact time-out.
dataru[s+34..s+35]	Discontact retry limit.
dataru[s+36..s+37]	Negative poll time-out.
dataru[s+38..s+39]	Negative poll retry limit.
dataru[s+40..s+41]	T1 (no acknowledgment) time-out.
dataru[s+42..s+43]	T2 (acknowledgment) time-out.
dataru[s+44..s+45]	Remote station busy time-out.
dataru[s+46..s+47]	Remote station busy retry limit.

Link timers	Description
dataru[s+48..s+49]	Idle time-out.

dataru [s+50.. s+51]	Idle retry limit.
dataru [s+52.. s+53]	Nonproductive receive time-out.
dataru [s+54.. s+55]	Nonproductive receive retry limit.
dataru [s+56.. s+57]	Write time-out.
dataru [s+58.. s+59]	Write retry limit.
dataru [s+60.. s+61]	Link connection time-out.
dataru [s+62.. s+63]	Link connection retry limit. 0xFFFF for infinite retry.
dataru [s+64.. s+65]	Reserved.
dataru [s+66]	Configuration options: Bit 0 : 1 = Constant carrier selected Bit 1 : 1 = NRZI 0 = NRZ Bit 2 : = Reserved Bit 3 : 1 = Full-duplex 0 = Half-duplex Bit 4 : 0 = External clocking Bit 5 : 1 = Data signal rate select high 0 = Data signal rate select low Bit 6 : 1 = Select standby on 0 = Select standby off Bit 7 : = Reserved
dataru [s+67]	Configuration options: line type 0x00 leased 0x01 switched manual dial 0x02 switched auto-dial

Note that for configuration options, bit 0 is the most significant option and bit 7 is the least significant. Reserved bits are not always zero, so always use a bitwise **AND** operation when testing these bits.

The configuration options byte is also valid for incoming calls.

- Optional Second Element (Only Used by X.25 SVC)

Expanded Information About Message Formats for Open(LINK) Request with SDLC

The following list supplements the information found in the table in Open(LINK) Request. The timers described in the lists are used by a synchronous data link control (SDLC) link service to determine when to retry communication and when to generate outages. Generally, after the time interval specified by the time-out (usually 1000 milliseconds), the communication is retried. The cycle of time-out and retry is repeated until the retry limit is reached. Then an Outage message is sent by the SDLC link service.

With some timers, there are no communication retries. Such timers simply cycle through the time-out as many times as allowed in the retry limit (without actually retrying), then generate an **Outage** message.

Each description indicates whether you can configure the field through a Microsoft Host Integration Server 2009 interface (such as the SNA Manager program). If the field is not configurable, the built-in setting for the field is shown.

SDLC Link Data

- *dataru[s+22] XID supplied*

  This field controls whether an initial exchange identification (XID) is sent on this connection. The value used is determined by the leased or switched setting for the line:

  Leased line: 0x00 Do not send an initial XID. Switched line: 0x01 Send an initial XID (may be a NULL XID).

  A line is configured as leased or switched in Host Integration Server Setup.

- *dataru[s+24] Use Reject_Command indicator*

  This field determines that the link service will not send a Reject command (an SDLC command, not often used, value 0x19) if a frame is received with an invalid next-to-send (NS) value. Instead, the link service waits until the next poll before requesting retransmission of the frame.

  This field is not configurable and must remain at the setting of "Do not use."

- *Station Timers (described for SDLC only)*

- dataru[s+28..s+29] Contact time-out

- dataru[s+30..s+31] Contact retry limit

  This timer is started when an XID or set normal response mode (SNRM) is transmitted. If the time-out expires without acknowledgment, the frame is retransmitted. When the number of retransmitted frames reaches the retry limit, an outage is generated. Note that for XIDs, the time-out value is randomized to prevent possible clashes between two servers sending XIDs simultaneously.

  This timer is configurable in SNA Manager, in the advanced settings for an SDLC connection.

- *dataru[s+32..s+33] Discontact time-out*

- *dataru[s+34..s+35] Discontact retry limit*

  This timer is started when a discontact (DISC) is sent. It is stopped when an unnumbered acknowledgment (UA) or disconnect mode (DM) is received. If the number of sent DISCs reaches the retry limit, an outage is generated.

  This timer is not configurable. The discontact time-out is 1000 milliseconds; the discontact retry limit is 3.

- *dataru[s+36..s+37] Negative poll time-out*

- *dataru[s+38..s+39] Negative poll retry limit*

  This timer is used for primary SDLC only. At intervals specified by the negative poll time-out, a receive ready (RR) is transmitted. The negative poll retry limit is set at no limit; therefore, no outage is generated, no matter how many RRs are transmitted without acknowledgment being received.

  The negative poll time-out is configurable in SNA Manager, in the advanced settings for an SDLC connection, where the time-out is called poll rate. Poll rate is set in polls per second (and translated internally into the negative poll time-out, timed in milliseconds).

  The negative poll retry limit is not configurable. It is set at –1, meaning no limit.

- *dataru[s+40..s+41] T1 (no acknowledgment) time-out*

- *dataru[s+42..s+43] N2 (no acknowledgment) retry limit*

  This timer is used for primary SDLC and is started when a poll/final bit is expected. If the time-out expires before a frame containing a poll/final bit is received, an RR is sent. When the number of sent RRs reaches the retry limit, an outage is generated.

  This timer is configurable in SNA Manager, in the advanced settings for an SDLC connection, where it is called the poll time-out and poll retry limit.

- *dataru[s+44..s+45] Remote station busy time-out*

- *dataru[s+46..s+47] Remote station busy retry limit*

  This timer is used for primary SDLC and is started when a receive not ready (RNR) is received. It is stopped when an RR is received. If the time-out expires the number of times specified by the retry limit, an outage is generated.

  This timer is not configurable. The remote station busy time-out is 1000 milliseconds. The remote station busy retry limit is 30. Therefore, the time allowed before an outage is 30 seconds.

Link Timers (described for SDLC only)

- *dataru[s+48..s+49] Idle time-out*

- *dataru[s+50..s+51] Idle retry limit*

  This timer is configurable in SNA Manager, in the advanced settings for an SDLC connection.

- *dataru[s+52..s+53] Nonproductive receive time-out*

- *dataru[s+54..s+55] Nonproductive receive retry limit*

  This timer is used for secondary SDLC only and is started when any frame is received for this station. It is stopped when additional frames are received for this station. If the time-out expires the number of times specified by the retry limit, the link service causes a pop-up message, but does not generate an outage (because multidrop lines can be very slow).

  This timer is not configurable. The nonproductive receive time-out is 1000 milliseconds (1 second); the nonproductive receive retry limit is 60. Therefore, the time allowed before a pop-up message is 60 seconds.

- *dataru[s+56..s+57] Write time-out*

- *dataru[s+58..s+59] Write retry limit*

  This timer is started after an information frame has been transmitted to the hardware and stopped when the hardware

acknowledges the frame. If the time-out expires the number of times specified by the retry limit, an outage is generated.

This timer is not configurable. The write time-out is 1000 milliseconds (one second). The write retry limit is 15. Therefore, the time allowed before an outage is 15 seconds.

- *dataru[s+60..s+61] Link connection time-out*

- *dataru[s+62..s+63] Link connection retry limit*

This timer is started when an open link for a leased line is received, and stopped when Data Set Ready (DSR) is raised. If the time-out expires the number of times specified by the retry limit, an outage is generated.

This timer is not configurable. The link connection time-out is 1000 milliseconds (one second). The link connection retry limit is 300. Therefore, the time allowed before an outage is 300 seconds.

X.25 link data	**Description**
dataru[s+22]	Circuit type 0x00 PVC 0x01 SVC
dataru[s+23]	PVC alias, starting at 1 for lowest PVC channel number (reserved for SVC).
dataru[s+24..s+25]	PVC packet size (reserved for SVC).
dataru[s+26]	Default level 3 window size for PVC (reserved for SVC).
dataru[s+27]	Link role: 0x00 Primary 0x01 Secondary 0x02 Negotiable

802.2 link data	**Description**
dataru[s+22]	Maximum receives without a transmit acknowledgment.
dataru[s+23]	Maximum transmits without a receive acknowledgment.
dataru[s+24]	Dynamic window increment value.
dataru[s+25]	Remote local service access point (SAP) address.
dataru[s+26]	Local SAP address (for incoming calls).
dataru[s+27]	Value for t1 timer multiplier.
dataru[s+31]	Value for t2 timer multiplier.
dataru[s+35]	Value for t3 timer multiplier.
dataru[s+42]	Maximum retry count (N2 value). Note that this 802.2 link data is required for the 802.2 command DLC.OPEN.STATION.

Note that if the fields in the preceding table for timer multipliers are set to zero, the SNALink should use appropriate defaults.

End of link data section	**Description**
dataru[s+68..s+69]	Length of link connection data (= a) (0x0000) None present
dataru[s+70..s+70+a]	Link connection data

dataru[s+70+b..s+71+b]	Where b is maximum of a and 20. Size of XID I-frame (= n) (0x0000) NULL XID
dataru[s+72+b]	XID

Note that if there are 20 or fewer bytes of link connection data, the XID length is at s+90 and the actual XID starts at s+92.

The link connection data can contain one of the following:

- Media access control (MAC) address of remote station
- X.25 address of remote station
- Dial-digits for manual or auto-dial modems

Optional Second Element (Only Used by X.25 SVC)

Element 2

Field	Type	Description
hdreptr–>elteptr–>eltept r	PTRBFELT	Pointer to next buffer element: NULL
hdreptr–>elteptr–>startd	INTEGER	Index to start of data in this buffer element's data array: 1
hdreptr–>elteptr–>endd	INTEGER	Index to last byte of data in this buffer element's data array
hdreptr–>elteptr–>datar u	CHAR[SNANBEDA]	Defined as follows, where s = startd–1
dataru[s]	Not applicable	Length of facilities data field (= c) inclusive of this length byte 0x01 no facilities d ata
dataru[s+1..s+c–1]	Not applicable	CHAR[c–1]Facilities data
dataru[s+c]	Not applicable	CHARLength of user data field (= d) inclusive of this length byte 0x01 no user dat a
dataru[s+c+1..s+c+d]	Not applicable	User data

Open(LINK) Response

Flow : DLC ------> NODE

Header

Field	Type	Description
nxtqptr	PTRBFHDR	Pointer to next buffer header in a queue
hdreptr	PTRBFELT	Pointer to first buffer element
numelts	CHAR	Number of buffer elements: 1
msgtype	CHAR	Message type: OPENMSG (0x01)
srcl	CHAR	Source locality
srcp	CHAR	Source partner
srci	INTEGER	Source index
destl	CHAR	Destination locality
destp	CHAR	Destination partner
desti	INTEGER	Destination index
ophdr.openqual	CHAR	Open qualifier - RSPOK (0x02) - RSPERR (0x03)
ophdr.opentype	CHAR	Open type - LINK (0x10)
ophdr.opresid	INTEGER	Resource identifier
ophdr.oprr1	INTEGER	Error code (see immediately following the table)
ophdr.oprr2	INTEGER	Reserved
hdreptr–>elteptr	PTRBFELT	Pointer to next buffer element: NULL
hdreptr–>startd	INTEGER	Index to start of data in this buffer element's data array: 1
hdreptr–>endd	INTEGER	Index to last byte of data in this buffer element's data array
hdreptr–>dataru	CHAR[SNANBEDA]	Defined as follows, where s = startd–1
dataru[s..s+9]	Not applicable	Source name—same as destination name from **Open(LINK) Request**
dataru[s+10..s+19]	Not applicable	Destination name—name of local node; same as source name from **Open(LINK) Request**

dataru[s+22..s+23]	Not applicable	The maximum BTU size supported by SNALink. This size is 65,536 (largest number in an unsigned short) for channel connections and 32,768 for non-channel connections. Note that this limit does not guarantee that the SNA connection will actually use this value. The individual link service or the host can negotiate it downward.

The error codes (for an ERROR-RESPONSE) are defined as follows in SNA_CNST.H:

Symbolic constant	Value	Description
ERINIFAIL	0x01	Hardware initialization failed
ERINVXID	0x08	Invalid XID length
ERLINKOPN	0x09	Link already open
ERLLCERR	0x0A	LCC error; fatal hardware failure
ERBADINDX	0x0B	Invalid link index
ERBADOPN	0x0C	**Open(LINK)** has insufficient data
ERCONNTO	0x0D	Link connection time-out
ERNORES	0x0E	Maximum connection count reached –or– No more internal control blocks
EROPNPND	0x11	**Close(LINK)** arrived while **Open(LINK)** pending
ERDUPREQ	0x12	Duplicate request

Close(LINK)

Close(LINK) is used by the node to close the LINK LPI connection.

Close(LINK) Request

Flow : NODE ------> DLC

Header

Field	Type	Description
nxtqptr	PTRBFHDR	Pointer to next buffer header in a queue
hdreptr	PTRBFELT	Pointer to first buffer element: NULL
numelts	CHAR	Number of buffer elements: 0
msgtype	CHAR	Message type: CLOSEMSG (0x02)
srcl	CHAR	Source locality
srcp	CHAR	Source partner
srci	INTEGER	Source index
destl	CHAR	Destination locality
destp	CHAR	Destination partner
desti	INTEGER	Destination index
clhdr.closqual	CHAR	Close qualifier: REQU (0x01)
clhdr.clstype	CHAR	Close type: LINK (0x10)

Note that the message consists of a buffer header only.

Close(LINK) Response

Flow : DLC ------> NODE

Header

Field	Type	Description
nxtqptr	PTRBFHDR	Pointer to next buffer header in a queue
hdreptr	PTRBFELT	Pointer to first buffer element: NULL
numelts	CHAR	Number of buffer elements: 0
msgtype	CHAR	Message type: CLOSEMSG (0x02)
srcl	CHAR	Source locality
srcp	CHAR	Source partner
srci	INTEGER	Source index
destl	CHAR	Destination locality
destp	CHAR	Destination partner
desti	INTEGER	Destination index
clhdr.closqual	CHAR	Close qualifier - RSPOK (0x02) - RSPERR (0x03)
clhdr.clstype	CHAR	Close type: LINK (0x10)
clhdr.clserr1	INTEGER	Error code (see immediately following the table)

The error codes (for an ERROR-RESPONSE) are defined as:

- 0x03 — Link not open
- 0x04 — Invalid link index

Note
The **Close(LINK)** message unconditionally shuts down the link.

Open(STATION)

Open(STATION) is used by the node to open the STATION LPI connection.

Open(STATION) Request

Flow : NODE ------> DLC

Header

Field	Type	Description
nxtqptr	PTRBFHDR	Pointer to next buffer header in a queue
hdreptr	PTRBFELT	Pointer to first buffer element
numelts	CHAR	Number of buffer elements: 1
msgtype	CHAR	Message type: OPENMSG (0x01)
srcl	CHAR	Source locality
srcp	CHAR	Source partner
srci	INTEGER	Source index
destl	CHAR	Destination locality
destp	CHAR	Destination partner
desti	INTEGER	Destination index
ophdr.openqual	CHAR	Open qualifier: REQU (0x01)
ophdr.opentype	CHAR	Open type: STAT (0x11)
ophdr.opresid	INTEGER	Resource identifier
ophdr.icreditr	INTEGER	Initial credit for flow DLC –> NODE

Element

Field	Type	Description
hdreptr–>elteptr	PTRBFELT	Pointer to optional second buffer element (NULL if only one element)
hdreptr–>startd	INTEGER	Index to start of data in this buffer element's data array: 1
hdreptr–>endd	INTEGER	Index to last byte of data in this buffer element's data array
hdreptr–>dataru	CHAR[SNANBEDA]	Defined as follows, where s = startd–1
dataru[s..s+9]	Not applicable	Source name—name of local node
dataru[s+10..s+19]	Not applicable	Destination name
dataru[s+20..s+21]	Not applicable	Link index as specified in **Open(LINK) Request**
dataru[s+22]	Not applicable	If NODE is primary, address of secondary station to initiate contact procedure with. 0x00 if NODE is secondary

dataru[s+23]	Not applicable	FID2 indicator 0x00 FID2 used
dataru[s+24]	Not applicable	Station type 0x00 Subarea 0x01 Peer
dataru[s+25..s+26]	Not applicable	Length of network name from received XID 0000 = No name
dataru[s+27..s+27+n]	Not applicable	Network name from received XID, in local character set, or if this is null, the name of the remote PU record in the COM.CFG file. This name can be fully qualified and has a maximum length of 17 characters.
dataru[s+44..s+89]	Not applicable	Link data—a copy of that supplied on the **Open(LINK) Request**
dataru[s+90..s+91]	Not applicable	The maximum BTU size to be used with this station. This size is 65,536 (largest number in an unsigned short) for channel connections and 32,768 for non-channel connections. Note that this limit does not guarantee that the SNA connection will actually use this value. The individual link service or the host can negotiate it downward.
dataru[s+m+1]	Not applicable	Local service access point (SAP) used by remote station. The remote SAP information is only allowed for 802.2 connections, and may only be present if Signaling information is present. It is used along with the Signaling Information to identify the remote station.

Open(STATION) OResponse

srcl	CHAR	Source locality
srcp	CHAR	Source partner
srci	INTEGER	Source index
destl	CHAR	Destination locality
destp	CHAR	Destination partner
desti	INTEGER	Destination index
clhdr.closqual	CHAR	Close qualifier: REQU (0x01)
clhdr.clstype	CHAR	Close type: STAT (0x11)

Note that the message consists of a buffer header only.

Close(STATION) Response

Flow : DLC ------> NODE

Header

Field	Type	Description
nxtqptr	PTRBFHDR	Pointer to next buffer header in a queue
hdreptr	PTRBFELT	Pointer to first buffer element: NULL
numelts	CHAR	Number of buffer elements: 0
msgtype	CHAR	Message type: CLOSEMSG (0x02)
srcl	CHAR	Source locality
srcp	CHAR	Source partner
srci	INTEGER	Source index
destl	CHAR	Destination locality
destp	CHAR	Destination partner
desti	INTEGER	Destination index
clhdr.clsequal	CHAR	Close qualifier - RSPOK (0x02) - RSPERR (0x03)
clhdr.clstype	CHAR	Close type: STAT (0x11)
clhdr.clserr1	INTEGER	Error code

The error codes (for an ERROR-RESPONSE) are defined as:

- 0x03 — Station not open
- 0x04 — Link not connected
- 0x05 — Invalid station index
- 70x06 — Duplicate request

Note
The message consists of a buffer header only.

Note
The Close(STATION) message unconditionally closes the station connection.

Request-Open-Station

Flow : DLC ------> NODE (link connection)

Header

Field	Type	Description
nxtqptr	PTRBFHDR	Pointer to next buffer header in a queue
hdreptr	PTRBFELT	Pointer to first buffer element if present
numelts	CHAR	Number of buffer elements
msgtype	CHAR	Message type: DLCSTAT (0x11)
srcl	CHAR	Source locality
srcp	CHAR	Source partner
srci	INTEGER	Source index
destl	CHAR	Destination locality
destp	CHAR	Destination partner
desti	INTEGER	Destination index
dshdr.dstype	CHAR	Status type: QOPNSTN (0x16)
dshdr.dsqual	CHAR	Station address on XID or mode-set command. Set to 0x01 for 802.2
dshdr.dsmdset	CHAR	Rcv-Set-Mode flag 0x00 XID received 0x01 Mode set command received for example, SNRM for SDLC SABME for 802.2 QSM for X.25

Element field	Type	Description
hdreptr–>eltptr	PTRBFELT	Pointer to next buffer element (NULL is only one element)
hdreptr–>startd	INTEGER	Index to start of data in this buffer element's data array: 1
hdreptr–>endd	INTEGER	Index to last byte of data in this buffer element's data array
hdreptr–>dataru	CHAR[SNANBEDA]	Defined as follows, where s = startd–1
dataru[s..s+n–1]	Not applicable	XID-starting at first byte of received XID information field. 0x00 NULL XID received (n = 1) and signaling information present.

Optional Signaling Information

Field	Description
dataru[s+n]	Length of data, including this byte
dataru[s+n+1]	Type of data (not used at present)

dataru[s+n+2..s+m]	Address or other identifier data. For example, media access control (MAC) address of remote station X.25 address of remote station

- The signaling information is used by the node to identify the remote station on 802.2 and X.25 links.

Note
If a NULL XID is received and no signaling information is required, the element can be omitted.

Note
If a NULL XID is received and signaling information is required, an 0x00 byte should be put in the element followed by the signaling information.

Note
If the Rcv-Set-Mode flag is set to 0x01, the element can be omitted.

Station-Contacted

Flow : DLC ------> NODE (station connection)

Header

Field	Type	Description
nxtqptr	PTRBFHDR	Pointer to next buffer header in a queue
hdreptr	PTRBFELT	Pointer to first buffer element: NULL
numelts	CHAR	Number of buffer elements: 0
msgtype	CHAR	Message type: DLCSTAT (0x11)
srcl	CHAR	Source locality
srcp	CHAR	Source partner
srci	INTEGER	Source index
destl	CHAR	Destination locality
destp	CHAR	Destination partner
desti	INTEGER	Destination index
dshdr.dstype	CHAR	Status type: STNCTCTD (0x17)

Note that this message contains a buffer header only.

Outage

Flow : DLC ------> NODE (link or station connection)

Header

Field	Type	Description
nxtqptr	PTRBFHDR	Pointer to next buffer header in a queue
hdreptr	PTRBFELT	Pointer to first buffer element: NULL
numelts	CHAR	Number of buffer elements: 0
msgtype	CHAR	Message type: DLCSTAT (0x11)
srcl	CHAR	Source locality
srcp	CHAR	Source partner
srci	INTEGER	Source index
destl	CHAR	Destination locality
destp	CHAR	Destination partner
desti	INTEGER	Destination index
dshdr.dstype	CHAR	Status type: OUTAGE (0x18)
dshdr.dsqual	CHAR	Outage qualifier
dshdr.dsoutsq	CHAR	Outage subqualifier (optional)

Note the following:

- This message contains a buffer header only.
- Outage qualifier codes are given in Outages.

Status-Resource

Flow : DLC <------> NODE (station connection)

Header

Field	Type	Description
nxtqptr	PTRBFHDR	Pointer to next buffer header in a queue
hdreptr	PTRBFELT	Pointer to first buffer element: NULL
numelts	CHAR	Number of buffer elements: 0
msgtype	CHAR	Message type: DLCSTAT (0x11)
srcl	CHAR	Source locality
srcp	CHAR	Source partner
srci	INTEGER	Source index
destl	CHAR	Destination locality
destp	CHAR	Destination partner
desti	INTEGER	Destination index
dshdr.dstype	CHAR	Status type: RESOURCE (0x04)
dshdr.dlccred	INTEGER	DLC credit

Note

This message contains a buffer header only.

Note

The **dlccred** field indicates that the message sender can receive a further **dlccred DLC-Data** message.

Send-XID

Flow : NODE ------> DLC (link connection)

Header

Field	Type	Description
nxtqptr	PTRBFHDR	Pointer to next buffer header in a queue
hdreptr	PTRBFELT	Pointer to first buffer element
numelts	CHAR	Number of buffer elements
msgtype	CHAR	Message type: DLCSTAT (0x11)
srcl	CHAR	Source locality
srcp	CHAR	Source partner
srci	INTEGER	Source index
destl	CHAR	Destination locality
destp	CHAR	Destination partner
desti	INTEGER	Destination index
dshdr.dstype	CHAR	Status type: SENDXID (0x1A)
dshdr.dsqual	CHAR	Station address on XID

Element

Field	Type	Description
hdreptr–>elteptr	PTRBFELT	Pointer to next buffer element: (NULL is only one element)
hdreptr–>startd	INTEGER	Index to start of data in this buffer element's data array: 1
hdreptr–>endd	INTEGER	Index to last byte of data in this buffer element's data array
hdreptr–>dataru	CHAR[SNANBEDA]	Defined as follows, where s = startd–1
dataru[s..s+n–1]	Not applicable	XID information frame

Note that the **dshdr.dsqual** field is valid only for primary multipoint connections where station is specified on a multidrop line that the XID should be sent to. In all other cases, it is set to 0xFF.

In situations where the link protocol requires the address field on the XID to be set to a value other than 0xFF (for example, to specify that the XID is a response), it is the responsibility of the link service to set this byte appropriately.

The **Send-XID** message can contain zero elements (**numelts** = 0) or a single, empty element (**hdreptr–>startd** < **hdreptr–>endd**). In these cases, the link service is expected to transmit a NULL XID.

DLC-Data

Flow : DLC <------> NODE

Header

Field	Type	Description
nxtqptr	PPTRBFHDR	Pointer to next buffer header in a queue
hdreptr	PPTRBFELT	Pointer to first buffer element
numelts	CCHAR	Number of buffer elements
msgtype	CCHAR	Message type: DLCDATA (0x10)
srcl	CCHAR	Source locality
srcp	CCHAR	Source partner
srci	INTEGER	Source index
destl	CCHAR	Destination locality
destp	CCHAR	Destination partner
desti	INTEGER	Destination index
ddhdr.ddth01	CCHAR[6]	Transmission header

Element

Field	Type	Description
hdreptr–>eltept r	PPTRBFELT	Pointer to next buffer element: (NULL is only one element)
hdreptr–>startd	INTEGER	Index to start of data in this buffer element's data array: 1
hdreptr–>endd	INTEGER	Index to last byte of data in this buffer element's data array
hdreptr–>datar u	CHAR[SNANBEDA]	Defined as follows, where s = startd–1
dataru[s..s+n–1]	Not applicable	SNA request/response header (RH) if present, and request/response unit (RU) if not prese nt

Configuration Entry Points

The following topics describe the entry points used by SNALink to obtain configuration information.

In This Section

- SNAGetConfigValue
- SNAGetSystemInfo
- pCSInfo

SNAGetConfigValue

SNALink calls the **SNAGetConfigValue** function to obtain the value of a specific configuration parameter.

Syntax

```
USHORT SNAGetConfigValue(
UCHAR *entryName,
VOID *pBuffer,
ULONGbufferLen,
UCHARparmType,
ULONG *pRetLength
);
```

Parameters

entryName

The name of the configuration parameter required.

pBuffer

A pointer to a buffer (if the parameter is a string), or a pointer to a LONGINT (if the parameter is an integer).

bufferLen

The length of the buffer. Only required if the parameter is TYPESTRING.

parmType

TYPESTRING if the parameter is a string.

TYPELONG if the parameter is an integer.

pRetLength

Number of bytes returned if the parameter is TYPESTRING, or number of bytes available if the buffer was too short.

Return Value

NO_ERROR

OK.

ERBADCFG

Error reading configuration file.

ERNOTFND

Entry not found in configuration record.

ERTOOLONG

Data available exceeded the size of the buffer.

ERBADTYPE

A bad type was specified for the *parmType* parameter.

Remarks

It is strongly recommended that SNALink read all required configuration parameters at initialization time (when SNALinkInitialize is called by the Base).

SNAGetSystemInfo

SNALink calls the **SNAGetSystemInfo** function to obtain information about the SNA server and the network operating system.

Syntax

```
INTEGER SNAGetSystemInfo(
struct cs_info *pCSInfo
);
```

Parameters

pCSInfo

Pointer to a buffer supplied by the application that contains a data structure in which system information is returned. The application must set the **length** field in this data structure. (For details, see Remarks.) The other fields should be set to nulls or blanks.

Return Value

NO_ERROR

OK.

ERNOCFGSVR

No configuration file server available.

ERMOREDATA

Supplied buffer was too small.

Remarks

The application must set the **length** parameter to the length of the **cs_info** structure (86 bytes in the current version). Any other value is rejected. This parameter is used to ensure compatibility with future versions. An application supplying this length will always obtain the information shown, but in future versions it may be possible to specify larger values and obtain further information.

On successful return, the **cs_info** data structure contains the version number of the SNA server, the path to the current configuration file, and the network operating system over which the SNA server is running.

If there is no configuration file server available, only the version number fields are valid. The other fields should not be checked.

pCSInfo

Syntax

```
struct cs_info {
    unsigned short  length;
    unsigned char   major_ver;
    unsigned char   minor_ver;
    unsigned char   config_share[80];
    unsigned short  nos;
};
```

Members

length

Length of the data structure supplied by the application.

major_ver

Major version number:

1 for Communications Server 1.1

2 for SNA Server 2.0 or 2.1

3 for SNA Server 3.0

4 for SNA Server 4.0

minor_ver

Minor version number (decimal):

10 for Communications Server 1.1

00 for SNA Server 2.0

20 for SNA Server 2.1

00 for SNA Server 3.0

00 for SNA Server 4.0

config_share[80]

The name of the share point of the current configuration file (\\server\share\, for example). This path name must be a null-terminated string.

nos

Transport protocol in use:

bit 0: LAN Manager/LAN Server (named pipes)

bit 1: NetWare (IPX/SPX)

bit 2: AppleTalk (Not supported in Host Integration Server 2009)

bit 3: Banyan VINES (VINES IP)

bit 4: TCP/IP

Setup Functions

This section provides a reference for the functions used with the integrated link service dynamic-link library (DLL) architecture as well as INF-based Setup.

This section contains:

- Integrated Link Service Configuration Functions
- Inf-Based Setup Functions

Integrated Link Service Configuration Functions

This section provides a reference for exported dynamic-link library (DLL) entry points and utility functions used when building an integrated link service configuration dynamic-link library (DLL).

This section contains:

- Functions Exported from a Link Service Configuration DLL
- Utility Functions Used by a Link Service Configuration DLL

Functions Exported from a Link Service Configuration DLL

This section provides a reference for functions that must be exported from an integrated link service configuration dynamic-link library (DLL).

In This Section

- CommandLineAdd
- ConfigureLinkService
- ConfigureLinkServiceEx
- DisplayHelpInfo
- RemoveAllLinkServices
- RemoveLinkService

CommandLineAdd

The **CommandLineAdd** function is used to add a new link service using a command-line interface. This function must be exported from a link service configuration dynamic-link library (DLL) supplied with each link service.

Syntax

```
__declspec(dllexport) BOOL WINAPI CommandLineAdd(  LPSTRszCommandLine,
  LPSTR *szConfigInfo,
  LPDWORD dConfigInfoSize);
```

Parameters

szCommandLine

This supplied parameter specifies the command line containing information on the computer and link service to be configured.

szConfigInfo

This supplied and returned parameter points to a configuration buffer that is used to configure the link service.

dConfigInfoSize

This supplied parameter specifies the size of the sz*ConfigInfo* configuration buffer .

Return Value

TRUE

The function executed successfully.

FALSE

One or more of the parameters passed to this function are invalid or the function failed.

ConfigureLinkService

The **ConfigureLinkService** function is used to add or modify a link service. This function must be exported from a link service configuration dynamic-link library (DLL) supplied with each link service.

Syntax

```
          __declspec(dllexport) BOOL WINAPI ConfigureLinkService(
    LPSTR szComputerName,
    LPSTRszLinkServiceTitle);
```

Parameters

szComputerName

This supplied parameter specifies the name of the computer that is to be configured.

szLinkServiceTitle

This supplied parameter specifies the title of the link service that is to be configured.

Return Value

TRUE

The function executed successfully and network bindings need to be recalculated.

FALSE

One or more of the parameters passed to this function are invalid or network bindings do not need to be recalculated.

ConfigureLinkServiceEx

The **ConfigureLinkServiceEx** function is used to add or modify a link service. This function must be exported from a link service configuration dynamic-link library (DLL) supplied with each link service.

Syntax

```
          __declspec(dllexport) BOOL WINAPI ConfigureLinkServiceEx(
    LPSTRszComputerName,
    LPSTRszLinkServiceTitle,
    LPSTR* pvConfigInfo,
    LPDWORD dConfigInfoSize);
```

Parameters

szComputerName

This supplied parameter specifies the name of the computer that is to be configured.

szLinkServiceTitle

This supplied parameter specifies the title of the link service that is to be configured.

pvConfigInfo

This supplied and returned parameter points to a configuration buffer that is used to configure the link service.

dConfigInfoSize

This supplied parameter specifies the size of the *pvConfigInfo* configuration buffer.

Return Value

TRUE

The function executed successfully and network bindings need to be recalculated.

FALSE

One or more of the parameters passed to this function are invalid or network bindings do not need to be recalculated.

DisplayHelpInfo

The **DisplayHelpInfo** function is used to generate help information used by the command-line interface to a link service dynamic-link library (DLL). This function must be exported from a link service configuration DLL supplied with each link service.

Syntax

```
            __declspec(dllexport) BOOL WINAPI DisplayHelpInfo(
    LPSTR*szHelpInfoBuffer);
```

Parameters

szHelpInfoBuffer

This supplied and returned parameter points to a buffer that on successful return contains help information that can be used to configure the link service.

Return Value

TRUE

The function executed successfully.

FALSE

The parameter passed to this function is invalid or the function failed.

RemoveAllLinkServices

The **RemoveAllLinkServices** function is used to remove all link services from a machine. This function must be exported from a link service configuration dynamic-link library (DLL) supplied with each link service.

Syntax

```
          __declspec(dllexport) BOOL WINAPI RemoveAllLinkServices(
   LPSTRszComputerName);
```

Parameters

szComputerName

This supplied parameter specifies the name of the computer that is to have all link services removed.

Return Value

TRUE

The function executed successfully and network bindings need to be recalculated.

FALSE

The parameter passed to this function is invalid or network bindings do not need to be recalculated.

RemoveLinkService

The **RemoveLinkService** function is used to remove a link service. This function must be exported from a link service configuration dynamic-link library (DLL) supplied with each link service.

Syntax

```
          __declspec(dllexport) BOOL WINAPI RemoveLinkService(
    LPSTRszComputerName,
    LPSTRszLinkServiceTitle);
```

Parameters

szComputerName

This supplied parameter specifies the name of the computer that is to have the link service removed.

szLinkServiceTitle

This supplied parameter specifies the title of the link service that is to be removed.

Return Value

TRUE

The function executed successfully and network bindings need to be recalculated.

FALSE

One or more of the parameters passed to this function are invalid or network bindings do not need to be recalculated.

This section contains:

- Utility Functions Used by a Link Service Configuration DLL

Utility Functions Used by a Link Service Configuration DLL

This section provides a reference for utility functions used by an integrated link service configuration dynamic-link library (DLL).

This section contains:

AddPerfmonCounters

The **AddPerfmonCounters** function is used to add Perfmon counters to a link service. This utility function is used to construct an integrated link service configuration dynamic-link library (DLL).

Syntax

```
          void AddPerfmonCounters(
    LPSTRpszComputerName,
    LPSTRpszService);
```

Parameters

pszComputerName

This supplied parameter specifies the name of the computer that is to have Perfmon counters added.

pszService

This supplied parameter specifies the name of the link service that is to have Perfmon counters added.

Return Value

None.

Remarks

SNA RPC Service must be running or an error message will indicate a failure.

bCreateService

The **bCreateService** function is used to create a service on a computer for a link service. This utility function is used to construct an integrated link service configuration dynamic-link library (DLL).

Syntax

```
          BOOL bCreateService(
    LPSTRszComputerName,
    LPSTRszServiceName,
    LPSTRszServicePath,
    LPSTRszServiceDependencies,
    DWORDdServiceType,
    DWORDdServiceLoadType,
    LPSTRszDomainName,
    LPSTRszUserid,
    LPSTRszPassword);
```

Parameters

szComputerName

This supplied parameter specifies the name of the computer to create the service on.

szServiceName

This supplied parameter specifies the name of the link service that is to be created. This parameter is passed unchanged to the Microsoft® Windows® 2000 **CreateService** function.

szServicePath

This supplied parameter specifies the binary path to the link service that is to be created. This parameter is passed unchanged to the Windows 2000 **CreateService** function.

szServiceDependencies

This supplied parameter specifies the service dependencies of the link service that is to be created. This parameter is passed unchanged to the Windows 2000 **CreateService** function.

dServiceType

This supplied parameter specifies the type of service that is to be created. This parameter is passed unchanged to the Windows 2000 **CreateService** function.

dServiceLoadType

This supplied parameter specifies the load type of service that is to be created. This parameter is passed unchanged to the Windows 2000 **CreateService** function.

szDomainName

This supplied parameter specifies the domain name for the service to run in.

szUserid

This supplied parameter specifies the user identifier for the service to run in.

szPassword

This supplied parameter specifies the password for the domain account.

Return Value

TRUE

The function executed successfully and the service was created.

FALSE

One or more of the parameters passed to this function are invalid or the function failed.

Remarks

If the *szUserid* parameter is not supplied, then the *szDomainName* parameter is used to construct the Account parameter passed to the Windows 2000 **CreateService** function.

bDeleteService

The **bDeleteService** function is used to delete a service on a computer for a link service. This utility function is used to construct an integrated link service configuration dynamic-link library (DLL).

Syntax

```
          BOOL bDeleteService(
    LPSTRszComputerName,
    LPSTRszServiceName);
```

Parameters

szComputerName

This supplied parameter specifies the name of the computer to delete the service on.

szServiceName

This supplied parameter specifies the name of the service that is to be deleted. This parameter is passed unchanged to the Microsoft® Windows® 2000 **OpenService** function.

Return Value

TRUE

The function executed successfully and the service was deleted.

FALSE

One or more of the parameters passed to this function are invalid or the function failed.

bStopService

The **bStopService** function is used to stop a service running on a computer for a link service. This utility function is used to construct an integrated link service configuration dynamic-link library (DLL).

Syntax

```
          BOOL bStopService(
    LPSTRszServiceName,
    LPSTRszComputerName);
```

Parameters

szServiceName

This supplied parameter specifies the name of the service that is to be stopped. This parameter is passed unchanged to the Microsoft® Windows® 2000 **OpenService** function.

szComputerName

This supplied parameter specifies the name of the computer to stop the service on.

Return Value

TRUE

The function executed successfully and the service was stopped.

FALSE

One or more of the parameters passed to this function are invalid or the function failed.

CheckForExistingLinkService

The **CheckForExistingLinkService** function is used to check to see if a link service of this type exists with this title. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
          BOOL bCreateService(
    HKEY *hGlobalKey,
    LPSTRszLinkRegistryRoot,
    LPSTRszTitle);
```

Parameters

hGlobalKey

This supplied parameter specifies the handle of the registry to search.

szLinkRegistryRoot

This supplied parameter specifies the registry root for this type of link service to search for.

szTitle

This supplied parameter specifies the title of the link service to search for.

Return Value

TRUE

The link service was located.

FALSE

One or more of the parameters passed to this function are invalid or the link service was not located.

ConvertHexStringToDWORD

The **ConvertHexStringToDWORD** function is used to convert a hexadecimal string to a DWORD value. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
          BOOL ConvertHexStringToDWORD(
    LPSTRszHexString,
    LPDWORDdHexValue);
```

Parameters

szHexString

This supplied parameter specifies the hexadecimal string to be converted.

dHexValue

This supplied and returned parameter contains the DWORD value of the hexadecimal string if the function was successful.

Return Value

TRUE

The function executed successfully and the hexadecimal string was converted.

FALSE

One or more of the parameters passed to this function are invalid or the function failed.

Remarks

This function scans until a nonhexadecimal character is encountered. The hexadecimal formats recognized are xnnnn, 0xnnnn, or nnnn.

ExtractNextParameter

The **ExtractNextParameter** function is used to get the next parameter from a buffer. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
          BOOL ExtractNextParameter(
    LPSTRszSourceBuffer,
    LPSTRszParameter,
    LPDWORDdStartIndex);
```

Parameters

szSourceBuffer

This supplied parameter specifies the source buffer.

szParameter

This supplied and returned parameter specifies the return buffer for parameters.

dStartIndex

This supplied parameter contains the DWORD index to begin parameter scan.

Return Value

TRUE

The function executed successfully and the next parameter was located and returned in the *szParameter* argument.

FALSE

The function failed.

Remarks

Parameters are delimited by a space character. Quotes can be used to include spaces in a parameter.

fAddRegistryEntry

The **fAddRegistryEntry** function is used to add a new registry value to the registry. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
          BOOL fAddRegistryEntry(
    HKEY *hGlobalKey,
    char *szRegistryValue,
    char *szRegistryData,
    DWORDdType,
    DWORDdSize);
```

Parameters

hGlobalKey

This supplied parameter specifies the handle of the registry to modify.

szRegistryValue

This supplied parameter specifies the registry value name to add.

szRegistryData

This supplied parameter specifies the registry value data to add.

dType

This supplied parameter specifies the registry value type. This parameter is supplied unchanged to the Win32® **RegSetValueEx** function.

dSize

This supplied parameter specifies the size of the registry value data. This parameter is supplied unchanged to the Win32 **RegSetValueEx** function.

Return Value

TRUE

The function executed successfully and the registry entry was added.

FALSE

The function failed and the registry entry was not added.

fCanWeAdministerRemoteBox

The **fCanWeAdministerRemoteBox** function is used to determine if the caller has administrative privileges on the remote computer. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
            BOOL fCanWeAdministerRemoteBox(
    HKEY *hGlobalKey);
```

Parameters

hGlobalKey

This supplied parameter specifies the handle to the remote computer's registry.

Return Value

TRUE

The caller has administrative privileges on the remote computer.

FALSE

The caller lacks administrative privileges.

fConnectRegistry

The **fConnectRegistry** function is used to connect to a remote computer's registry and return a handle to the remote registry. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
          BOOL fConnectRegistry(
    HKEY *hGlobalKey,
    LPSTR *szComputerName);
```

Parameters

hGlobalKey

This supplied parameter specifies the handle of the registry to connect to.

szComputerName

This supplied parameter specifies the computer name to connect to.

Return Value

TRUE

The function executed successfully and the function was able to connect to the registry.

FALSE

The function failed.

fDisconnectRegistry

The **fDisconnectRegistry** function is used to disconnect from a remote computer's registry. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
            BOOL fDisconnectRegistry(
    HKEY *hGlobalKey);
```

Parameters

hGlobalKey

This supplied parameter specifies the handle of the registry from which to disconnect.

Return Value

TRUE

The function executed successfully and the function was able to disconnect from the registry.

FALSE

The function failed.

fFindAndReplaceString

The **fFindAndReplaceString** function is used to find and replace a substring within a string. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
          BOOL fFindAndReplaceString(
    LPSTRszStringBuffer,
    LPSTRszSearchString,
    LPSTRszReplaceString);
```

Parameters

szStringBuffer

This supplied parameter specifies the string buffer to search.

szSearchString

This supplied parameter specifies the string to search for.

szReplaceString

This supplied parameter specifies the replacement string.

Return Value

TRUE

The string was found.

FALSE

The string was not found.

fFindString

The **fFindString** function is used to determine if a string exists within a string buffer. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
          BOOL fFindString(
    LPSTRszStringBuffer,
    LPSTRszSearchString);
```

Parameters

szStringBuffer

This supplied parameter specifies the string buffer to search.

szSearchString

This supplied parameter specifies the string to search for.

Return Value

TRUE

The string was found.

FALSE

The string was not found.

fFindStringInMultiSZ

The **fFindStringInMultiSZ** function is used to determine if string exists in a REG_MULTI_SZ string list and return entire string. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
        BOOL fFindString(
        LPSTR
        szStringBuffer,
    LPSTRszSearchString,
    LPSTRszFoundString);
```

Parameters

szStringBuffer

This supplied parameter specifies the string buffer to search.

szSearchString

This supplied parameter specifies the string to search for.

szFoundString

This supplied and returned parameter specifies the full string containing string if successful.

Return Value

TRUE

The string was found and returned.

FALSE

The string was not found.

fQueryRegistryValue

The **fQueryRegistryValue** function is used to query a value from the registry. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
        BOOL fQueryRegistryValue(
        HKEY *
        hGlobalKey,
    LPSTRszRegistryKey,
    LPSTRszRegistryValue,
    LPSTRszRegistryData,
    LPDWORDdSize);
```

Parameters

hGlobalKey

This supplied parameter specifies the handle of the registry.

szRegistryKey

This supplied parameter specifies the registry key.

szRegistryValue

This supplied parameter specifies the registry value name.

szRegistryData

This supplied parameter specifies the registry value data.

dSize

This supplied parameter specifies the size of the registry data.

Return Value

TRUE

The function executed successfully and the function was able to connect to the registry.

FALSE

The function failed.

fRegistryKeyExists

The **fRegistryKeyExists** function is used to determine if a registry key already exists in the registry. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
            BOOL fRegistryKeyExists (
   HKEY *hGlobalKey,
   LPSTRszRegistryKey
 );
```

Parameters

hGlobalKey

This supplied parameter specifies the handle of the registry.

szRegistryKey

This supplied parameter specifies the registry key.

Return Value

TRUE

The registry key exists.

FALSE

The function failed or the registry key does not exist.

fRemoveRegistryEntry

The **fRemoveRegistryEntry** function is used to remove a registry key from the registry. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
            BOOL
            fRemoveRegistryEntry
            (
            HKEY *
            hGlobalKey,
    char *szRegistryKey
);
```

Parameters

hGlobalKey

This supplied parameter specifies the handle of the registry.

szRegistryKey

This supplied parameter specifies the registry key.

Return Value

TRUE

The function was successful and the registry key was removed.

FALSE

The function failed or the registry key could not be removed.

fRemoveRegistryValue

The **fRemoveRegistryValue** function is used to remove a registry value from the registry. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
            BOOL fRemoveRegistryValue (
            HKEY *
            hGlobalKey,
    char *szRegistryKey,
    char *szRegistryValue
);
```

Parameters

hGlobalKey

This supplied parameter specifies the handle of the registry.

szRegistryKey

This supplied parameter specifies the registry key.

szRegistryValue

This supplied parameter specifies the registry value to remove.

Return Value

TRUE

The function was successful and the registry value was removed.

FALSE

The function failed or the registry value could not be removed.

fStringCompare

The **fStringCompare** function is used to determine if string exists in another string. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
BOOL fStringCompare (
  LPSTR lpszString1,
  LPSTR lpszString2
);
```

Parameters

lpszString1

This supplied parameter specifies the string to search for.

lpszString2

This supplied parameter specifies the string to compare.

Return Value

TRUE

The string was found.

FALSE

The string was not found.

LoadStringResource

The **LoadStringResource** function is used to load a string from a string resource. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
          void LoadStringResource (
   DWORDdStringResource,
   LPSTRpszString);
```

Parameters

dStringResource

This supplied parameter specifies the resource ID of the string resource.

pszString

This supplied and returned parameter specifies the buffer to place the string in.

Return Value

None

ParseNextField

The **ParseNextField** function is used to parse and return the next field from string. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
        void ParseNextField(
        LPSTR
        szParseString,
    LPSTRszField,
    charscDelimiter,
    LPDWORDdStartIndex);
```

Parameters

szParseString

This supplied parameter specifies the string to parse.

szField

This supplied and returned specifies the return buffer for the next field.

scDelimiter

This supplied parameter specifies the delimiter character for the end of a field.

dStartIndex

This supplied parameter specifies a pointer to the index in bytes from beginning of the *szParseString* to start the search from.

Return Value

TRUE

The next field was found.

FALSE

The next field was not found.

Note
The **'^'** character can be used as an escape character to allow the delimiter to be used.

RemovePerfmonCounters

The **RemovePerfmonCounters** function is used to remove counters from a link service. This utility function is used to construct an integrated link service configuration DLL.

Syntax

```
          void RemovePerfmonCounters(
    LPSTRpszComputerName,
    LPSTRpszService);
```

Parameters

pszComputerName

This supplied parameter specifies the name of the computer that is to have Perfmon counters removed.

pszService

This supplied parameter specifies the name of the link service that is to have Perfmon counters removed.

Return Value

None.

Remarks

SNA RPC Service must be running or an error message will indicate a failure.

Inf-Based Setup Functions

This section provides a reference for some of the useful entry points in the .inf file that contains utility functions. The file name is in the variable *UtilityInf*; usually set to SNAUTILS.INF.

This section contains:

CreateSNARegEntry

The **CreateSNARegEntry** function creates the necessary entries for an instance in the **SOFTWARE\Microsoft** registry tree. If the product is not already in the registry, it creates an entry for the product. It then creates an entry for the particular instance of the product and for the **NetRules** key under that entry. This function leaves open handles to all the important subkeys for further use.

Parameters
Argument 0

Name of the top-level registry node to use. This should be a full registry path. For most scenarios, this is the value held in the *ProductRegBase* variable (**SOFTWARE\Microsoft**).

Argument 1

Name of the product. This is the name of the key that will be created for this product.

Argument 2

Instance index. This is the index of this particular instance of this product.

Return Values
Return 0

Status of the operation:

- STATUS_SUCCESSFUL: Operation succeeded.
- STATUS_FAILED: Operation failed.

Return 1

Handle to the top-level registry node.

Return 2

Handle to the products registry key under the top-level node.

Return 3

Handle to the instance entry under the product key.

Return 4

Handle to the NetRules entry under the instance key.

CreateSNAService

The **CreateSNAService** function creates the necessary entries for an instance in the **Services** registry tree. This function adds particular values that are necessary for the service as well as all the subkeys under the service key, including **Parameters** and **ExtraParameters**.

Parameters
Argument 0

Name of the service to be created.

Argument 1

Type of SNA Service (*SNAServiceType* variable).

Argument 2

Image path of this component (*ImagePath* variable).

Argument 3

Dependency list (*ProductDepends* variable).

Argument 4

Parameter list (*ProductParams* variable).

Argument 5

Extra parameter list (*ProductExtraParams* variable).

Argument 6

Event Log message file.

Argument 7

Event types supported (usually 0x07).

Return Values
Return 0

Status of the operation:

- STATUS_SUCCESSFUL: Operation succeeded.
- STATUS_FAILED: Operation failed.

Return 1

Handle to the service key.

Return 2

Handle to the **Parameters** key under the service key.

Return 3

Handle to the **ExtraParameters** key under the **Parameters** key.

DeleteSNAService

The **DeleteSNAService** function deletes a particular service using the Service Control Manager. All the keys for the service are deleted as well.

Parameters
Argument 0

Name of the service to be deleted.

Return Values
Return 0

Status of the operation.

EnterServiceName

The **EnterServiceName** function presents the user with an algorithmically determined service name for a component and allows the user to change it before returning the final value. This function ensures that the new service name is unique in the Service Control Architecture before accepting it.

Parameters
Argument 0

Title of the product the user should be queried about.

Argument 1

Default service name prefix.

Argument 2

Index for this instance of the product. The algorithm uses this index to determine the default name.

Return Values
Return 0

Status of the operation:

- STATUS_SUCCESSFUL: Operation succeeded.
- STATUS_NOSUCHLANGUAGE: The language specified is not supported.
- STATUS_USERCANCEL: User pressed the **Cancel** button.

Return 1

Service name that the user entered.

FindNextAvailableIndex

The **FindNextAvailableIndex** function is used to determine the index a new instance should receive. For example, if the current indexes in use are { 01, 02, 04 }, this function would return 03 as its return value.

Parameters
Argument 0

A list of the indexes currently in use. This list can be obtained by using the FindSNAProductServices function.

Return Values
Return 0

Status of the operation:

- STATUS_SUCCESSFUL: Operation succeeded.
- STATUS_FAILED: Operation failed.

Return 1

First available index for the list.

FindSNAProductServices

The **FindSNAProductServices** function enumerates all instances of a product. It returns lists of information for the instances that can be used in the script. This function can also be used to determine whether or not a product exists in the registry by analyzing the return status.

Parameters
Argument 0

Name of top-level registry node to use.

Argument 1

Name of the product.

Return Values
Return 0

Status of the operation:

- STATUS_SUCCESSFUL: Operation succeeded.
- STATUS_NOSUCHPRODUCT: The product does not exist in the registry.
- STATUS_FAILED: Operation failed.

Return 1

List of indexes for the instances of this product.

Return 2

List of service names for the instances of this product.

Return 3

List of titles for the instances of this product.

Return 4

List of descriptions for the instances of this product.

FindSNARegEntry

The **FindSNARegEntry** function is written as a parallel to CreateSNARegEntry. When called, it attempts to open all of the necessary registry keys and return open handles to them.

Parameters
Argument 0

Name of the top-level registry node to use.

Argument 1

Name of the product.

Argument 2

Instance index.

Return Values
Return 0

Status of the operation.

Return 1

Handle to the top-level registry node.

Return 2

Handle to the products registry key under the top-level node.

Return 3

Handle to the instance entry under the product key.

Return 4

Handle to the NetRules entry under the instance key.

FindSNAService

The **FindSNAService** function is written as a parallel to CreateSNAService. It is written to provide an easy way to access the keys for a particular service.

Parameters
Argument 0

Name of the service to look for.

Return Values
Return 0

Status of the operation.

Return 1

Handle to the service key.

Return 2

Handle to the **Parameters** key under the service key.

Return 3

Handle to the **ExtraParameters** key under the **Parameters** key.

GrepUniqueServiceInfo

The **GrepUniqueServiceInfo** function is used to determine information about a particular instance when only one of the four elements (index, name, title, or description) is available. Because there is no way to determine the position of an element in a list, it is hard to figure out the respective name, title, or description of an instance given only the index. This function searches the list and returns the rest of the information about the instance.

Parameters
Argument 0

Type of information to search:

- INDEX: Search the list of indexes.
- NAME: Search the list of service names.
- TITLE: Search the list of titles.
- DESC: Search the list of descriptions.

Argument 1

Keyword to search for in the list.

Argument 2

List of indexes for the instances of this product.

Argument 3

List of service names for the instances of this product.

Argument 4

List of titles for the instances of this product.

Argument 5

List of descriptions for the instances of this product.

Return Values
Return 0

Status of the operation.

Return 1

Index for this instance of the product.

Return 2

Service name for this instance of the product.

Return 3

Title for this instance of the product.

Return 4

Description for this instance of the product.

SetupMessage

The **SetupMessage** function displays a dialog box with user-defined text plus **OK** and **Cancel** buttons. It is useful for debugging.

Parameters
Argument 0

Language to use (*STF_LANGUAGE*).

Argument 1

Which icon to display in the dialog box: STATUS, WARNING, NONFATAL, and so on.

Argument 2

The text to be displayed. Can contain line feeds using the LF symbol.

Return Values
Return 0

Status of the operation.

IOCTL Commands

This section provides reference information about the IOCTL functions.

This section contains:

Function 0x41: Set Event/Semaphore Handle

This function supplies the driver with the handle of an event that can be used for signaling the SNALink software.

Parameters
IRP.UserEvent

This parameter is taken from the IOCTL call, and is an event handle. The handle must refer to an Event/Semaphore owned by the SNALink process. The driver sets the event to indicate the completion of a transmission or the availability of received data or status. Although not required by the driver, the event passed here by the SNALink is normally the global Base event.

Return Values

If the supplied parameter is NULL, the function returns a status of STATUS_INVALID_PARAMETER, with additional information of INFO_SET_EVENT_NO_EVENT. For any other illegal parameter, an exception is raised.

Remarks

This function should be called only once, immediately after the **OPEN** is issued. The event is set when:

- IFrames are transmitted from the driver buffers.
- IFrames are received into the driver buffers.
- IStatus information is updated in the Interface Record (see function 0x64).

Function 0x42: Set Link Characteristics

This function sets the link protocol parameters required by the driver.

Packet Formats

Type	Description
WORD	Frame Size
DWORD	Data rate
BYTE	Station address 1
BYTE	Station address 2
BYTE	Link Options
BYTE	Reserved

Parameters

Frame Size(packet format WORD)

Indicates to the driver the minimum amount of contiguous receiver buffering that must be available for any individual frame.

Data Rate(packet format DWORD)

Line speed in bits per second. If *Link Options* bit 3 is not set, this field is ignored.

Station Address 1(packet format BYTE)

Station Address 2(packet format BYTE)

Station addresses that the user wishes to receive on if selective reception is to be used (typically for multidropped secondaries). Only frames of data beginning with either of these values will be passed to the user—others are ignored or discarded.

If the SNALink wishes to listen on only one station address, *Station Address 2* should be set to zero.

A value of zero in both fields indicates that all error-free received frames are to be passed to the SNALink, regardless of the contents of their first address byte.

Link Options(packet format BYTE)

Link Options is a bitmap. The default is all values set to zero. The bits are used as shown in the following table. Note that not all of these options are supported by the standard Microsoft Host Integration Server 2009 synchronous card drivers.

Bit	Value
Bit 7	1 = Four wire (constant RTS/CTS). 0 = Two wire (switched RTS/CTS).
Bit 6	1 = NRZI encoding. 0 = NRZ encoding.
Bit 5	1 = HDLC level 1 conventions. 0 = SDLC level 1 conventions.
Bit 4	1 = Full-duplex (simultaneous 2-way) data. 0 = Half-duplex (alternating 1-way) data.
Bit 3	1 = Generate internal clocking. 0 = Take external clocking.
Bit 2	1 = Use DMA if available. 0 = Do not use DMA on this link.
Bit 1	1 = Reset all statistics to zero. 0 = Leave accumulated statistics as is.

Bit 0	Reserved.

Reserved(packet format BYTE).

Reserved.

Note
Not all of the above options are supported by the standard Host Integration Server synchronous card drivers.

Return Values

IoStatus.Status	**IoStatus.Information**	**Description**
STATUS_INVALID_PARAMETER	IO_ERR_LINKCHARBUF_ WRONG_SIZE	
STATUS_INVALID_PARAMETER	IO_ERR_FRAME_BUF_ TOO_SMALL	Buffer must be at least 268 bytes.
STATUS_INVALID_PARAMETER	IO_ERR_FRAME_BUF_ TOO_BIG	Buffer maximum size is 2048 bytes.
STATUS_INVALID_PARAMETER	IO_ERR_NO_CLOCKS	No internal clocking available.
STATUS_DATA_ERROR	IO_ERR_HARDWARE_ 8273CMD_TIMEOUT	
STATUS_SUCCESS	IO_ERR_NO_DMA_FDX	DMA requested, but cannot be used.

Remarks

The driver should always start the receiver after processing this request. If either the transmitter or receiver is active when this request is issued, the driver stops the current frame before resetting the link characteristics, and then restarts the previous operation.

Link Service DLLs that support the synchronous dumb card interface use the following registry entries to the control this feature.

SYSTEM\CurrentControlSet\Services\<linkService>\Parameters

where **<linkService>** is the name of the link service.

Under this node, the following entries and values must be entered or modified:

A node called **ExtraParameters** must be created or modified with the following registry entries and values:

InternalClock

The value of this entry should be defined and set to a REG_DWORD of any value to enable the internal clock.

InternalClockRate

The value of this entry should be set to a REG_DWORD equal to the number of bits per second.

Function 0x43: Set V24 Output Status

This function allows the SNALink software to alter the modem output status on the adapter V.24 interface. There is no parameter or data packet on this request. The relevant V.24 settings are put into the driver interface record (see function 0x61) by the SNALink prior to calling the driver.

Return Values

IoStatus.Status	**IoStatus.Information**
STATUS_DATA_ERROR	IO_ERR_HARDWARE_8273CMD_TIMEOUT

Function 0x44: Transmit Frame

The SNALink calls this function to transfer a frame of data to the driver.

Parameters

IRP.CurrentStackLocation.OutputBufferLength

Frame length—the size of the frame pointed to by the data buffer pointer. The frame includes the control, address, and information field (if present), but no allowance should be made for flags or CRC bytes.

IRP.UserBuffer

Frame data—the contents of the frame.

Return Values

IoStatus.Status	**IoStatus.Information**
STATUS_BUFFER_TOO_SMALL	IO_ERR_TX_BUFFER_FULL
STATUS_INVALID_PARAMETER	IO_ERR_TX_FRAME_TOO_BIG

Refer also to the description of the interface record—the driver updates a field within the interface record reflecting the amount of buffer space available.

Remarks

In two-wire configurations, the driver must raise RTS and wait for CTS from the modem before initiating a transmission. The driver should then drop RTS when all frames have been transmitted. The driver assumes that the transmission is complete when both of the following are true:

- The transmit buffer becomes empty (if the link is configured as half-duplex).
- The last frame transmitted had the Poll/Final bit set in the second byte.

Function 0x45: Abort Transmitter

The SNALink calls this function to clear down the driver's transmitter.

Remarks

This request causes the driver to stop the current frame transmission and to flush its internal buffers of any further data pending transmission. In two-wire configurations, the driver should also drop RTS.

Function 0x46: Abort Receiver

The SNALink calls this function to clear down the driver's receiver.

Remarks

This request causes the driver to stop the receiver and to flush its internal buffers of any received data. It should be used to clear down the receiver, for instance, before altering the link characteristics.

Function 0x47: Off-Board Load

This function is not supported.

Function 0x61: Get/Set Interface Record

This function has been superseded by Function 0x64: Read Interface Record.

Function 0x62: Get V24 Status

The SNALink calls this function to read the current state of the modem interface lines. No parameter or data packet is passed. This request causes the driver to update the Input V.24 Status field in the driver interface record.

Function 0x63: Receive Frame

The SNALink calls this function to read a data frame from the driver's buffers.

Parameters

IRP.CurrentStackLocation.OutputBufferLength

Frame length—the size of the frame transferred into the data buffer by the driver. The frame includes the control, address, and information field (if present), but no flags or CRC bytes. When the request is issued, frame length is set to the maximum length of the buffer addressed by the data packet pointer.

IRP.UserBuffer

Frame data—the contents of the frame that has been received.

Return Values

IoStatus.Status	**IoStatus.Information**
STATUS_BUFFER_TOO_SMALL	None

Remarks

The driver transfers the next available received frame to the supplied buffer. Note that if the buffer is not large enough, a buffer overflow error is returned. This allows the application to decide if oversize frames are an error. If not, then a second attempt to read should be made, using a buffer at least Frame Length bytes long. A length of zero is returned if there are no frames ready to be received.

Function 0x64: Read Interface Record

This function reads the driver's interface record and copies it into the buffer passed by the SNALink. The buffer must be allocated by the SNALink prior to making this call.

Parameters
IRP.System.Buffer

Interface Record Address (IN)—a 32-bit pointer to the driver's interface record area.

The interface record format is as follows:

Description	Type
Received Frames	**int**
Transmit Buffer Space	**int**
Status Events	**int**
Input V.24 Status	**UCHAR**
Output V.24 Status	**UCHAR**
Statistics Counters	**int[11]**

- Received Frames is the number of frames currently queued in the driver receive buffers.
- Transmit Buffer Space is used to signal to the SNALink:

  Whether more frames can be provided to the driver.

  Whether the driver still has frames waiting to be sent.

  The Transmit Buffer Space field indicates the maximum frame size that the driver can currently accept. This is updated after each successful Transmit Frame IOCTL, and should be checked by the SNALink before sending further frames to the driver.
- Status Events is a count of the total number of increments made to the Statistics Counters.
- Input V.24 Status is a bitmap of the current logical state of the input interface lines, a value of 1 meaning ON and a value of 0 meaning OFF. The pins are mapped as follows:

Bit number	V.24 circuit name	Circuit number	RS-232C pin
7 - 5	Reserved	142	25
4	Test Indicator	125	22
3	Calling Indicator	125	22
2	RLSD (commonly DCD)	109	8
1	Data Set Ready (DSR)	107	6
0	Clear to send (CTS)	106	5

- Output V.24 Status is a bitmap of the current logical state of the output interface lines, a value of 1 meaning ON and a

value of 0 meaning OFF. The pins are mapped as follows:

Bit number	V.24 circuit name	Circuit number	RS-232C pin
7 - 5	Reserved		
4	Maintenance Test	140	18
3	Select Standby	116	11
2	Data Signal Rate Selector	111	23
1	Data Terminal Ready (DTR)	108/2	22
0	Request to Send (RTS)	105	4

Note that the driver will raise and lower RTS as necessary while transmitting, reflecting the state of RTS in the output V.24 status field. The application should not, therefore, try to manipulate RTS.

- The Statistics Counters are running counts of various kinds of link status information.The events they relate to are:

Counter number	Description
1	Frames received with incorrect CRC.
2	Frames larger than the maximum size received.
3	Frames smaller than 32 bits received.
4	Frames received that are not a multiple of 8 bits.
5	Aborted frames received.
6	Transmitter underruns.
7	Receiver overruns.
8	RLSD drops in mid-reception.
9	CTS drops in mid-transmission.
10	DSR drops.
11	Hardware failures (adapter or modem).

Remarks

The interface record provides a fast mechanism to use to decide whether a frame can be transmitted, whether there are any frames to be received, and so on. The driver maintains this information. Each time the SNALink requires this information, it calls **Read Interface Record** to get a copy of the current interface record. After each call, the driver clears the statistics counters in its own interface record. The V.24 status and transmit and receive data information are unchanged.

SNA Modem API

This section provides reference material for the SNA Modem API structure and functions.

In This Section

- MODEM_STATUS
- SNAModemInitialize
- SNAModemAddLink
- SNAModemDeleteLink
- SNAModemTerminate

MODEM_STATUS

A **MODEM_STATUS** structure for each SNA link contains status information used by the SNA Modem Status interface.

Syntax

```
struct _ModemStatus{
....char LSName[12];
    char V24In;
    char V24Out;
    unsigned short RxFrameCount;
    unsigned short TxFrameCount;
    char Reserved[6];
} MODEM_STATUS;
```

Remarks

Members

LSName

A character array containing the link service name.

V24In

A set of bit fields representing the V.24 input flags that determine which signal lines to mask. These bit fields can be joined with **OR** to create a complete mask. The defined bit fields for **V24In** are as follows:

MASK_CTS Mask the clear to send line.

MASK_DSR Mask the data set ready line.

MASK_DCD Mask the data carrier detect line.

MASK_DRI Mask the data ring indicator line.

V24Out

A set of bit fields representing the V.24 output flags that determine which signal lines to mask. These bit fields can be joined with **OR** to create a complete mask. The defined bit fields for **V24Out** are as follows:

MASK_RTS Mask the request to send line.

MASK_DTR Mask the data terminal ready line.

RxFrameCount

A count of received frames.

TxFrameCount

A count of transmitted frames.

Reserved

Padding for future expansion.

SNAModemInitialize

The **SNAModemInitialize** function should be called once per link service process at initialization. This function initializes the communication path to the SNA Modem application. The ideal place to call this function is in the **SNALinkInitialize** function.

Syntax

```
void SNAModemInitialize();
```

See Also

Reference

SNALinkInitialize

SNAModemAddLink

The **SNAModemAddLink** function should be called once per link initialization. For link services that support more than a single SNA link, this call can be made multiple times. For link services that support only a single link, this call can be made immediately after **SNAModemInitialize**; otherwise it is preferable to call **SNAModemAddLink** as each port is initialized.

Syntax

```
            void SNAModemAddLink(
  MODEM_STATUS **ppModemStatus);
```

Parameters

ppModemStatus

The address of a pointer to a **MODEM_STATUS** structure that will be used for storing modem status information. The returned **MODEM_STATUS** structure will contain a link service name.

Remarks

Note

The IHV should declare a pointer to a **MODEM_STATUS** structure and pass its address to **SNAModemAddLink**.

Note

The **LSName** is initially the name of the link service, but may need to be altered for multiport link services.The IHV can replace the link service name returned in the **MODEM_STATUS** structure to differentiate between possible multiple connections through a single link service.

Note

The IHV should maintain the various input and output signal lines and the data flow frame counts in the returned **MODEM_STATUS** structure. The Microsoft Host Integration Server 2009 Modem Monitor application will periodically read and display the data stored in this **MODEM_STATUS** structure.

Note

Internally **SNAModemAddLink** increments the usage count of the shared memory, and signals the Host Integration Server 2009 Modem Monitor application that a new link has been added.

See Also

Reference

MODEM_STATUS

SNAModemInitialize

SNAModemDeleteLink

The **SNAModemDeleteLink** function should be called when a link is terminating to delete the resources associated with the link. The parameters passed in must correspond to those returned by a call to **SNAModemAddLink**.

Syntax

```
            void SNAModemDeleteLink(
  MODEM_STATUS *pModemStatus);
```

Parameters

pModemStatus

A pointer to a **MODEM_STATUS** structure that was passed to the **SNAModemAddLink** function used for storing modem status interface.

Remarks

All resources in the link service associated with the modem status are deleted, and they must not be accessed by the IHV code after calling this function.

See Also

Reference

MODEM_STATUS

SNAModemAddLink

SNAModemTerminate

The **SNAModemTerminate** function should be called once per link service process, at termination. The ideal place is **SNALinkTerminate**. If the link service supports a single link, it is appropriate to call **SNAModemDeleteLink** immediately before **SNAModemTerminate**. Otherwise it is better to call **SNAModemDeleteLink** as each link instance is terminated.

Syntax

```
void SNAModemTerminate();
```

See Also

Reference

SNALinkTerminate

SNAModemDeleteLink

SNA Perfmon API

This section provides reference material for the SNA performance monitoring structures and functions.

In This Section

- ADAPTERCOUNTER
- ADAPTERPERFDATA
- SNAInitLinkPerfmon
- SNAGetLinkPerfArea
- SNAGetPerfValues

ADAPTERCOUNTER

The **ADAPTERCOUNTER** structure represents an individual SNA Perfmon event that can be monitored, such as the total bytes transmitted. All of the data needed to display a single Perfmon event is stored in this structure.

Syntax

```
typedef struct adaptercounter
{
    ULONG count;
    ULONG type;
    LONG scale;
} ADAPTERCOUNTER;
```

Members

count

The count for a specific Perfmon event since startup of the link service. Each time a Perfmon event takes place, the count is incremented accordingly, based on the type of event being counted. This count is maintained by the link service.

type

The event type that is being monitored with this **ADAPTERCOUNTER**. The **type** member instructs Perfmon whether the **count** member represents a numeric counter such as number of connection failures, a rate such as throughput in bytes transferred per second, or a percentage. For suitable values, see the platform SDK documentation of **PERF_COUNTER_*** (for example, **PERF_COUNTER_COUNTER** or **PERF_COUNTER_RAWCOUNT**).

scale

The default scale to be used by the Perfmon application when displaying this event. The **count** member is scaled by 10 raised to the power of scale such that a scale member of –1 multiplies **count** by 0.1.

ADAPTERPERFDATA

The **ADAPTERPERFDATA** structure groups all of the ADAPTERCOUNTER structures for an SNA link service together into a single block. It also has a few fields used internally by the SNA Perfmon code. The SNA link driver should not change the first three members of this structure.

Syntax

```
typedef struct adapterperfdata
{
    ULONG inuse;
    ULONG ServiceNameIndex;
    ULONG FirstCounterIndex;
    ADAPTERCOUNTER TotalBytesReceived;
    ADAPTERCOUNTER TotalBytesTransmitted;
    ADAPTERCOUNTER TotalFramesReceived;
    ADAPTERCOUNTER TotalFramesTransmitted;
    ADAPTERCOUNTER SuccessfulConnects;
    ADAPTERCOUNTER ConnectionFailures;
    ADAPTERCOUNTER TotalBytesThroughput;
    ADAPTERCOUNTER TotalFramesThroughput;
    ADAPTERCOUNTER AdapterFailures;
    ADAPTERCOUNTER reserved[11];
    ULONG pad;
} ADAPTERPERFDATA;
```

Members

inuse

A flag that indicates that the link service is using this section of shared memory.

ServiceNameIndex

An index into an array of strings describing events that can be monitored by the Perfmon functions. These strings are stored in the registry under the HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Perflib key.

FirstCounterIndex

An index into an array of events that can be monitored by the Perfmon functions.

TotalBytesReceived

The number of data bytes received per second.

TotalBytesTransmitted

The number of data bytes transmitted per second.

TotalFramesReceived

The number of data frames received per second. A frame is an information structure recognized by one of the various protocols related to SNA. Frames contain multiple bytes of data.

TotalFramesTransmitted

The number of data frames transmitted per second.

SuccessfulConnects

The number of times since startup that a successful connection has been made.

ConnectionFailures

The number of times since startup that a connection has encountered an error condition.

TotalBytesThroughput

The total number of bytes flowing through Host Integration Server 2009 per second. This includes both incoming and outgoing bytes, and is a good indicator of how heavily your Host Integration Server is loaded.

TotalFramesThroughput

The total number of data frames flowing through Host Integration Server per second. This includes both incoming and outgoing frames, and is a good indicator of how heavily your Host Integration Server is loaded.

AdapterFailures

The number of times since startup that a network adapter has encountered an error condition.

reserved

An array of **ADAPTERCOUNTER** structures for future expansion.

pad

Padding.

SNAInitLinkPerfmon

The **SNAInitLinkPerfmon** function initializes the Perfmon data structures and code for an SNA link. The user defines the address of a handle and a void pointer that are passed as parameters to this function. This function returns values in these parameters that are then used by subsequent calls to the Perfmon code. The SNA link driver should not modify the parameters returned by this function.

Syntax

```
            void SNAInitLinkPerfmon(
    HANDLE *shrlockmutx,
        void **shrptr
);
```

Parameters

shrlockmutx

An address of a handle of a mutex used to protect a block of shared memory. This handle address is used when calling other Perfmon functions after initialization.

shrptr

The address of a pointer to a block of shared memory used by subsequent Perfmon functions.

SNAGetLinkPerfArea

The **SNAGetLinkPerfArea** function returns a pointer to the shared data area used by the Perfmon application to store the link statistics. The parameters are the returned values from **SNAInitLinkPerfmon**. The SNA link then maintains the **ADAPTERCOUNTER** members of the returned **ADAPTERPERFDATA** structure.

Syntax

```
            ADAPTERPERFDATA * SNAGetLinkPerfArea(
HANDLEshrlockmutx,
ADAPTERPERFDATA *shrptr
);
```

Parameters

shrlockmutx

The handle of a mutex used to protect a block of shared memory that will contain the **ADAPTERPERFDATA** structure for this SNA link. The address of this handle is returned by the **SNAInitLinkPerfmon** function.

shrptr

A pointer to a block of shared memory returned by **SNAInitLinkPerfmon** that will contain the **ADAPTERPERFDATA** structure used by the Perfmon functions for this SNA link.

See Also

Reference

ADAPTERPERFDATA

SNAInitLinkPerfmon

SNAGetPerfValues

The **SNAGetPerfValues** function is used to provide pointers to the *ServiceNameIndex* and *FirstCounterIndex* variables so that the Perfmon application knows where to get the descriptions of the performance counters from the registry. These variables are returned as members in the **ADAPTERPERFDATA** structure returned by the **SNAGetLinkPerfArea** function.

Syntax

```
            USHORT SNAGetPerfValues(
            int *pServiceNameIndex,int *pFirstCounterIndex
);
```

Parameters

pServiceNameIndex

A pointer to the **ServiceNameIndex** member of the **ADAPTERPERFDATA** structure.

pFirstCounterIndex

A pointer to the **FirstCounterIndex** member of the **ADAPTERPERFDATA** structure.

Session Integrator Programmer's Guide

IcomLU0 Members

The following table shows the IcomLU0 members.

Public Methods

Method	Description
IcomLUO.CreateSession Method	Creates a new LU0 session.
IcomLUO.SetProperty Method	Allows the comLU0 client to set property values for a session.
IcomLUO.GetProperty Method	Extracts both pre-defined and application-specific properties for the session.
IcomLUO.Connect Method	Connects a comLU0 client to an existing session.
IcomLUO.Disconnect Method	Disconnects the comLU0 client from a previously-connected session.
IcomLUO.Receive Method	Receives outbound data on a LU0 session.
IcomLUO.Send Method	Sends a complete inbound chain of data on an LU0 session.
IcomLUO.SendResponse Method	Sends a response or courtesy acknowledgement to the host.
IcomLUO.Online Method	Sets the LU0 session back in an on-line state after a call to Offline.
IcomLUO.Offline Method	Switches the LU0 session into an off-line state, which in turn causes the underlying SNA session to deactivate.

IcomLU0 Interface

IcomLU0 Methods

The methods of the IcomLU0 interfaces are listed in the following table. For a complete list of the IcomLU0 members, see IcomLU0 Members.

Public Methods

Method	Description
IcomLUO.CreateSession Method	Creates a new LU0 session.
IcomLUO.SetProperty Method	Allows the comLU0 client to set property values for a session.
IcomLUO.GetProperty Method	Extracts both pre-defined and application-specific properties for the session.
IcomLUO.Connect Method	Connects a comLU0 client to an existing session.
IcomLUO.Disconnect Method	Disconnects the comLU0 client from a previously-connected session.
IcomLUO.Receive Method	Receives outbound data on a LU0 session.
IcomLUO.Send Method	Sends a complete inbound chain of data on an LU0 session.
IcomLUO.SendResponse Method	Sends a response or courtesy acknowledgement to the host.
IcomLUO.Online Method	Sets the LU0 session back in an on-line state after a call to Offline.
IcomLUO.Offline Method	Switches the LU0 session into an off-line state, which in turn causes the underlying SNA session to deactivate.

Concepts

IcomLU0 Interface

IcomLUO.CreateSession Method

Creates a new LU0 session.

Syntax

```
void CreateSession(
   string connectionSTR,
   short initType,
   ref System.Array data,
   int timeout,
   out object sessionHandle
)
```

Parameters

Parameter	Description
connectionSTR	NULL-terminated string that indicates the connection properties of the new session. The string is presented in a "PROPERTY=VALUE", space-delineated format. Connection property names and values are case insensitive. For more information about connection properties, see IcomLUO Session Properties.
initType	Contains the session initialization type. For more information, see the Comments section.
data	Pointer an array of type unsigned char that contains the INITSELF or SSCP logon message. Used only if *initType* contains INIT_INITSELF or INIT_LOGON.
timeout	The period of time in milliseconds to wait for the BIND and SDT commands to arrive. If the timeout expires before the SDT arrives the SNA server LU will be released and an error returned. Entering **0xffffffff** into *timeout* indicates an infinite wait time.
sessionHandle	When this method successfully returns, contains a pointer to the IUnknown interface to the comLU0 session object representing the underlying LU0 session. As along as a reference is kept to this interface, the session object will remain intact. This interface may be passed to the IcomLU0.Connect method to connect to the comLU0 object with the session. If no LU property is specified, comLU0 will select the best available LU assigned to the user account under which it is running.

Return Value

The following table describes the return codes for CreateSession.

Value	Description
S_OK	The LU0 session was successfully created. The LU session is active and ready to receive input.
CLU0_S_SSCP_ACTIVE	The LU0 session was successfully created. The SSCP session is active and ready to receive input. This return code is valid only when *initType* is set to **INIT_SSCP**.
CLU0_E_NEG_RESPONSE	The host or SNA server sent a negative response to the INITSELF. Optionally, the host or SNA server may have sent an unformatted logon command. This is true only if *initType* is set to **INIT_INITSELF** or **INIT_LOGON**.
CLU0_E_BADPARM	*connectionStr* contained an invalid property setting.

CLU0_E_NOFREELU	The LU specified in *luname* is an SNA server LU pool. The pool does not currently have any free LUs.
CLU0_E_LUINUSE	The LU specified in *luname* is an SNA server LU. This LU is currently being used by another application.
CLU0_E_LUNOTFOUND	The LU or pool name does not exist.
CLU0_E_TIMEDOUT	The session was not started within the specified timeout.
CLU0_E_SESSION_FAILED	The session failed to activate and is not connected to any TSS LU0 session. The application should attempt to create a new session using the same or different connection properties, or else connect to a different TSS session handle.
CLU0_E_ACCESSDENIED	The user account for the client does not have permission to use the requested LU or pool.
CLU0_E_ALREADY_CONNECTED	The comLU0 client is already connected to another session.
CLU0_E_SYSERROR	Failed due to an internal error.

Remarks

The following table contains the possible values for *initType*.

Name	**Value**	**Description**
INIT_BIND	0	Wait for an unsolicited BIND and SDT from the PLU.
INIT_SSCP	1	Wait for a BIND and SDT to arrive but allow access to the SSCP session for the application to send SSCP data and commands.
INIT_INITSELF	2	Wait for a BIND and SDT to arrive after sending the INITSELF command specified in *data*.
INIT_LOGON	3	Wait for a BIND and SDT to arrive after sending the UNFORMATTED SSCP logon message specified in *data*.

Example

This is the description for a Code Example.

Using Session Integrator for LU0

IcomLUO.SetProperty Method

Allows the comLU0 client to set property values for a session.

Syntax

```
void SetProperty(
   string PropertyName,
    ref object value)
```

Parameters

Parameter	Description
PropertyName	The name of the property to be added or updated.
Value	The value of the specified property.

Return Value

Value	Description
S_OK	The requested property was added successfully.
CLU0_S_PROP_UPDATED	The existing property specified was updated successfully
CLU0_E_NOT_CONNECTED	The comLU0 client object is not connected to a session object through a call to the IcomLU0.Connect method.
CLU0_E_SERVER_FAILURE	The TSS session is no longer valid. You should release the session handle.
CLU0_E_WAITING	Another thread has issued a Receive call for the specified comLU0 method which has not yet returned.
CLU0_E_BADPARAM	The specified property is a pre-defined session property, and therefore could not be updated.

Remarks

Property names are case-insensitive.

You cannot use SetProperty to modify any of the predefined connection properties. Instead, you can change only the properties defined with CreateSession.

See Also

Concepts

IcomLU0 Methods

Other Resources

Using Session Integrator for LU0

IcomLUO.GetProperty Method

Extracts both pre-defined and application-specific properties for the session.

Syntax

```
void SetProperty(
   string PropertyName,
   ref object value)
```

Parameters

Parameter	Description
PropertyName	The Name of the property to be extracted.
value	When the method returns, contains the value of the specified property.

Return Value

Value	Description
S_OK	The method completed successfully.
CLU0_E_NOT_CONNECTED	The comLU0 client object is not connected to a session object through a call to Icom3270.Connect.
CLU0_E_SERVER_FAILURE	The TSS session is no longer valid. You should release the session handle.
CLU0_E_WAITING	Another thread has issued a Receive call for the specified comLU0 method, and has not yet returned.
CLU0_E_BADPARAM	The specified property has not been defined for this session.

Remarks

You can use getParameter, to determine the name of the pooled LU selected for the session when an LU0 session was originally created using an SNA Server pool name.

See Also

Concepts

IcomLU0 Methods

Other Resources

Using Session Integrator for LU0

IcomLUO.Connect Method

Connects a comLU0 client to an existing session.

Syntax

```
Void Connect(
   object sessionHandle
)
```

Parameters

Parameter	Description
sessionHandle	Pointer to an IUnknown that contains the session handle of the session to connect to.

Return Value

Value	Description
S_OK	The method has completed successfully.
CLU0_S_SSCP_ACTIVE	The comLU0 session is connected to an SSCP initiated session whose LU-LU session is not yet active. You should send the appropriate messages to the SSCP to solicit activation of the session.
CLU0_S_OFFLINE	The comLU0 session is connected to an SNA session that is currently offline. You should call IcomLU0.Online to activate the session.
CLU0_E_SESSION_FAILED	The underlying SNA session failed. You must disconnect and release the server session.
CLU0_E_ALREADY_CONNECTED	Another comLU0 client is connected to this session.
CLU0_E_SYSERROR	Connect failed due to an internal systems error.
E_NOINTERFACE	The session handle is not a valid IUnknown interface pointer.

Exceptions

Remarks

Once you connect successfully to a session, you are responsible for calling IcomLU0.Receive to provide processing time for outbound data.

You are guaranteed exclusive access to the session until you call IcomLU0.Disconnect.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

IcomLUO.Disconnect Method

Disconnects from a previously-connected session.

Syntax

```
void Disconnect()
```

Parameters

Return Value

Value	Description
S_OK	The method completed successfully.
CLU0_E_NOTCONNECTED	The comLU0 client is not connected to a session through a call to IcomLU0.Connect.
CLU0_E_SERVER_FAILURE	The TSS session is no longer valid. You should release the session handle.
CLU_E_WAITING	Another thread has issued a receive call for this comLU0 method, and has not yet returned.
CLU0_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

After your call to Disconnect is complete, you must call Connect again in order to access the session. This is true regardless of whether your call to Disconnect was successful.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Using Session Integrator for LU0

IcomLUO.Receive Method

Receives outbound data on a LU0 session.

Syntax

```
void Receive(
   int timeout,
   ref int datasize,
   out int indication,
   out short seqno,
   ref System.Array data
)
```

Parameters

Value	Description
timeout	The period of time in milliseconds that the thread can wait for data to arrive. By setting *dataSize*, you can indicate if the application is willing to accept partial data after a timeout. Entering 0xffffffff into *howLong* indicates an infinite length of time.
datasize	The maximum amount of data that the application is willing to accept. If *dataSize* bytes of data are received before the timeout is compete, Receive will return the partial chain. When this method returns, contains the number of bytes present in the data buffer.
indication	One or more flags in a bitwise OR containing additional information about the outbound datastream. For more information, see the Remarks section.
seqno	When this method returns, contains the SNA sequence number of the chain. If NEG_RESPONSE is set in *indication*, *seqno* may instead contain the sequence number of the chain to which the host sent a response. The value returned in *seqno* may be used in IcomLU0.SendResponse to transmit a SNA response.
data	An array containing the data to receive.

Return Value

Value	Description
S_OK	A complete, or else the remainder of a partial, chain of data was received into the data buffer.
CLU0_S_PARTIAL_CHAIN	A partial chain of data was received into the data buffer.
CLU0_S_TIMEOUT	No data was received within the timeout specified. You should issue another Receive.
CLU0_E_SESSIONFAILURE	The LU0 session failed.
CLU0_E_SERVER_FAILURE	The TSS session is no longer valid. The application should release the session handle.

CLU0_E_WAITING	Another thread has issued a Receive call for this method, and has not yet returned.
CLU0_E_SESSION_FAILED	The underlying SNA session failed, possibly due to a link outage or other transient failure. You must either disconnect and release the server session. Alternately, you may call IcomLU0.Offline to reset the session, and then call IcomLU0.Online to reactive the session.
CLU0_E_NOTCONNECTED	The comLU0 client is not connected to a session through a call to Icom3270.Connect.
CLU0_E_BADPARAM	One of the parameters contained an invalid value.
CLU0_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

Normally, Receive blocks until a complete chain of SNA data is available. However, the application can control the block through *howLong*, *maxData*, and *incompleteData*.

Receive returns only application-level data. Specifically, Receive will not return the SNA TH and RH headers.

The following table describes the possible values for *indication*.

Value	**Description**
SESSION_STARTED	One of the following: • The SSCP-initiated session has been activated. • A session that was reset by a CLEAR has been restarted by an SDT. • A session that previously received an UNBIUND has been reactivated by a BIND and SDT.
BEGIN_BRACKET	The host started a new bracket.
END_BRACKET	The host terminated the current bracket.
SEND	The host has given permission to send.
DATA_COMPLETE	The data represents a complete data chain or the end of a data chain.
DATA_INCOMPLETE	The data represents an incomplete data chain.
CANCEL	The last chain from the host was cancelled.
NO_RESPONSE	The application should not send a response to the data.
EXCEPTION_RESPONSE1/2	The application may send a negative response to reject the data, or a courtesy acknowledgement.
DEFINITE_RESPONSE1/2	The application must send a response to the data.
POS_RESPONSE	The host sent a positive response.

NEG_RESPONSE	The host sent a negative response.
EXR_REQUEST	The SNA server converted the host request into an exception request.
CHASE	The host requests that all outstanding responses be sent.
NORMAL_DATA	The data was received on the normal data flow.
EXPEDITED_DATA	The data was received on the expedited data flow.
APPL_DATA	The data is application (FMD) data.
FM_DATA	The data is Function Management (FMH) data.
LU_DATA	The data was received on the LU session.
SSCP_DATA	The data was received on the SSCP session.
CLEAR	The host has cleared the session.
QUIESCE	The host has quiesced the session.
SHUTDOWN	The host is shutting down the session.
RELEASE	The host cancelled the quiesce or shutdown state.
UNBIND	The host unbound the LU-LU session.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

See Also
Concepts
IcomLU0 Methods
Other Resources
Using Session Integrator for LU0

IcomLUO.Send Method

Sends a complete inbound chain of data on an LU0 session.

Syntax

```
void Send(
   int hint,
   ref System.Array data,
    out short seqno)
```

Parameters

Parameter	Description
hint	A hint from the application regarding how the data is to be processed. For more information, see the remarks section.
data	The data to send.
seqno	When this method returns, contains the SNA sequence number of the chain. You can use the value returned by *seqno* to correlate any response the host may send later.

Return Value

Value	Description
S_OK	The data was sent successfully. If relevant, positive response was also received.
CLU0_S_MULTI_CHAIN	The session does not support multi-RU chains, but the data was larger than the RU size. comLU0 sent the data as a sequence of single RU chains.
CLU0_S_DEFINITE_RSP_MODE	comLU0 sent the data using DEFINITE_RESPONSE mode when EXCEPTION_RESPONSE or NO_RESPONSE was requested.
CLU0_S_EXCEPTION_RSP_MODE	comLU0 send the data using EXCEPTION_RESPONSE mode when DEFINITE_RESPONSE or NO_RESPONSE was requested.
CLU0_S_NO_RSP_MODE	comLU0 sent the data using NO_RESPONSE mode when DEFINITE_RESPONSE or EXCEPTION_RESPONSE was requested.
CLU0_E_NEG_RESPONSE	The host or SNA server sent a negative response to the DEFINITE_RESPONSE.
CLU0_E_NO_RSP_REQUESTED	No response was received from the host to a RQD request. You should call IcomLU0.Receive to determine the reason that he response was not received. For example, a CLEAR may have been received, or the session experienced an outage.
CLU0_E_BRACKED_NOT_ALLOWED	The session was between brackets but comLU0 was not allowed to start a new bracket. This occurred due to comLU0 receiving an SBI from the host.
CLU0_E_SESSION_FAILED	The underlying SNA session failed, possibly do to a link outage or other transient failure. You must disconnect and release the server session. Optionally, you may call IcomLU0.Offline to reset the session, and then call IcomLU0.Online to reactive the session.

CLU0_E_RECEIVE_IN_PROGRESS	The application has not completed receiving the last chain sent by the host. This is likely indicated by Receive returning the DATA_INCOMPLETE message. You should re-issue IcomLU0.Receive call to collect the remaining data and then call Send again.
CLU0_E_SERVER_FAILURE	The TSS session is no longer valid. You should release the session handle.
CLU0_E_WAITING	Another thread has issued a Receive call for this method, which has not yet returned.
CLU0_E_SESSIONFAILURE	The LU0 session failed.
CLU0_E_NOTCONNECTED	The comLU0 client is not connected to a session through a call to Icom3270.Connect.
CLU0_E_SYSERROR	The send failed due to a system error.

Exceptions

Remarks

The SNA TH and RH are provided by comLU0 and must not be present in the data presented by the application.

The following table describes the possible values for *hint*.

Value	**Description**
END_BRACKET	comLU0 should end the current bracket.
PREPARE_TO_RECEIVE	The application is about to enter the receive state.
NO_RESPONSE	The application does not need a response from the host.
EXCEPTION_RESPONSE1/2	The application requires that the host send a negative response only.
DEFINITIE_RESPONSE1/2	The application requires that the host send a response to the data.
NORMAL_DATA	The application is sending the on the normal data flow.
EXPEDITED_DATA	The application is sending the data on the expedited data flow.
APPL_DATA	The data is application (FMD) data.
FM_DATA	The data is Function Management (FMH) data
LU_DATA	The application is sending the data on the LU session.
SCP_DATA	The application is sending the data on the SSCP session.

Example

This is the description for a Code Example.

Optional comments.

Using Session Integrator for LU0

IcomLUO.SendResponse Method

Sends a response or courtesy acknowledgement to the host.

Syntax

```
void SendResponse(
   int senseCode,
   int hint,
   short seqno
)
```

Parameters

Parameter	Description
senseCode	The sense code to send to the host, in Intel byte order. 0x00000000 indicates a positive response or a courtesy acknowledgement to exception response data.
hint	A hint to indicate the message flow on which the response is to be sent. Hint should be a bitwise combination of LU_DATA or SSCP_DATA and NORMAL_DATA or EXPEDITED_DATA.
seqno	The sequence number of the request to respond to. The value used in *seqno* is returned by IcomLU0.Receive.

Return Value

Value	Description
S_OK	The method sent the message successfully.
CLU0_E_SESSION_FAILED	The underlying SNA session failed, possibly due to a link outage or other transient failure. You must disconnect and release the server session. Optionally, you may issue a call to IcomLU0.Offline to reset the session, and then reactivate the session with a call to IcomLU0.Online.
CLU0_E_RECEIVE_IN_PROGRESS	The application has not completed receiving the last chain sent by the host. This may be indicated by Receive returning DATA_INCOMPLETE. The you should re-issue the IcomLU0.Receive call to collect the remaining data and then retry the call to SendResponse.
CLU0_E_SERVER_FAILURE	The TSS session is no longer valid. You should release the session handle.
CLU0_E_WAITING	Another thread has issued a Receive call for this comLU0 method which has not yet returned.
CLU0_E_NOTCONNECTED	The comLU0 client is not connected to a session object through a call to Connect.
CLU0_E_SYSERROR	This method failed due to an internal error.

Exceptions

Remarks

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Using Session Integrator for LU0

IcomLUO.Online Method

Sets the LU0 session back in an on-line state after a call to Offline.

Syntax

```
void Online(
   short initType,
   ref System.Array data,
   int timeout)
```

Parameters

Parameter	Description
initType	Describes the session initiation type. For more information, see the Remarks section.
data	Contains the INITSELF or SSCP logon message, if necessary.
timeout	The period of time in milliseconds to wait for the BIND and SDT to arrive. If the timeout expires before the SDT arrives, the SNA server LU will be released and an error returned. 0xffffffff indicates an infinite timeout.

Return Value

Value	Description
S_OK	The LU0 session was successfully reactivated and the LU session is active and ready to receive input.
CLU0_S_SSCP_ACTIVE	The LU0 session was successfully reactivated and the SSCP session is active and ready to receive input. Valid only when *initType* is set to INIT_SSCP.
CLU0_E_NEG_RESPONSE	The host or SNA server sent a negative response to the INITSELF or unformatted logon command. Valid only if *initType* is set to INIT_INITSELF or INIT_LOGON
CLU0_E_BADPARAM	*connectionStr* contained an invalid property setting.
CLU0_E_NOFREELU	*luname* specified an SNA server LU pool, and no LUs are free in that pool.
CLU0_E_LUINUSE	*luname* specified an SNA server LU, and the LU is currently in use by another application.
CLU0_E_LUNOTFOUND	The LU or pool name does not exist.
CLU0_E_TIMEDOUT	The session was not started within the timeout specified.
CLU0_E_SESSION_FAILED	The underlying SNA session failed, possibly due to a link outage or other transient failure. You must disconnect and release the server session. Optionally, you may issue a call to Icom3270.Offline to reset the server, and then reactivate the session using a call to Icom3270.Online.

CLU0_E_SERVER_FAILURE	The TSS session is no longer valid. You should release the session handle.
CLU_E_WAITING	Another thread has issued a Receive call for this method, which has not yet returned.
CLU_E_SYSERROR	This method failed due to an internal error.

Exceptions

Remarks

Online will attempt to acquire the same SNA server LU, and therefore the same SNA server, used when the session was last on-line.

The following table describes the possible values for *initType*.

Name	Value	Description
INIT_BIND	0	Wait for unsolicited BIND and SDT from the PLU.
INIT_SSCP	1	Wait for a BIND and SDT to arrive but allow access to the SSCP session for the application to send SSCP data and commands.
INIT_INITSELF	2	Wait for a BIND and SDT to arrive after sending the INITSELF command specified in *data*.
INIT_LOGON	3	Wait for a BIND and SDT to arrive after sending the UNFORMATTED SSCP logon message specified in *data*.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

See Also
Concepts
IcomLU0 Methods
Other Resources
Using Session Integrator for LU0

IcomLUO.Offline Method

Switches the LU0 session into an off-line state, which in turn causes the underlying SNA session to deactivate.

Syntax

```
void Offline()
```

Parameters

Return Value

Value	Description
S_OK	The session has been successfully deactivated.
CLU0_E_WAITING	Another thread has issued a Receive call for this comLU0 method, which has not yet returned.
CLU_E_SERVER_FAILURE	The TSS session is no longer valid. The application should release the session handle.
CLU0_E_RECEIVE_IN_PROGRESS	The application has not yet completed receiving the last chain sent by the host. This may be indicated by Receive returning DATA_INCOMPLETE. You should re-issue the IcomLU0.Receive call to collect the remaining data, and then call IcomLU0.Offline again.
CLU0_E_SYSERROR	This method failed due to an internal error.

Exceptions

Remarks

After calling Offline, the client application can later reactivate the session using a call to Online.

Note that Offline releases the SNA server LU. Therefore, it is possible for another application to acquire the LU before your application calls Online again.

You can use Online to recover a session that has returned CLU0_E_SESSION_FAILED.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270 Interface

The Icom3270 interface allows access to an LU0 session.

Note
For more information about accessing IcomLU0 from managed text, see Microsoft.HostIntegration.SNA.Session.

Requirements

Type Library: COM3270 1.0 Type Library (siproxy.dll)

Platforms: Windows Server 2003 SP1 Standard and Enterprise Editions.

Icom3270 Members

The following table describes the Icom3270 members.

Public Methods

Method	Description
Icom3270.createSession Method	Creates a new 3270 session.
Icom3270.getProperty Method	Describes the properties of a session.
Icom3270.connect Method	Connects a com3270 client to an existing session.
Icom3270.disconnect Method	Disconnects from a session.
Icom3270.setCursorPosition Method	Sets the position of the cursor on the 3270 screen.
Icom3270.getCursorPosition Method	Retrieves the current cursor position as an offset of the 3270 display buffer.
Icom3270.sendKey Method	Sends one or more keystrokes to the Host session.
Icom3270.wait Method	Waits for the session to enter a state where input is allowed or the screen is modified.
Icom3270.getOIA Method	Returns a copy of the Operator Information Area (OIA) for the 3270 session.
Icom3270.getScreenSize Method	Returns the size, in rows and columns, of the current 3270 screen.
Icom3270.getField Method	Returns the starting position and length of the field containing the specified screen offset .
Icom3270.getNextField Method	Finds the starting position and length of the field located after the specified offset.
Icom3270.getPrevField Method	Finds the starting position and length of the field before the specified screen offset.
Icom3270.getFieldData Method	Extracts the data contents of the specified field.
Icom3270.setFieldData Method	Sets the data contents pf the specified field.
Icom3270.findFieldData Method	Searches the specified field for the specified data string.
Icom3270.getScreenData Method	Extracts the data contents of the 3270 screen.
Icom3270.setScreenData Method	Copies data characters, character attributes, and extended attributers to all or part of the screen.
Icom3270.findScreenData Method	Searches the screen for a specified data string.

Concepts

Icom3270 Interface

Icom3270 Methods

The methods of the Icom3720 interfaces are listed in the following table. For a complete list of the IcomLU0 members, see Icom3270 Members.

Public Methods

Method	Description
Icom3270.createSession Method	Creates a new 3270 session.
Icom3270.getProperty Method	Describes the properties of a session.
Icom3270.connect Method	Connects a com3270 client to an existing session.
Icom3270.disconnect Method	Disconnects from a session.
Icom3270.setCursorPosition Method	Sets the position of the cursor on the 3270 screen.
Icom3270.getCursorPosition Method	Retrieves the current cursor position as an offset of the 3270 display buffer.
Icom3270.sendKey Method	Sends one or more keystrokes to the Host session.
Icom3270.wait Method	Waits for the session to enter a state where input is allowed or the screen is modified.
Icom3270.getOIA Method	Returns a copy of the Operator Information Area (OIA) for the 3270 session.
Icom3270.getScreenSize Method	Returns the size, in rows and columns, of the current 3270 screen.
Icom3270.getField Method	Returns the starting position and length of the field containing the specified screen offset.
Icom3270.getNextField Method	Finds the starting position and length of the field located after the specified offset.
Icom3270.getPrevField Method	Finds the starting position and length of the field before the specified screen offset.
Icom3270.getFieldData Method	Extracts the data contents of the specified field.
Icom3270.setFieldData Method	Sets the data contents pf the specified field.
Icom3270.findFieldData Method	Searches the specified field for the specified data string.
Icom3270.getScreenData Method	Extracts the data contents of the 3270 screen.
Icom3270.setScreenData Method	Copies data characters, character attributes, and extended attributers to all or part of the screen.
Icom3270.findScreenData Method	Searches the screen for a specified data string.

Icom3270.createSession Method

The creaetSession method creates a new 3270 session.

Syntax

```
void CreateSession(
   string connectionStr,
   out object sessionHandle
)
```

Parameters

Parameter	Description
connectionStr	NULL-terminated string containing the connection properties of the new session. The string is presented in a space-delineated "PROPERTY=VALUE" format. Property names and values are case-insensitive. For more information, see Icom3270 Session Properties.
sessionHandle	When this method returns, contains a pointer to the IUnknown interface for the comSNA3270 session. This session represents the underlying SNA session. You will use *sessionHandle* in Icom3270.Connect to connect the com3270 object with the session.

Return Value

Value	Description
C3270_S_LINKINAC	The SNA session was successfully created, but the underlying SNA connection is not yet active. You should use Icom3270.wait to wait for the session to become active.
C3270_S_PUINAC	The SNA session was successfully created, but the SNA PU is not yet active. You should use Icom3270.wait to wait for the session to become active.
C3270_S_LUINAC	The SNA session was successfully created, but he LU is not yet active. You should use Icom3270.wait to wait for the session to become active.
C3270_S_TN3270E	The TN3270 session was successfully created in TN3270E, or RFC 1647, mode.
C3270_S_TN3270	The TN3270 session was successfully created in TN3270, or RFC 1576, mode.
S_OK	The SNA or local session was successfully created and the LU_SSCP session is active and ready to receive input.
C3280_E_BADPARAM	*connectionStr* contained an invalid property setting.
C3270_E_NOFREELU	*luname* specified an SNA Server LU pool. However, there are no LUs free in that pool.
C3270_E_LUINUSE	*luname* specified an SNA server LU pool. However, the LU is currently in use by another application.
C3270_E_LUNOTFOUND	The LU or pool name does not exist.
C3270_E_SYSERROR	The method failed due to an internal error.

C3270_E_ACCESSDENIED	The user account for the client does not have permission to use the requested LU or pool.
C3270_E_NOTFOUND	The remote system specified by the IP property in *connectionStr* could not be located.
C3270_E_REFUSED	The remote system specified by the IP and PORT properties in *connectionSTR* refused the connection string.

Exceptions

Remarks

The following list describes the location of the session, as determined by to the session type. A session type is also known as the MODE property.

- Local session - created on the client.
- SNA session - created on the SNA server machine that is configured with the requested LU or pool.
- TN3270 session - created on the COM server specified by the SERVER property.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.getProperty Method

The getProperty method describes the properties of a session.

Syntax

```
void GetProperty(
   string PropertyName,
   out object value
)
```

Parameters

Parameter	Description
propertyName	The name of the property to be returned.
propertyValue	When this method returns, contains the value of the specified property.

Return Value

Value	Description
S_OK	The method completed successfully.
C3270_E_NOT_CONNECTED	The com3270 client is not connected to a session object through Icom3270.Connect.
C3270_E_INVALIDMODE	The property described in *propertyName* is not valid for the session MODE setting.

Exceptions

Remarks

You can use getProperty to determine the name of the pooled LU selected for the session when an SNA session was originally created using an SNA server pool name. For more information, see Supported com3270 Session Properties.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.connect Method

The connect method connects a com3270 client to an existing session.

Syntax

```
void Connect(
   object sessionHandle
)
```

Parameters

Parameter	Description
sessionHandle	Session handle of the session to connect to.

Return Value

Value	Description
S_OK	The method completed successfully.
C3270_E_ALREADY_CONNECTED	Another com3270 client is connected to the specified session.
C3270_E_SYSERROR	The method failed due to an internal error.
E_NOINTERFACE	The specified session handle is not a valid comSNA3270, COMTN3270, or comLocal3270 IUnknown interface pointer.

Exceptions

Remarks

Once you connect successfully to a session, you are responsible for calling Icom3270.wait in order to provide processing time for incoming 3270 data stream packets.

You are guaranteed exclusive access to the session until you call disconnect. Specifically, the screen buffers and screen size are guarnenteed not to change unless you call Icom3270.wait.

If connect completes successfully, you should then call Icom3270.wait. Calling wait allows you to process any unprocessed 3270 data and to ensure that the session is in an unlocked state. After calling wait, you can then update or read the display buffers or send keystrokes to the host application.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.disconnect Method

The disconnect method disconnects from a session.

Syntax

```
void Disconnect()
```

Parameters

Return Value

Value	Description
S_OK	The method completed successfully
C3270_E_NOTCONNECTED	The com3270 client is not connected to a session through a call to Icom3270.connect.
C3270_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

After you call disconnect, even if the call fails, you must call Icom3270.connect again before accessing the session.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements

Subhead

Icom3270.setCursorPosition Method

The setCursorPosition sets the position of the cursor on the 3270 screen.

Syntax

```
void SetCursorPosition(
   ushort position
)
```

Parameters

Parameter	Description
pos	A 0-based offset within the screen buffer that describes the location of the cursor.

Return Value

Value	Description
S_OK	The method has completed successfully.
C3270_E_INVALIDPOS	The specified screen position is greater than the maximum character position for the current screen size.
C3270_E_SESSIONBUSY	The 3270 session is busy. You may call Icom3270.wait to determine when input is allowed. Afterwards, you can attempt to call setCursorPosition again.
C3270_E_NOTCONNECTED	The com3270 client is not connected to a session through a call to Icom3270.connect.
C3270_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

After you call setCursor, you may call sendKey. Calling sendKey will write printable character, starting from the location specified by setCursor.

To determine the offset of a particular row and column character address, you can use getScreenSize to retrieve the number of columns in each screen row.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.getCursorPosition Method

The getCursorPosition method retrieves the current cursor position as an offset of the 3270 display buffer.

Syntax

```
void GetCursorPosition(
   out ushort position
)
```

Parameters

Parameter	Description
position	When this method returns, contains a 0-based offset describing the current cursor position.

Return Value

Value	Description
S_OK	The method has completed successfully.
C3270_E_SESSIONBUSY	The 3270 session is busy. You may call wait to determine when input is allowed and getCurrentPosition can be retried.
C3270_E_NOTCONNECTED	The com3270 client is not connected to a session through a call to Icom3270.connect.
C3270_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

The cursor position may change as a result of a call to setCursorPosition, sendKey, or wait.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.sendKey Method

The sendKey method sends one or more keystrokes to the Host session.

Syntax

```
void SendKey(
   ushort count,
   ref System.Array keys
)
```

Parameters

Parameter	Description
count	The number of bytes in the buffer.
keys	A pointer to the buffer containing the keystrokes to send.

Return Value

Value	Description
S_OK	The method has returned successfully.
C3270_E_BADPARAM	One of the parameters is invalid.
C3270_E_SESSIONBUSY	The 3270 session is busy. You may call Icom3270.wait to determine when input is allowed before retrying sendKey.
C3270_E_SESSIONLOCKED	The 3270 session is locked due to a local lock condition. You may examine the OIA buffer to determine the reason for the error. Afterwards, you may want to send a RESET keystroke to unlock the keyboard before calling sendKey again or any other recovery action.
C3270_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

sendKey emulates a user typing at the 3270 keyboard. You can use sendkey to send3270 functions, such as RESET, INSERT, or TAB, to the session. You can also send both single and double-byte graphic keys to the session.

Note that if you send an AID key, the host will ignore any subsequent keys in the buffer. As such, the AID key should be the last keystroke you send.

Graphic keys are represented by their EBCIDIC character balue, or two characters for DBCS in the Host code page. 3270 Function and AID keys are represented by the multi-byte EBCIDIK key codes described in the Microsoft SNA Server Windows HLLAPI Specification.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.wait Method

The wait method waits for the session to enter a state where input is allowed or the screen is modified.

Syntax

```
void Wait(
   uint howLong,
   int waitForUpdate
)
```

Parameters

Parameters	Value
howLong	A period of time, measured in units of 0.5 seconds, that the thread is willing to waif for input to be enabled or the screen to be updated. 0xffffffff indicates that the thread should wait indefinitely.
waitForUpdate	If false, this method will return as soon as the session is in an input allowed state. The session returns immediately if the session is currently in an input allowed state. For more information, see the Remarks section.

Return Value

Value	Description
S_OK	The session is available for input.
C3270_S_SIZECHANGED	The session is available for input, but the screen size was modified during the invocation of wait. You should gall getScreenSize to determine the new screen size.
C3270_E_SESSIONBUSY	The 3270 session is still busy, but the time-out period specified by howLong expired. You should perform any necessary processing before calling wait again.
C3270_E_SESSSIONLOCKED	The 3270 session is locked due to a local lock condition. You should examine the OIA buffer to determine the reason for the error. You may also send a RESET keystroke to unlock the keyboard before calling wait again or performing any other recovery action.
C3270_E_SESSIONFAILURE	The 3270 session failed. Either the PLU_SLU or SSCP session was deactivated while the wait was in progress. You should examine the session status in the OIA for the session and take appropriate recovery action.
C3270_E_SYSERROR	The method failed due to an internal error.

Remarks

Calling wait allows the session to process messages from the host when the application is active, connected to the host, and waiting for data.

You should set waitForUpdate to true when the Host unlocks the keyboard and sends screen updates in separate operations. In particular, you should do this on the SSCP session, where input is enabled on receipt of an SNA response to data from the client. The reply data is dent on a subsequent message.

Example

Icom3270.getOIA Method

The getOIA method returns a copy of the Operator Information Area (OIA) for the 3270 session.

Syntax

```
void GetOIA(
   out System.Array oiaBuffer
)
```

Parameters

Parameter	Description
oiaBuffer	When this method returns, contains the buffer into which the current OIA is copied. For more information, see the Remarks section.

Return Value

Value	Description
S_OK	The method has completed successfully.
C3270_NOTCONNECTED	The com3270 client is not connected to a session through a call to Icom3270.connect.
C3270_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

The OIA is a bit map that provides information regarding the status of the current screen. You may use the OIA to determine the ownership of the session, and the reason for input-inhibited errors.

As defined by COM, it is your responsibility to release the memory of the returned SAFEARRAY structures.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.getScreenSize Method

The getScreenSize method returns the size, in rows and columns, of the current 3270 screen.

Syntax

```
void GetScreenSize(
   out ushort rows,
   out ushort cols
)
```

Parameters

Parameter	Description
rows	When this method returns, contains the number of rows on the current screen.
cols	When this method returns, contains the number of columns on the current screen.

Return Value

Value	Description
S_OK	The method has returned successfully.
C3270_E_NOTCONNECTED	The com3270 client is not connected to a session through a call to Icom3270.connect.
C3270_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

You should call getScreenSize immediately after Icom3270.wait to determine whether the screen size has changed as a result of a Host application command.

You should not attempt to access or modify the screen buffers returned by the Icom3270.connect beyond the limits of the current screen size.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.getField Method

The getField method returns the starting position and length of the field containing the specified screen offset.

Syntax

```
void GetField(
   ref ushort position,
   out ushort length
 )
```

Parameters

Parameter	Description
position	The 0-based screen offset of a character in the desired field. Note that the calculation used by getField considers the field attribute character part of the field. The field attribute character immediately precedes the field data. When this method returns, contains the 0-based offset of the first data position of the field.
length	When this method returns, contains the length of the desired field, excluding the field attribute character. Possible values range between 0 and (screen size - 1).

Return Value

Value	Description
S_OK	The method has completed successfully.
C3270_E_INVALIDPOS	The screen position specified is greater than the maximum character position for the current screen size.
C3270_E_UNFORMATTED	The screen is unformatted. Therefore, the specified field does not exist.
C3270_E_NOTCONNECTED	The com3270 client is not connected to a session object through a call to Icom3270.connect.
C3270_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.getNextField Method

The getNextField method finds the starting position and length of the field located after the specified offset.

Syntax

```
void GetNextField(
   ref ushort position,
   ushort fieldType,
   out ushort length
)
```

Parameters

Parameter	Description
position	The 0-based screen offset from which to start the search. When this method returns, contains the 0-based offset of the first data position of the following field.
fieldType	The type of field requested. For more information, see the Remarks section.
length	When this method returns, contains the length of the desired field, excluding the field attribute character. Possible values are 0 through (screen size - 1).

Return Value

Value	Description
S_OK	The method has returned successfully.
C3270_E_INVALIDPOS	The specified screen position is greater than the maximum character position for the current screen size.
C3270_E_UNFORMATTED	The screen is unformatted. Therefore, the specified field does not exist.
C3270_E_NOTFOUND	The specified field could not be found.
C3270_E_NOTCONNECTED	The com3270 client is not connected to a session through a call to Icon3270.connect.
C3270_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

For the purpose of this search, the field attribute character is considered part of the field. The field attribute character immediately precedes the field data.

The following table describes the possible values for fieldType.

Value	Description
0	Either protected or unprotected.
1	Unprotected field only.
2	Protected field only.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.getPrevField Method

The getPrevField finds the starting position and length of the field before the specified screen offset.

Syntax

```
void GetPrevField(
   ref ushort position,
   ushort fieldType,
   out ushort length
)
```

Parameters

Parameter	Description
position	The 0-based screen offset to start searching from. When this method returns, contains the 0-based offset of the first data position in the previous field.
fieldType	The type of field requested. For more information, see the Remarks section.
length	When this method returns, contains the length of the desired field, excluding the field attribute character. Possible values are 0 through (screen size - 1).

Return Value

Value	Description
S_OK	The method has returned successfully
C3270_E_INVALIDPOS	The specified screen position is greater than the maximum character position for the current screen size.
C3270_E_UNFORMATTED	The screen is unformatted. Therefore, the specified field does not exist.
C3270_E_NOTCONNECTED	The com3270 client is not connected to a session through a call to Icom3270.connect.
C3270_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

For the purpose of getPrevField, the field attribute character is considered part of the field. The field attribute character immediately precedes the field.

The following table describes the possible values for *fieldType*.

Value	Description
0	Either protected or unprotected
1	Unprotected field only
2	Protected field only

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.getFieldData Method

Extracts the data contents of the specified field.

Syntax

```
void GetFieldData(
   ushort position,
   ushort dataRequested,
   ushort maxLen,
   out System.Array dbuf,
   out System.Array abuf,
   out System.Array eabuf
)
```

Parameters

Parameter	Description
position	The 0-based screen offset of a character in the specified field.
dataRequested	A bitwise combination describing the data requested. For more information, see the Remarks section.
maxLen	The maximum number of .screen positions requested. 0 indicates a request for the entire field.
dbuf	When this method returns, contains the screen data buffer data, if necessary.
abuf	When this method returns, contains the screen character attribute buffer data, if necessary.
eabuff	When this method returns, contains the screen extended attribute buffer data, if necessary.

Property Value/Return Value

Exceptions

Remarks

getFieldData does not extract the Field Attribute character.

You may request any combination of the displayable characters, character attributes, and extended attributes of the field.

You are responsible for releasing the SAFEARRAYs that the method returns the specified data in.

For the purpose of getFieldData the field attribute character, which immediately precedes the field data, is considered part of the field.

The following table describes the possible values for *dataRequested*.

Value	Description
1	Display buffer data
2	Character attribute buffer data
4	Extended attribute buffer data

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.setFieldData Method

The setFieldData method sets the data contents of the specified field.

Syntax

```
void SetFieldData(
   ushort position,
   ushort length,
   int overwriteProtected,
   ref System.Array dbuf,
   ref System.Array abuf,
   ref System.Array eabuf
)
```

Parameters

Parameter	Value
position	The 0-based screen offset of a character in the desired field.
length	The length of the data to copy.
overwriteProtected	If true, allows you to write data to a protected file. Otherwise, attempting to write to a protected field will cause an error.
dbuf	The data to copy to the screen data buffer data. NULL indicates that you do not want to alter the screen data.
abuf	The data to copy to the screen character attribute buffer data. NULL indicates that you do not want to alter the character attribute buffer.
eabuf	When this method returns, contains the data to copy to the screen extended attribute buffer data. NULL indicates that you do not want to alter the extended attribute buffer.

Return Value

Value	Description
S_OK	The method completed successfully.
C3270_S_TRUNCATED	The copy extended past the end of the field. Therefore, the extra data was ignored.
C3270_E_INVALIDPOS	The screen position specified is greated than the maximum character position for the current screen size.
C3270_E_INVALIDDATA	The bounds of any of the non-NULL SAFEARRA parameters were not identical.
C3270_E_UNFORMATTED	The screen is unformatted. As such, the specified field does not exist.
C3270_E_SESSIONBUSY	The 3270 session is busy. Call Icom3270.wait to determine when input is allowed so that you may call this method again.
C3270_E_SESSIONLOCKED	The 3270 session is loced due to a local lock condition. Examine the OIA buffer to determine the reason for the error. Also, you may also send a RESET keystroke to unlock the keyboard before calling this method or taking any other recovery action.

C3270_E_NOTCONNECTED	The com3270 client is not connected to a session through a call to Icom3270.connect.
C3270_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

You cannot use setFieldData to modify the Field attribute character.

For the purpose of setFieldData, the field attribute character is considered part of the field. The field attribute character immediately precedes the field data.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.findFieldData Method

The findFieldData method searches the specified field for the specified data string.

Syntax

```
void FindFieldData(
   ref ushort position,
   ushort length,
   ref System.Array dbuf
)
```

Parameters

Parameter	Description
pos	The 0-based screen offset of a character in the field to search. When this method returns, contains the screen offset of the start of the data string, if the string was found.
length	The length of the data to search on
dbuf	Array containing the data to search on.

Return Value

Value	Description
S_OK	The method has completed successfully.
C3270_S_TRUNCATED	The copy extended past the end of the field. The extra data was ignored.
C3270_E_UNFORMATTED	The screen is formatted; therefore, the specified field does not exist.
C3270_E_NOTFOUND	The specified data string could not be found.
C3270_E_NOTCONNECTED	The com3270 client is not connected to a session through a call to Icom3270.connect.
C3270_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

For the purpose of findFieldData, the field attribute character is considered part of the field. The field attribute character immediately precedes the field data.

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.getScreenData Method

The getScreenData method extracts the data contents of the 3270 screen.

Syntax

```
void GetScreenData(
   ushort position,
   ushort dataRequested,
   ushort maxLen,
   out System.Array dbuf,
   out System.Array abuf,
   out System.Array eabuf
)
```

Parameters

Parameter	Description
position	The 0-based screen offset of the first character requested.
dataRequested	A bitwise combination describing the requested data. For more information, see the Remarks section.
maxLen	The maximum number of .screen position requested. Setting maxLen to 0 requests the remainder of the screen.
dbuf	When this method returns, contains the screen data buffer data, if requested.
abuf	When this method returns, contains the screen character attribute buffer data, if requested.
eabuf	When this method returns, contains the screen extended attribute buffer data, if requested.

Return Value

Value	Description
S_OK	The method has returned successfully
C3270_E_INVALIDPOS	The specified screen position is greater than the maximum character position for the current screen size.
C3270_E_NOTCONNECTED	The com3270 client is not connected to a session through a call to Icom3270.connect.
C3270_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

You may request any combination of the displayable characters, character attributes, and extended attributes, of the screen.

Note that the returned data is contained in one or more SAFEARRAYS. You are responsible for releasing the SAFEARRAYS after processing.

The following table describes the possible values of dataRequested.

Value	Description
1	Display buffer data
2	Character attribute buffer data

4	Extended attribute buffer data

Example

This is the description for a Code Example.

Optional comments.

.NET Framework Equivalent

Optional .NET Framework equivalent section.

Requirements
Subhead

Icom3270.setScreenData Method

The **setScreenData** method copies data characters, character attributes, and extended attributers to all or part of the screen.

Syntax

```
void SetScreenData(
   ushort position,
   ushort length,
   int overwriteProtected,
   ref System.Array dbuf,
   ref System.Array abuf,
   ref System.Array eabuf
)
```

Parameters

Parameter	Description
position	The 0-based screen offset of the screen position to start copying.
length	The length of the data to search on.
overwriteProtected	true to allow the application to write data to a protected field; otherwise attempting to write to a protected field will cause an error.
dbuf	The data to copy to the screen data buffer data. NULL indicates that you do not want to alter the data buffer.
abuf	The data to copy to the screen character attribute buffer data. NULL indicates that you do not want to alter the character attribute buffer.
eabuf	When this method returns, contains the data to copy to the screen extended attribute buffer data. NULL indicates that you do not want to alter the extended attribute buffer.

Return Value

Value	Description
S_OK	The method has returned successfully
C3270_E_TRUNCATED	The copy extended past the end of the buffer screen. The extra data was ignored.
C3270_E_INVALIDPOS	The specified screen position is greater than the maximum character position for the current screen size.
C3270_E_INVALIDDATA	The bounds of any non-NULL SAFEARRAY parameters were not identical.
C3270_E_SESSIONBUSY	The 3270 session was busy. You should call Icom3270.wait to determine when input is allowed and this method can be retried.
C3270_E_SESSIONLOCKED	The 3270 session is locked to to a local lock condition. You should examine the OIA buffer to determine the reason for the lock. You may also send a RESET keystroke to unlock the keyboard before calling this method again.
C3270_E_NOTCONNECTED	The com3270 client is not connected to a session through a call to Icom3270.connect.

C3270_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks
Example

This is the description for a Code Example.

Optional comments.

Icom3270.findScreenData Method

The findScreenData method searches the screen for a specified data string.

Syntax

```
void FindScreenData(
   ref ushort position,
   ushort length,
   ref System.Array dbuf
)
```

Parameters

Parameter	Description
position	on input, the 0-based screen offset describing the location on which to begin the search. On a successful return, contains the screen offset of the start of the data string.
length	The length of the array containing the data to search on.
dbuf	An array containing the data to search on.

Return Value

Value	Description
S_OK	The method has returned successfully
C3270_E_INVALIDPOS	The specified screen position is greater than the maximum character position for the current screen size.
C3270_E_NOTFOUND	The specified data string could not be found.
C3270_E_NOTCONNECTED	The com3270 client is not connected to a session through a call to Icom3270.connect.
C3270_E_SYSERROR	The method failed due to an internal error.

Exceptions

Remarks

Example

This is the description for a Code Example.

Optional comments.

Client-Based BizTalk Adapter for WebSphere MQ Programmer's Reference

The following section describes the data types and context properties for the Client-Based BizTalk adapter for WebSphere MQ.

In This Section

Data Type

Context Properties

See Also

Other Resources

Messaging Programmer's Reference

Data Type

Header properties in MQSeries messages are data structures contained in the message itself. The adapter automatically validates and converts certain values in MQSeries message headers when sending and receiving messages.

The following table describes the MQSeries data types and their validation and conversion.

MQSeries Data Type	Validation and Conversion
MQLONG	MQSeries performs the validation. Converts to a long integer. Values that are not valid prevent the message from going to the MQSeries queue.
MQCHAR	Converts to a string.
MQBYTE	Converts to a string that contains the characters 0-9, and a-f or A-F, representing the hexadecimal value of the number.

Many of the MQSeries properties are 32-bit (4-byte) unsigned integers. Because uint is not a Common Language Specification (CLS)-compliant type, you must assign them to object types before using them in .NET methods. For more information about CLS-compliant types, see "What Is the Common Language Specification?" in .NET Framework Help.

Network Integration Programmer's Reference

BizTalk-Specific Properties

These context properties are only meaningful from BizTalk Server concepts and are available to be used by BizTalk applications.

Name	Type	Receive and/or Send	Description
URI	String	Receive and send	The URI defines the end-point for receive locations and send ports. The URI for receive locations and send ports for MQSC Adapter are in the following format: mqsc://<CHANNELNAME>/<TRANSPORTTYPE>/ <CONNECTIONNAME>/<QUEUEMANAGERNAME>/<QUEUENAME> Receive example: mqsc://MYCHANNEL/tcp/MQSERVER(1414)/QM1/RECVQ Send example: mqsc://MYCHANNEL/tcp/MQSERVER(1414)/QM2/SENDQ
BizTalk_CorrelationID	String	Receive	Use this property to have the MQSeries server generate a correlation identifier for use with the message.

Advanced End-Point Configuration Properties

The following topics describe the Advanced End-Point configuration properties for the Client-Based BizTalk Adapter for WebSphere MQ.

In This Section

MQSeries.MQSPropertySchema Properties

MQSeriesEx.MQSPropertySchema Properties

See Also
Other Resources
Context Properties

MQSeries.MQSPropertySchema Properties

The MQSC Adapter exposes the following context properties that are not related to MQSeries Message Descriptor or other MQSeries header structures that can be used in your BizTalk applications. These are part of the MQSeries.dll property schema assembly (MQSeries.MQSPropertySchema) that is deployed in the BizTalk Management database from the server-based MQSeries Adapter. The same property schema is used by the MQSC (client-based) adapter.

Name	Type	Receive and/or Send	Description
CompleteMessage	String	Receive	Set MQSeries to assemble segmented messages or to get the message as is. Use NoAction to read messages from the MQSeries queue without enabling segmentation. Use CompleteMessage to have MQSeries assemble segmented messages before passing them on to the adapter. Default: No Action This is not applicable to the MQSC Adapter. Used only for the Server-Based MQSeries Adapter in 'dynamic receive' type scenarios.
DataConversion	String	Receive	Character set to which the message should be converted to when retrieving messages from the MQSeries Queue. If this property is set to a value other than 'None', the adapter sets the MQGMO CONVERT option when performing an MQGet. None - Do not convert. UCS-2 and UTF-16 - Convert to these character sets. MQSeries does not distinguish between them. UTF-8 - Convert to the UTF-8 character set. Default: None Note – Not supported in this pre-release.
Ordered	String	Receive	Specify Yes to maintain the order of the messages as they are received from the MQSeries queue and submitted to the BizTalk Server Message Box. For the send side, the adapter sends the message to the queue in the same order that it receives it from the message box. Specify No to not maintain message order. Note – For send side ordering, if you are not using Orchestration, you must enable 'Ordered Delivery' in the 'Transport Advanced Options' in the send port configuration. Note – For receive, if you are using Orchestration, you must also set the Ordered Delivery property to True in your orchestration for this receive location. Note – If ordering is enabled, the adapter switches to single-thread mode and uses synchronous-mode delivery of messages into BizTalk Server. This results in performance degradation, so unless you require ordered delivery, it is not recommended to enable this feature. Default: No
SegmentationAllowed	String	Send	Set this to Yes to tell MQSeries Queue Manager to create segmented messages when submitting large messages to MQSeries Queues. Default: No
SSOAffiliateApplication	String	Send	Sets the Single Sign-On (SSO) Affiliate Application name. You use the user ID and password from SSO for the MQMD_UserIdentifier, and the MQIIH_Authenticator (or MQCIH_Authenticator) property respectively. Default: Blank

WaitInterval	Int	Receive	When performing MQGet, specify the Wait Interval MQGMO option in seconds by setting this property. If there are no messages in the queue, the client will continue waiting for messages in the Queue without closing the connection. Unit – Seconds Default – 3
TransactionSupported	String	Receive and Send	When set to Yes, the adapter begins a Microsoft Distributed Transaction Coordinator (DTC) transaction between BizTalk Server and MQSeries. This guarantees once and only once delivery of messages and prevents loss of messages. Setting this option to Yes means that WebSphere MQ Extended Transactional Client (Extended-Client) is used on the BizTalk Server computer by the adapter. When set to No, there could be message duplication. In this case, the adapter uses the non-transactional WebSphere MQ Client (Base-Client) for integration with MQSeries. Default: Yes

MQSeriesEx.MQSPropertySchema Properties

This contains additional context properties that are applicable only to the MQSC adapter (client-based MQSeries Adapter) for receive location and send port configurations. They are not applicable to the server-based adapter. These properties are associated with the channel configuration.

Name	Type	Receive and/or Send	Description
Channel_HeartBeat	unsignedInt	Receive and Send	The time between checks to verify if the client-server connection is working. Unit – Seconds Default - 300
Channel_UserId	String	Receive and Send	Set MQSeries to assemble segmented messages or to get the message as is. Use NoAction to read messages from the MQSeries queue without enabling segmentation. Use CompleteMessage to have MQSeries assemble segmented messages before passing them on to the adapter. Default: NoAction
Channel_Password	String	Receive and Send	The password may be used by the MCA when attempting to initiate a secure LU 6.2 session with a remote MCA. The initial value is null. This is an optional property.
Channel_SslCipherSpecification	String	Receive and Send	This defines a single CipherSpec for an SSL connection that will be used by the end-point configured in the adapter. Both ends of a WebSphere MQ SSL channel definition must include the attribute and the value specified here should match the name specified on the server end of the channel. The value is a string with a maximum length of 32 characters. This is required only when SSL is configured for the MQSeries Client to remote Queue Managers communication.
Channel_SslClientAuthentication	String	Receive and Send	This property determines whether the channel needs to receive and authenticate an SSL certificate from an SSL client. This is Optional by default. If two-way authentication (client/server) is required, this property should be set to Required. Before doing this, you must have configured SSL in MQSeries to enable client/server authentication so that the SSL client can send a valid certificate for authentication to succeed. Default: Optional
Channel_SslPeerName	String	Receive and Send	The property is used to check the Distinguished Name (DN) of the certificate from the peer queue manager or client at the other end of a WebSphere MQ channel. If the DN received from the peer does not match this value, the channel does not start. This is required only when SSL is configured for the MQSeries Client to Queue Managers communication.

MQSeries Header Properties

MQSC Adapter provides a set of context properties, specific to MQSeries, for use in your applications. You can use these properties in pipeline components, in your orchestrations and in filter expressions. For easy programmatic access, MQMD, MQXQH, MQCIH and MQIIH header structures can be directly accessed using these context properties.

All other MQSeries header structures (example: MQRFH) are supported by the MQSC Adapter. However, to access these headers, you need to do so with custom pipeline components and retrieve them from the body of the message. If you are setting them in the outbound message, then the pipeline component is responsible for ensuring that the message is constructed correctly.

To assign MQSeries context properties to a message destined to a send port that is bound to MQSC Adapter, use the message assignment operator and specify one of the available context properties in the MQSeries namespace.

The following is an example of setting the MQSeries MQMD_UserIdentifier property:

```
Message_2(MQSeries.MQMD_UserIdentifier) = "MeMyselfAndI";
```

You must obtain enumerated values from the C programming language header files included with the IBM MQSeries SDK. You can find these files in the Program Files\IBM\WebSphere MQ\Tools\c\include folder. These files define the values to use when setting or reading MQSeries context property values.

Hexadecimal string values are character strings representing binary values. They do not have a prefix such as 0x. They contain digits from 0 through 9 and letters from "a" through "f" or "A" through "F". The adapter ignores white space in them.

For more information about these properties, see the IBM WebSphere MQ documentation.

In This Section

Message Descriptor Properties

Additional MQSeries Related Properties

Context Properties

Message Descriptor Properties

The following table shows the complete set of available Message Descriptor (MQMD structure) properties and their corresponding types and values. These are part of the MQSeries.dll assembly that is deployed with the server-based MQSeries Adapter. The same assembly is used by the MQSC Adapter.

Name	Type	Length	Value
MQMD_AccountingToken	String	64	Hexadecimal string
MQMD_ApplIdentityData	String	32	Hexadecimal string
MQMD_ApplOriginData	String	4	String Default: space
MQMD_BackoutCount	unsigned int	4	Number Read only Default: 0
MQMD_CodedCharSetId	unsigned int	4	Number Default: 0
MQMD_CorrelId	String	48	Hexadecimal string
MQMD_Encoding	unsigned int	4	Number Use header file value. Default: 0
MQMD_Expiry	unsigned int	4	Number
MQMD_Feedback	unsigned int	4	Number Use header file value. Default: 0
MQMD_Format	String	8	String If set to MQXMIT, makes sure that the MQXQH properties have values.
MQMD_GroupID	String	48	Hexadecimal string
MQMD_MsgFlags	unsigned int	4	Number Use header file value. Default: 0
MQMD_MsgId	String	48	Hexadecimal string
MQMD_MsgSeqNumber	unsigned int	4	
MQMD_MsgType	unsigned int	4	Number Use header file value.
MQMD_Offset	unsigned int	4	
MQMD_OriginalLength	unsigned int	4	
MQMD_Persistence	unsigned int	4	Number Use header file value.
MQMD_Priority	unsigned int	4	Number

MQMD_PutApplName	string	28	String Default: space
MQMD_PutApplType	unsigned int	4	Number Use header file value. Default: 0
MQMD_PutDate	string	8	Date
MQMD_PutTime	string	8	Time
MQMD_ReplyToQ	string	48	String Default: space
MQMD_ReplyToQMgr	string	48	String Default: space
MQMD_Report	unsigned int	4	Number Use header file value.
MQMD_UserIdentifier	string	12	String Contains the user identifier when you use the SSOAffiliateApplication property.

When receiving messages directly from MQSeries transmission queues, BizTalk Adapter for MQSeries formats the transmission queue header properties (the MQXQH data structure) and places them in their corresponding context properties. When sending messages directly to MQSeries transmission queues, the header properties are formatted and assigned values from the corresponding context properties only if the MQMD_Format property has a value of MQXMIT. The following table describes the properties.

Name	Type	Length	Value
MQXQH_RemoteQMgrName	String	48	string
MQXQH_RemoteQName	String	48	string

Together with the properties listed earlier in this topic, the adapter populates the following Message Descriptor values following the same rules. The adapter prefixes these property names with MQXQH_ instead of MQMD_, but otherwise they map directly to those properties defined in the Message Descriptor table:

- MQXQH_MsgDesc_AccountingToken
- MQXQH_MsgDesc_ApplIdentityData
- MQXQH_MsgDesc_ApplOriginData
- MQXQH_MsgDesc_BackoutCount
- MQXQH_MsgDesc_CodedCharSetId
- MQXQH_MsgDesc_CorrelId
- MQXQH_MsgDesc_Encoding
- MQXQH_MsgDesc_Expiry
- MQXQH_MsgDesc_Feedback

- MQXQH_MsgDesc_Format
- MQXQH_MsgDesc_MsgId
- MQXQH_MsgDesc_MsgType
- MQXQH_MsgDesc_Persistence
- MQXQH_MsgDesc_Priority
- MQXQH_MsgDesc_PutApplName
- MQXQH_MsgDesc_PutApplType
- MQXQH_MsgDesc_PutDate
- MQXQH_MsgDesc_PutTime
- MQXQH_MsgDesc_ReplyToQ
- MQXQH_MsgDesc_ReplyToQMgr
- MQXQH_MsgDesc_Report
- MQXQH_MsgDesc_UserIdentifier

Additional MQSeries Related Properties

There are additional MQSeries-related properties included in the property schema and available for use within your BizTalk Server application. These are applicable when dealing with CICS or IMS applications. The following table lists these properties.

Name	Type	Length	Value
MQCIH_AbendCode	String	4	
MQCIH_ADSDescriptor	unsigned int	4	
MQCIH_AttentionId	string	4	
MQCIH_Authenticator	string	8	Set to the SSO password when you use the SSOAffiliateApplication property.
MQCIH_CancelCode	string	4	
MQCIH_CompCode	unsigned int	4	
MQCIH_ConversationalTask	unsigned int	4	
MQCIH_CursorPosition	unsigned int	4	
MQCIH_ErrorOffset	unsigned int	4	
MQCIH_Facility	string	16	Hexadecimal string
MQCIH_FacilityKeepTime	unsigned int	4	
MQCIH_FacilityLike	String	4	
MQCIH_Flags	unsigned int	4	
MQCIH_Format	String		
MQCIH_Function	String	4	
MQCIH_GetWaitInterval	unsigned int	4	
MQCIH_LinkType	unsigned int	4	
MQCIH_NextTransactionId	String	4	
MQCIH_OutputDataLength	unsigned int	4	
MQCIH_Reason	unsigned int	4	
MQCIH_ReplyToFormat	String		
MQCIH_ReturnCode	unsigned int	4	
MQCIH_StartCode	String	4	
MQCIH_TaskEndStatus	unsigned int	4	

MQCIH_TransactionId	String	4	
MQCIH_UOWControl	unsigned int	4	
MQIIH_Authenticator	String	8	Set to the SSO password when you use the SSOAffiliateApplication property.
MQIIH_CommitMode	String		
MQIIH_Flags	unsigned int	4	
MQIIH_Format	String		
MQIIH_LTermOverride	String	8	
MQIIH_MFSMapName	String	8	
MQIIH_ReplyToFormat	String		
MQIIH_SecurityScope	String		
MQIIH_TranInstanceId	String	32	Hexadecimal string
MQIIH_TranState	String		

Administration and Management Programmer's Reference

Host Integration Server 2009 included the following Windows Management Interface (WMI) providers to enable scripted management.

For general information about programming for WMI providers, see Administration and Management Programmer's Guide section of the SDK.

For sample code illustrating WMI providers, see Administration and Management Samples.

In This Section

Configuration Provider WMI Programmer's Reference

The Configuration Provider WMI Programmer's Reference describes the classes you can use to monitor the configuration of Host Integration Server 2009.

In This Section

- wmiHIS WMI Provider Classes

wmiHIS WMI Provider Classes

Microsoft® Host Integration Server provider supplies information regarding the configuration of Host Integration Server. As an instance provider, the wmiHIS provider implements the standard **IWbemProviderInit** interface and the following **IWbemServices** methods:

- **CreateInstanceEnumAsync**
- **DeleteInstanceAsync**
- **GetObjectAsync**
- **PutInstanceAsync**

For more information on **IWbemProviderInit** and **IWbemServices**, see "COM API for WMI" in the MSDN Library at http://msdn.microsoft.com/library.

You can access the WmiHIS provider classes in the \root\MicrosoftHIS namespace.

Class	Description
MsHis_Locale	Queries for locale support.
MsHis_CodePage	Queries for code page support.

MsHis_Locale

The **MsHIS_Locale** class is used to query for locale support.

The following syntax is simplified from MOF code.

Syntax

```
class MsHis_Locale : MsHis_Config
{
   uint32 ID;
   string Name;
   boolean Available;
};
```

Properties

ID

Data Type: **uint32**

Qualifiers: **Key**

Access Type: Read-Only

The locale identifier. Used for internal reference.

Name

Data Type: **String**

Access Type: Read-Only

The locale name.

Available

Data Type: **Boolean**

Access Type: Read-Only

true if the locale is available on the system; otherwise, **false**.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

Administration and Management Programmer's Guide

MsHis_CodePage Class

The **MsHIS_CodePage** class is used to query for code page support.

The following syntax is simplified from MOF code.

Syntax

```
class MsHis_CodePage : MsHis_Config
{
   uint32 ID;
   string Name;
   boolean Available;
   uint32 CodePage;
   boolean DBCSEnabled;
   boolean SBCSEnabled;
   boolean MBCSEnabled;
   boolean EuroEnabled;
};
```

Properties

ID

Data Type: **uint32**

Qualifiers: **Key**

Access Type: Read-Only

The code page identifier. Used for internal reference.

Name

Data Type: **String**

Access Type: Read-Only

The name of the code page.

Available

Data Type: **Boolean**

Access Type: Read-Only

true if the code page is supported by code page translations using SNANLS; otherwise, **false**.

CodePage

Data Type: **uint32**

Access Type: Read-Only

The number of the NLS code page.

DBCSEnabled

Data Type: **Boolean**

Access Type: Read-Only

true if this code page supports Double Byte Character Sets; otherwise, **false**.

SBCSEnabled

Data Type: **Boolean**

Access Type: Read-Only

true if this code page supports Single Byte Character Sets; otherwise, **false**.

MBCSEnabled

Data Type: **Boolean**

Access Type: Read-Only

true if this code page supports Multi-Byte Character Sets; otherwise, **false**.

EuroEnabled

Data Type: **Boolean**

Access Type: Read-Only

true if this code page has Euro support; otherwise, **false**.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

Administration and Management Programmer's Guide

IPC-DLC WMI Programmer's Reference

The IPC-DLC WMI Programmer's Reference describes the classes you can use to monitor the Host Integration Server 2009 link service.

In This Section

WmiSnaLinkServiceMS WMI Provider Classes

The following table describes the Common Information Model (CIM) classes used by the **WmiSnaLinkService** instance and method Windows Management Instrumentation (WMI) provider.

Class	Description
MsSna_LinkService	SNA Link service base class.
MsSna_LinkService_IpDlc	SNA IP-DLC link service.

MsSna_LinkService Class

The abstract **MsSna_LinkService** class represents an SNA link service.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_LinkService
{
   String Name;
   String DllName;
   Boolean IsRemotable;
   String Title;
   String DriverName;
   uint32 Type;
}
```

Properties

Name

Data Type: **String** Qualifiers: **Key**, **MaxLen(8)** Access Type: Read-Only

A US_ASCII string containing the name of the link service. The name will be assigned automatically for a new link service.

DllName

Data Type: **String**Access Type: Read-Only

The name of the .dll that implements the link service.

IsRemotable

Data Type: **Boolean**Access Type: Read/Write

true if the link service can be used from a remote node; otherwise, **false**.

Title

Data Type: **String**Qualifiers: **MaxLen(255)** Access Type: Read/Write

The title of the link service, up to 128 symbols long.

DriverName

Data Type: **String** Access Type: Read-Only

The device driver associated with the link service.

Type

Data Type: **uint32** Access Type: Read-Only

The type of link service. The following table describes the possible values for **Type**.

Value	Meaning
3	SDLC
4	X25
10	DFT
11	DLC8022
31	TWINAX

32	CHANNEL
35	IPDLC

Requirements

Windows Server 2003, Windows XP Professional, Windows 2000

Administration and Management Programmer's Guide

MsSna_LinkService_IpDlc Class

The **MsSna_LinkService_IpDlc** class represents the SNA IP-DLC link service.

The following syntax is simplified from MOF code and includes all inherited properties. For reference information about methods, see the table of methods later in this topic.

Syntax

```
Class MsSna_LinkService_IpDlc : MsSNA_LinkService
{
   String Name;
   String DllName;
   Boolean IsRemotable;
   String Title;
   String DriverName;
   uint32 Type;
   String PrimaryNNS;
   String BackupNNS;
   uint32 AddressType;
   String LocalAddress;
   String NetworkName;
   String CPName;
   String NodeID;
   String LENNode;
   String ResolvedIP;
}
```

Properties

Name

Data Type: **String** Qualifiers: **Key**, **MaxLen(8)** Access Type: Read-Only

A US_ASCII string containing the name of the link service. The name will be assigned automatically for a new link service.

DllName

Data Type: **String**Access Type: Read-Only

The name of the .dll that implements the link service.

IsRemotable

Data Type: **Boolean**Access Type: Read/Write

true if the link service can be used from a remote node; otherwise, **false**. **IsRemotable** is always **false** for the IP-DLC link service.

Title

Data Type: **String**Qualifiers: **MaxLen(255)** Access Type: Read/Write

The title of the link service, up to 128 symbols long.

DriverName

Data Type: **String** Access Type: Read-Only

The device driver associated with the link service. **DriverName** is used for the IP-DLC link service.

Type

Data Type: **uint32** Access Type: Read-Only

The type of link service. The following table describes the possible values for **Type**.

Value	Meaning
3	SDLC

4	X25
10	DFT
11	DLC8022
31	TWINAX
32	CHANNEL
35	IPDLC

As an IP-DLC link service, **MsSna_LinkService_IpDlc.Type** will always be set to 35.

PrimaryNNS

Data Type: **String** Qualifiers: **MaxLen(128)** Access Type: Read/Write

Contains the name of the primary NNS server.

BackupNNS

Data Type: **String** Qualifiers: **MaxLen(1024)** Access Type: Read-Only

Contains the list of backup NNS delimited with semicolons. While **BackupNNS** may contain additional names, the current build is tested only for **BackupNNS** to be equal to the **PrimaryNNS**.

AddressType

Data Type: uint32 Access Type: Read/Write

Describes the local address type. The following table describes the possible values of **AddressType**.

Value	Description
1	ADAPTER
2	STATICIP

LocalAddress

Data Type: **String** Qualifiers: **MaxLen(256)** Access Type: Read/Write

Contains the local network adapter or address. If **AddressType** contains a 1, **LocalAddress** will contain a valid network adapter; otherwise, **LocalAddress** contains a static IP address.

NetworkName

Data Type: **String** Qualifiers: **MaxLen(8)**, **ToUpperCase** Access Type: Read/Write

The network name of the Branch Network Node as implemented by the link service. The string will be a Type A string containing up to eight symbols.

CPName

Data Type: **String** Qualifiers: **MaxLen(8)**, **ToUpperCase** Access Type: Read/Write

Control point name of the Branch Network Node as implemented by the link service. The string will be a Type A string containing up to eight symbols.

NodeID

Data Type: **String** Qualifiers: **MaxLen(9)** Access Type: Read/Write

The identity of the Branch Network Node as implemented by the link service. **NodeID** will be in format HHH.HHHHH, where H is a hexadecimal digit.

LENNode

Data Type: **String** Qualifiers: **MaxLen(20)** Access Type: Read/Write

Data Type: **String** Qualifiers: **MaxLen(20)** Access Type: Read/Write

The name of the Associated LEN node.

ResolvedIP

Data Type: **String** Access Type: Read-only

The resolved IP address of the network adapter or local address.

Methods

The following table describes the methods implemented for the **MsSna_LinkService_IpDlc** class.

Method	Description
GetAllStaticIPs	Returns the list of all the static IP addresses on the local machine.
GetAllNetworkAdapters	Returns the list of all network adapters with the IP protocols enabled.
GetNextAvailableOrdinal	Internal. Provides the next available link service number.

Requirements

Windows Server 2003, Windows XP Professional, Windows 2000

MsSna_LinkService_IpDlc.GetAllStaticIPs Method

The **GetAllStaticIPs** method returns the list of all the static IP addresses on the local machine.

Syntax

```
void GetAllStaticIps(
   string IPs[]
);
```

Parameters

IPs

[out] Returns an array of strings containing the static IP addresses on the local machine.

Requirements

Windows Server 2003, Windows XP Professional, Windows 2000

MsSna_LinkService_IpDlc.GetAllNetworkAdapters Method

The **GetAllNetworkAdapters** method returns the list of all network adapters with the IP protocols enabled.

Syntax

```
void GetAllNetworkAdapters(
   string Adapters[]
);
```

Parameters

Adapters

[out] Returns an array of strings containing the network adapters with the IP protocols enabled.

Requirements

Windows Server 2003, Windows XP Professional, Windows 2000

MsSna_LinkService_IpDlc.GetNextAvailableOrdinal Method

Internal. The **GetNextAvailableOrdinal** method returns the next available link service number.

Syntax

```
uint32 GetNextAvailableOrdinal()
```

Return Value

The next available link service number.

Remarks

GetNextAvailableOrdinal is an internal method, and as such should not be used by third parties.

Requirements

Windows Server 2003, Windows XP Professional, Windows 2000

SNA Trace Provider WMI Programmer’s Reference

The SNA Trace Provider WMI Programmer's Reference describes the Windows Management Instrumentation (WMI) classes you can use to capture trace messages from your Host Integration Server 2009 enterprise application.

For more information, see How to Capture a Trace with WMI.

In This Section

WmiSnaTrace WMI Provider Classes

WmiSnaTrace WMI Provider Classes

The Microsoft Host Integration Server SNA Trace provider supplies information regarding the SNA service trace. As an instance and method provider, the WmiSnaStatus provider implements the standard **IWbemProviderInit** interface and the following **IWbemServices** methods:

- **CreateInstanceEnumAsync**
- **DeleteInstanceAsync**
- **ExecMethodAsync**
- **GetObjectAsync**
- **PutInstanceAsync**

For more information on **IWbemProviderInit** and **IWbemServices**, see "COM API for WMI" in the MSDN Library at http://msdn.microsoft.com/library.

You can access these provider classes in the \root\MicrosoftHIS namespace.

Class	Description
MsHisTrace_Global	Contains the global settings for Host Integration Server tracing.
MsHisTrace_COMTI	Describes tracing properties for Transaction Integrator (TI).
MsHisTrace_SharedFoldersGateway	Contains tracing properties for the Shared Folders Gateway service.
MsHisTrace_SNAApplication	Contains tracing properties for any application that runs on top of Host Integration Server 2009.
MsHisTrace_SNAManageClient	Contains tracing properties for the SNA Manage Client.
MsHisTrace_SNAMngAgent	Contains tracing properties for the SNA Manage Agent.
MsHisTrace_SNAServerManager	Contains tracing properties for the SNA Manager.
MsHisTrace_SNABase	Contains tracing properties for the SNA Base service.
MsHisTrace_SNANetMn	Contains tracing properties for an SNA Net Manager.
MsHisTrace_SNAPrint	Contains tracing properties for the Host Print service.
MsHisTrace_SNAServer	Contains tracing properties for an SNA service
MsHisTrace_TN3270	Contains tracing properties for the TN3270 service.
MsHisTrace_Config	Contains tracing properties for the TN5250 service.
MsHisTrace_ExtendedStatus	Returns error information.
MsHisTrace_Event	Retrieves error information.

MsHisTrace_Config Class

The abstract **MsHisTrace_Config** class describes the general properties of a configuration file.

The following syntax is simplified from MOF code.

Syntax

```
class MsHisTrace_Config
{
   string Name;
};
```

Properties

Name

Data Type: **String** Qualifiers: **Key** Access Type: Read/Write

Name of the configuration file.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

See Also

Other Resources

WmiSnaTrace WMI Provider Classes

MsHisTrace_Global Class

The **MsHisTrace_Global** class contains the global settings for Microsoft® Host Integration Server tracing.

The following syntax is simplified from MOF code.

Syntax

```
class MsHisTrace_Global : MsHisTrace_Config
{
   string Name;
   uint32 AsyncThreadPriority;
   Boolean AsyncTraceFlag;
   uint32 FlipLength;
   string TraceFileDirectory;
};
```

Properties

Name

Data Type: **String** Qualifiers: **Key** Access Type: Read/Write

Name of the configuration file.

AsyncThreadPriority

Data Type: **uint32** Access Type: Read/Write

If *AsyncTraceFlag* is **true**, *AsyncThreadFlag* specifies the level of priority for tracing to run within the Windows® operating system.

AsyncTraceFlag

Data Type: **Boolean** Access Type: Read/Write

true to cause tracing to be run on a background thread; otherwise, **false**.

FlipLength

Data Type: **uint32** Access Type: Read/Write

The size a trace file should be before the trace utility switches to recording trace data in a second file.

TraceFileDirectory

Data Type: **String** Access Type: Read/Write

The directory in which to store trace files.

Requirements

Platforms: Microsoft Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

WmiSnaTrace WMI Provider Classes

Administration and Management Programmer's Guide

MsHisTrace_COMTI Class

The **MsHisTrace_COMTI** class describes tracing properties for Transaction Integrator (TI).

The following syntax is simplified from MOF code.

Syntax

```
class MsHisTrace_COMTI : MsHisTrace_Config
{
   string Name;
   uint32 EnabledTraces;
   Boolean InternalMessageTrace;
   Boolean DPLHeaderTrace;
   Boolean LU62Trace;
   Boolean BriefLU62Trace;
   Boolean COMTIProxy;
   Boolean PipeLine;
   Boolean BlackBoard;
   Boolean GeneralService;
   Boolean Repository;
   Boolean DataTransit;
   Boolean DataLayout;
   Boolean Conversions;
   Boolean Transport;
   Boolean Registrar;
   Boolean Scripting;
   Boolean SessionManager;
};
```

Properties

Name

Data Type: **String** Qualifiers: **Key** Access Type: Read/Write

Name of the configuration file.

EnabledTraces

Data Type: **uint32** Qualifiers: **Qualifiers** Access Type: Read-Only

Bitmap that indicates which Internal Trace conditions to record. The following table describes the possible values for **EnabledTraces**.

Value	Description
1	Fatal trace mask
2	Error trace mask
4	Debug trace mask
8	State trace mask
16	Function trace mask
32	Message trace mask
64	Custom trace mask
128	Plan enter exit mask

InternalMessageTrace

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of internal messages; otherwise, **false**.

DPLHeaderTrace

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of DPL Headers; otherwise, **false**.

LU62Trace

Data Type: **Boolean** Access Type: Read/Write

true to enable LU 6.2 tracing; otherwise, **false**.

BriefLU62Trace

Data Type: **Boolean** Access Type: Read/Write

true to enable a briefer version LU 6.2 tracing; otherwise, **false**.

COMTIProxy

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of the COMPI Proxy API; otherwise, **false**.

PipeLine

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of the PipeLine API; otherwise, **false**.

BlackBoard

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of the BlackBoard API; otherwise, **false**.

GeneralService

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of the GeneralService API; otherwise, **false**.

Repository

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of the Repository API; otherwise, **false**.

DataTransit

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of the DataTransit API; otherwise, **false**.

Conversions

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of the Conversions API; otherwise, **false**.

Transport

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of the Transport API; otherwise, **false**.

Registrar

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of the Registrar API; otherwise, **false**.

Scripting

Data Type: **Boolean** Access Type: Read/Write

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of the Scripting API; otherwise, **false**.

SessionManager

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of the SessionManager API; otherwise, **false**.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsHisTrace_SharedFoldersGateway Class

The **MsHisTrace_SharedFoldersGateway** class contains tracing properties for the Shared Folders Gateway service.

The following syntax is simplified from MOF code.

Syntax

```
class MsHisTrace_SharedFoldersGateway : MsHisTrace_Config
{
   string Name;
   uint32 EnabledTraces;
   Boolean InternalMessageTrace;
   Boolean T3270Trace;
   Boolean LU62Trace;
   Boolean APPCTrace;
   Boolean CPICTrace;
   Boolean LUATrace;
   Boolean CSVTrace;
};
```

Properties

Name

Data Type: **String** Qualifiers: **Key** Access Type: Read/Write

Name of the configuration file.

EnabledTraces

Data Type: **uint32** Access Type: Read/Write

Bitmap that indicates which Internal Trace conditions to record. The following table describes the possible values for **EnabledTraces**.

Value	Description
1	Fatal trace mask
2	Error trace mask
4	Debug trace mask
8	State trace mask
16	Function trace mask
32	Message trace mask
64	Custom trace mask
128	Plan enter exit mask

InternalMessageTrace

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of internal messages; otherwise, **false**.

T3270Trace

Data Type: **Boolean** Access Type: Read/Write

true to enable T3270 tracing; otherwise, **false**.

LU62Trace

Data Type: **Boolean** Access Type: Read/Write

true to enable LU 6.2 tracing; otherwise, **false**.

APPCTrace

Data Type: **Boolean** Access Type: Read/Write

true to enable APPC tracing; otherwise, **false**.

CPICTrace

Data Type: **Boolean** Access Type: Read/Write

true to enable CPI-C tracing; otherwise, **false**.

LUATrace

Data Type: **Boolean** Access Type: Read/Write

true to enable LUA tracing; otherwise, **false**.

CSVTrace

Data Type: **Boolean** Access Type: Read/Write

true to enable CSV tracing; otherwise, **false**.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsHisTrace_SNAApplication Class

The **MsHisTrace_SNAApplication** class contains tracing properties for any application that runs on top of Host Integration Server 2009.

The following syntax is simplified from MOF code.

Syntax

```
class MsHisTrace_SNAApplication : MsHisTrace_Config
{
   string Name;
   uint32 EnabledTraces;
   Boolean InternalMessageTrace;
   Boolean T3270Trace;
   Boolean LU62Trace;
   Boolean APPCTrace;
   Boolean CPICTrace;
   Boolean LUATrace;
   Boolean CSVTrace;
};
```

Properties

Name

Data Type: **String** Qualifiers: **Key** Access Type: Read/Write

Name of the configuration file.

EnabledTraces

Data Type: **uint32** Access Type: Read/Write

Bitmap indicating which Internal Trace conditions to record. The following table describes the possible values for **EnabledTraces**.

Value	Description
1	Fatal trace mask
2	Error trace mask
4	Debug trace mask
8	State trace mask
16	Function trace mask
32	Message trace mask
64	Custom trace mask
128	Plan enter exit mask

InternalMessageTrace

Data Type: **Boolean** Access Type: Read/Write

true to enable tracing of internal messages; otherwise, **false**.

T3270Trace

Data Type: **Boolean** Access Type: Read/Write

true to enable T3270 tracing; otherwise, **false**.

LU62Trace

Data Type: **Boolean** Access Type: Read/Write

true to enable LU 6.2 tracing; otherwise, **false**.

APPCTrace

Data Type: **Boolean** Access Type: Read/Write

true to enable APPC tracing; otherwise, **false**.

CPICTrace

Data Type: **Boolean** Access Type: Read/Write

true to enable CPI-C tracing; otherwise, **false**.

LUATrace

Data Type: **Boolean** Access Type: Read/Write

true to enable LUA tracing; otherwise, **false**.

CSVTrace

Data Type: **Boolean** Access Type: Read/Write

true to enable CSV tracing; otherwise, **false**.

Administration and Management Programmer's Guide

SNA Status Provider WMI Programmer's Reference

The SNA Status Provider WMI Programmer's Reference describes the Windows Management Instrumentation (WMI) classes you can use to monitor the health of your SNA servers for Host Integration Server 2009.

For more information, see How to Monitor the Health of Host Integration Server with WMI.

In This Section

WmiSnaStatus WMI Provider Classes

WmiSnaStatus WMI Provider Classes

The Microsoft® Host Integration Server SNA Status provider supplies information regarding the SNA service status. As an instance and method provider, the WmiSnaStatus provider implements the standard **IWbemProviderInit** interface and the following **IWbemServices** methods:

CreateInstanceEnumAsync

DeleteInstanceAsync

ExecMethodAsync

ExecQueryAsync

GetObjectAsync

PutInstanceAsync

For more information on **IWbemProviderInit** and **IWbemServices**, see "COM API for WMI" in the MSDN Library at http://msdn.microsoft.com/library.

The WmiSnaStatus.mof and WmiSnaStatus_XP file contains the WMISNA provider, and association and registration classes. You can access these provider classes in the \root\MicrosoftHIS namespace.

Class	Description
MsSnaStatus_EventServiceSna	Describes a change to the **EventServiceSna** class.
MsSnaStatus_EventConnection	Describes a change to the **EventConnection** class
MsSnaStatus_EventLu3270	Describes a change to the **EventLu3270** class.
MsSnaStatus_EventUser	Describes a change to the **EventUser** class.
MsSnaStatus_EventAppcLocalLu	Describes a change to the **EventAppcLocalLu** class.
MsSnaStatus_EventAppcSession	Describes a change to the **EventAppcSession** class.
MsSnaStatus_EventServicePrint	Describes a change to the **EventServicePrint** class.
MsSnaStatus_EventPrintSession	Describes a change to the **EventPrintSession** class.
MsSnaStatus_EventServiceTN3270	Describes a change to the **EventServiceTN3270** class.
MsSnaStatus_EventTN3270Session	Describes a change to the **EventTN3270Session** class.
MsSnaStatus_EventServiceTN5250	Describes a change to the **EventTN5250Session** class.
MsSnaStatus_EventServiceSharedFolder	Describes a change to the **EventServiceSharedFolder** class.
SNA_ExtendedStatus	Used to return error information if required.
MsSnaStatus_ServiceSna	Get information on the status of the SNA service.
MsSnaStatus_Connection	Represents a SNA Service connection status.
MsSnaStatus_Lu3270	Represents a SNA Service display LU, printer LU, or LUA LU status.
MsSnaStatus_ClientConnections	Represents a SNA Service client connection status.

MsSnaStatus_AppcLocalLu	Represents an APPC Local LU status.
MsSnaStatus_AppcSession	Represents an APPC session status.
MsSnaStatus_ServicePrint	Represents an Host Printer service status.
MsSnaStatus_PrintSession	Represents an Host Printer session status.
MsSnaStatus_ServiceTN3270	Represents a TN3270 service status.
MsSnaStatus_TN3270Session	Represents a TN3270 session status.
MsSnaStatus_ServiceTN5250	Represents a TN5250 service status.
MsSnaStatus_TN5250Session	Represents a TN5250 session status.
MsSnaStatus_ServiceSharedFolder	Represents a TN3270 service status.
MsSnaStatus_Lu3270ToActiveUser	Represents an association between a User connection and a 3270 type LU.
MsSnaStatus_APPCSessionToActiveUser	Represents an association between a User connection and an APPC session.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSnaStatus_EventServiceSna Class

The **MsSnaStatus_EventServiceSna** class describes a change to the **EventServiceSna** class.

The following syntax is simplified from MOF code.

Syntax

```
class MsSnaStatus_EventServiceSna : MsSnaStatus_Event

    object ref Path;
    sint16 Action;
};
```

Remarks

Path

Data Type: **Object ref**Access Type: Read-Only

The relative path to the corresponding object.

Action

Data Type: **sint16** Access Type: Read-Only

The event that occurred to the object specified in **Path**. The following table describes the valid values for **Action**.

Value	Description
0	Create
1	Destroy
2	Modify

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSnaStatus_EventConnection Class

The **MsSnaStatus_EventConnection** class describes a change to the **EventConnection** class.

The following syntax is simplified from MOF code.

Syntax

```
class MsSnaStatus_EventConnection: MsSnaStatus_Event

    object ref Path;
    sint16 Action;
};
```

Remarks

Path

Data Type: **Object ref**Access Type: Read-Only

The relative path to the corresponding object.

Action

Data Type: **sint16** Access Type: Read-Only

The event that occurred to the object specified in **Path**. The following table describes the valid values for **Action**.

Value	Description
0	Create
1	Destroy
2	Modify

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSnaStatus_EventLu3270 Class

The **MsSnaStatus_EventLu3270** class describes a change to the **EventLu3270** class.

The following syntax is simplified from MOF code.

Syntax

```
class MsSnaStatus_EventLu3270: MsSnaStatus_Event

    object ref Path;
    sint16 Action;
};
```

Remarks

Path

Data Type: **Object ref**Access Type: Read-Only

The relative path to the corresponding object.

Action

Data Type: **sint16** Access Type: Read-Only

The event that occurred to the object specified in **Path**. The following table describes the valid values for **Action**.

Value	Description
0	Create
1	Destroy
2	Modify

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSnaStatus_EventUser Class

The **MsSnaStatus_EventUser** class describes a change to the **EventUser** class.

The following syntax is simplified from MOF code.

Syntax

```
class MsSnaStatus_EventUser: MsSnaStatus_Event

    object ref Path;
    sint16 Action;
};
```

Remarks

Path

Data Type: **Object ref**Access Type: Read-Only

The relative path to the corresponding object.

Action

Data Type: **sint16** Access Type: Read-Only

The event that occurred to the object specified in **Path**. The following table describes the valid values for **Action**.

Value	Description
0	Create
1	Destroy
2	Modify

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSnaStatus_EventAppcLocalLu Class

The **MsSnaStatus_EventAppcLocalLu** class describes a change to the **EventAppcLocalLu** class.

The following syntax is simplified from MOF code.

Syntax

```
class MsSnaStatus_EventAppcLocalLu: MsSnaStatus_Event

    object ref Path;
    sint16 Action;
};
```

Remarks

Path

Data Type: **Object ref**Access Type: Read-Only

The relative path to the corresponding object.

Action

Data Type: **sint16** Access Type: Read-Only

The event that occurred to the object specified in **Path**. The following table describes the valid values for **Action**.

Value	Description
0	Create
1	Destroy
2	Modify

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server2003

MsSnaStatus_EventAppcSession Class

The **MsSnaStatus_EventAppcSession** class describes a change to the **EventAppcSession** class.

The following syntax is simplified from MOF code.

Syntax

```
class MsSnaStatus_EventAppcSession: MsSnaStatus_Event

    object ref Path;
    sint16 Action;
};
```

Remarks

Path

Data Type: **Object ref**Access Type: Read-Only

The relative path to the corresponding object.

Action

Data Type: **sint16** Access Type: Read-Only

The event that occurred to the object specified in **Path**. The following table describes the valid values for **Action**.

Value	Description
0	Create
1	Destroy
2	Modify

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSnaStatus_EventServicePrint Class

The **MsSnaStatus_EventServicePrint** class describes a change to the **EventServicePrint** class.

The following syntax is simplified from MOF code.

Syntax

```
class MsSnaStatus_EventServicePrint: MsSnaStatus_Event

    object ref Path;
    sint16 Action;
};
```

Remarks

Path

Data Type: **Object ref**Access Type: Read-Only

The relative path to the corresponding object.

Action

Data Type: **sint16** Access Type: Read-Only

The event that occurred to the object specified in **Path**. The following table describes the valid values for **Action**.

Value	Description
0	Create
1	Destroy
2	Modify

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSnaStatus_EventPrintSession Class

The **MsSnaStatus_EventPrintSession** class describes a change to the **EventPrintSession** class.

The following syntax is simplified from MOF code.

Syntax

```
class MsSnaStatus_EventPrintSession: MsSnaStatus_Event

    object ref Path;
    sint16 Action;
};
```

Remarks

Path

Data Type: **Object ref**Access Type: Read-Only

The relative path to the corresponding object.

Action

Data Type: **sint16** Access Type: Read-Only

The event that occurred to the object specified in **Path**. The following table describes the valid values for **Action**.

Value	Description
0	Create
1	Destroy
2	Modify

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSnaStatus_ServiceSna Class

The **MsSnaStatus_ServiceSna** class is used to get information on the status of the SNA service.

Syntax

```
class MsSnaStatus_ServiceSna : MsSnaStatus_Config
{
   string Name;
   sint32 Status;
   string StatusText;
   Boolean bOutOfDate;
   uint16 AppcSessions;
   uint16 LU3270Sessions;
   uint16 Users;
}
```

Properties

Name

Data Type: **String** Qualifiers: **Key** Access Type: Read-Only

The name of the service. The string can contain more than one service, in the following format:<ComputerName>, <ComputerName>.01, <ComputerName>.02, <ComputerName>.03

Status

Data Type: **sint32** Access Type: Read-Only

The current status of the service. The following table describes the possible values for **Status**.

Value	Description
0	
1	Inactive
2	Pending
3	Stopping
4	Active

StatusText

Data Type: **String** Access Type: Read-Only

One of the status values.

bOutOfDate

Data Type: **Boolean** Access Type: Read-Only

true indicates that the configuration has changed and that the service must be restarted; otherwise, **false**.

AppcSessions

Data Type:**uint16** Access Type: Read-Only

Statistics on APPC sessions on the service.

LU3270Sessions

Data Type:**uint16** Access Type: Read-Only

Statistics on LU 3270 sessions on the service.

Users

Data Type:**uint16** Access Type: Read-Only

Statistics on users on the service.

Methods

Method	Description
GetObject	Retrieves the instance.
EnumerateInstances	Enumerates all instances of the object.
ExecMethod	Executes the specified method.
Start	Starts the service.
Stop	Stops the service.
Pause	Pauses the service.
Resume	Resumes the service.

For more information on **GetObject**, **EnumerateInstances**, and **ExecMethod**, see "IWbemServices interface" in the MSDN Library at http://msdn.microsoft.com/library.

Remarks

There may be more than one service running on a computer.

MsSnaStatus_Connection Class

The **MsSnaStatus_Connection** class represents a SNA service connection status.

The following is simplified MOF syntax.

Syntax

```
class MsSnaStatus_Connection : MsSnaStatus_Config
{
   string Name;
   string ServiceName;
   uint32 Status;
   string StatusText;
   uint32 InactiveState;
   uint16 Failcode;
   DateTime FailTime;
}
```

Properties

Name

Data Type: **String** Qualifiers: **Key** Access Type: Read-Only

The name of the connection.

ServiceName

Data Type: **String** Access Type: Read-Only

Name of the SNA service to which this connection belongs.

Status

Data Type: **uint32** Access Type: Read-Only

Name of the SNA service to which this connection belongs.

Value	Description
0	
1	Inactive
2	Pending
3	Stopping
4	Active

StatusText

Data Type: **String** Access Type: Read-Only

One of the status values. The following table describes the potential values for **StatusText**.

Value	Description
0	
1	Stopping
2	Active

3	Incoming
4	OnDemand
5	OnDemandIncoming

InactiveState

Data Type: **uint32** Access Type: Read-Only

Additional detail on inactive connections. The following table describes the possible values for **InactiveState**.

Value	Description
0	Inactive
1	Incoming
2	OnDemand
3	OnDemandIncoming

Failcode

Data Type: **uint16** Access Type: Read-Only

The failure code. 0 indicates a non-failure.

FailTime

Data Type: **DateTime** Access Type: Read-Only

The time the failure occurred. Valid only if **Failcode** is not 0.

Methods

Method	Description
GetObject	Retrieves the instance.
EnumerateInstances	Enumerates all instances of the object.
ExecMethod	Executes the specified method.
Start	Starts the connection.
Stop	Stops the connection.

For more information on **GetObject**, **EnumerateInstances**, and **ExecMethod**, see "IWbemServices interface" in the MSDN Library at http://msdn.microsoft.com/library.

MsSnaStatus_Lu3270 Class

The **MsSnaStatus_Lu3270** class represents a SNA Service display LU, printer LU, or LUA LU status.

Syntax

```
class MsSnaStatus_Lu3270 : MsSnaStatus_Config
{
   string Name;
   string ConnectionName;
   uint32 Status;
   string StatusText;
   uint32 ActiveState;
   string HostAppl;
}
```

Properties

Name

Data Type: **String** Qualifiers: **Key** Access Type: Read-Only

The name of the LU.

ConnectionName

Data Type: **String** Access Type: Read-Only

The connection on which this LU is defined.

Status

Data Type: **uint32** Access Type: Read-Only

The current status of the connection. The following table describes the potential values for **Status**.

Value	Description
0	
1	Inactive
2	Pending
3	Stopping
4	Active

StatusText

Data Type: **String** Access Type: Read-Only

One of the status values. The following table describes the potential values for **StatusText**.

Value	Description
0	
1	Inactive
2	Pending
3	Stopping

4	Available
5	InSession
6	SSCP

ActiveState

Data Type: **uint32** Access Type: Read-Only

Additional detail on active ULs. The following table describes the possible values for **ActiveState**.

Value	Description
0	Available
1	InSession
2	SSCP

HostAppl

Data Type: **string** Access Type: Read-Only

The short name of the host application.

Methods

Method	Description
GetObject	Retrieves the instance.
EnumerateInstances	Enumerates all instances of the object.
ExecMethod	Executes the specified method.
Stop	Stops the LU.

For more information on **GetObject**, **EnumerateInstances**, and **ExecMethod**, see "IWbemServices interface" in the MSDN Library at http://msdn.microsoft.com/library.

MsSnaStatus_Lu3270.Stop Method

Stops the LU.

Syntax

```
void Stop();
```

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSnaStatus_ClientConnections Class

The **MsSnaStatus_ClientConnections** class represents a SNA service client connection status.

Syntax

```
class MsSnaStatus_ClientConnections : MsSnaStatus_Config
{
   string UserId;
   string Domain;
   string User;
   string ClientMachine;
   DateTime ClientConnectTime;
   string ClientAppl;
};
```

Properties

UserId

Data Type: **String** Qualifiers: **Key** Access Type: Read-Only

An arbitrary unique key.

Domain

Data Type: **String** Access Type: Read-Only

The domain on which the user is located.

User

Data Type: **String** Access Type: Read-Only

The username of the user.

ClientMachine

Data Type: **String** Access Type: Read-Only

The computer name on which the client application is running.

ClientConnectTime

Data Type: **DateTime** Access Type: Read-Only

The client-server connection start time.

ClientAppl

Data Type: **string** Access Type: Read-Only

The name of the client application.

Methods

Method	Description
GetObject	Retrieves the instance.
EnumerateInstances	Enumerates all instances of the object.

For more information on **GetObject** and **EnumerateInstances**, see "IWbemServices interface" in the MSDN Library at http://msdn.microsoft.com/library.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

See Also

Reference

MsSnaStatus_AppcLocalLu Class

The **MsSnaStatus_AppcLocalLu** class represents an APPC Local LU status.

Syntax

```
class MsSnaStatus_AppcLocalLu : MsSnaStatus_Config
{
   string Name;
   string ServiceName;
   uint16 SessionLimit;
   uint16 SessionCount;
};
```

Properties

Name

Data Type: **String** Qualifiers: **Key** Access Type: Read-Only

The Local LU alias.

ServiceName

Data Type: **String** Access Type: Read-Only

The name of the SNA service on which this Local LU is defined.

SessionLimit

Data Type: **uint16** Access Type: Read-Only

The session limit for the LU.

SessionCount

Data Type: **uint16** Access Type: Read-Only

The current session count.

Methods

Method	Description
GetObject	Retrieves the instance.
EnumerateInstances	Enumerates all instances of the object.

For more information on **GetObject** and **EnumerateInstances**, see "IWbemServices interface" in the MSDN Library at http://msdn.microsoft.com/library.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSnaStatus_AppcSession Class

The **MsSnaStatus_AppcSession** class represents an APPC session status.

Syntax

```
class MsSnaStatus_AppcSession : MsSnaStatus_Config
{
   string APPCLU;
   string SessionID;
   string PartnerLU;
   string Mode;
};
```

Properties

APPCLU

Data Type: **String** Qualifiers: **Key** Access Type: Read-Only

The Local APPC LU.

SessionID

Data Type: **String** Access Type: Read-Only

A unique ID for this session.

PartnerLU

Data Type: **String** Access Type: Read-Only

The Partner LU alias. **PartnerLU** can be a Remote LU or another Local LU.

Mode

Data Type: **String** Access Type: Read-Only

The mode name for this session.

Methods

Method	Description
GetObject	Retrieves the instance.
EnumerateInstances	Enumerates all instances of the object.
ExecMethod	Executes the specified method.
Stop	Stops the session.

For more information on **GetObject**, **EnumerateInstances**, and **ExecMethod**, see "IWbemServices interface" in the MSDN Library at http://msdn.microsoft.com/library.

MsSnaStatus_ServicePrint Class

The **MsSnaStatus_ServicePrint** class represents an SNA Print service status.

Syntax

```
class MsSnaStatus_ServicePrint : MsSnaStatus_Config
{
   string Name;
   sint32 Status;
   string StatusText;
};
```

Properties

Name

Data Type: **String** Qualifiers: **Key** Access Type: Read-Only

The name of the Print Service. **Name** will be the same as the computer name.

Status

Data Type: **sint32** Access Type: Read-Only

The current status of the service. The following table describes the possible values for **Status**.

Value	Description
0	Inactive
1	Pending
2	Stopping
3	Active

StatusText

Data Type: **String** Access Type: Read-Only

One of the **Status** values.

Mode

Data Type: **String** Access Type: Read-Only

The mode name for this session.

Methods

Method	Description
GetObject	Retrieves the instance.
EnumerateInstances	Enumerates all instances of the object.
ExecMethod	Executes the specified method.
Start	Starts the print service.
Stop	Stops the print service

For more information on **GetObject**, **EnumerateInstances**, and **ExecMethod**, see "IWbemServices interface" in the MSDN Library at http://msdn.microsoft.com/library.

MsSnaStatus_PrintSession Class

The **MsSnaStatus_PrintSession** class represents an SNA Print session status.

Syntax

```
class MsSnaStatus_PrintSession : MsSnaStatus_Config
{
   string Name;
   uint32 Status;
   string StatusText;
   uint32 PrintState;
   uint16 Type;
}
```

Properties

Name

Data Type: **String** Qualifiers: **Key** Access Type: Read-Only

A unique ID for the session.

Status

Data Type: **sint32** Access Type: Read-Only

The current status of the service. The following table describes the possible values for **Status**.

Value	Description
0	Inactive
1	Pending
2	Stopping
3	Active

StatusText

Data Type: **String** Access Type: Read-Only

One of the **Status** values. The following describes the possible values for **StatusText**.

Value
Inactive
Pending
Stopping
Spooling
Printing
Paper Out
Printer Offline
Printer Error

Printer Paused
Printer Idle
InSession
Ready
Paused
Unknown

PrintState

Data Type: **String** Access Type: Read-Only

The printer state that indicates the status of the printer or any printer errors. The following table describes the possible values for **PrintState**.

Value
Spooling
Printing
Paper Out
Printer Offline
Printer Error
Printer Paused
Printer Idle
InSession
Ready
Paused
Unknown

Type

Data Type: **uint16** Access Type: Read-Only

The type of print session. The following table describes the possible values for **Type**.

Value	**Description**
0	3270
1	APPC

Methods

Method	**Description**
GetObject	Retrieves the instance.

EnumerateInstances	Enumerates all instances of the object.
ExecMethod	Executes the specified method.
Start	Starts the print session.
Stop	Stops the print session.
Pause	Pauses the print session.
Restart	Restarts the print session.
PA1Key	Simulates pressing the PA1Key.
PA2Key	Simulates pressing the PA2Key.
Cancel	Cancels the print session.

For more information on **GetObject**, **EnumerateInstances**, and **ExecMethod**, see "IWbemServices interface" in the MSDN Library at http://msdn.microsoft.com/library.

MsSnaStatus_ServiceTN3270 Class

The **MsSnaStatus_ServiceTN3270** class represents a TN3270 service status.

Syntax

```
class MsSnaStatus_ServiceTN3270 : MsSnaStatus_Config
{
   string Name;
   sint32 Status;
   string StatusText;
}
```

Properties

Name

Data Type: **String** Qualifiers: **Key** Access Type: Read-Only

The service name. **Name** will be identical to the local computer name.

Status

Data Type: **sint32** Access Type: Read-Only

The current status of the service. The following table describes the possible values for **Status**.

Value	Description
0	
1	Inactive
2	Pending
3	Stopping
4	Active

StatusText

Data Type: **String** Access Type: Read-Only

One of the status values.

Methods

Method	Description
GetObject	Retrieves the instance.
EnumerateInstances	Enumerates all instances of the object.
ExecMethod	Executes the specified method.
Start	Starts the service.
Stop	Stops the service.

For more information on **GetObject**, **EnumerateInstances**, and **ExecMethod**, see "IWbemServices interface" in the MSDN Library at http://msdn.microsoft.com/library.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSnaStatus_TN3270Session Class

The **MsSnaStatus_TN3270Session** class represents a TN3270 session status.

Syntax

```
class MsSnaStatus_TN3270Session : MsSnaStatus_Config
{
   string Name;
   string Client;
};
```

Properties

Name

Data Type: **String** Qualifiers: **Key** Access Type: Read-Only

The service name. **Name** will be identical to the LUA LU or Pool name.

Client

Data Type: **String** Access Type: Read-Only

The client computer name or IP address.

Methods

Method	Description
GetObject	Retrieves the instance.
EnumerateInstances	Enumerates all instances of the object.

For more information on **GetObject**, **EnumerateInstances**, and **ExecMethod**, see "IWbemServices interface" in the MSDN Library at http://msdn.microsoft.com/library.

MsSnaStatus_TN5250Session Class

The **MsSnaStatus_TN5250Session** class represents a TN5250 session status.

Syntax

```
class MsSnaStatus_TN5250Session : MsSnaStatus_Config
{
   string TNSessionID;
   string APPCLU;
   string PartnerLU;
   string Mode;
   string Client;
};
```

Properties

TNSessionID

Data Type: **String** Qualifiers: **Key** Access Type: Read-Only

An arbitrary unique ID representing the session ID.

APPCLU

Data Type: **String** Access Type: Read-Only

APPC Local LU alias.

PartnerLU

Data Type: **String** Access Type: Read-Only

APPC Partner LU alias. **PartnerLU** can be a Remote LU or another Local LU.

Mode

Data Type: **String** Access Type: Read-Only

The mode name for this session.

Client

Data Type: **String** Access Type: Read-Only

The client computer name or IP address.

Methods

Method	Description
GetObject	Retrieves the instance.
EnumerateInstances	Enumerates all instances of the object.

For more information on **GetObject** and **EnumerateInstances**, see "IWbemServices interface" in the MSDN Library at http://msdn.microsoft.com/library.

MsSnaStatus_Lu3270ToActiveUser Class

The **MsSnaStatus_Lu3270ToActiveUser** class represents an association between a User connection and a 3270 type LU.

Syntax

```
class MsSnaStatus_Lu3270ToActiveUser : MsSnaStatus_Association
{
   MsSnaStatus_Lu3270 ref PathToLU3270;
   MsSnaStatus_ActiveUser ref PathToUser;
};
```

Properties

PathToLU3270

Data Type: **MsSnaStatus_Lu3270 ref** Qualifiers: **Key** Access Type: Read-Only

The path to the APPC session.

PathToUser

Data Type: **MsSnaStatus_ActiveUser ref** Qualifiers: **Key** Access Type: Read-Only

The path to the user.

Methods

Method	Description
GetObject	Retrieves the instance.
EnumerateInstances	Enumerates all instances of the object.

SNA Provider WMI Programmer's Reference

The SNA Provider WMI Programmer's Reference describes the Windows® Management Instrumentation (WMI) classes you can use to monitor and control SNA services.

For more information, see Controlling Services and Connections with WMI.

In This Section

- WMISNA WMI Provider Classes

WMISNA WMI Provider Classes

The Microsoft Host Integration Server SNA configuration provider supplies information regarding the SNA service configuration. As an instance and method provider, the WMISNA provider implements the standard **IWbemProviderInit** interface and the following **IWbemServices** methods:

- **CreateInstanceEnumAsync**
- **DeleteInstanceAsync**
- **ExecMethodAsync**
- **ExecQueryAsync**
- **GetObjectAsync**
- **PutInstanceAsync**

For more information on **IWbemProviderInit** and **IWbemServices**, see "COM API for WMI" in the MSDN Library at http://msdn.microsoft.com/library.

The WmiSna.mof and WmiSna_XP.mof files contain the WMISNA provider, and association and registration classes. You can access the WMISNA provider classes in the \root\MicrosoftHIS namespace.

Class	Description
MsSna_Domain	Global properties that affect all servers in the group. Sometimes called a subdoma in or OU.
MsSna_ServiceSNA	SNA service implements the SNA protocol. Contains the connections and LU reso urces.
MsSna_ServiceTN3270	TN3270 service enables clients to connect to a host via the TN3270 protocol.
MsSna_ServiceTN5250	TN5250 service enables clients to connect via the TN5250 protocol to a host.
MsSna_ServiceSharedFolder	The Shared Folders Gateway service for AS/400 file access.
MsSna_ServicePrint	Host Print service contains print sessions.
MsSna_UserInfo	Base class for a User or Group account configured in SNA.
MsSna_ConfiguredUser	A User or Group account configured in SNA. Can determine access to LUs and poo ls.
MsSna_LogInUserAndGroups	For the logged-on user, an enumeration returns the configured user and groups.
MsSna_Workstation	A workstation configured in SNA, specified by name or IP address. Can determine access to LUs and pools.
MsSna_Lu3270	Base class for 3270 LU resource. Each 3270 LU must belong to a connection.
MsSna_LuDisplay	A 3270 LU display resource. Often used for terminal emulator access.
MsSna_LuLua	A 3270 LU LUA resource. Often used for programmatic access.

MsSna_TN3270Session	The part of the TN3270 session that specifies client configuration. References a SNA_LU_LUA class.
MsSna_TN3270Port	Describes a port with security properties.
MsSna_TN3270SessionIPFilter	An IP address/name assigned to a TN3270 session. Multiple IP address/name pairs of these can be assigned to one session.
MsSna_TN5250SessionIPFilter	An IP address/name assigned to a TN5250 session. Multiple IP address/name pairs of these can be assigned to one session.
MsSna_LuPassThrough	One half of the dowstream LU/pool pairs. Represents a downstream LU/pool that is associated with a downstream connection.
MsSna_LuDown	A 3270 LU downstream resource. Reserved for use with downstream connections.
MsSna_LuPrint	A 3270 LU printer resource. Used by Print Session or by printer emulator.
MsSna_Pool	Base class for 3270 LU pools. A pool is associated with one or more 3270 LUs.
MsSna_PoolDisplay	The 3270 LU display pool.
MsSna_PoolLua	The 3270 LU LUA pool.
MsSna_PoolDown	The 3270 LU downstream pool.
MsSna_LuAppcLocal	An APPC Local LU resource. Used for LU 6.2 protocol.
MsSna_LuAppcRemote	An APPC remote LU resource. Used for LU 6.2 protocol. References a connection.
MsSna_AppcMode	An APPC Mode definition. Defines properties of an LU 6.2 session.
MsSna_Connection	Base class for SNA connection. Belongs to an SNA service. May own 3270 LUs.
MsSna_Connection8022Dlc	A type of SNA connection that uses DLC 802.2 protocol over Token Ring or Ethernet.
MsSna_ConnectionSdlc	A type of SNA connection that uses SDLC protocol over dial-up or leased lines.
MsSna_ConnectionX25	A type of SNA connection that uses X.25 protocol over dial-up or leased lines.
MsSna_ConnectionChannel	A type of SNA connection that uses Channel links.
MsSna_ConnectionDft	A type of SNA connection that uses DFT over coaxial cable.
MsSna_ConnectionTwinax	A type of SNA connection that uses twinax cable. Host Integration Server 2009 does not support twinax cable.
MsSna_Cpic	A global CPI-C definition for APPC.
MsSna_TN5250Definition	The definition of a TN5250 session.
MsSna_PrintSession	Base class for a print session on a Host Print service.

MsSna_PrintSession3270	Extends a Print session. Uses 3270 protocols to communicate with the host.
MsSna_PrintSessionAppc	Extends a Print session. Uses APPC LU 6.2 protocols to communicate with the host.
MsSna_AppcPartner	A preconfigured combination of APPC Local LU, Remote LU, and Mode.
MsSna_AccountAssigned3270	Used to query for 3270 LUs assigned to a specific workstation or user.
MsSna_AccountAssignedLua	Used to query for LUA LUs assigned to a specific workstation or user.
MsSna_AccountAssigned3270Services	Used to query for services on which a specific workstation or user has 3270 LUs/pools.
MsSna_AccountAssignedLuaServices	Used to query for services on which a specific workstation or user has LUA LUs/pools.
MsSna_AccountAvailableAppcLu	For the logged-on user account and workstation, the assigned APPC LU resources.
MsSna_AdapterOnMachine	Associates an adapter with a computer.
MsSna_ConnectionOnServer	Associates a connection with a server.
MsSna_Lu3270OnConnection	Associates a 3270 LU with a connection.
MsSna_LuDisplayAssignedToUser	Associates a display LU with a user.
MsSna_LuPrintAssignedToUser	Associates a print LU with a user.
MsSna_LuLuaAssignedToUser	Associates an LUA LU with a user.
MsSna_PoolDisplayAssignedToUser	Associates a display pool with a user.
MsSna_PoolLuaAssignedToUser	Associates the pool LUA with a user.
MsSna_LuDisplayAssignedToWorkstation	Associates a display LU with a workstation.
MsSna_LuPrintAssignedToWorkstation	Associates a print LU with a workstation.
MsSna_LuLuaAssignedToWorkstation	Associates an LUA LU with a workstation.
MsSna_PoolDisplayAssignedToWorkstation	Associates a display pool with a workstation.
MsSna_PoolLuaAssignedToWorkstation	Associates an LUA pool with a workstation.
MsSna_ConnectionUsingAdapter	Associates a connection with an adapter.
MsSna_Lu3270AssignedToPool	Associates a 3270 LU with a pool.
MsSna_PoolOnServer	Associates a pool with a server.
MsSna_ExtendedStatus	Describes the extended status of a specified message.

MsSna_Domain Class

Contains global properties that affect all servers in the group.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_Domain : MsSna_Config
{
   String Name;
   String NetViewConnection;
   String DispVerbConnection;
   String EventlogServer;
   String PopupServer;
   sint16 AuditLevel;
   sint32 BroadcastMeanTime;
   boolean NamedPipes;
   boolean IpxSpx;
   boolean BanyanVines;
   boolean TcpIp;
   boolean RTMOverflow;
   boolean RTMEndOfSession;
   sint16 RTMTimerUntil;
   sint16 RTMThreshold1;
   sint16 RTMThreshold2;
   sint16 RTMThreshold3;
   sint16 RTMThreshold4;
   String ConfigServer;
   String ClientBackupSponsorNames;   // names separated by ';'
   String ClientBackupDomainName;
   sint16 ClientDomainBackupType;
   boolean Security3270;
   boolean SecurityLUA;
   boolean SecurityAPPC;
   sint32 Status;
   datetime DateTimeSaved;
};
```

Properties

Name

Data Type: **String**

Qualifiers: **Key**

Access Type: Read-Only

The name of the subdomain.

NetViewConnection

Data Type: **String**

Qualifiers: **MAXLEN(8)**

Access Type: Read/Write

A connection to which NetView data should be sent.

DispVerbConnection

Data Type: **String**

Qualifiers: **MAXLEN(8)**

Access Type: Read/Write

The default connection for Display verbs. If set to **null**, selects a random connection.

EventlogServer

Data Type: **String**

Qualifiers: **MAXLEN(16)**

Access Type: Read/Write

The name of the server on which Windows 2000 Event Logs for this server installation should be stored.

PopupServer

Data Type: **String**

Qualifiers: MAXLEN(16)

Access Type: Read/Write

The name of the server to which pop-up error messages should be routed.

AuditLevel

Data Type: **sint16**

Qualifiers: **QualifierType**

Access Type: Read/Write

The default audit log level, which determines what events, if any, are audited. The following table describes the possible values for **AuditLevel**.

Value	Description
0	Detailed
1	General
2	Significant
3	Disabled

BroadcastMeanTime

Data Type: **sint32**

Qualifiers: **MINVALUE(45), MAXVALUE(65535), UNITS("sec")** Access Type: Read/Write

The interval at which server broadcasts are repeated.

NamedPipes

Data Type: **Boolean**

Access Type: Read/Write

true to send server broadcasts over Windows Networking, also known as named pipes; otherwise, **false**.

IpxSpx

Data Type: **Boolean**

Access Type: Read/Write

true to sends server broadcasts over IPX/SPX, also known as Novell NetWare; otherwise, **false**.

BanyanVines

Data Type: **Boolean**

Access Type: Read/Write

true to send server broadcasts over Banyan VINES; otherwise, **false**.

TcpIp

Data Type: **Boolean**

Access Type: Read/Write

true to send server broadcasts over TCP/IP; otherwise, **false**.

RTMOverflow

Data Type: **Boolean**

Access Type: Read/Write

true to cause Response Time Monitor (RTM) data to be sent to the host when the number of host responses in a given time period overflows the size of the available counter; otherwise, **false**.

RTMEndOfSession

Data Type: **Boolean**

Qualifiers: **QualifierType**

Access Type: Read-Only

true to cause Response Time Monitor (RTM) data to be sent to the host at the end of each LU-to-LU session; otherwise, **false**.

RTMTimerUntil

Data Type: **sint16**

Access Type: Read-Only

The point at which the Response Time Monitor (RTM) registers that a host has responded, at which point the RTM stops the timers. The following table describes the possible values for **RTMTimerUnit**.

Value	Description
0	FirstData
1	Unlock
2	AllowSent

RTMThreshold1

Data Type: **sint16**

Qualifiers: **MINVALUE(1), MAXVALUE(1000), UNITS("tenthsec")**

Access Type: Read/Write

The cut-off times at which the RTM saves the count of host responses, and then restarts the count.

RTMThreshold2

Data Type: **sint16**

Qualifiers: **MINVALUE(1), MAXVALUE(1000), UNITS("tenthsec")**

Access Type: Read/Write

The cut-off times at which the RTM saves the count of host responses, and then restarts the count.

RTMThreshold3

Data Type: **sint16**

Qualifiers: **MINVALUE(1), MAXVALUE(1000), UNITS("tenthsec")**

Access Type: Read/Write

The cut-off times at which the RTM saves the count of host responses, and then restarts the count.

RTMThreshold4

Data Type: **sint16**

Qualifiers: **MINVALUE(1), MAXVALUE(1000), UNITS("tenthsec")**

Access Type: Read/Write

The cut-off times at which the RTM saves the count of host responses, and then restarts the count.

ConfigServer

Data Type: **sint16**

Qualifiers: **MAXLEN(16)**

Access Type: Read/Write

The primary configuration server for the subdomain.

ClientBackupSponsorNames

Data Type: **String**

Qualifiers: **MAXLEN(256)**

Access Type: Read/Write

A list describing all of the SNA sponsor servers to which the server updates the client. The names of each server must be separated with a semicolon (;).

ClientBackupDomainName

Data Type: **String**

Qualifies: **MAXLEN(16)**

Access Type: Read/Write

A list of backup SNA subdomains with which the server updates the client.

ClientDomainBackupType

Data Type: **sint16**

Access Type: Read/Write

A value describing how client backup information is sent. The following table describes the possible values for **ClientDomainBackupType**.

Value	Description
0	None
1	Domain
2	Sponsors

Security3270

Data Type: **Boolean**

Access Type: Read/Write

true if access to 3270 LUs is restricted to users assigned to the LU; otherwise, **false**.

SecurityLUA

Data Type: **Boolean**

Access Type: Read/Write

true if access to LUA LUs is restricted to users assigned to the LU; otherwise, **false**.

SecurityAPPC

Data Type: **Boolean**

Access Type: Read/Write

true if access to APPC LUs is restricted to users assigned to the LU; otherwise, **false**.

Status

Data Type: **sint32**

Access Type: Read-Only

The status of the subdomain.

DateTimeSaved

Data Type: **datetime**

Access Type: Read-Only

The time and date for which the object was saved.

Remarks

The object **MsSna_Domain** represents can also be referred to as a subdomain or OU.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_ServiceSNA Class

Implements the SNA protocol, which contains the connections and LU resources.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_ServiceSNA : MsSna_Service
{
   String Name;
   String Comment;
   String ControlPoint;
   String NetworkName;
   String StatusText;
   sint32 Status;
};
```

Properties

Name

Data Type: **String Qualifier: Key, MAXLEN(20)** Access Type: Read-Only

The service name.

Comment

Data Type: **String**Qualifiers: **MAXLEN(25)** Access Type: Read/Write

An optional comment field.

ControlPoint

Data Type: **String**Qualifiers: **MAXLEN(8)** Access Type: Read/Write

The control point for this SNA node.

NetworkName

Data Type: **String**Qualifiers: **MAXLEN(8)** Access Type: Read/Write

The Network Name name for this SNA node.

StatusText

Data Type: **String**Access Type: Read-Only

The status of the service. The following table describes the possible values for **StatusText**.

Value	Description
Not configured	The service is not currently configured.
Inactive	The service is inactive.
Stopping	The service is in the process of stopping.
Active	The service is active.
Out of Date	The service is out-of-date.
Paused	The service is paused.

Status

Data Type: **sint32**Access Type: Read-Only

The status of the service. The following table describes the status of the service:

Value	Description
0	Not configured
1	Inactive
2	Inactive
3	Stopping
4	Active
5	
6	Out-of-date
7	Paused
8	
9	

Methods

Method	Description
Start	Starts the service.
Stop	Stops the service.
Pauses	Pauses the service.
Resume	Restarts a paused service.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_ServiceSNA.Start Method

Starts the service.

Syntax

```
void Start();
```

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_ServiceTN3270 Class

Enables clients to connect to a host via the TN3270 protocol.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_ServiceTN3270 : MsSna_Service
{
   String Name;
   String Comment;
   boolean LogNormal;
   boolean LogSna;
   boolean UseNameResolution;
   boolean PrinterFlowControl;
   boolean TNModeOnly;
   sint32 CloseDelay;
   sint32 IdleTimeout;
   sint32 InboundRU;
   sint32 OutboundRU;
   sint32 RefreshTime;
   sint32 StatusDelay;
      sint32 Port;
   String StatusText;
};
```

Properties

Name

Data Type: **String**Qualifiers: **MAXLEN(16)** Access Type: Read-Only

The TN3270 service name. **Name** is the same as the computer name.

Comment

Data Type: **String**Qualifiers: **MAXLEN(25)** Access Type: Read/Write

An optional comment string.

LogNormal

Data Type: **Boolean**Access Type: Read/Write

true if access to log successful client connections and successful client terminations; otherwise, **false**.

LogSna

Data Type: **Boolean**Access Type: Read/Write

true to log all TN3270 service event messages to the Event Log being used by the Host Integration Server 2009 system, instead of to the Event Log on the local computer; otherwise, **false**.

UseNameResolution

Data Type: **Boolean**Access Type: Read/Write

true to specify the name of a computer rather than the IP address—use only if you are running a domain name resolver; otherwise, **false**.

PrinterFlowControl

Data Type: **Boolean**Access Type: Read/Write

true to have the TN3270 service send all messages to a TN3270 printer client as RESPONSE-REQUIRED, and not to send any messages until it has received a response for the previous message; otherwise, **false**.

SocketListen

Data Type: **Boolean**Access Type: Read/Write

To have the TN3270 service stop listening on this socket once all of the defined LUs are in use; otherwise, **false**.

TNModeOnly

Data Type: **Boolean**Access Type: Read/Write

true to prevent the TN3270 service from using TN3270E, an enhancement to TN3270; otherwise, **false**.

CloseDelay

Data Type: **sint32**Qualifiers: **MINVALUE(0), MAXVALUE(86400),UNITS("sec")** Access Type: Read/Write

The time between sending a disconnect message to the client computer and closing the socket with the client computer.

IdleTimeout

Data Type: **sint32**Qualifiers: **MINVALUE(0), MAXVALUE(70560),UNITS("min")** Access Type: Read/Write

The time in which the session idles before the TN3270 service disconnects the client system. Specifying 0 means there will be no time-out.

InboundRU

Data Type: **sint32**Qualifiers: **MINVALUE(256), MAXVALUE(32768),UNITS("bytes")** Access Type: Read/Write

The RU, or SNA message, size used by the TN3270 service for logon messages from the host.

OutboundRU

Data Type: **sint32**Qualifiers: **MINVALUE(256), MAXVALUE(32768),UNITS("bytes")** Access Type: Read/Write

The RU, or SNA message, size used by the TN3270 service for logon messages to the host.

RefreshTime

Data Type: **sint32**Qualifiers: **MINVALUE(0), MAXVALUE(60),UNITS("sec")** Access Type: Read/Write

The delay between updates of the status on the display.

StatusDelay

Data Type: **sint32**Qualifiers:MINVALUE**(0), MAXVALUE(86400),UNITS("sec")** Access Type: Read/Write

The delay between the time when TN3270 service connects to a host session and the time the TN3270 service starts updating the client screen.

Port

Data Type: **sint32**Qualifiers: **MINVALUE(0), MAXVALUE(9999)**Access Type: Read/Write

The default port number for the TN3270 service. You can override **Port** on a per-session basis. Use 0 for the default TN3270 port.

StatusText

Data Type: **String**Access Type: Read-Only

The current status of the service. The following table describes the possible values for **StatusText**.

Value	Description
Not configured	The status is not configured.
Inactive	The status is inactive.
Pending	The status is pending.
Stopping	The status is stopping.
Active	The status is active.
Out of Date	The status is out-of-date.

Paused	The status is paused.

Methods

Method	Description
Start	Starts the service.
Stop	Stops the service.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsSna_ServiceTN3270.Start Method

Starts the service.

The following syntax is simplified from MOF code.

Syntax

```
void Start();
```

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_ServiceTN5250 Class

Enables clients to connect via the TN5250 protocol to a host.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_ServiceTN5250 : MsSna_Service
{
   String Name;
   String Comment;
   sint32 Port;
   String StatusText;
};
```

Remarks

Name

Data Type: **String**Qualifiers: **Key, MAXLEN(16)**Access Type: Read-Only

The TN5250 service name. **Name** is the same as the computer name.

Comment

Data Type: **String**Qualifiers: **MAXLEN(25)**Access Type: Read/Write

An optional comment field.

Port

Data Type: **sint32**Qualifiers: **MINVALUE(0), MAXVALUE(9999)**Access Type: Read/Write

The default port number for the TN5250 service. Port can be overridden on a per-session basis. Use 0 for the default TN5250 port.

StatusText

Data Type: **String**Access Type: Read-Only

The current status of the service. The following table describes the possible values for **StatusText**.

Value	Description
Not configured	The service is not configured.
Inactive	The service is inactive.
Pending	The service is pending.
Stopping	The service is stopping.
Active	The service is active.
Out of Date	The service is out-of-date.
Paused	The service is paused.

Methods

Method	Description
Start	Starts the service.
Stop	Stops the service.

MsSna_ServiceSharedFolder Class

Describes a service for AS/400 file access.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_ServiceSharedFolder : MsSna_Service
{
   String Name;
   String Comment;
   String StatusText;
};
```

Properties

Name

Data Type: **String**Qualifiers: **Key, MAXLEN(16)**Access Type: Read-Only

The Shared Folder Gateway service name. **Name** is the same as the computer name.

Comment

Data Type: **String**Qualifiers: **MAXLEN(25)**Access Type: Read/Write

An optional comment field.

StatusText

Data Type: **String**Access Type: Read/Write

The current status of the service. The following table describes the possible values for **StatusText**.

Value	Description
Not configured	The service is not configured.
Inactive	The service is inactive.
Pending	The service is pending.
Stopping	The service is stopping.
Active	The service is active.
Out of Date	The service is out-of-date.
Paused	The service is paused.

Methods

Method	Description
Start	Starts the service.
Stop	Stops the service.

MsSna_ServicePrint Class

Contains print sessions.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_ServicePrint : MsSna_Service
{
   String Name;
   boolean NoEventLogOnSkippingTransparentSection;
   boolean UseProportionalFontChange;
   boolean FlushFinalFF;
   boolean DelayPrintStart;
   boolean AlwaysDoNL;
   boolean NoSpaceAfterFF;
   boolean DoAllFF;
   boolean IgnoreCharsUnder3F;
   boolean UseFixedTabs;
   sint32 ActivationRetryInterval;
   sint32 ActivationRetryLimit;
   String StatusText;
};
```

Properties

Name

Data Type: **String**Qualifiers: **Key, MAXLEN(16)**Access Type: Read/Write

The Host Print service name. **Name** is the same as the machine name.

NoEventLogOnSkippingTransparentSection

Data Type: **Boolean**Access Type: Read/Write

true to prevent an entry in the Event Log every time a print service skips a transparent section found while printing a host print job; otherwise, **false**.

UseProportionalFontChange

Data Type: **Boolean**Access Type: Read/Write

true to prevent overlapping characters in documents containing nonfixed type fonts printed through Host Print service; otherwise, **false**.

FlushFinalFF

Data Type: **Boolean**Access Type: Read/Write

true to cause Host Print service to explicitly form-feed the document at the end of a print job; otherwise, **false**.

DelayPrintStart

Data Type: **Boolean**Access Type: Read/Write

true to delay the start of the print job until printable data is received by Host Print services; otherwise, **false**.

AlwaysDoNL

Data Type: **Boolean**Access Type: Read/Write

true to insert a new line when the Host Print service determines that the Maximum Print Position has been reached for a particular line of data; otherwise, **false**.

NoSpaceAfterFF

Data Type: **Boolean**Access Type: Read/Write

true to prevent print services from inserting a space character following a form feed; otherwise, **false**.

DoAllFF

Data Type: **Boolean**Access Type: Read/Write

true to force the printer driver to honor all form-feed commands; otherwise, **false**.

IgnoreCharsUnder3F

Data Type: **Boolean**Access Type: Read/Write

true to cause the Host Print service to ignore hexadecimal characters 3F and below; otherwise, **false**.

UseFixedTabs

Data Type: **Boolean**Access Type: Read/Write

true to disable normal tab functionality (such as aligning tabs in columns) and interpret each tab as a fixed number of spaces; otherwise, **false**.

ActivationRetryInterval

Data Type: **sint32**Access Type: Read/Write

The number of seconds to wait before trying to print the job again. The default value is 10 seconds.

ActivationRetryLimit

Data Type: **sint32**Access Type: Read/Write

The number of times Host Print service attempts to activate the APPC conversation following a terminated connection. The default value is -1 (infinite).

StatusText

Data Type: **String**Access Type: Read/Write

The current status of Host Print service. The following table describes the possible values for **StatusText**.

Value	Description
Not configured	The service is not configured.
Inactive	The service is inactive.
Pending	The service is pending.
Stopping	The service is stopping.
Active	The service is active.
Out of Date	The service is out-of-date.
Paused	The service is paused.

Methods

Method	Description
Start	Starts the service.
Stop	Stops the service.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_UserInfo Class

Base class for a User or Group account configured in SNA.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_UserInfo : MsSna_Config
{
   String Name;
   sint32 UserType;
   boolean DynRemote;
   String DefLocalLu;
   String DefRemoteLu;
   boolean Encryption;
};
```

Properties

Name

Data Type: **String**Qualifiers: **Key, MAXLEN(255)**Access Type: Read-Only

The user name.

Comment

Data Type: **String**Qualifiers: **MAXLEN(25)**Access Type: Read/Write

An optional comment field.

UserType

Data Type: **String**Access Type: Read-Only

The account type. The following table describes the possible values for **UserType**.

Value	Description
1	User
2	Group
3	Domain
4	Alias
5	WellKnownGroup
6	DeletedAccount
7	Invalid
8	Unknown
9	Computer

DynRemote

Data Type: **Boolean**Access Type: Read/Write

true to let this user or group use dynamically created APPC LUs.

DefLocalLu

Data Type: **String**Qualifiers: **MAXLEN(8)**Access Type: Read/Write

A default local APPC LU to be used when the user starts APPC programs.

DefRemoteLu

Data Type: **String**Qualifiers: **MAXLEN(8)**Access Type: Read/Write

A default remote APPC LU to be used when the user starts APPC programs.

Encryption

Data Type: **Boolean**Access Type: Read/Write

true to enable encryption between the client system and Host Integration Server 2009; otherwise, **false**.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsSna_ConfiguredUser Class

Describes a User or Group account configured in SNA.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_ConfiguredUser : MsSna_UserInfo
{
};
```

Remarks

MsSna_ConfiguredUser can determine access to LUs and Pools.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_Workstation Class

Describes a workstation configured in SNA, specified by name or IP address.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_Workstation : MsSna_Config
{
   String Name;
   sint32 IdType;
   sint16 Secure;
   String IPmask;
   boolean DynRemote;
   String Comment;
};
```

Properties

Name

Data Type: **String**Qualifiers: **Key, MAXLEN(20)**Access Type: Read-Only

The workstation ID. **Name** is usually the workstation name.

IdType

Data Type: **sint32**Access Type: Read/Write

The type of workstation specified in **Name**. The following table describes the possible values for **IdType**.

Value	Description
0	Name
1	IPAddress
2	IPSubnet

Secure

Data Type: **sint16**Access Type: Read/Write

Describes a value indicating whether the workstation can access LUs that are not directly assigned to it. The following table describes the possible values for **Secure**.

Value	Description
0	False
1	True

IPmask

Data Type: **String**Qualifiers: **MAXLEN(20)**Access Type: Read/Write

The IP Subnet mask. Use **IPmask** only if **WorkstationIdType** is set to **IPSubnet**.

DynRemote

Data Type: **Boolean**Access Type: Read/Write

true to enable users access to remote APPC LU as they are created; otherwise, **false**.

Comment

Data Type: **String**Qualifiers: **MAXLEN(25)**Access Type: Read/Write

An optional comment field.

Remarks

MsSna_Workstation can describe access to LUs and Pools.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_Lu3270 Class

Describes the base class for a 3270 LU resource.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_Lu3270 : MsSna_Resource
{
   String Name;
   String ConnectionName;
   String Comment;
   String PoolName;
   sint16 Number;
   boolean Compression;
   boolean UserWksSecure;
};
```

Properties

Name

Data Type: **String**Qualifiers: **Key, MAXLEN(8), TOUPPERCASE**Access Type: Read-Only

The LU Name.

ConnectionName

Data Type: **String**Qualifiers: **MAXLEN(8), TOUPPERCASE**Access Type: Read/Write

The connection on which this LU is defined.

Comment

Data Type: **String**Qualifiers: **MAXLEN(25)**Access Type: Read/Write

An optional comment field.

PoolName

Data Type: **String**Qualifiers: **MAXLEN(8)**Access Type: Read-Only

The pool name. **PoolName** is valid only if the LU has already been assigned to a pool.

Number

Data Type: **sint16**Qualifiers: **MINVALUE(1), MAXVALUE(254)** Access Type: Read/Write

The LU Number for LUs on 802.2, SDLC, or X.25. For a DFT connection, **Number** is `(Port Number * 16 + LT Number)`.

Compression

Data Type: **Boolean**Access Type: Read/Write

true to enable 3270 LU data stream compression; otherwise, **false**. This option must also be set in the host VTAM configuration for the LU.

UserWksSecure

Data Type: **Boolean**Access Type: Read/Write

true to require both the user and the workstation be assigned to this LU in order to acquire it; otherwise, **false**.

Remarks

Each 3270 LU must belong to a connection.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

Administration and Management Programmer's Guide

MsSna_LuDisplay Class

Describes a 3270 LU display resource.

Syntax

```
class MsSna_LuDisplay : MsSna_Lu3270
{
   sint16 Model;
   boolean ModelOverride;
   String AssociatedLU;
};
```

Properties

Model

Data Type: **sint16**Access Type: Read/Write

The default display model for Terminal service. The following table describes the possible values for **Model**.

Value	Description
0	Model12
1	Model13
2	Model14
3	Model1215

ModelOverride

Data Type: **Boolean**Access Type: Read/Write

true to indicate whether the default model can be overridden; otherwise, **false**. Some emulators can only emulate certain display models.

AssociatedLU

Data Type: **String**Qualifiers:**MAXLEN(8)**Access Type: Read-Only

Associates a printer LU with the current object.

Remarks

MsSna_LuDisplay is often used for terminal emulator access.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_LuLua Class

Describes a 3270 LU LUA resource.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_LuLua : MsSna_Lu3270
{
   boolean HighPriorityMode;
};
```

Properties

HighPriorityMode

Data Type: **Boolean**Access Type: Read/Write

true to increase the priority for this LU; otherwise, **false**.

Remarks

MsSna_LuLua is often used for programmatic access.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_TN3270Session Class

Describes the part of the TN3270 session that specifies client configuration.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_TN3270Session : MsSna_Config
{
   String Name;
   String ConnectionName;
   String Comment;
   String PoolName;
   sint16 Number;
   boolean Compression;
   boolean UserWksSecure;
   String Service;
   sint32 TnType;
   sint32 NumSessions;
   sint32 TermTypes;
   String AssociatedLu;
   sint32 Port;
};
```

Properties

Name

Data Type: **String**Qualifiers: **Key, MAXLEN(8)**Access Type: Read-Only

The LU name.

ConnectionName

Data Type: **String**Qualifiers: **MAXLEN(8)**Access Type: Read-Only

The connection on which this LU is defined.

Comment

Data Type: **String**Qualifiers: **MAXLEN(25)**Access Type: Read/Write

An optional comment field.

PoolName

Data Type: **String**Qualifiers: **MAXLEN(8)**Access Type: Read-Only

If the LU has already been assigned to a pool, the pool name appears here.

Number

Data Type: **sint16**Qualifiers: **MINVALUE(1), MAXVALUE(254)** Access Type: Read/Write

The LU Number for LUs on 802.2, SDLC, or X.25. For a DFT connection, this should be the Port Number * 16 + LT Number.

Compression

Data Type: **Boolean**Access Type: Read/Write

true to enable 3270 LU data stream compression; otherwise, **false**. This option must also be set in the host VTAM configuration for the LU.

UserWksSecure

Data Type: **Boolean**Access Type: Read/Write

true to require both the user and the workstation to be assigned to this LU in order to acquire it; otherwise, **false**.

Service

Data Type: **String**Qualifiers: **Key, MAXLEN(20)**Access Type: Read/Write

The SNA service to which this LU belongs.

TnType

Data Type: **sint32**Access Type: Read/Write

The display or printer type. The following table describes the possible values for **TnType**.

Value	Description
0	Generic
1	Specific
2	GenericPrinter
3	SpecificPrinter
4	AssoicatedPrinter

NumSessions

Data Type: **sint32**Qualifiers: **MINVALUE(0), MAXVALUE(65535)**Access Type: Read/Write

This is the number of TN3270 sessions allowed for the selected LU or pool.

TermTypes

Data Type: **sint32**Access Type: Read/Write

The terminal names supported by this LU. The following table describes the possible values for **TermTypes**.

Value	Description
0	3275-2
1	3276_2
2	3277_2
3	3278_2
4	3278_2_E
5	3279_2
6	3279_2_
7	E 3276_3
8	3278_3
9	3278_3_E
10	3279_3
11	3279_3_E
12	3276_4

13	3278_4
14	3278_4_E
15	3279_4
16	3279_4_E
17	3278_5
18	3278_5_E
19	3279_5
20	3279_5_E

AssociatedLu

Data Type: **String**Qualifiers: **MAXLEN(8)**Access Type: Read/Write

Used to associate a printer LU with this display LU.

Port

Data Type: **sint32**Qualifiers: **MINVALUE(0), MAXVALUE(9999)**Access Type: Read/Write

The port to be used for this session—or 0 to use the default TN3270 port.

Remarks

MsSna_TN3270Session references a SNA_LU_LUA class.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_TN3270Port Class

Describes a port with security properties.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_TN3270Port : MsSna_Config
{
   String Service;
   sint32 Port;
   String Comment;
   sint16 Security;
   boolean ClientCertVal;
   boolean Default;
   String Name;
};
```

Properties

Service

Data Type: **String**Qualifiers: **Key, MAXLEN(20)**Access Type: Read/Write

The TN service to which this LU belongs.

Port

Data Type: **sint32**Qualifiers: **Key, MINVALUE(1), MAXVALUE(0xffff)** Access Type: Read/Write

The port number.

Comment

Data Type: **String**Qualifiers: **MAXLEN(25)**Access Type: Read/Write

An option comment field.

Security

Data Type: **sint16**Access Type: Read/Write

The security level. The following table describes the possible values for **Security**.

Value	Description
0	Unsecured
1	Low
2	Medium
3	High

ClientCertVal

Data Type: **Boolean**Access Type: Read/Write

true to indicate that the client ceritificate should be validated; otherwise, **false**.

Default

Data Type: **Boolean**Qualifiers: **(TRUE)**Access Type: Read-Only

true to indicate a default port; otherwise, **false**.

Name

Data Type: **String**Qualifiers: **Something**Access Type: Read/Write

Name of the port.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_TN3270SessionIPFilter Class

An IP address or name assigned to a TN3270 session.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_TN3270SessionIPFilter : MsSna_Config
{
   String Name;
   String Session;
   sint16 Type;
   String SubnetMask;
};
```

Properties

Name

Data Type: **String**Qualifiers: **Key, MAXLEN(15)**Access Type: Read-Only

The IP address or name of the computer assigned to the TN3270 session.

Session

Data Type: **String**Qualifiers: **Key, MAXLEN(8)**Access Type: Read-Only

The TN3270 session name.

Type

Data Type: **sint16**Qualifiers: **Key**Access Type: Read/Write

A value that determines if **Name** contains an IP address or a name. The following table describes the possible values for **Type**.

Value	Description
0	Name
1	IPAddress

SubnetMask

Data Type: **String**Access Type: Read/Write

The IP Subnet mask, if an IP address is specified for **Name**.

Remarks

Multiple IP addresses or names can be assigned to one session.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_TN5250SessionIPFilter Class

Contains the IP address or name assigned to a TN5250 session.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_TN5250SessionIPFilter : MsSna_Config
{
   String Name;
   String AS400;
   sint16 Type;
   String SubnetMask;
};
```

Properties

Name

Data Type: **String**Qualifiers: **Key, MAXLEN(15)**Access Type: Read-Only

The IP address or name of the computer assigned to the TN5250 session.

AS400

Data Type: **String**Qualifiers: **Key, MAXLEN(8)**Access Type: Read-Only

The AS/400 definition.

Type

Data Type: **sint16**Qualifiers: **Key**A value that indicates whether **Name** contains an IP address or a name. The following table describes the possible values for **Type**.

Value	Description
0	Name
1	IPAddress

SubnetMask

Data Type: **String**Access Type: Read/Write

The IP Subnet mask, if an IP address is specified for 'Name'.

Remarks

You may assign multiple IP addresses or names in a single session.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_LuPassThrough Class

Contains one half of a dowstream LU/pool pair.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_LuPassThrough : MsSna_Config
{
   String Connection;
   sint16 Number;
   String Name;
   boolean IsPool;
};
```

Properties

Connection

Data Type: **String**Qualifiers: **Key, MAXLEN(8)**Access Type: Read-Only

The associated downstream connection.

Number

Data Type: **sint16**Qualifiers: **Key, MINVALUE(0)**Access Type: Read-Only

The number of the downstream connection.

Name

Data Type: **String**Qualifiers: **MAXLEN(8)**Access Type: Read/Write

The downstream LU or pool name.

IsPool

Data Type: **Boolean**Access Type: Read/Write

true to indicate that the object is a downstream a pool; **false** to indicate that the object is a downstream LU.

Remarks

MsSna_LuPassThrough represents a downstream LU/pool associated with a downstream connection.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_LuDown Class

A 3270 LU downstream resource.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_LuDown   : MsSna_Lu3270
{
};
```

Remarks

MsSna_LuDown is reserved for use with downstream connections.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_LuPrint Class

Describes a 3270 LU printer resource.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_LuPrint   : MsSna_Lu3270
{
   String AssociatedLU;
};
```

Properties

AssociatedLU

Data Type: **String**Qualifiers: **MAXLEN(8)**Access Type: Read/Write

The associated display LU.

Remarks

MsSna_LuPrint is used by Print session or by printer emulation.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_Pool Class

Base class for 3270 LU pools.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_Pool : MsSna_Resource
{
   String Name;
   String Comment;
};
```

Properties

Name

Data Type: **String**Qualifiers: **Key, MAXLEN(8)**Access Type: Read-Only

The pool name.

Comment

Data Type: **String**Qualifiers: **MAXLEN(25)**Access Type: Read/Write

An optional comment field.

Remarks

A pool is associated with one or more 3270 LUs.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_PoolDisplay Class

Contains the 3270 LU Display pool.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_PoolDisplay : MsSna_Pool
{
   sint16 Model;
   boolean ModelOverride;
   boolean AssocPrint;
};
```

Properties

Model

Data Type: **sint16** Access Type: Read/Write

The default display model for terminal emulation. The following table describes the possible values for **Model**.

Value	Description
0	Model2
1	Model3
2	Model4
3	Model5

ModelOverride

Data Type: **Boolean** Access Type: Read/Write

true to indicate that the default model can be overridden; otherwise, **false**. Some emulators can only emulate certain display models.

AssocPrint

Data Type: **Boolean** Qualifiers: **Something** Access Type: Read/Write

true to associate a printer LU with this display LU pool; otherwise, **false**.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_LuAppcLocal Class

An APPC local LU resource.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_LuAppcLocal : MsSna_Config
{
   String Service;
   String Alias;
   String Comment;
   String NetName;
   String LUName;
   boolean PoolMember;
   String IncomingLu;
   sint16 TpTimeout;
   sint16 Number;
   string Connection;
   boolean SyncPoint;
   String SyncPointClient;
};
```

Properties

Service

Data Type: **String** Qualifiers: **Key, MAXLEN(20), TOUPPERCASE** Access Type: Read-Only

The SNA service to which this LU belongs.

Alias

Data Type: **String** Qualifiers: **Key, MAXLEN(8), TOUPPERCASE** Access Type: Read-Only

The LU alias.

Comment

Data Type: **String** Qualifiers: **MAXLEN(25)** Access Type: Read/Write

An optional comment field.

NetName

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

The network name, which must match that configured on the remote computer.

LUName

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

The LU name, which can be the same as the LU alias.

PoolMember

Data Type: **Boolean** Access Type: Read/Write

true to indicate that this LU is a member of the default outgoing Local APPC LU pool; otherwise, **false**.

IncomingLu

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

An implicit incoming remote LU.

TpTimeout

Data Type: **sint16** Qualifiers: **MINVALUE(0), MAXVALUE(3600)** Access Type: Read/Write

The time-out value, in seconds. If you want to manually start the invokable TP, be sure to specify at least 60 seconds; this will give the operator sufficient time to perform the necessary actions.

Number

Data Type: **sint16** Qualifiers: **MINVALUE(0), MAXVALUE(254)** Access Type: Read/Write

The LU number, for dependent LUs.

Connection

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

The connection on which a dependent LU is configured.

SyncPoint

Data Type: **Boolean** Access Type: Read/Write

true to indicate that you have a very specialized transaction program (TP) that requires Resync Service; otherwise, **false**.

SyncPointClient

Data Type: **String** Qualifiers: **MAXLEN(15)** Access Type: Read/Write

The IP address or the name of the client computer.

Remarks

MsSna_LuAppcLocal is used for LU 6.2 protocols.

Requirements

Platforms: Microsoft Windows Server 2003, Windows® XP Professional, Windows 2000 Server

MsSna_LuAppcRemote Class

An APPC remote LU resource.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_LuAppcRemote : MsSna_Config
{
   String Service;
   String Connection;
   String Alias;
   String Comment;
   String NetName;
   String LUName;
   String UnName;
   boolean Parallel;
   String IncomingMode;
   sint16 Security;
   String SecKeyHex;
   String SecKeyChar;
   boolean SyncPoint;
};
```

Properties

Service

Data Type: **String** Qualifiers: **MAXLEN(20), TOUPPERCASE** Access Type: Read-Only

The SNA service to which this LU belongs.

Connection

Data Type: **String** Qualifiers: **Key,MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

The connection on which a dependent LU is configured.

Alias

Data Type: **String** Qualifiers: **Key, MAXLEN(8)** Access Type: Read-Only

The LU Alias.

Comment

Data Type: **String** Qualifiers: **MAXLEN(25)** Access Type: Read/Write

An optional comment field.

NetName

Data Type: **String** Qualifiers: **MAXLEN(8)** Access Type: Read/Write

The network name. You can obtain the correct name from the host or peer administrator.

LUName

Data Type: **String** Qualifiers: **MAXLEN(8)** Access Type: Read/Write

The LU name, which can be the same as the LU alias.

UnName

Data Type: **String** Qualifiers: **MAXLEN(8)** Access Type: Read/Write

The uninterpreted LU name for LUs, which are paired with a dependent local APPC LU.

Parallel

Data Type: **String** Access Type: Read/Write

A value that indicates that parallel sessions will be used. **Parallel** must be used with an independent, local LU.

IncomingMode

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

The implicit incoming mode for this LU.

Security

Data Type: **sint16** Access Type: Read/Write

A value that indicates what sort of session-level security will be used with this LU. The following table describes the possible values for **Security**.

Value	Description
0	None
1	Hex
2	Characters

SecKeyHex

Data Type: **String** Qualifiers: **MAXLEN(16)** Access Type: Read/Write

The security key, in hexadecimal. Requires that **Security** be set to '**1**'.

SecKeyChar

Data Type: **String** Qualifiers: **MAXLEN(8)** Access Type: Read/Write

The security key, in characters. Requires that **Security** be set to **2**.

SyncPoint

Data Type: **Boolean** Access Type: Read/Write

true to enable **SyncPoint**; otherwise, **false**. **SyncPoint** requires that the Local LU alias be unique.

Remarks

MsSna_LuAppcRemote is used for LU 6.2 protocol, and references a connection.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_AppcMode Class

Contains an APPC Mode definition.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_AppcMode : MsSna_Config
{
   String Name;
   String Comment;
   sint32 SessionLimit;
   sint32 MinContWin;
   sint32 PartMinContWin;
   sint32 AutoActivate;
   boolean Priority;
   sint32 TxPacing;
   sint32 RxPacing;
   sint32 TxRu;
   sint32 RxRu;
   sint16 MaxSendCompression;
   sint16 MaxRcvCompression;
   boolean AllowLZandRLE;
   boolean EndpointOnly;
};
```

Properties

Name

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE** Access Type: Read-Only

The mode name.

Comment

Data Type: **String** Qualifiers: **MAXLEN(25)** Access Type: Read/Write

An optional comment field.

SessionLimit

Data Type: **sint32** Qualifiers: **MINVALUE(0), MAXVALUE(15000)** Access Type: Read/Write

The maximum number of parallel sessions allowed with this mode.

MinContWin

Data Type: **sint32** Qualifiers: **MINVALUE(0), MAXVALUE(15000)** Access Type: Read/Write

The minimum contention winner limit.

PartMinContWin

Data Type: **sint32** Qualifiers: **MINVALUE(0), MAXVALUE(15000)** Access Type: Read/Write

The partner minimum contention winner limit.

AutoActivate

Data Type: **sint32** Qualifiers: **MINVALUE(0), MAXVALUE(15000)** Access Type: Read/Write

The number of contention winner sessions to be activated for the local LU whenever the connection for this mode is started.

Priority

Data Type: **Boolean** Access Type: Read/Write

true to give preference to communication with this mode over communication with a low-priority mode; otherwise, **false**.

TxPacing

Data Type: **sint32** Qualifiers: **MINVALUE(0), MAXVALUE(63)** Access Type: Read/Write

The maximum number of frames for the local LU to send without an SNA pacing response from the partner LU. Setting **TxPacing** to 0 indicates a unlimited number of frames.

RxPacing

Data Type: **sint32** Qualifiers: **MINVALUE(0), MAXVALUE(63)** Access Type: Read/Write

The maximum number of frames for the local LU to receive from the partner LU before the local LU sends an SNA pacing response. Setting **RxPacing** to **0** (zero) indicates a unlimited number of frames.

TxRu

Data Type: **sint32** Qualifiers: **MINVALUE(256), MAXVALUE(65527)** Access Type: Read/Write

The maximum size for RUs sent by the TPs on the local system.

RxRu

Data Type: **sint32** Qualifiers: **MINVALUE(256), MAXVALUE(65527)** Access Type: Read/Write

The maximum size for RUs received from the TPs on the remote system.

MaxSendCompression

Data Type: **sint32** Access Type: Read/Write

The maximum compression allowed when sending. The following table describes the possible values for **MaxSendCompression**.

Values	Description
0	None
1	RLE
2	LZ9

MaxRcvCompression

Data Type: **sint16** Access Type: Read/Write

The maximum compression allowed when receiving. The following table describes the possible values for **MaxRcvCompression**.

Values	Description
0	None
1	RLE
2	LZ9

AllowLZandRLE

Data Type: **Boolean** Access Type: Read/Write

true to compress data using RLE before being further compressed using LZ9; otherwise, **false**. **AllowLZandRLE** is valid only if you are using LZ9.

EndpointOnly

Data Type: **Boolean** Access Type: Read/Write

true to allow intermediate nodes to use compression if one of the endpoints does not support or otherwise does not use compression; otherwise, **false**.

Remarks

MsSna_AppcMode defines properties of an LU 6.2 session.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_Connection Class

Base class for SNA connection.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_Connection : MsSna_Config
{
   String Service;
   String Name;
   String Comment;
   String Adapter;
   sint32 RemoteEnd;
   sint16 PeerRole;
   sint16 Activation;
   boolean AllowIncoming;
   boolean DynamicLuDef;
   String PartnerConnectionName;
   String BlockId;
   String NodeId;
   String RemoteNetName;
   String RemoteControlPoint;
   String RemoteBlockId;
   String RemoteNodeId;
   sint16 XIDFormat;
   String LocalNetName;
   String LocalControlPoint;
   sint16 CompressionLevel;
   sint16 RetryLimit;
   sint16 RetryDelay;
   String StatusText;
}
```

Properties

Service

Data Type: **String** Qualifiers: **MAXLEN(20)** Access Type: Read-Only

The SNA service to which this connection belongs.

Name

Data Type: **String** Qualifiers: **Key, MAXLEN(8)** Access Type: Read-ONly

The connection name.

Comment

Data Type: **String** Qualifiers: **MAXLEN(25)** Access Type: Read/Write

An optional comment field.

Adapter

Data Type: **String** Qualifiers: **MAXLEN(8)** Access Type: Read/Write

The link service to be used by this connection.

RemoteEnd

Data Type: **sint32** Access Type: Read/Write

The remote end. The following table describes the possible values of **RemoteEnd**.

Value	Description
0	Host

1	Peer
2	Downstream
3	Passthrough

For 3270 or LUA access, be sure to set **RemoteEnd** to *Host*.

PeerRole

Data Type: **String** Access Type: Read/Write

The peer role. The following table describes the possible values of **PeerRole**.

Value	Description
0	Primary
1	Secondary
2	Negotiable
-1	Invalid

PeerRole only applies to connections with **RemoteEnd** set to **Peer** or **Passthrough**.

Activation

Data Type: **sint16** Access Type: Read/Write

The activation setting. Applicable only if Outgoing Calls are included in Allowed Directions. The following table describes the possible values for **Activation**.

Value	Description
0	Initial
1	OnDemand
2	Administrator
3	Incoming

AllowIncoming

Data Type: **Boolean** Access Type: Read/Write

true to indicate that incoming calls are allowed; otherwise, **false**.

DynamicLuDef

Data Type: **Boolean** Access Type: Read/Write

true to automatically configure the APPC Remote LUs as users request them; otherwise, **false**. **DynamicLuDef** requires that an APPN End Node or Net Node be available on the connection.

PartnerConnectionName

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

The name of the connecting partner. Valid only if **RemoteEnd** is of **Passthrough**.

BlockId

Data Type: **String** Qualifiers: **MAXLEN(3), TOUPPERCASE** Access Type: Read/Write

The block ID.

NodeId

Data Type: **String** Qualifiers: **MAXLEN(5), TOUPPERCASE** Access Type: Read/Write

The local node ID. Applicable only for connections which use a switched SDLC line (standard telephone line) to connect to a host system.

RemoteNetName

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

The network name of the remote system. Applicable if you are using Format 3 XIDs.

RemoteControlPoint

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

The control point of the reomote system. Applicable if you are using Format 3 XIDs.

RemoteBlockId

Data Type: **String** Qualifiers: **MAXLEN(3), TOUPPERCASE** Access Type: Read/Write

The remote block ID.

RemoteNodeId

Data Type: **String** Qualifiers: **MAXLEN(5), TOUPPERCASE** Access Type: Read/Write

The remote node ID.

XIDFormat

Data Type: **sint16** Access Type: Read/Write

The XID Type. The following table describes the possible values for **XIDFormat**.

Value	Description
0	Format 0
3	Format 3

Most systems use Format 3.

LocalNetName

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

The network name that, along with the **LocalControlPoint**, identifies a system.

LocalControlPoint

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

The control point that, along with **LocalNetName**, identifies a system.

CompressionLevel

Data Type: **sint16** Access Type: Read/Write

The compression type used by this connection. The following table describes the possible values for **CompressionLevel**.

Value	Description
0	None
1	RLE
2	LZ9

3	LZ10
4	LZ12

RetryLimit

Data Type: **sint16** Qualifiers: **MINVALUE(0), MAXVALUE(255)** Access Type: Read/Write

The number of times the local system tries to send data to the remote system if there is no response.

RetryDelay

Data Type: **String** Qualifiers: **MINVALUE(0), MAXVALUE(255), UNITS("sec")** Access Type: Read/Write

The length of time for the local system to wait for a response to a transmission before trying again.

StatusText

Data Type: **String** Access Type: Read-Only

The current status of the connection. The following table describes the possible values of **StatusText**.

Value	Description
0	Unconfigured
1	Inactive
2	Incoming
3	OnDemand
4	OnDemand/Incoming
5	Pending
6	Stopping
7	Active
8	Error
9	

Name

Data Type: **String** Qualifiers: **Something** Access Type: Read/Write

The name of the connection.

Methods

Method	Description
Start	Starts the connection.
Stop	Stops the connection.
ExchangePassthroughLus	Returns a value that determines if two LUs are part of a passthrough connection pair.

Remarks

MsSna_Connection belongs to a SNA service, and may own 3270 LUs.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_Connection.ExchangePassthroughLus Method

Returns a value that determines if two LUs are part of a passthrough connection pair.

The following syntax is simplified from MOF code.

Syntax

```
boolean ExchangePassthroughLus
(
```

Parameters

FirstLu

The first LU.

SecondLu

The second LU.

Return Value

true if the LUs are part of a passthrough pair; otherwise, **false**.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

Administration and Management Programmer's Guide

MsSna_Connection8022Dlc Class

Describes a type of SNA connection that uses DLC 802.2 protocol over a Token Ring or Ethernet.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_Connection8022Dlc : MsSna_Connection
{
   String Address;
   sint16 DlcRetryLimit;
   sint16 DlcTimerT1;
   sint16 DlcTimerT2;
   sint16 DlcXidRetry;
   sint16 DlcRecvThresh;
   sint16 DlcSendLimit;
   sint16 DlcRemoteSAP;
   sint16 DLCType;
   sint16 DlcLocalSAP;
   sint32 MaxBtu;
};
```

Parameters

Address

Data Type: **String** Qualifiers: **MAXLEN(12), TOUPPERCASE** Access Type: Read/Write

The 12-digit hexadecimal remote network address. You can receive the correct value for **Address** by contacting the administrator of the remote system.

DlcRetryLimit

Data Type: **sint16** Qualifiers: **MINVALUE(0), MAXVALUE(255)** Access Type: Read/Write

The number of times that the local system should retransmit a frame if no response is received from the remote system.

DlcTimerT1

Data Type: **sint16** Access Type: Read/Write

The amount of time that the local system should wait for the remote system to respond to a transmission before the local system tries again. The following table describes the possible values for **DlcTimer**.

Value	Description
0	Default
1	200 ms
2	400 ms
3	600 ms
4	800 ms
5	1000 ms
6	1 s
7	2 s
8	3 s

9	4 s
10	5 s

DlcTimerT2

Data Type: **sint16** Access Type: Read/Write

The maximum amount of time that should be allowed before the local system sends an acknowledgment of a received transmission. The following table describes the possible values for **DlcTimerT2**.

Value	Description
0	Default
1	40 ms
2	80 ms
3	120 ms
4	160 ms
5	200 ms
6	400 ms
7	800 ms
8	1200 ms
9	1600 ms
10	2000 ms

DlcXidRetry

Data Type: **sint16** Qualifiers: **QualiferValueHere** Access Type: Read/Write

The amount of time that the link can be inactive before the local system treats it as nonfunctioning and shuts it down. The following table describes the possible values for **DlcXidRetry**.

Value	Description
0	1 s
1	2 s
2	3 s
3	4 s
4	5 s
5	5 s (2)
6	10 s

7	15 s
8	20 s
9	25 s

DlcXidRetry

Data Type: **sint16** Qualifiers: **MINVALUE(0), MAXVALUE(30)** Access Type: Read/Write

The number of times that the local system should retransmit an XID, an identifying message, if no response is received from the remote system.

DlcRecvThresh

Data Type: **sint16** Qualifiers: **MINVALUE(0), MAXVALUE(127)** Access Type: Read/Write

The maximum number of frames that the local system can receive from the remote system before sending a response.

DlcSendLimit

Data Type: **sint16** Qualifiers: **MINVALUE(0), MAXVALUE(127)** Access Type: Read/Write

The maximum number of frames that the local system can send without receiving a response from the remote system.

DlcRemoteSAP

Data Type: **sint16** Qualifiers: **MINVALUE(4), MAXVALUE(252)** Access Type: Read/Write

A 2-digit hexadecimal number that is a multiple of 04, between 04 and EC. See your Token Ring or Ethernet manual for more information.

DLCType

Data Type: **sint16** Access Type: Read-Only

The DLC type. The following table describes the possible values for **DLCType**.

Value	Description
0	Token
1	Ether

DlcLocalSAP

Data Type: sint16 Qualifiers: **MINVALUE(4), MAXVALUE(252)** Access Type: Read/Write

A 2-digit hexadecimal number that is a multiple of 04, between 04 and EC. See your Token Ring or Ethernet manual for more information.

MaxBtu

Data Type: **sint16** Qualifiers: **MINVALUE(265), MAXVALUE(16393)** Access Type: Read/Write

The maximum Basic Transmission Unit (BTU) Length.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

WMISNA WMI Provider Classes

Administration and Management Programmer's Guide

MsSna_ConnectionSdlc Class

A type of SNA connection that uses SDLC protocol over dial-up or leased lines.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_ConnectionSdlc : MsSna_Connection
{
   String DialData;
   sint16 SdlcEncoding;
   sint16 SdlcDuplex;
   String SdlcPollAddress;
   boolean SdlcLeasedLine;
   sint16 SdlcDataRate;
   sint16 SdlcContactLimit;
   sint16 SdlcContactTO;
   sint16 SdlcIdleLimit;
   sint16 SdlcIdleTO;
   boolean SdlcMultiPrimary;
   sint16 SdlcPollLimit;
   sint16 SdlcPollTO;
   sint16 SdlcPollRate;
   boolean SdlcStandby;
   sint16 SdlcSwitchTO;
   sint32 MaxBtu;
};
```

Parameters

DialData

Data Type: **String** Qualifiers: **MAXLEN(40)** The dial data for connections which use a switched line and the phone number is not stored in the modem.

SdlcEncoding

Data Type: **sint16** Access Type: Read/Write

The encoding scheme (NRZ or NRZI) for the modem to use. The following table describes the possible values for **3dlcEncoding**.

Value	Description
0	NRZ
1	NRZI

SdlcEncoding must match the remote modem.

SdlcDuplex

Data Type: **sint16** Access Type: Read/Write

The duplex setting of the modem. The following table describes the possible values for **SdlcDuplex**.

Value	Description
0	Half
1	Full

SdlcPollAddress

Data Type: **String** Qualifiers: **MAXLEN(2)** Access Type: Read/Write

A 2-digit hexadecimal number describing the poll address. Contact the administrator of the remote system to determine the appropriate value.

SdlcLeasedLine

Data Type: **Boolean** Access Type: Read-Only

The value depends on the Link service.

SdlcDataRate

Data Type: **sint16** Access Type: Read/Write

The data rate for transmissions between the communications adapter and the modem. The following table describes the possible values for **SdlcDataRate**.

Value	Description
0	Low
1	High

SdlcContactLimit

Data Type: **String** Qualifiers: **MINVALUE(1), MAXVALUE(20)** Access Type: Read/Write

The maximum number of times the link service resends an XID or SNRM before declaring an outage to Host Integration Server 2009.

SdlcContactTO

Data Type: **String** Qualifiers: **MINVALUE(5), MAXVALUE(300)** Access Type: Read/Write

The length of time, in tenths of a second, which the SDLC link service waits for an XID or SNRM response before resending the XID or SNRM.

SdlcIdleLimit

Data Type: **sint16** Qualifiers: **MINVALUE(1), MAXVALUE(255)** Access Type: Read/Write

The number of times for the local system to try to send data to the remote system if there is no response.

SdlcIdleTO

Data Type: **sint16** Access Type: **MINVALUE(1), MAXVALUE(300)**

The length of time, in tenths of a second, for the local system to wait for a response to a transmission before trying again.

SdlcMultiPrimary

Data Type: **Boolean** Access Type: Read/Write

true to indicate this is a leased SDLC line to downstream systems, and this server will be the primary station for a multidrop connection; otherwise, **false**.

SdlcPollLimit

Data Type: **sint16** Qualifiers: **MINVALUE(1), MAXVALUE(255)** Access Type: Read/Write

The number of times for the local system to poll the remote system, if there is no response.

SdlcPollTO

Data Type: **sint16** Qualifiers: **MINVALUE(1), MAXVALUE(300)** Access Type: Read/Write

The length of time, in tenths of a second, for the local system to wait for a response to a poll before trying again.

SdlcPollRate

Data Type: **sint16** Qualifiers: **MINVALUE(1), MAXVALUE(50)** Access Type: Read/Write

The poll rate, in polls per second. Valid only if the remote system is a peer or downstream system.

SdlcStandby

Data Type: **Boolean** Access Type: Read/Write

true to set the Standby line to of a modem; otherwise, **false**.

SdlcSwitchTO

Data Type: **sint16** Qualifiers: **MINVALUE(10), MAXVALUE(500)** Access Type: Read/Write

The number of seconds that are allowed for the user or modem to dial and make a connection to the remote computer.

MaxBtu

Data Type: **sint32** Qualifiers: **MINVALUE(265), MAXVALUE(16393)** Access Type: Read/Write

The Maximum Basic Transmission Unit (BTU) length.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

WMISNA WMI Provider Classes

Administration and Management Programmer's Guide

MsSna_ConnectionX25 Class

Describes a type of SNA connection that uses X.25 protocol over dial-up or leased lines.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_ConnectionX25 : MsSna_Connection
{
   String Address;
   sint16 PVCAlias;
   sint16 VCType;
   String X25Facility;
   String X25UserData;
   sint16 X25PacketSize;
   sint16 X25WindowSize;
   sint32 MaxBtu;
};
```

Parameters

Address

Data Type: **String** Qualifiers: **MAXLEN(15), TOUPPERCASE** Access Type: Read/Write

The Switched Virtual Circuit (SVC) address of the host for connections using switched virtual circuit.

PVCAlias

Data Type: **sint16** Qualifiers: **MINVALUE(1), MAXVALUE(65535)** Access Type: Read/Write

The Permanent Virtual Circuit (PVC) alias of the host for connections using permanent virtual circuit.

VCType

Data Type: **sint16** Access Type: Read/Write

The type of virtual circuit used by the connection. The following table describes the possible values for **VCType**.

Value	Description
0	Switched
1	Permanent

X25Facility

Data Type: **String** Qualifiers: **MAXLEN(132), TOUPPERCASE** Access Type: Read/Write

The codes for any Facility Data required by your network provider or by the administrator of the remote system. Valid only for an SVC channel.

X25UserData

Data Type: **String** Qualifiers: **MAXLEN(32), TOUPPERCASE** Access Type: Read/Write

The codes for any User Data required by your network provider. Valid only for an SVC channel.

X25PacketSize

Data Type: **sint16** Qualifiers: **QualiferValueHere** Access Type: Read/Write

The maximum number of data bytes, not header bytes, to be sent in a frame. The following table describes the possible values for **X25PacketSize**.

Value	Description
0	64

1	128
2	256
3	512
4	1024

X23PacketSize is valid only for a PVC channel.

X25WindowSize

Data Type: **sint16** Qualifiers: **MINVALUE(1), MAXVALUE(7)** Access Type: Read/Write

The maximum number of frames that the local system can send without receiving a response from the remote system. Valid only for a PVC channel.

MaxBtu

Data Type: **sin32** Qualifiers: **MINVALUE(265), MAXVALUE(16393)** Access Type: Read/Write

The Maximum Basic Transmission Unit (BTU) length.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_ConnectionChannel Class

A type of SNA connection that uses channel links.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_ConnectionChannel : MsSna_Connection
{
   String Address;
   String CtrlUnit;
   sint32 MaxBtu;
};
```

Properties

Address

Data Type: **String** Qualifiers: **MAXLEN(2)** Access Type: Read/Write

A 2-digit hexadecimal number identifying the channel. The range is from 00 through FF; the default is FF.

CtrlUnit

Data Type: **String** Qualifiers: **MAXLEN(1)** Access Type: Read-Only

A value for the control unit image number. The range is 0 through F; the default is 0 (zero).

MaxBtu

Data Type: **String** Qualifiers: **MINVALUE(265), MAXVALUE(65536)** Access Type: Read/Write

The Maximum Basic Transmission Unit (BTU) length.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_ConnectionDft Class

A type of SNA connection that uses DFT over a coaxial cable.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_ConnectionDft : MsSna_Connection
{
};
```

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_ConnectionTwinax Class

A type of SNA connection that uses a Twinax cable.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_ConnectionTwinax : MsSna_Connection
{
};
```

Remarks

Twinax is not supported by Host Integration Server 2009.

Requirements

Operating Systems: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsSna_Cpic Class

A global CPI-C definition for APPC.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_Cpic : MsSna_Config
{
   String Name;
   String ApplicationTPName;
   String ServiceTPHexName;
   String FullLUName;
   String FullNetName;
   sint16 SecurityType;
   String UserId;
   String Password;
   String AliasLUName;
   sint16 LUNameType;
   sint16 TPNameType;
   String ModeName;
};
```

Parameters

Name

Data Type: **String** Qualifiers: **Key, MAXLEN(8), TOUPPERCASE** Access Type: Read-Only

The Symbolic Destination name.

Comment

Data Type: **String** Qualifiers: **MAXLEN(25)**Access Type: Read/Write

An optional comment field.

ApplicationTPName

Data Type: **String** Qualifiers: **MAXLEN(64)**Access Type: Read/Write

The application TP name.

ServiceTPHexName

Data Type: **String** Qualifiers: **MAXLEN(8)** Access Type: Read/Write

A hexadecimal value describing the SNA service TP number.

FullLUName

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE**Access Type: Read/Write

The partner LU name. Valid only for identifying a partner LU with a fully qualified name.

FullNetName

Data Type: **String** Qualifiers: **MAXLEN(8)**Access Type: Read/Write

The partner network name. Valid only for identifying a partner LU with a fully qualified name.

SecurityType

Data Type: **sint16** Qualifiers: **QualiferValueHere** Access Type: Read/Write

The **Conversation Security** option to be used. The following table describes the possible values for **SecurityType**.

Value	Description
0	None

1	Same
2	Program

UserId

Data Type: **String** Qualifiers: **MAXLEN(10)** Access Type: Read/Write

The user ID to be used when specifying *Program* for **SecurityType**.

Password

Data Type: **String** Qualifiers: **MAXLEN(10)** Access Type: Read/Write

The password to be used when specifying *Program* for **SecurityType**

AliasLUName

Data Type: **String** Qualifiers: MAXLEN(8), TOUPPERCASE Access Type: Read/Write

An alias. Valid only when identifying the Partner LU by alias.

LUNameType

Data Type: **sint16** Access Type: Read/Write

A value that indicates whether the Partner LU name is specified with an alias or a fully qualified LU name. The following table describes the possible values for **LUNameType**.

Value	Description
0	Alias
1	Full

TPNameType

Data Type: **sint16** Qualifiers: **QualiferValueHere** Access Type: Read/Write

A value that indicates whether the Partner TP name is specified in characters or hex. The following table describes the possible values for **TPNameType**.

Value	Description
0	Character
1	Hex

ModeName

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE**Access Type: Read/Write

The name of the mode to be used.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_TN5250Definition Class

The definition of a TN5250 session.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_TN5250Definition : MsSna_Config
{
   String Name;
   String Service;
   String RemoteLUAlias;
   String LocalLUAlias;
   String Comment;
   String User;
   String Password;
   String Mode;
   sint32 TermTypes;
   sint32 Port;
};
```

Parameters

Name

Data Type: **String** Qualifiers**: Key,MAXLEN(10)** Access Type: Read/Write

The session name.

Service

Data Type: **String** Qualifiers: **MAXLEN(20), TOUPPERCASE** Access Type: Read/Write

The SNA service to which this session belongs.

RemoteLUAlias

Data Type: **String** Qualifiers: **MAXLEN(8)**Access Type: Read/Write

The local LU alias used in the session.

LocalLUAlias

Data Type: **String** Qualifiers: **MAXLEN(8)** Access Type: Read/Write

The local LU alias used in the session.

Comment

Data Type: **String** Qualifiers: **MAXLEN(25)**Access Type: Read/Write

An optional comment field.

User

Data Type: **String** Qualifiers: **MAXLEN(10)**Access Type: Read/Write

The AS/400 user name used in the session.

Password

Data Type: **String** Qualifiers: **MAXLEN(10)**Access Type: Read/Write

The AS/400 password used in the session.

Mode

Data Type: **String** Access Type: Read/Write

The mode used in the session (QPCSUPP).

TermTypes

Data Type: **String** Qualifiers: **QualiferValueHere** Access Type: Read/Write

The terminal types allowed for the session. The following list describes the possible values for **TermType.**

- 5555_C01
- 5555_B01
- 3477_FC
- 3180_2
- 3179_2
- 3196_A1
- 5292_2
- 5291_1
- 5251_11

Port

Data Type: **sint32** Qualifiers: **MINVALUE(0), MAXVALUE(9999)**Access Type: Read/Write

The port used for the session. By default the value is 0.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

Administration and Management Programmer's Guide

MsSna_PrintSession Class

A base class for a print session on a Print service.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_PrintSession : MsSna_Config
{
   String Name;
   String Service;
   String Comment;
   String StatusText;
   sint16 Activation;
   sint16 CodePage;
   sint16 CodePageLanguage;
   String PrinterDeviceName;
   String CodePageCustomFile;
   String PrinterFile;
   boolean PrintToFile;
   String FaceName;
   boolean FaceNameOverride;
   sint32 LeftMargin;
   sint32 RightMargin;
   sint32 TopMargin;
   sint32 BottomMargin;
   boolean MarginOverride;
   boolean UniqueExtension;
   String PDTFile;
   boolean CheckPDTFile;
   String Filter;
   boolean bFilter;
   sint16 FontSize;
   sint16 SessionType;
   sint16 LinesPerInch;
   sint16 CharsPerLine;
   boolean IgnoreTransparentSections;
   boolean NoHorizontalScaling;
   boolean NoVerticalScaling;
   boolean LPIOverride;
   boolean PageSetupOverride;
};
```

Parameters

Name

Data Type: **String** Qualifiers: **Key, MAXLEN(32), TOUPPERCASE**Access Type: Read/Write

The session name, which distinguishes different printers on the network.

Service

Data Type: **String** Qualifiers: **MAXLEN(20)**Access Type: Read/Write

The SNA service to which the print session belongs.

Comment

Data Type: **String** Qualifiers: **MAXLEN(25)**Access Type: Read/Write

An optional comment field.

StatusText

Data Type: **String** Access Type: Read/Write

The status of the print session.

Activation

Data Type: **String** Access Type: Read/Write

The print session activation. The following table describes the possible values for **Activation**.

Value	Description
0	Automatic. Activates the print session automatically when the Host Print service is started
1	Manual. Activates the print session manually.

CodePage

Data Type: **sint16**Access Type: Read/Write

A value that indicates whether a standard language code or a custom code page will be used. The following table describes the possible values for **CodePage**.

Value	Description
0	Language
1	Custom

CodePageLanguage

Data Type: **sint16**Access Type: Read/Write

The code page to be used in the print session. For more information about the possible values for **CodePageLanguage**, see the **Remarks** section.

PrinterDeviceName

Data Type: **String** Qualifiers: **MAXLEN(256)**Access Type: Read/Write

The name of the destination printer.

CodePageCustomFile

Data Type: **String** Qualifiers: **MAXLEN(256)**Access Type: Read/Write

The file name if a custom code page is to be used.

PrinterFile

Data Type: **String** Qualifiers: **MAXLEN(256)**Access Type: Read/Write

The name of the file. Valid only when printing to a file.

PrintToFile

Data Type: **Boolean** Access Type: Read/Write

true to indicate that the print job will be sent to a file; otherwise, **false**. Note that you must still configure a destination printer.

FaceName

Data Type: **String** Qualifiers: **MAXLEN(31)**Access Type: Read/Write

The name of the face.

FaceNameOverride

Data Type: **Boolean** Access Type: Read/Write

true to override the host commands; otherwise, **false**.

LeftMargin

Data Type: **sint32** Qualifiers: **MINVALUE(0), MAXVALUE(255)**Access Type: Read/Write

The left margin, in inches.

RightMargin

Data Type: **sint32** Qualifiers: **MINVALUE(0), MAXVALUE(255)** Access Type: Read/Write

The right margin, in inches.

TopMargin

Data Type: **String** Qualifiers: **MINVALUE(0), MAXVALUE(255)** Access Type: Read/Write

The top margin, in inches.

BottomMargin

Data Type: **sint32** Qualifiers: **MINVALUE(0), MAXVALUE(255)**Access Type: Read/Write

The bottom margin, in inches.

MarginOverride

Data Type: **Boolean** Access Type: Read/Write

true to override the host margin commands; otherwise, **false**.

UniqueExtension

Data Type: **Boolean** Access Type: Read/Write

true to instruct the print service to give each file a unique extension when printing a file.

PDTFile

Data Type: **String** Qualifiers: **MAXLEN(256)**Access Type: Read/Write

A PDT file used to format the print job.

CheckPDTFile

Data Type: **Boolean** Access Type: Read/Write

true to indicate that a PDT file will be used to format the print job; otherwise, **false**.

Filter

Data Type: **String** Qualifiers: **MAXLEN(256)**Access Type: Read/Write

The filter DLL to be used to filter the printer data stream.

bFilter

Data Type: **Boolean** Qualifiers: **QualiferValueHere** Access Type: Read/Write

true to indicate that a filter DLL will be used to filter the printer data stream; otherwise, **false**.

FontSizeOverride

Data Type: **Boolean** Access Type: Read/Write

true to override the host font size commands.

FontSize

Data Type: **sint16** Qualifiers: **MINVALUE(0), MAXVALUE(3276)** Access Type: Read/Write

The font size to be used when printing.

SessionType

Data Type: **sint16** Access Type: Read/Write

A value that indicates whether this is an APPC or 3270 print session. The following table describes the possible values for **SessionType**.

Value	Description
0	APPC

1	3270

LinesPerInch

Data Type: **sint16** Qualifiers: **MINVALUE(1), MAXVALUE(12)** Access Type: Read/Write

The number of lines per inch to be printed.

CharsPerLine

Data Type: **sint16** Access Type: Read/Write

The number of characters per line to be printed.

IgnoreTransparentSections

Data Type: **Boolean** Access Type: Read/Write

true to ignore sections of the print data stream that have been marked as Transparent; otherwise, **false**. This value is valid only when using a PDT file to format the data.

NoHorizontalScaling

Data Type: **Boolean** Access Type: Read/Write

true to turn off off the horizontal scaling feature of the printer driver; otherwise, **false**.

NoVerticalScaling

Data Type: **Boolean** Access Type: Read/Write

true to turn off off the vertical scaling feature of the printer driver; otherwise, **false**.

LPIOverride

Data Type: **Boolean** Access Type: Read/Write

true to enable host commands for lines per inch to be overridden; otherwise, **false**.

PageSetupOverride

Data Type: **String** Access Type: Read/Write

The override for the page setup.

Remarks

The following table describes the possible values for **CodePageLanguage**.

0	Afrikaans[500]
1	Albanian[870]
2	Arabic (Algeria)[420]

WMISNA WMI Provider Classes

Administration and Management Programmer's Guide

MsSna_PrintSession3270 Class

Extends a print session.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_PrintSession3270 : MsSna_PrintSession
{
   sint16 JobTermination;
   sint16 JobTimeoutSecs;
   boolean JobTimeout;
   boolean UseGDI;
   boolean TRNisASCII;
   boolean CustomTRN;
   sint32 CustomTRNChar;
   String LUName;
   boolean MonitorJob;
   boolean LineWrap;
   boolean JobRenderedAtHost;
};
```

Parameters

JobTermination

Data Type: **sint16** Access Type: Read/Write

'EndBracket' means the job completes when the print server receives the End Bracket notification—otherwise, the print server spools the job until the session ends. The following table describes the possible values for **JobTermination**.

Value	Description
0	EndBracket
1	UnBind

JobTimeoutSecs

Data Type: **sint16** Qualifiers: **MINVALUE(0),MAXVALUE(99),UNITS("sec")** Access Type: Read/Write

The timeout for terminating 3270 print jobs—use with 'JobTimeout'.

JobTimeout

Data Type: **Boolean** Access Type: Read/Write

true to indicate whether a time-out will be used; otherwise, **false**. **JobTimeout** is most often used with **JobTimeoutSecs**.

UseGDI

Data Type: **Boolean** Access Type: Read/Write

true to indicate that the Windows Graphical Device Interface (GDI) is used to format the print job; otherwise, **false**.

TRNisASCII

Data Type: **Boolean** Access Type: Read/Write

true to indicate that transparent data from the host is in ASCII and needs no translation from EBCDIC to ASCII; otherwise, **false**.

CustomTRN

Data Type: **Boolean** Access Type: Read/Write

true to indicate that a custom transparency byte, such as one other than the IBM standard of 0x35, will be used; otherwise, **false**.

CustomTRNChar

Data Type: **sint32** Qualifiers: **MINVALUE(0),MAXVALUE(255)**Access Type: Read/Write

The custom transparency byte—use this with 'CustomTRN' set to **true**.

LUName

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE**Access Type: Read/Write

The 3270 printer LU for the print session.

MonitorJob

Data Type: **Boolean** Access Type: Read/Write

true to cause the print server to send a message to the host stating that the print job completed; otherwise, **false**.

LineWrap

Data Type: **Boolean** Access Type: Read/Write

true to line wrap; otherwise, **false**.

JobRenderedAtHost

Data Type: **Boolean** Access Type: Read/Write

true to indicate that the print job is rendered at the host rather than by the Host Integration Server Host Print service; otherwise, **false**.

Remarks

MsSna_PrintSession3270 uses 3270 protocols to communicate with the host.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

WMISNA WMI Provider Classes

Administration and Management Programmer's Guide

MsSna_PrintSessionAppc Class

Extends a print session. Uses APPC LU 6.2 protocols to communicate with the host.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_PrintSessionAppc : MsSna_PrintSession
{
   String LocalLUAlias;
   String RemoteLUAlias;
   String RemoteFQName;
   sint16 Remote;
   String Mode;
   String UserId;
   String Password;
   String AS400Device;
   sint16 System36;
   sint16 HostPrintTransform;
   sint16 DeviceType;
   String FontId;
   String MsgQName;
   String MsgLibName;
   String PrinterName;
   sint16 PaperSrc1;
   sint16 PaperSrc2;
   sint16 CodePage899;
   String SpecialObjName;
   String SpecialLibName;
};
```

Parameters

LocalLUAlias

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE**Access Type: Read/Write

The local LU alias to be used for this print session. Valid only when a **RemoteLUAlias** is provided.

RemoteLUAlias

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE**Access Type: Read/Write

The remote LU alias. Valid only if a fully qualified name is not provided.

RemoteFQName

Data Type: **String** Qualifiers: **MAXLEN(17)**Access Type: Read/Write

The remote LU fully qualified name. Valid only if **RemoteLUAlias** and **LocalLUAlias** are not provided.

Remote

Data Type: **sint16** Access Type: Read/Write

A value that specifies what type of connection to use: either a remote APPC LU alias or a fully qualified name. The following table describes the possible values for **Remote**.

Value	Description
0	Alias
1	Fully qualified name

Mode

Data Type: **String** Qualifiers: **MAXLEN(8), TOUPPERCASE**Access Type: Read/Write

The name of the mode to use. The default mode name is QPCSUPP.

UserId

Data Type: **String** Qualifiers: **MAXLEN(10)**Access Type: Read/Write

The remote user name.

Password

Data Type: **String** Qualifiers: **MAXLEN(10)** Access Type: Read/Write

The remote password.

AS400Device

Data Type: **String** Qualifiers: **MAXLEN(10), TOUPPERCASE** Access Type: Read/Write

The name for the AS/400 printer device. **AS400Device** should be a descriptive name that distinguishes different printers on the network.

System36

Data Type: **sint16** Access Type: Read/Write

A value that indicates whether the remote system is an AS/400 or a System/36. The following table describes the possible values for **System36**.

Value	Description
0	AS400
1	System/36

HostPrintTransform

Data Type: **sint16** Access Type: Read/Write

A value that indicates whether Host Print Transform (HPT) will be used. The following table describes the possible values for **HostPrintTransform**.

Value	Description
0	FALSE
1	TRUE

DeviceType

Data Type: **sint16** Access Type: Read/Write

The print device for Host Print Transform. The following table describes the possible values for **DeviceType**.

Value	Description
0	5224
1	3812

The default value for **DeviceType** is 5224.

FontId

Data Type: **String** Qualifiers: **MAXLEN(10)** Access Type: Read/Write

A font, which should be used instead of the default.

MsgQName

Data Type: **String** Qualifiers: **MAXLEN(10)** Access Type: Read/Write

The qualified name of the message queue to which operational messages for this device are sent.

MsgLibName

Data Type: **String** Qualifiers: **MAXLEN(10)** Access Type: Read/Write

The name of the library in which the message queue is located.

PrinterName

Data Type: **TOUPPERCASE** Access Type: Read/Write

The printer type to be used with Host Print Transform. For more information on the possible values for **PrinterName**, see the **Remarks** section.

PaperSrc1

Data Type: **sint16** Access Type: Read/Write

The type of paper used in paper source 1. The following table describes the possible values for **PaperSrc1**.

Value	Description
0	Default
1	Letter (8.5 x 11 inches)
2	Legal (8.5 x 14 inches)
3	Executive (7.25 x 10.5 inches)
4	A4 (210 x 297 mm)
5	A5 (148 x 210 mm)
6	B5 (182 x 257 mm)
7	Continuous Form (8.0 inches)
8	Continuous Form (13.2 inches)
9	None

PaperSrc2

Data Type: **sint16** Access Type: Read/Write

The type of paper used in paper source 2. The following table describes the possible values for **PaperSrc2**.

Value	Description
0	Default
1	Letter (8.5 x 11 inches)
2	Legal (8.5 x 14 inches)
3	Executive (7.25 x 10.5 inches)
4	A4 (210 x 297 mm)
5	A5 (148 x 210 mm)
6	B5 (182 x 257 mm)

7	Continuous Form (8.0 inches)
8	Continuous Form (13.2 inches)
9	None

CodePage899

Data Type: **sint16** Access Type: Read/Write

A value that indicates whether code page 899 is used. The following table describes the possible values of **CodePage899**.

Value	Description
0	FALSE
1	TRUE

SpecialObjName

Data Type: **String** Qualifiers: **MAXLEN(10)** Access Type: Read/Write

The name of the special object.

SpecialLibName

Data Type: **String** Qualifiers: **MAXLEN(10)** Access Type: Read/Write

The name of the special library.

Remarks

The following table describes the possible values for **PrinterName**.

Value	Description
0	*IBM2380

Administration and Management Programmer's Guide

MsSna_AppcPartner Class

A preconfigured combination of APPC local LU, remote LU, and Mode.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_AppcPartner : MsSna_Config
{
   String Mode;
   String Server;
   String LocalLUAlias;
   String PartnerLUAlias;
   String Connection;
};
```

Properties

Mode

Data Type: **String** Qualifiers: **Key, MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

The mode to be used in the partnership.

Server

Data Type: **String** Qualifiers: **Key, MAXLEN(16), TOUPPERCASE** Access Type: Read/Write

The Host Integration Server name on which this partnership will be added.

LocalLUAlias

Data Type: **String** Qualifiers: **Key, MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

The Local LU alias to be used in the partnership.

PartnerLUAlias

Data Type: **String** Qualifiers: **Key, MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

The partner LU. **PartnerLUAlias** can be a Remote LU or a different Local LU.

Connection

Data Type: **String** Qualifiers: **Key, MAXLEN(8), TOUPPERCASE** Access Type: Read/Write

The connection name for the Remote LU.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

Administration and Management Programmer's Guide

MsSna_AccountAssigned3270 Class

This is used to query for 3270 LUs assigned to a specific workstation or user.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_AccountAssigned3270 : MsSna_Assigned
{
   String Wks;
   String IPAddress;
   String MacAddress;
   String Account;
   String Service;
   String LU;
   boolean IsPool;
   boolean IsAssociatedPrinterLU;
   boolean ModelOverridable;
   sint16 Model;
};
```

Parameters

Wks

Data Type: **String** Qualifiers**: MAXLEN(20)**Access Type: Read/Write

The workstation name. By default, returns LUs assigned to all workstations.

IPAddress

Data Type: **String** Qualifiers: **MAXLEN(20)**Access Type: Read/Write

The workstation IP. By default, returns LUs assigned to all workstations.

MacAddress

Data Type: **String** Qualifiers: **MAXLEN(20)**Access Type: Read/Write

A value that returns LUs configured to a specific media access control (MAC) address.

Account

Data Type: **String** Access Type: Read/Write

The user for which to query for LUs. By default, will return LUs assigned to all users.

Service

Data Type: **String** Access Type: Read/Write

The SNA service on which to query for LUs.

LU

Data Type: **String** Qualifiers: Key, MAXLEN(8) Access Type: Read/Write

A value that indicates whether the returned LU is part of an LU pool.

IsPool

Data Type: **Boolean** Access Type: Read/Write

true to indicate that the returned LU is part of an LU pool; otherwise, **false**.

IsAssociatedPrinterLU

Data Type: **Boolean** Access Type: Read/Write

true to indicate that the returned LU has an Associated Printer LU; otherwise, **false**.

ModelOverridable

Data Type: **Boolean** Access Type: Read/Write

true to indicate that the returned LU has an display model which can be overridden; otherwise, **false**.

Model

Data Type: **sint16** Access Type: Read/Write

The default display model of the returned LU. The following table describes the possible values for **Model**.

Value	Description
0	Model12
1	Model13
2	Model14
3	Model15

Remarks

MsSna_AccountAssigned3270 is used in querying for LUA LUs assigned to a workstation as well as to the specified user.

On specifying "" for **Workstation**, only the LUs for the user will be returned.

On specifying "*" for **User**, the LUs for the logged in user will be returned.

If User is omitted, LUs assigned to all Users will be returned.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_AccountAssignedLua Class

Used to query for LUA LUs assigned to a specific workstation or user.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_AccountAssignedLua : MsSna_Assigned
{
   String Wks;
   String IPAddress;
   String MacAddress;
   String Account;
   String Service;
   String LU;
   boolean IsPool;
   boolean ModelOverridable;
};
```

Properties

Wks

Data Type: **String** Qualifiers: **MAXLEN(20)** Access Type: Read/Write

The workstation name. By default, LUs assigned to all workstations are returned.

IPAddress

Data Type: **String** Qualifiers: **MAXLEN(20)** Access Type: Read/Write

The workstation IP. By default, LUs assigned to all workstations are returned.

MacAddress

Data Type: **String** Access Type: Read/Write

The user for which to query for LUs. By default, returns LUs assigned to all users.

Account

Data Type: **String** Qualifiers: **Key** Access Type: Read/Write

The name of the service.

Service

Data Type: **String** Qualifiers: **Key** Access Type: Read/Write

The SNA service on which to query for LUs.

LU

Data Type: **String** Qualifiers: **Key, MAXLEN(8)** Access Type: Read/Write

The name of the LU.

IsPool

Data Type: **Boolean** Access Type: Read/Write

true to indicate that the returned LU is part of an LU pool; otherwise, **false**.

ModelOverridable

Data Type: **Boolean** Access Type: Read/Write

true if the LU has a display model which can be overridden.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_AccountAssigned3270Services Class

Used to query for services on which a specific workstation or user has 3270 LUs/pools.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_AccountAssigned3270Services : MsSna_Assigned
{
   String Wks;
   String IPAddress;
   String MacAddress;
   String Account;
   String Service;
};
```

Properties

Wks

Data Type: **String** Qualifiers: **MAXLEN(20)** Access Type: Read/Write

The workstation name. By default, those assigned to all workstations are returned.

IPAddress

Data Type: **String** Qualifiers: **MAXLEN(20)** Access Type: Read-Only

The workstation IP address. By default, those assigned to all workstations are returned.

MacAddress

Data Type: **String** Qualifiers: **MAXLEN(20)** Access Type: Read/Write

Returns services with LUs configured to a specific media access control (MAC) address.

Account

Data Type: **String** Access Type: Read/Write

The user to which the LUs are assigned. By default, returns services with LUs assigned to all users.

Service

Data Type: **String** Qualifiers: **Key** Access Type: Read/Write

The name of the service.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_AccountAssignedLuaServices Class

Used to query for services on which a specific workstation or user has LUA LUs/pools.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_AccountAssignedLuaServices : MsSna_Assigned
{
   String Wks;
   String IPAddress;
   String MacAddress;
   String Account;
   String Service;
};
```

Properties

Wks

Data Type: **String** Qualifiers: **MAXLEN(20)** Access Type: Read/Write

The workstation name. By default, those assigned to all workstations are returned.

IPAddress

Data Type: **String** Qualifiers: **MAXLEN(20)** Access Type: Read/Write

The workstation IP address. By default, those assigned to all workstations are returned.

MacAddress

Data Type: **String** Qualifiers: **MAXLEN(20)** Access Type: Read/Write

Returns services with LUs configured to a specific media access control (MAC) address.

Account

Data Type: **String** Access Type: Read/Write

The user to which the LUs are assigned. By default, returns services with LUs assigned to all users.

Service

Data Type: **String** Qualifiers: **Key** Access Type: Read/Write

Returns the name of the service.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsSna_AccountAvailableAppcLu Class

For the logged-on user account and workstation, the assigned APPC LU resources.

The following syntax is simplified from MOF code.

Syntax

```
class MsSna_AccountAvailableAppcLu : MsSna_Assigned
{
   String LocalLu;
   String RemoteLu;
   String Wks;
   String IPAddress;
   String MacAddress;
};
```

Properties

LocalLu

Data Type: **String** Qualifiers: **MAXLEN(8)** Access Type: Read/Write

The local LU name.

RemoteLu

Data Type: **String** Qualifiers: **MAXLEN(8)** Access Type: Read/Write

The remote LU name.

Wks

Data Type: **String** Qualifiers: **MAXLEN(20** Access Type: Read/Write

The workstation name.

IPAddress

Data Type: **String** Qualifiers: **MAXLEN(20)** Access Type: Read/Write

The workstation IP address.

MacAddress

Data Type: **String** Qualifiers: **MAXLEN(20)** Access Type: Read/Write

The MAC address.

Remarks

MsSna_AccountAvailableAppcLu is used in querying for the remote APPC LUs for a given local APPC LU on a given workstation and associated with the logged-on user.

Requirements

class MsSna_LuDisplayAssignedToWorkstation : MsSna_Lu3270AssignedToWorkstation
{
   MsSna_LuDisplay ref PathToLuDisplay;
   MsSna_Workstation ref PathToWorkstation;
};
```

Properties

MsSna_LuDisplay

Data Type: **ref PathToLuDisplay** Qualifiers: **Key** Access Type: Read-Only

The display LU to associate with.

MsSna_Workstation

Data Type: **ref PathToWorkstation** Qualifiers: **Key** Access Type: Read-Only

The user to associate with.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

{
};
```

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MQBridge WMI Programmer's Reference

The MQBridge WMI Programmer's Reference describes the WMI provider classes that you can use to monitor the MSMQ-MQSeries Bridge.

For general information about programming for messaging, see theMessaging Programmer's Guide section of the SDK.

For sample programs illustratating MSMQ-MQSeries Bridge, see the Messaging Samples section of the SDK.

This section contains:

- WMIMQBridge WMI Provider Classes

WMIMQBridge WMI Provider Classes

The Microsoft® Host Integration Server MSMQ-MQSeries Bridge provider supplies information regarding the MSMQ-MQSeries Bridge. As an instance and method provider, the WMIMQBridge provider implements the standard **IWbemProviderInit** interface and the following **IWbemServices** methods:

- **CreateInstanceEnumAsync**
- **DeleteInstanceAsync**
- **ExecMethodAsync**
- **GetObjectAsync**
- **PutInstanceAsync**

For more information on **IWbemProviderInit** and **IWbemServices**, see "COM API for WMI" in the MSDN Library at http://msdn.microsoft.com/library.

You can access these provider classes in the \root\MicrosoftHIS namespace.

Class	Description
MsHisBridge_ExtendedStatus	Returns error information.
MsHisBridge_Service	Describes the MQSeries Bridge service.
MsHisBridge_Channel	Describes an MQI channel.
MsHisBridge_Channel_In_Service	Associates the channel and the service.
MsHisBridge_MessagePipe	Describes an MSMQ-MQSeries message pipe.
MsHisBridge_ConnectedNetwork	Describes a connected network.
MsHisBridge_ConnectedNetwork_In_Service	Associates the connected network to a specified service.

Requirements

Platforms: Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsHisBridge_ExtendedStatus Class

Returns error information.

The following syntax is simplified from MOF code.

Syntax

```
class MsHisBridge_ExtendedStatus : __ExtendedStatus
{
};
```

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsHisBridge_Service Class

Describes the MQSeries Bridge service.

The following syntax is simplified from MOF code.

Syntax

```
class MsHisMQBridge_Service : MsHisMQBridge_Config
{
   string Name;
   uint32 F2QR_MaxThreads;
   uint32 F2QT_MaxThreads;
   uint32 Q2FD_MaxThreads;
   uint32 Q2FO_MaxThreads;
   uint32 CacheReresh;
   Boolean Encryption;
};
```

Properties

Name

Data Type: **String**

Qualifiers: **key**Access Type: Read/Write

The name of the computer.

F2QR_MaxThreads

Data Type: **uint32**

Access Type: Read/Write

The maximum number of threads for the MSMQ-to-MQSeries High service message pipe.

F2QT_MaxThreads

Data Type: **uint32**

Access Type: Read/Write

The maximum number of threads for the MSMQ-to-MQSeries Normal service message pipe.

Q2FD_MaxThreads

Data Type: **uint32**

Access Type: Read/Write

The maximum number of threads for the MQSeries-to-MSMQ High service message pipe.

Q2FO_MaxThreads

Data Type: **uint32**

Access Type: Read/Write

The maximum number of threads for the MQSeries-to-MSMQ Normal service message pipe.

CacheReresh

Data Type: **uint32**

Access Type: Read/Write

The interval (in minutes) at which the message pipes check for Cache Time-out.

Encryption

Data Type: **Boolean**

Access Type: Read/Write

Enables the Encryption feature from MSMQ to MSMQ-MQSeries Bridge.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

Administration and Management Programmer's Guide

MsHisBridge_Channel Class

Describes an MQI channel.

The following syntax is simplified from MOF code.

Syntax

```
class MsHisMQBridge_Channel : MsHisMQBridge_Config
{
   string Name;
   string QueueManagerName;
   uint32 TransportType;
   string TCPAddress;
   string TCPPort;
   string LU62SideInfoRecord;
   string McaUser;
};
```

Properties

Name

Data Type: **String**

Qualifiers: **key**Access Type: Read/Write

The name of the computer.

QueueManagerName

Data Type: **String**Access Type: Read/Write

The MQSeries Queue Manager to which the channel connects.

TransportType

Data Type: **uint32**Access Type: Read-Only

Specifies whether TCP/IP or SNA LU 6.2 communication will be used. The following table describes the possible values for **TransportType**.

Value	Description
1	LU 6.2
2	TCP/IP

TCPAddress

Data Type: **String**Access Type: Read/Write

The TCP/IP Address of the MQSeries listener (used with TCP/IP transport).

TCPPort

Data Type: **String**Access Type: Read/Write

The TCP/IP Port of the MQSeries listener (used with TCP/IP transport).

LU62SideInfoRecord

Data Type: **String**Access Type: Read/Write

The CPI-C Symbolic Name defined in Host Integration Server 2009 (used with SNA LU 6.2 transport).

McaUser

Data Type: **String**Access Type: Read/Write

An existing or new MQSeries user name, such as *FMQUSER1*, under which the server side of the MQI channel runs.

Requirements

Platforms: Microsoft Windows Server 2003, Windows XP Professional, Windows 2000 Server

MsHisBridge_Channel_In_Service Class

Associates the channel and the service.

Syntax

```
class MsHisMQBridge_Channel_In_Service : MsHisMQBridge_Association
{
   MsHisMQBridge_Channel ref PathToChannel;
   MsHisMQBridge_Service ref PathToService;
};
```

Properties

PathToChannel

Data Type: **MsHisMQBridge_Channel ref**Qualifiers: **key**Access Type: Read-Only

The path to the channel.

PathToService

Data Type: **MsHisMQBridge_Service ref**Qualifiers: **key**Access Type: Read-Only

The path to the service.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

Reference

WMIMQBridge WMI Provider Classes

MsHisBridge_MessagePipe Class

Describes an MSMQ-MQSeries message pipe.

The following syntax is simplified from MOF code.

Syntax

```
class MsHisMQBridge_MessagePipe
{
   string TransmitQueue;
   uint32 Startup;
   uint32 MaxMessageCount;
   uint32 MaxMessageSize;
   uint32 MaxTime;
   uint32 CacheReresh;
   uint32 ShortRetryCount;
   uint32 ShortRetryDelay;
   uint32 LongRetryCount;
   uint32 LongRetryDelay;
};
```

Properties

TransmitQueue

Data Type: **String**Access Type: Read/Write

A unique MQSeries transmission queue name for the pipe. The default names are *<CN name>.XMITQ* for the transactional message pipe, and *<CN name>.XMITQ.HIGH* for the nontransactional message pipe.

Startup

Data Type: **uint32**Access Type: Read/Write

Enabled or disabled at MSMQ-MQSeries Bridge Startup.

MaxMessageCount

Data Type: **uint32**Access Type: Read/Write

The maximum number of messages in a batch.

MaxMessageSize

Data Type: **uint32**Access Type: Read/Write

The maximum size (in bytes) of a batch.

MaxTime

Data Type: **uint32**Access Type: Read/Write

The interval (in minutes) at which the message pipes check for Cache Time-out.

CacheReresh

Data Type: **uint32**Access Type: Read/Write

The maximum time (in milliseconds) during which messages are batched.

ShortRetryCount

Data Type: **uint32**Access Type: Read/Write

The maximum number of retries for the short retry cycle.

ShortRetryDelay

Data Type: **uint32**Access Type: Read/Write

The interval between retries for the short retry cycle.

LongRetryCount

Data Type: **uint32**Access Type: Read/Write

The maximum number of retries for the long retry cycle.

LongRetryDelay

Data Type: **uint32**Access Type: Read/Write

The interval between retries for the long retry cycle.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

Administration and Management Programmer's Guide

MsHisBridge_ConnectedNetwork Class

Describes a connected network.

The following syntax is simplified from MOF code.

Syntax

```
class MsHisMQBridge_ConnectedNetwork : MsHisMQBridge_Config
{
   string Name;
   string MQSeriesQMNGR;
   string ReplyToQMNGR;
   uint32 Startup;
   MsHisMQBridge_MessagePipe MSMQ2MQSeries_MessagePipe;
   MsHisMQBridge_MessagePipe MSMQ2MQSeriesTx_MessagePipe;
   MsHisMQBridge_MessagePipe MQSeries2MSMQ_MessagePipe;
   MsHisMQBridge_MessagePipe MQSeries2MSMQTx_MessagePipe;
};
```

Properties

Name

Data Type: **String**

Qualifiers: **key**Access Type: Read/Write

The name of the computer.

MQSeriesQMNGR

Data Type: **String**Access Type: Read/Write

The MQSeries Queue Manager to which this CN is connected.

ReplyToQMNGR

Data Type: **String**Access Type: Read/Write

The default MSMQ QM to which MQSeries should return report or acknowledgment messages. Ordinarily, **ReplyToQMNGR** contains the name of the MSMQ-MQSeries Bridge computer.

Startup

Data Type: **uint32**Access Type: Read/Write

Enabled or disabled at MSMQ-MQSeries Bridge Startup.

MSMQ2MQSeries_MessagePipe

Data Type: **MsHisMQBridge_MessagePipe**Access Type: Read/Write

The MSMQ to MQ Series High service (nontransacted) message pipe.

MSMQ2MQSeriesTx_MessagePipe

Data Type: **MsHisMQBridge_MessagePipe**Access Type: Read/Write

The MSMQ to MQ Series Normal service (transacted) message pipe.

MQSeries2MSMQ_MessagePipe

Data Type: **MsHisMQBridge_MessagePipe**Access Type: Read/Write

The MQ Series to MSMQ High service (nontransacted) message pipe.

MQSeries2MSMQTx_MessagePipe

Data Type: **MsHisMQBridge_MessagePipe**Access Type: Read/Write

The MQ Series to MSMQ Normal service (transacted) message pipe.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

MsHisBridge_ConnectedNetwork_In_Service Class

Associates the connected network to a specified service.

The following syntax is simplified from MOF code.

Syntax

```
class MsHisMQBridge_ConnectedNetwork_In_Service : MsHisMQBridge_Association
{
   MsHisMQBridge_ConnectedNetwork ref PathToConnectedNetwork;
   MsHisMQBridge_Service ref PathToService;
};
```

Properties

PathToConnectedNetwork

Data Type: **MsHisMQBridge_ConnectedNetwork ref**

Qualifiers: **key**Access Type: Read-Only

The path to the connected network.

PathToService

Data Type: **MsHisMQBridge_Service ref**

Qualifiers: **key**Access Type: Read-Only

The path to the service.

Requirements

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

Administration and Management Programmer's Guide

Messaging Programmer's Reference

This section of the Microsoft Host Integration Server 2009 Developer's Guide lists the extensions and components that make up the MSMQ-MQSeries Bridge.

For general information about programming for the MSMQ-MQSeries Bridge, see the Messaging Programmer's Guide section of the SDK.

For sample code using the MSMQ-MQSeries Bridge, see the Messaging Programmer's Guide section of the SDK.

In This Section

- MSMQ-MQSeries Bridge Extensions Reference
- SDComponents for MSMQ-MQSeries Bridge Extensions

MSMQ-MQSeries Bridge Extensions Reference

This section provides an alphabetic reference to all of the API calls for the Microsoft® MSMQ-MQSeries Bridge Extension Property API.

In This Section

EPAdd

The **EPAdd** function adds a new extension field at the end of an existing **EP** object and optionally returns a cursor pointing to the new extension field in the **EP** object.

Syntax

```
HRESULT EPAdd(
        HANDLE hExtension,
    PCGUID pFieldID
        void *pFieldData,
        DWORD dwDataLength,
        PHANDLE phCursor
    );
```

Parameters

hExtension

Supplied parameter. The **EP** object handle to the **EP** object that is to have data added.

pFieldID

Supplied parameter. A pointer to the GUID of the new extension field. A GUID is 16 bytes in length.

pFieldData

Supplied parameter. A pointer to the buffer containing the data for the new extension field.

dwDataLength

Supplied parameter. The length of the buffer containing the data for the new extension field.

phCursor

Supplied and returned parameter. A pointer to a cursor, which points to the new extension field. If *phCursor* is NULL when this function is called; the cursor is not created.

Return Codes

MQ_OK

The function executed successfully.

MQ_ERROR_ALLOC_FAIL

The function failed because memory could not be allocated for the internal data buffers used to extend the **EP** object.

MQ_ERROR_INVALID_HANDLE

The function failed because the **EP** object handle passed to the function is invalid.

MQ_ERROR_INVALID_PARAMETER

The function failed because one or more of the parameters passed to this function are invalid.

Remarks

In an **EP** object possessing a cursor, the extension fields are sorted in ascending order based on the GUID of each extension field. The message extension API functions may run more slowly while the cursor is in effect.

All cursors are canceled if the **EPDeleteAll** function is called with a *pFieldID* of NULL.

The following example illustrates how to use this function.

```
HANDLE hExt;
HANDLE hCursor;
GUID guid;
...
/* Add a new field containing the data "test" */
EPAdd(hExt, &guid, "test", 5, NULL);
```

```
/* Add a new field and create a cursor */
EPAdd(hExt, &guid, "another test", 13, &hCursor);
```

See Also

Reference

EPDelete

EPDeleteAll

EPClose

The **EPClose** function closes an open **EP** object freeing the extension handle and associated memory of an **EP** object. The entire contents of the object are deleted.

Syntax

```
HRESULT EPClose(
    PHANDLE phExtension
    );
```

Parameters

phExtension

Supplied and returned parameter. A pointer to an existing **EP** object handle to close.

Return Codes

MQ_OK

The function executed successfully.

MQ_ERROR_INVALID_HANDLE

The function failed because the **EP** object handle passed to the function is invalid.

MQ_ERROR_INVALID_PARAMETER

The function failed because the parameter passed to this function is invalid.

Remarks

If the **EP** object handle is successfully closed, *phExtension* is reset to NULL on output.

See Also

Reference

EPOpen

EPDelete

The **EPDelete** function deletes a single extension field from an existing **EP** object.

Syntax

```
HRESULT EPDelete(
    HANDLE hExtension,
        PHANDLE phCursor
    );
```

Parameters

hExtension

Supplied parameter. The **EP** object handle to the **EP** object that is to have extension field deleted.

phCursor

Supplied and returned parameter. On input, *phCursor* is a cursor pointing to the extension field to be deleted. On output, *phCursor* is set to the next extension field in the extension, or to NULL if there are no more fields.

Return Codes

MQ_OK

The function executed successfully.

MQ_ERROR_INVALID_HANDLE

The function failed because the **EP** object handle passed to the function is invalid.

MQ_ERROR_INVALID_PARAMETER

The function failed because one or more of the parameters passed to this function are invalid.

Remarks

After successful deletion, the cursor is set to point to the next field after the deleted one. If the last field is deleted, the cursor is set to NULL (to the beginning).

In an **EP** object possessing a cursor, the extension fields are sorted in ascending order based on the GUID of each extension field. The message extension API functions may run more slowly while the cursor is in effect.

All cursors are canceled if the **EPDeleteAll** function is called with a *pFieldID* of NULL.

See Also

Reference

EPDeleteAll

EPDeleteAll

The **EPDeleteAll** function deletes all extension fields from an existing **EP** object or all extension fields matching a specific GUID.

Syntax

```
HRESULT EPDeleteAll(
    HANDLEhExtension,
        PCGUIDpFieldsId,
        PHANDLEphCursor
    );
```

Parameters

hExtension

Supplied parameter. The **EP** object handle to the **EP** object that is to have extension field deleted.

pFieldsId

Supplied parameter. A pointer to a 16-byte buffer containing the GUID of the fields to delete. If this parameter is NULL, all extension fields are deleted.

phCursor

Supplied and returned parameter. On output, this field is a pointer to an extension field cursor. The cursor is positioned at the first field of the next higher GUID after the one that was deleted. If there are no more GUIDs, or if all fields were deleted, *phCursor* is set to NULL. The *phCursor* may be NULL on input if no cursor is desired.

Return Codes

MQ_OK

The function executed successfully.

MQ_ERROR_EXTENSION_FIELD_NOT_FOUND

The function failed because the extension field matching the specified GUID could not be found.

MQ_ERROR_INVALID_HANDLE

The function failed because the **EP** object handle passed to the function is invalid.

MQ_ERROR_INVALID_PARAMETER

The function failed because one or more of the parameters passed to this function are invalid.

Remarks

If the *phCursor* parameter is not NULL, **phCursor* will point to the next field after all the deleted ones (even if MQ_ERROR_EXTENSION_FIELD_NOT_FOUND is returned). If the last field is deleted, the cursor is set to NULL.

In an **EP** object possessing a cursor, the extension fields are sorted in ascending order based on the GUID of each extension field. The message extension API functions may run more slowly while the cursor is in effect.

All cursors are canceled if the **EPDeleteAll** function is called with a *pFieldID* of NULL.

The following example illustrates how to use this function.

```
HANDLE hExt;
GUID guid;
HANDLE hCursor;
...
/* Delete all fields having a specified GUID and set a cursor */
EPDeleteAll(hExt, &guid, &hCursor);

/* Delete all extension fields */
EPDeleteAll(hExt, NULL, NULL);
```

See Also

Reference

EPDelete

EPGet

The **EPGet** function reads a specified extension field from an **EP** object, storing the GUID, length, and data subfields in separate variables. **EPGet** can also be used to locate extension fields containing a specified GUID

Syntax

```
HRESULT EPGet(
        HANDLE hExtension,
        NAVTYPE Directive,
        PHANDLE phCursor,
        GUID *pFieldID,
        void *pFieldData,
        PDWORD pdwDataLength,
    );
```

Parameters

hExtension

Supplied parameter. The **EP** object handle.

Directive

Supplied parameter. This parameter and *phCursor* together control the behavior of the function. Possible values and their usage are discussed in the table following this parameter list.

phCursor

Supplied and returned parameter. A pointer to a cursor, which points to the matching extension field. If *phCursor* is NULL, the first field having a GUID matching *pFieldID* is read, and the cursor is positioned to this field. See the *Directive* argument in this list for specific details.

pFieldID

Supplied and returned parameter. If the *Directive* argument is EP_NEXT_KEY_FIELD, *pFieldId* is a pointer to a 16-byte buffer containing the GUID to be read. If the *Directive* argument is EP_CURRENT_FIELD or EP_NEXT_FIELD, on output this parameter is a pointer to a 16-byte buffer where the function stores the GUID. The GUID can be NULL if the GUID output is not desired.

pFieldData

Supplied and returned parameter. On input, a pointer to a buffer where the function should store the extension field data. On input, this parameter can be NULL if the data output is not desired. On output, a pointer to a buffer where the function stores the extension field data.

pdwDataLength

Supplied and returned parameter. On input, the length of the buffer for the data from the extension field. On output, the actual length of the data. If the buffer is too short or NULL, the data is not read but *pdwDataLength* is reset to the required buffer length.

Values for the Directive parameter

Directive	Description
EP_CURRENT_FIELD	Retrieves the extension field pointed to by the *phCursor* parameter, which must be a valid non-NULL cursor handle.

EP_NEXT_FIELD	Advances the cursor and reads the next field. If there are no more fields, returns MQ_ERROR_EXTENSION_FIELD_NOT_FOUND and *phCursor* is set to NULL. If *phCursor* is NULL or **phCursor* is NULL, the cursor is positioned to the first field (sorted in ascending order of GUID) and this field is read. If *phCursor* is not NULL, **phCursor* is set to the extension field. If *phCursor* is not NULL and **phCursor* is not NULL, the cursor (*phCursor*) is positioned to the first field (sorted in ascending order of GUID) and this field's ID and data are read and returned.
EP_NEXT_KEY_FIELD	Advances the cursor and reads the next field having a GUID matching *pFieldID*. If there are no more matching fields, returns MQ_ERROR_EXTENSION_FIELD_NOT_FOUND and sets phCursor to the first field having the next higher GUID, or to NULL if there are no more fields. If *phCursor* is NULL or **phCursor* is NULL, then the first field having a GUID matching *pFieldID* is read, and the cursor is positioned to this field. If the field is found, its field ID and data are returned and if *phCursor* is not NULL, **phCursor* is set to the field.

Return Codes

MQ_OK

The function executed successfully.

MQ_ERROR_ALLOC_FAIL

The function failed because memory could not be allocated for the internal data buffers used for the **EP** object.

MQ_ERROR_EXTENSION_FIELD_NOT_FOUND

The function failed because the extension field matching the specified GUID could not be found.

MQ_ERROR_INVALID_HANDLE

The function failed because the **EP** object handle passed to the function is invalid.

MQ_ERROR_INVALID_PARAMETER

The function failed because one or more of the parameters passed to this function are invalid.

MQ_ERROR_USER_BUFFER_TOO_SMALL

The function failed because the length of the buffer passed was too small for the data.

Remarks

In an **EP** object possessing a cursor, the extension fields are sorted in ascending order based on the GUID of each extension field. The message extension API functions may run more slowly while the cursor is in effect.

All cursors are canceled if the **EPDeleteAll** function is called with a *pFieldID* of NULL.

The following example illustrates how to use this function.

```
HANDLE hExt;
HANDLE hCursor;
GUID guid;
void *pBuffer;
DWORD dwSize, dwCount;
DWORD dwTotalSize = 0;
...

/* Retrieve one field by GUID */
dwSize = 1024;
EPGet(hExt, EP_NEXT_KEY_FIELD, NULL, &guid, pBuffer, &dwSize);

/* Count the fields in a message extension */
for (hCursor = NULL, dwCount = 0;
     EPGet(hExt, EP_NEXT_FIELD, &hCursor, NULL, NULL, NULL)==MQ_OK;
     dwCount++);

/* Compute the total length of all extension fields
   having a given GUID */
```

```
for (hCursor = NULL, dwCount = 0;
          EPGet(hExt, EP_NEXT_KEY_FIELD, &hCursor, &guid, NULL,
              &dwSize) == MQ_OK;
      dwTotalSize += dwSize);
```

Reference

EPDelete

EPDeleteAll

EPGetBuffer

The **EPGetBuffer** function converts an **EP** object to a message extension (PROPID_M_EXTENSION format) that can be sent in a message and packs the message extension into the supplied buffer.

Syntax

```
HRESULT EPGetBuffer(
    HANDLE hExtension,
        void *pBuf,
        PDWORD pdwBufLength,
    );
```

Parameters

hExtension

Supplied parameter. The **EP** object handle.

pBuf

Supplied parameter. A pointer to the buffer where this function will store the PROPID_M_EXTENSION message extension.

pdwBufLength

Supplied and returned parameter. On input, the length of the buffer for the message extension. On output, the actual length of the stored data. If the buffer is too short or NULL, the data is not converted but *pdwBufLength* is reset to the required buffer length.

Return Codes

MQ_OK

The function executed successfully.

MQ_ERROR_INVALID_HANDLE

The function failed because the **EP** object handle passed to the function is invalid.

MQ_ERROR_INVALID_PARAMETER

The function failed because one or more of the parameters passed to this function are invalid.

MQ_ERROR_USER_BUFFER_TOO_SMALL

The function failed because the length of the buffer passed was too small for the data.

Remarks

If this function executed successfully, the *pdwBufLength* parameter contains the actual length of the packed extension buffer. If MQ_ERROR_USER_BUFFER_TOO_SMALL is returned, *pdwBufLength* contains the required buffer length.

The following example illustrates how to use this function.

```
HANDLE hExt;
void *pBuffer;
DWORD dwSize;

/* Read the required buffer length */
dwSize = 0;
EPGetBuffer(hExt, NULL, &dwSize);

/* Allocate the buffer */
pBuffer = malloc(dwSize);

/* Write the message extension to the buffer */
EPGetBuffer(hExt, pBuffer, &dwSize);
```

Reference

EPAdd
EPOpen

EPOpen

The **EPOpen** function creates an **EP** object and optionally unpacks the supplied message extension buffer into it.

Syntax

```
HRESULT EPOpen(
    PHANDLE phExtension,
        Void *pExtBuffer,
        DWORD dwExtBufLength
        );
```

Parameters

phExtension

Returned parameter. A pointer to an **EP** object handle of the **EP** object that is created.

pExtBuffer

Supplied parameter. The pointer to a buffer containing the message extension data in the sequence GUID (16 bytes), length of data (4 bytes), data, GUID, length of data, data, etc.

dwExtBufLength

Supplied parameter. The length of the buffer containing the message extension data.

Return Codes

MQ_OK

The function executed successfully.

MQ_ERROR_ALLOC_FAIL

The function failed because memory could not be allocated for the **EP** object handle and internal data buffers.

MQ_ERROR_CORRUPTED_EXTENSION_BUFFER

The function failed because the buffer containing the message extension data was corrupted.

MQ_ERROR_INVALID_PARAMETER

The function failed because one or more of the parameters passed to this function are invalid.

Remarks

If a NULL pointer is passed for *pExtBuffer* or *dwExtBufLength* is zero, an **EP** object with no extension fields is created.

The following example illustrates how to use this function.

```
HANDLE hExt1, hExt2;
void *pBuffer;
DWORD dwBufLength;
...
/* Create an empty EP object */
EPOpen(&hExt1, NULL, 0);
/* Create an EP object, copying data from a message extension */
EPOpen(&hExt2, pBuffer, dwBufLength);
```

See Also

Reference

EPClose

EPUpdate

The **EPUpdate** function updates (replaces) the data and length subfields of an existing extension field in an **EP** object.

Syntax

```
HRESULT EPUpdate(
    HANDLE hExtension,
        HANDLE hCursor
        void *pFieldData,
        DWORD dwDataLength,
    );
```

Parameters

hExtension

Supplied parameter. The **EP** object handle to the **EP** object that is to have data updated.

hCursor

Supplied parameter. The cursor pointing to the extension field to be updated which must not be NULL.

pFieldData

Supplied parameter. A pointer to the buffer containing the new data for the extension field. This parameter may be NULL for an empty data subfield.

dwDataLength

Supplied parameter. The length of the buffer containing the new data for the extension field.

Return Codes

MQ_OK

The function executed successfully.

MQ_ERROR_ALLOC_FAIL

The function failed because memory could not be allocated for the internal data buffers used to update the **EP** object.

MQ_ERROR_INVALID_HANDLE

The function failed because the **EP** object handle passed to the function is invalid.

MQ_ERROR_INVALID_PARAMETER

The function failed because one or more of the parameters passed to this function are invalid.

Remarks

The following example illustrates how to use this function.

```
HANDLE hExt;
HANDLE hCursor;
GUID guid;
...
/* Find an extension field containing a specified GUID */
EPGet (hExt, EP_NEXT_KEY_FIELD, &hCursor, &guid, NULL, 0)
/* Change the length and data subfields of the extension field */
EPUpdate(hExt, hCursor, "newdata", 8);
```

SDComponents for MSMQ-MQSeries Bridge Extensions

The Host Integration Server 2009 SDK contains software components used for application integration using messaging and the MSMQ-MQSeries Bridge.

In This Section

Program and DLL Files for MSMQ-MQSeries Bridge

The following table lists the executable system files, DLL library files, and other files that are included with the Host Integration Server 2009 SDK for use with the MSMQ-MQSeries Bridge.

File name	Description
BCluster.exe	A program used to create or remove the MSMQ-MQSeries Bridge Service resource in a cluster.
explres.dll	The resource file for Q2QEXPL.exe, the MSMQ-MQSeries Bridge explorer program.
MQBInst.dll	The COM component used to create, delete, or modify MSMQ-MQSeries Bridge objects in Active Directory® directory service.
mqfrgnky.dll	A library to provide a function for the MSMQ-MQSeries Bridge to store a public key in a foreign computer object (for example, MQFrgn_StorePubKeysInDS).
MQSRRecv.exe	A sample program that uses the MQSeries API to receive messages from a specified MQSeries queue. This program can be used to test the operation of the MSMQ-MQSeries Bridge.
MQSRSend.exe	A sample program that uses the MQSeries API to send ten test messages to a specified MQSeries queue. This program can be used to test the operation of the MSMQ-MQSeries Bridge.
MSMQRecv.exe	A sample program that uses the Message Queuing (also known as MSMQ) API to receive messages from a specified Message Queuing queue. This program can be used to test the operation of the MSMQ-MQSeries Bridge.
MSMQSend.exe	A sample program that uses the Message Queuing API to sends 10 test messages to a specified Message Queuing local or foreign queue. This program can be used to test the operation of the MSMQ-MQSeries Bridge.
Q2QCLDLL.dll	A helper DLL (now obsolete) that contains functions to work with a cluster.
Q2QEXPL.exe	The MSMQ-MQSeries Bridge explorer program.
Q2QGW.exe	The MSMQ-MQSeries Bridge service program.
q2qmsg.dll	The Event Log message file.
q2qperf.ini	The performance counter definition file for the MSMQ-MQSeries Bridge.
q2qprfdl.dll	The performance counter implementation DLL for the MSMQ-MQSeries Bridge extension.
q2qprfsm.def	Defines the performance counter object in q2qperf.ini.
Q2QSHDLL.dll	A helper DLL (now obsolete) that contains functions for installing and uninstalling the MSMQ-MQSeries Bridge.
SHDLLRes.dll	The resource DLL (now obsolete) for Q2QSHDLL.DLL for installing and uninstalling the MSMQ-MQSeries Bridge.
wmiMQBridge.dll	The MSMQ-MQSeries Bridge Windows Management Instrumentation (WMI) Provider.

wmimqbridge.mof	The WMI Managed Object File (MOF) for the MSMQ-MQSeries Bridge.

Symbol Files for MSMQ-MQSeries Bridge

The following symbol files for use when debugging are included with Host Integration Server 2009 for use with the MSMQ-MQSeries Bridge. These files are installed as part of the Host Integration Server package and copies of these files are also located on the Host Integration Server CD under the Support\Symbols folder.

File name	Description
EXE\BCluster.dbg	Symbols from BCluster.exe
DLL\explres.dbg	Symbols from Explres.dll
DLL\MQBInst.dbg	Symbols from MQBInst.dll
EXE\MQSRRecv.dbg	Symbols from MQSRRecv.exe
EXE\MQSRSend.dbg	Symbols from MQSRSend.exe
EXE\MSMQRecv.dbg	Symbols from MSMQRecv.exe
EXE\MSMQSend.dbg	Symbols from MSMQSend.exe
DLL\Q2QCLDLL.dbg	Symbols from Q2QCLDLL.dll.
EXE\Q2QClIns.dbg	Symbols from Q2QClIns.exe.
EXE\Q2QClUni.dbg	Symbols from Q2QClUni.exe.
EXE\Q2QEXPL.dbg	Symbols from Q2QEXPL.exe.
EXE\Q2QGW.dbg	Symbols from Q2QGW.exe.
EXE\Q2QInst.dbg	Symbols from Q2QInst.exe.
DLL\q2qmsg.dbg	Symbols from q2qmsg.dll.
DLL\q2qprfdl.dbg	Symbols from q2qprfdl.dll.
DLL\Q2QSHDLL.dbg	Symbols from Q2QSHDLL.dll.
DLL\SHDLLRes.dbg	Symbols from SHDLLRes.dll.
DLL\wmiMQBridge.dbg	Symbols from wmiMQBridge.dll.

Header Files for MSMQ-MQSeries Bridge

Provider-specific header files needed to build the MSMQ-MQSeries Bridge sample applications are included with Host Integration Server 2009. These files are installed as part of the Host Integration Server package and copies of these files are also located on the Host Integration Server CD under the SDK\Include folder.

The following provider-specific files are provided with Host Integration Server for developing applications using the MSMQ-MQSeries Bridge.

File name	Description
msmqep.h	Globally unique identifier (GUID) definitions, enumeration constants, and error codes for use with the MSMQ-MQSeries Bridge.

Import Library Files for MSMQ-MQSeries Bridge

Provider-specific import library files needed to build the MSMQ-MQSeries Bridge extension sample applications are included with Host Integration Server 2009. These files are installed as part of the Host Integration Server package and copies of these files are also located on the Host Integration Server CD under the SDK\Lib folder.

The following provider-specific files are provided with Host Integration Server for developing applications using the MSMQ-MQSeries Bridge:

File name	Description
msmqep.lib	Import library of functions for use with the MSMQ-MQSeries Bridge extension.

IPropertyBag Interface

The IPropertyBag interface acts as a parameter for ISSOConfigStore, and also allows you to change the behavior of specific interfaces in the Enterprise Single Sign-On (SSO) object model.

Requirements

Type Library: SSOAdminLib 1.0 Type Library (SSOAdminLib.dll), SSOConfigStoreLib 1.0 Type Library (SSOConfigStoreLib), and SSOPSAdmin 1.0 Type Library (SSOPSAdmin.dll)

Platforms: Microsoft® Windows Server™ 2003, Windows® XP Professional, Windows 2000 Server

IPropertyBag Members

The member of the IPropertyBag interface is described in the following table.

Public Members

Member	Description
IPropertyBag.RemoteRead Method	Reads the specified Single Sign-On property.
IPropertyBag.Write Method	Writes the specified Single Sign-on property.

See Also

Concepts

IPropertyBag Interface

IPropertyBag Methods

The method of the IPropertyBag interface is described in the following table. For a complete list of IPropertyBag interface members, see IPropertyBag Members.

Public Methods

Method	Description
IPropertyBag.RemoteRead Method	Reads the specified Single Sign-On property.
IPropertyBag.Write Method	Writes the specified Single Sign-on property.

See Also

Concepts

IPropertyBag Interface

IPropertyBag.RemoteRead Method

Writes the specified Single Sign-on (SSO) property.

Syntax
C#

```
void RemoteRead(
string pszPropName,
[out] object pVar,
SSOAdminLib.IErrorLog pErrorLog,
uint varType,
object pUnkObj
);
```

Parameters

Parameters	Description
pszPropName	The property name to read.
pVar	When returned, the object containing the property value.
pErrorLog	An IErrorLog containing the error log, if applicable.
varType	The object type of the property.
pUnkObj	Pointer to the unknown object to read.

Remarks

You can use IPropertyBag.Read to read the current settings for the SSO object model.

See Also
Concepts
IPropertyBag Methods

IPropertyBag.Write Method

Writes the specified Single Sign-on property.

Syntax
C#

```
void Write(
      string pszPpropName,
      object pVar
)
```

Parameters

Parameters	Reference
pszPropName	The name of the property to write.
pVar	The value of the property to write.

Remarks

- If you call QueryInterface on an SSO object, you can retrieve the IPropertyBag interface and use it to change the behavior of your current object.

IPropertyBag Methods

ISSOAdmin Interface (COM)

The **ISSOAdmin** interface provides administration functions for the Enterprise Single Sign-On (SSO) server database.

Requirements

Type Library: SSOAdmin 1.0 Type Library (SSOAdmin.dll)

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

See Also

Concepts

ISSOAdmin Members

Other Resources

Programming with Enterprise Single Sign-On

ISSOAdmin Members

The following table shows the IISOAdmin members.

Public Methods

Member	Description
CreateApplication	Creates an application in the Single Sign-On (SSO) server database.
CreateFieldInfo	Creates field information for an application.
DeleteApplication	Deletes an application from the SSO server database.
GetApplicationInfo	Gets the application information from the SSO server database.
GetGlobalInfo	Returns the global SSO server configuration information from the SSO server database.
PurgeCacheForApplication	Purges the cached credentials for an application on all SSO servers.
UpdateApplication	Updates the application information in the SSO server database.

Concepts

ISSOAdmin Interface (COM)

ISSOAdmin Methods

The methods of the **ISSOAdmin** interface are listed in the following table. For a complete list of **ISSOAdmin** interface members, see ISSOAdmin Members.

Public Methods

Method	Description
CreateApplication	Creates an application in the Single Sign-On (SSO) server database.
CreateFieldInfo	Creates field information for an application.
DeleteApplication	Deletes an application from the SSO server database.
GetApplicationInfo	Gets the application information from the SSO server database.
GetGlobalInfo	Returns the global SSO server configuration information from the SSO server database.
PurgeCacheForApplication	Purges the cached credentials for an application on all SSO servers.
UpdateApplication	Updates the application information in the SSO server database.

ISSOAdmin Interface (COM)

ISSOAdmin.CreateApplication Method

The **CreateApplication** method creates an application in the Enterprise Single Sign-On (SSO) server database.

Syntax
C++

```
HRESULT CreateApplication(
BSTR bstrApplicationName,
BSTR bstrDescription,
BSTR bstrContactInfo,
BSTR bstrUserGroupName,
BSTR bstrAdminGroupName,
LONG lFlags,
LONG lNumFields
);
```

```
[Visual Basic]
Sub CreateApplication(
bstrApplicationName As String,
bstrDescription As String,
bstrContactInfo As String,
bstrUserGroupName As String,
bstrAdminGroupName As String,
lFlags As Long,
lNumFields As Long
)
```

Parameters
bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrDescription

[in] String that specifies the description for the application. This parameter can be NULL, an empty string, or contain spaces.

bstrDescription

[in] String that specifies the description for the application. This parameter can be NULL, an empty string, or contain spaces.

bstrContactInfo

[in] String that specifies the contact information for this application. This parameter can be NULL, an empty string, or contain spaces.

bstrContactInfo

[in] String that specifies the contact information for this application. This parameter can be NULL, an empty string, or contain spaces.

bstrUserGroupName

[in] String that specifies the application users group name. This parameter must contain a valid global group.

bstrUserGroupName

[in] String that specifies the application users group name. This parameter must contain a valid global group.

bstrAdminGroupName

[in] String that specifies the Application Administrator group name. This parameter must contain a valid global group.

bstrAdminGroupName

[in] String that specifies the Application Administrator group name. This parameter must contain a valid global group.

lFlags

[in] Long integer that specifies whether the application is a group application. If a group application is required, specify SSO_FLAG_APP_USES_GROUP_MAPPING.

lFlags

[in] Long integer that specifies whether the application is a group application. If a group application is required, specify SSO_FLAG_APP_USES_GROUP_MAPPING.

lNumFields

[in] Long integer that specifies the number of fields that will be added for this application. The minimum value is 1 (one external user ID). An application can have no credential fields.

lNumFields

[in] Long integer that specifies the number of fields that will be added for this application. The minimum value is 1 (one external user ID). An application can have no credential fields.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the Number property of the global **Err** object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Remarks

An application is always created as disabled.

After the field information is added by using the **CreateFieldInfo** method, then the application can be enabled by using the **UpdateApplication** method. The number of fields added by **CreateFieldInfo** must match the number of fields specified by the *numFields* parameter. The *numFields* value cannot be changed after the application is created.

To access this method, you must be an SSO Administrator or an SSO Affiliate Administrator.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

See Also

Programming with Enterprise Single Sign-On

ISSOAdmin.CreateFieldInfo Method

The **CreateFieldInfo** method creates field information for an application.

Syntax
C++

```
HRESULT CreateFieldInfo(
BSTR bstrApplicationName,
BSTR bstrLabel,
LONG lFlags
);
```

VB

```
Sub CreateFieldInfo(
bstrApplicationName As String,
bstrLabel As String,
lFlags As Long
)
```

Parameters
bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrLabel

[in] String that specifies the label value. This parameter cannot be NULL or an empty string.

bstrLabel

[in] String that specifies the label value. This parameter cannot be NULL or an empty string.

lFlags

[in] Long integer specifies whether the field is masked. If a field must be masked when displayed in the user interface, specify SSO_FLAG_FIELD_INFO_MASK. The flag parameter will be ignored for the first (user ID) field, as it will not be masked.

lFlags

[in] Long integer specifies whether the field is masked. If a field must be masked when displayed in the user interface, specify SSO_FLAG_FIELD_INFO_MASK. The flag parameter will be ignored for the first (user ID) field, as it will not be masked.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the Number property of the global **Err** object to one of the values in the following table.

Value	**Description**
S_OK	The method succeeded.

E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Remarks

The application must exist before its field information can be created. The number of fields added must equal the *numFields* value specified when the application was created, otherwise the application will be disabled at run time.

Although the external user ID is not considered to be an external credential, it requires a field to describe how it will be displayed by the user interface. The first field created will be considered as the field that describes the external user ID. A minimum of one field is required, and typically at least two fields should be specified to provide credentials. An application can have no credentials.

To access this method, you must be an SSO Administrator, SSO Affiliate Administrator, or an SSO Application Administrator.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOAdmin.DeleteApplication Method

The **DeleteApplication** method deletes an application from the Enterprise Single Sign-On (SSO) server database.

Syntax
C++

```
HRESULT DeleteApplication(
BSTR bstrApplicationName
);
```

VB

```
Sub DeleteApplication(
bstrApplicationName As String
)
```

Parameters
bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the Number property of the global **Err** object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
S_FALSE	The application was not found.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Remarks

All fields, mappings, and external credentials associated with this application are deleted.

To access this method, you must be an SSO Administrator or an SSO Affiliate Administrator.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

Programming with Enterprise Single Sign-On

ISSOAdmin.GetApplicationInfo Method

The **GetApplicationInfo** method gets the application information from the Enterprise Single Sign-On (SSO) server database.

Syntax

C++

```
HRESULT GetApplicationInfo(
BSTR bstrApplicationName,
BSTR* pbstrDescription,
BSTR* pbstrContactInfo,
BSTR* pbstrUserGroupName,
BSTR* pbstrAdminGroupName,
LONG* plFlags,
LONG* plNumFields
);
```

VB

```
Function GetApplicationInfo(
bstrApplicationName As String,
pbstrDescription As String,
pbstrContactInfo As String,
pbstrUserGroupName As String,
pbstrAdminGroupName As String,
plFlags As Long
)
As Long
```

Parameters

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

pbstrDescription

[out] Pointer to a string that receives the description for the application.

pbstrDescription

[out] String that receives the description for the application.

pbstrContactInfo

[out] Pointer to a string that receives the contact information for the application.

pbstrContactInfo

[out] String that receives the contact information for the application.

pbstrUserGroupName

[out] Pointer to a string that receives the application user group name.

pbstrUserGroupName

[out] String that receives the application user group name.

pbstrAdminGroupName

[out] Pointer to a string that receives the Application Administrator group name.

pbstrAdminGroupName

[out] String that receives the Application Administrator group name.

plFlags

[out] Pointer to a long integer that receives the flags currently set for the application.

plFlags

[out] Long that receives the flags currently set for the application.

plNumFields

[out] Pointer to a long integer that receives the number of fields associated with the application.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

This method returns a Long that receives the number of fields associated with the application.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the Number property of the global **Err** object to one of the values in the following table.

Value	**Description**
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Remarks

To access this method, you must be an SSO Administrator, SSO Affiliate Administrator, or an SSO Application Administrator.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

BSTR* pbstrAffiliateAppMgrGroup
);
```

VB

```
Function GetGlobalInfo(
plFlags As Long,
plAuditAppDeleteMax As Long,
plAuditMappingDeleteMax As Long,
plAuditNtpLookupMax As Long,
plAuditXpLookupMax As Long,
plTicketTimeout As Long,
plCredCacheTimeout As Long,
pbstrSecretServer As String,
pbstrSSOAdminGroup As String
)
As String
```

Parameters

plFlags

[out] Pointer to a long integer that receives the global flags.

plFlags

[out] Long that receives the global flags.

plAuditAppDeleteMax

[out] Pointer to a long integer that receives the current size of the AuditAppDelete table.

plAuditAppDeleteMax

[out] Long integer that receives the current size of the AuditAppDelete table.

plAuditMappingDeleteMax

[out] Pointer to a long integer that receives the current size of the AuditMappingDelete table.

plAuditMappingDeleteMax

[out] Long that receives the current size of the AuditMappingDelete table.

plAuditNtpLookupMax

[out] Pointer to a long integer that receives the current size of the AuditNtpLookup table.

plAuditNtpLookupMax

[out] Long that receives the current size of the AuditNtpLookup table.

plAuditXpLookupMax

[out] Pointer to a long integer that receives the current size of the AuditXpLookup table.

plAuditXpLookupMax

[out] Long that receives the current size of the AuditXpLookup table.

plTicketTimeout

[out] Pointer to a long integer that receives the current ticket time-out value in minutes.

plTicketTimeout

[out] Long that receives the current ticket time-out value in minutes.

plCredCacheTimeout

[out] Pointer to a long integer that receives the current credential cache time-out value in minutes.

plCredCacheTimeout

[out] Long that receives the current credential cache time-out value in minutes.

pbstrSecretServer

[out] Pointer to a string that receives the current secret server computer name.

pbstrSecretServer

[out] String that receives the current secret server computer name.

pbstrSSOAdminGroup

[out] Pointer to a string that receives the current SSO server Administrator group name.

pbstrSSOAdminGroup

[out] String that receives the current SSO server Administrator group name.

pbstrAffiliateAppMgrGroup

[out] Pointer to a string that receives the current SSO server Affiliate Administrator group name.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

This method returns a String that receives the current SSO server Affiliate Administrator group name.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the Number property of the global **Err** object to one of the values in the following table.

Value	**Description**
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Remarks

To access this method, you must be an SSO Administrator.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOAdmin.PurgeCacheForApplication Method

The **PurgeCacheForApplication** method purges the cached credentials for an application on all Enterprise Single Sign-On (SSO) servers.

Syntax

C++

```
HRESULT PurgeCacheForApplication(
BSTR bstrApplicationName
);
```

VB

```
Sub PurgeCacheForApplication(
bstrApplicationName As String
)
```

Parameters

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the Number property of the global **Err** object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Remarks

There may be a short time delay while this operation is applied to all SSO servers.

To access this method, you must be an SSO Administrator, SSO Affiliate Administrator, or an Application Administrator.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOAdmin.UpdateApplication Method

The **UpdateApplication** method updates the application information in the Enterprise Single Sign-On (SSO) server database.

Syntax

C++

```
HRESULT UpdateApplication(
BSTR bstrApplicationName,
BSTR bstrDescription,
BSTR bstrContactInfo,
BSTR bstrUserGroupName,
BSTR bstrAdminGroupName,
LONG lFlags,
LONG lFlagMask
);
```

VB

```
Function UpdateApplication(
bstrApplicationName As String,
bstrDescription As String,
bstrContactInfo As String,
bstrUserGroupName As String,
bstrAdminGroupName As String,
lFlags As Long
)
```

Parameters

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrDescription

[in] String that specifies the description of the application.

bstrDescription

[in] String that specifies the description of the application.

bstrContactInfo

[in] String that specifies the contact information for this application.

bstrContactInfo

[in] String that specifies the contact information for this application.

bstrUserGroupName

[in] String that specifies the Application Users group name. This must be a valid global group.

bstrUserGroupName

[in] String that specifies the Application Users group name. This must be a valid global group.

bstrAdminGroupName

[in] String that specifies the Application Administrator group name. This must be a valid global group. If running as an

Application Administrator, this parameter will be ignored.

bstrAdminGroupName

[in] String that specifies the Application Administrator group name. This must be a valid global group. If running as an Application Administrator, this parameter will be ignored.

lFlags

[in] Integer that specifies whether the application is enabled. To enable the application, set the SSO_FLAG_ENABLED flag.

lFlags

[in] Integer that specifies whether the application is enabled. To enable the application, set the SSO_FLAG_ENABLED flag.

lFlagMask

[in] To change the flag value, set this mask to the flag that you need to change. For example, to enable or disable Enterprise SSO, set this flag to SSO_FLAG_ENABLED. The *flagMask* parameter indicates which flag you want to change, while the *flags* parameter indicates the new value of that flag.

lFlagMask

[in] To change the flag value, set this mask to the flag that you need to change. For example, to enable or disable Enterprise SSO, set this flag to SSO_FLAG_ENABLED. The *flagMask* parameter indicates which flag you want to change, while the *flags* parameter indicates the new value of that flag.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the Number property of the global **Err** object to one of the values in the following table.

Value	**Description**
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Remarks

To access this method, you must be an SSO Administrator, SSO Affiliate Administrator, or an Application Administrator.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOAdmin2 Interface (COM)

The **ISSOAdmin2** interface provides additional administration functions for the Enterprise Single Sign-On (SSO) server database.

Requirements

Type Library: SSOAdmin 1.0 Type Library (SSOAdmin.dll)

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOAdmin2 Members

The following table shows the **IISOAdmin2** members.

Public Methods

Member	Description
ISSOAdmin.CreateApplication Method	Creates an application in the SSO server database.
ISSOAdmin.CreateFieldInfo Method	Creates field information for an application.
ISSOAdmin.DeleteApplication Method	Deletes an application from the SSO server database.
ISSOAdmin.GetApplicationInfo Method	Gets the application information from the SSO server database.
ISSOAdmin.GetGlobalInfo Method	Returns the global SSO server configuration information from the SSO server database.
ISSOAdmin.PurgeCacheForApplication Method	Purges the cached credentials for an application on all SSO server servers.
ISSOAdmin.UpdateApplication Method	Updates the application information in the SSO server database.
ISSOAdmin2.GetApplicationInfo2 Method	Gets the application information from the Enterprise Single Sign-On (SSO) server database.
ISSOAdmin2.UpdateApplication2 Method	Updates the application information in the Enterprise Single Sign-On (SSO) server database.

ISSOAdmin2 Methods

The following table shows the **IISOAdmin2** methods.

Public Methods

Method	Description
ISSOAdmin2.GetApplicationInfo2 Method	Gets the application information from the Enterprise Single Sign-On (SSO) server database.
ISSOAdmin2.UpdateApplication2 Method	Updates the application information in the Enterprise Single Sign-On (SSO) server database.

ISSOAdmin2.GetApplicationInfo2 Method

The **GetApplicationInfo2** method gets the application information from the Enterprise Single Sign-On (SSO) server database.

Syntax
VB

```
GetApplicationInfo2(
applicationName As String,
appInfoProps As object
)
```

C++

```
HRESULT GetApplicationInfo2(
BSTR applicationName,
IPropertyBag* appInfoProps
)
```

Parameters

applicationName

String containing the name of the application.

appInfoProps

IPropertyBag containing additional application information properties. For more information, see below.

Property Value/ Return Value

[C++] This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

[Visual Basic] Not Applicable.

Exceptions

[C++] This method returns an HRESULT containing one of the values in the following table.

[Visual Basic] This method indicates errors by setting the Number property of the global Err object to one of the values in the following table.

Value	Description
S_OK	The method succeeded
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDREG	An invalid parameter was detected.

Remarks

The following table describes the accepted values for appInfoProps:

propName	Type	ptrValue
Contact	VT_BSTR	Contact name
Computer	VT_BSTR	Computer name
appAdminAccount	VT_BSTR	Application admin account

appUserAccount	VT_BSTR	Application user account
windowsAccount	VT_BSTR	Windows account
appTicketTimeout	VT_UI4	Application ticket timeout

In addition, individual flags may also use the following values:

propName	**Type**	**ptrValue**
enableApp	VT_BOOL	Enable application
hostInitiatedSSO	VT_BOOL	Host initiated SSO
validatePassword	VT_BOOL	Validate password
allowTickets	VT_BOOL	Allow tickets
syncFromAdapter	VT_BOOL	Synchronize from adapter
syncToAdapter	VT_BOOL	Synchronize to adapter
changeWindowsPassword	VT_BOOL	Change windows password
verifyOldPassword	VT_BOOL	Verify old password
sendOldPassword	VT_BOOL	Send old password
allowMappingConflicts	VT_BOOL	Allow mapping conflicts
groupApp	VT_BOOL	Group application
groupAdapter	VT_BOOL	Group adapter
allowLocalAccounts	VT_BOOL	Allow local accounts
adminAccountSame	VT_BOOL	Administration account same
configStoreApp	VT_BOOL	Config store application
timeoutTickets	VT_BOOL	Timeout tickets
directPasswordSync	VT_BOOL	Direct password synchronization
windowsCreds	VT_BOOL	Windows credentials
restrictedCreds	VT_BOOL	Restricted credentials
showFilterOnly	VT_BOOL	Show filter only
restrictMappingCreate	VT_BOOL	Restrict mapping create
windowsInitiatedSSO	VT_BOOL	Windows-initiated SSO

disableCredCache	VT_BOOL	Disable credentials cache

ISSOAdmin2.UpdateApplication2 Method

The UpdateApplication2 method updates the application information in the Enterprise Single Sign-On (SSO) server database.

Syntax
VB

```
UpdateApplication2(
applicationName As String,
appInfoProps As object
);
```

C++

```
void UpdateApplication2(
string applicationName,
IPropertyBag appInfoProps
);
```

Parameters

applicationName

String containing the new application name.

appInfoProps

IPropertyBag containing additional application information properties. For more information, see below.

Property Value/ Return Value

[C++] This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

[Visual Basic] Not Applicable.

Exceptions

[C++] This method returns an HRESULT containing one of the values in the following table.

[Visual Basic] This method indicates errors by setting the Number property of the global Err object to one of the values in the following table.

Value	**Description**
S_OK	The method succeeded
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDREG	An invalid parameter was detected.

Remarks

The following table describes the accepted values for appInfoProps:

propName	**Type**	**ptrValue**
Contact	VT_BSTR	Contact name
Computer	VT_BSTR	Computer name
appAdminAccount	VT_BSTR	Application admin account
appUserAccount	VT_BSTR	Application user account

windowsAccount	VT_BSTR	Windows account
appTicketTimeout	VT_UI4	Application ticket timeout

In addition, individual flags may also use the following values:

propName	**Type**	**ptrValue**
enableApp	VT_BOOL	Enable application
hostInitiatedSSO	VT_BOOL	Host initiated SSO
validatePassword	VT_BOOL	Validate password
allowTickets	VT_BOOL	Allow tickets
syncFromAdapter	VT_BOOL	Synchronize from adapter
syncToAdapter	VT_BOOL	Synchronize to adapter
changeWindowsPassword	VT_BOOL	Change windows password
verifyOldPassword	VT_BOOL	Verify old password
sendOldPassword	VT_BOOL	Send old password
allowMappingConflicts	VT_BOOL	Allow mapping conflicts
groupApp	VT_BOOL	Group application
groupAdapter	VT_BOOL	Group adapter
allowLocalAccounts	VT_BOOL	Allow local accounts
adminAccountSame	VT_BOOL	Administration account same
configStoreApp	VT_BOOL	Config store application
timeoutTickets	VT_BOOL	Timeout tickets
directPasswordSync	VT_BOOL	Direct password synchronization
windowsCreds	VT_BOOL	Windows credentials
restrictedCreds	VT_BOOL	Restricted credentials
showFilterOnly	VT_BOOL	Show filter only
restrictMappingCreate	VT_BOOL	Restrict mapping create
windowsInitiatedSSO	VT_BOOL	Windows-initiated SSO
disableCredCache	VT_BOOL	Disable credentials cache

In addition, you may directly specify flags using the following properties:

propName	Type	ptrValue
flags	VT_UI4	Flags to specify
flagsMask	VT_UI4	Flag mask to specify

ISSOConfigDB Interface (COM)

The **ISSOConfigDB** object allows you to create and configure an SSO database.

Type Library: SSOConfigDB 1.0 Type Library (SSOConfigDB.dll)

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOConfigDB Members

The following table describes the **ISSOConfig DB** members.

Method	Description
ISSOConfigDB.CreateDatabase Method	Creates a SQL database for SSO.
ISSOConfigDB.GetDBInfo Method	Retrieves information about the specified database.
ISSOConfigDB.UpgradeDB Method	Upgrades the specified Single Sign-On (SSO) database to SSO version 3.

ISSOConfigDB Methods

The following table describes the **ISSOConfig DB** methods

Method	Description
ISSOConfigDB.CreateDatabase Method	Creates a SQL database for SSO.
ISSOConfigDB.GetDBInfo Method	Retrieves information about the specified database.
ISSOConfigDB.UpgradeDB Method	Upgrades the specified Single Sign-On (SSO) database to SSO version 3.

ISSOConfigDB.CreateDatabase Method

The CreateDatabase method creates a SQL database for SSO.

Syntax
VB

```
Sub CreateDatabase(
sqlServer As String,
sqlDatabase As String,
configureOnly As Boolean,
secretServer As String,
ssoAdminAccount As String,
ssoAffilateAdminAccount As String
);
```

C++

```
HRESULT CreateDatabase(
BSTR sqlServer,
BSTR sqlDatabase,
bool configureOnly,
BSTR secretServer,
BSTR ssoAdminAccount,
BSTR ssoAffilateAdminAccount
);
```

Parameters

Parameter	Description
sqlServer	String containing the name of the SQL server for the database.
sqlDatabase	String containing the name of the SQL database.
configureOnly	True to configure an already-existing database; otherwise, false.
secretServer	String containing the name of the secret server.
ssoAdminAccount	String containing the name of the SSO administration account for the server.
ssoAffilateAdminAccount	String containing the name of the SSO affiliate administration account.

Property Value/Return Value

[C++] This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

[Visual Basic] Not Applicable.

Exceptions

[C++] This method returns an HRESULT containing one of the values in the following table.

[Visual Basic] This method indicates errors by setting the Number property of the global Err object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.

E_INVALIDREG	An invalid parameter was detected.

ISSOConfigDB.GetDBInfo Method

The GetDBInfo method retrieves information about the specified database.

Syntax
VB

```
Sub GetDBInfo(
sqlServer As String,
sqlDatabase As String,
exists As Boolean,
isConfigured As Boolean,
needsUpgrade As Boolean,
secretServer As String,
ssoAdminAccount As String,
ssoAffilateAdminAccount As String
);
```

C++

```
HRESULT GetDBInfo(
string sqlServer,
string sqlDatabase,
out bool exists,
out bool isConfigured,
out bool needsUpgrade,
out string secretServer,
out string ssoAdminAccount,
out string ssoAffilateAdminAccount
);
```

Parameters

Parameter	Description
sqlServer	String containing the name of the SQL server.
sqlDatabase	String containing the name of the specified database.
exists	Returns true if the database exists; otherwise, false.
isConfigured	Returns true if the database is configured; otherwise, false.
needsUpgrade	Returns true if the database needs to be upgraded; otherwise, false.
secretServer	Returns a string containing the name of the secret server of the database.
ssoAdminAccount	Returns a string containing the name of the SSO administration account.
ssoAffilateAdminAccount	Returns a string containing the SSO affiliate administration account.

Property Value/Return Value

[C++] This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

[Visual Basic] Not Applicable.

Exceptions

[C++] This method returns an HRESULT containing one of the values in the following table.

[Visual Basic] This method indicates errors by setting the Number property of the global Err object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDREG	An invalid parameter was detected.

ISSOConfigDB.UpgradeDB Method

The UpgradeDatabase method upgrades the specified Single Sign-On (SSO) database to SSO version 3.

Syntax
VB

```
Sub UpgradeDB (
sqlServer As String,
sqlDatabase As String
);
```

C++

```
HRESULT UpgradeDB (
BSTR sqlServer,
BSTR sqlDatabase
);
```

Parameters

Parameter	Description
sqlServer	String containing the SQL server in which the database exists.
sqlDatabase	String containing the name of the database.

Property Value/Return Value

[C++] This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

[Visual Basic] Not Applicable.

Exceptions

[C++] This method returns an HRESULT containing one of the values in the following table.

[Visual Basic] This method indicates errors by setting the Number property of the global Err object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDREG	An invalid parameter was detected.

ISSOConfigOM Interface (COM)

The **ISSOConfigOM** grants access to the Single Sign-On (SSO) object model for server configuration.

Requirements

Type Library: SSOConfigOM 1.0 Type Library (SSOConfigOM.dll)

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOConfigOM Members

The following table shows the **ISSOConfigOM** members.

Public Methods

Method	Description
ISSOConfigOM.DiscoverServer Method	Discovers the currently-available servers.
ISSOConfigOM.GetServerStatus	Describes the status of the current server.

ISSOConfigOM Methods

The following table shows the **ISSOConfigOM** methods.

Public Methods

Method	Description
ISSOConfigOM.DiscoverServer Method	Discovers the currently-available servers.
ISSOConfigOM.GetServerStatus	Describes the status of the current server.

ISSOConfigOM.DiscoverServer Method

The **DiscoverServers** method discovers the currently-available servers.

Syntax
VB

```
  Servers As String
  );
```

C#

```
  BSTR Servers
  );
```

Parameters

Parameter	Reference
Servers	Returns a string containing the currently-available servers.

Exceptions

[C++] This method returns an HRESULT containing one of the values in the following table.

[Visual Basic] This method indicates errors by setting the Number property of the global Err object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDREG	An invalid parameter was detected.

ISSOConfigOM.GetServerStatus

The **GetServerStatus** method describes the status of the current server.

Syntax
VB

```
GetServerStatus(
flags As Integer,
ssoServerName As String,
sqlServer As String,
sqlDatabase As String,
serviceAccount As String,
computerNameCluster As String,
computerNameNode As String,
eventCountInformational As Integer,
eventCountWarning As Integer,
eventCountError As Integer,
versionInfoM As Integer,
versionInfoL As Integer,
auditLevelN As Integer,
auditLevelP As Integer,
passwordSyncAge As Integer,
statusFlags As Integer
);
```

C++

```
HRESULT GetServerStatus(
int flags,
BSTR ssoServerName,
BSTR sqlServer,
BSTR sqlDatabase,
BSTR serviceAccount,
BSTR computerNameCluster,
BSTR computerNameNode,
BSTR eventCountInformational,
int eventCountWarning,
int eventCountError,
int versionInfoM,
int versionInfoL,
int auditLevelN,
int auditLevelP,
int passwordSyncAge,
int statusFlags
);
```

Parameters

Parameter	Description
flags	Not used in this version. Should be set to zero.
ssoServerName	Returns a string containing the current SSO server name.
sqlServer	Returns a string containing the name of the SQL server of the current server.
sqlDatabase	Returns a string containing the name of the SQL database of the current server.
serviceAccount	Returns a string containing the current service account.

computerNameCluster	Returns a string containing the name of the current computer cluster.
computerNameNode	Returns the name of the current computer.
eventCountInformational	Returns an integer containing information regarding the event count.
eventCountWarning	Returns an integer containing the event count warning.
eventCountError	Returns an integer containing the event count error.
versionInfoM	Returns an integer containing the MSB version info.
versionInfoL	Returns an integer containing the LSB version info.
auditLevelN	Returns an integer containing the negative audit level.
auditLevelP	Returns an integer containing the positive audit level.
passwordSyncAge	Returns an integer containing the password sync age.
statusFlags	Returns an integer containing the status flags. For more information, see SSOStatusFlags.

Property Value/Return Value

[C++] This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

[Visual Basic] Not Applicable.

Exceptions

[C++] This method returns an HRESULT containing one of the values in the following table.

[Visual Basic] This method indicates errors by setting the Number property of the global Err object to one of the values in the following table.

Value	**Description**
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDREG	An invalid parameter was detected.

ISSOConfigSS Interface (COM)

The **ISSOConfigSS** interface configures the secret server.

Requirements

Type Library: SSOConfigSS 1.0 Type Library (SSOConfigSS.dll)

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOConfigSS Members

The following table describes the **ISSOConfigSS** members.

Method	Description
ISSOConfigSS.BackupSecret Method	Backs up the secret server.
ISSOConfigSS.GenerateSecret Method	Generates the secret for the secret server.
ISSOConfigSS.GetFilePasswordReminder Method	Retrieves the file password reminder for the secret server.
ISSOConfigSS.RestoreSecret Method	Restores the secret from the specified restore file.

ISSOConfigSS Methods

The following table describes the **ISSOConfigSS** methods.

Method	Description
ISSOConfigSS.BackupSecret Method	Backs up the secret server.
ISSOConfigSS.GenerateSecret Method	Generates the secret for the secret server.
ISSOConfigSS.GetFilePasswordReminder Method	Retrieves the file password reminder for the secret server.
ISSOConfigSS.RestoreSecret Method	Restores the secret from the specified restore file.

ISSOConfigSS.BackupSecret Method

The **BackupSecret** method backs up the secret server.

Syntax
VB

```
  backupFile As String,
  filePassword As String,
  filePasswordReminder As String
  );
```

C++

```
  BSTR backupFile,
  BSTR filePassword,
  BSTR filePasswordReminder
  );
```

Parameters

Parameter	**Description**
backupFile	String containing the path and name of the secret server backup file.
filePassword	String containing the backup file password.
filePasswordReminder	String containing the secret server file password reminder.

Property Value/Return Value

[C++] This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

[Visual Basic] Not Applicable.

Exceptions

[C++] This method returns an HRESULT containing one of the values in the following table.

[Visual Basic] This method indicates errors by setting the Number property of the global Err object to one of the values in the following table.

Value	**Description**
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDREG	An invalid parameter was detected.

ISSOConfigSS.GenerateSecret Method

The **GenerateSecret** method generates the secret for the secret server.

Syntax
VB

```
GenerateSecret(
backupFile As String,
filePassword As String,
filePasswordReminder As String
);
```

C++

```
HRESULT GenerateSecret(
BSTR backupFile,
BSTR filePassword,
BSTR filePasswordReminder
);
```

Parameters

Parameter	**Description**
backupFile	String containing the path and name of the backup file for the secret server.
filePassword	String containing the backup file password.
filePasswordReminder	String containing the secret server file password reminder

Property Value/Return Value

[C++] This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

[Visual Basic] Not Applicable.

Exceptions

C++] This method returns an HRESULT containing one of the values in the following table.

[Visual Basic] This method indicates errors by setting the Number property of the global Err object to one of the values in the following table.

Value	**Description**
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDREG	An invalid parameter was detected.

ISSOConfigSS.GetFilePasswordReminder Method

The **GetFilePasswordReminder** method gets the password reminder from the backup file.

Syntax
VB

```
Function GetFilePasswordReminder(
restoreFile as String);
```

C#

```
void GetFilePasswordReminder(
string restoreFile,
out string filePasswordReminder);
```

Parameters

Parameter	Description
restoreFile	The file from which the reminder is to be retrieved.
filePasswordReminder	The reminder for the file password.

Property Value/Return Value

[Visual Basic] The file password reminder.

Remarks

This function goes directly to the restore file to get the password reminder, hence the user must have read access to the restore file.

ISSOConfigSS.RestoreSecret Method

The **RestoreSecret** method restores master secrets from the password protected backup file.

Syntax
VB

```
Sub RestoreSecret(
restoreFile as String,
filePassword as String);
```

C#

```
void RestoreSecret(
string restoreFile,
string filePassword);
```

Parameters

Parameter	Description
restoreFile	The file from which the secrets are to be restored.
filePasswordReminder	The password used to protect the restore file.

ISSOConfigStore Interface (COM)

The **ISSOConfigStore** interface provides administration functions for the Enterprise Single Sign-On (SSO) config store.

Requirements

Type Library: SSOConfigStore 1.0 Type Library (SSOConfigStore.dll)

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOConfigStore::DeleteConfigInfo

The **DeleteConfigInfo** method deletes the configuration information from the config store.

Syntax
C++

```
HRESULT DeleteConfigInfo(
BSTR bstrApplication,
BSTR bstrIdentifier,
);
```

VB

```
DeleteConfigInfo(
bstrApplication As BSTR,
bstrIdentifier As BSTR,
)
```

Parameters
bstrApplication

[in] String containing the external application name.

bstrApplication

[in] String containing the external application name.

bstrIdentifier

[in] String containing the identifier for the config info. This will typically be a GUID string.

bstrIdentifier

[in] String containing the identifier for the config info. This will typically be a GUID string.

Return Value

This method does not return a value.

The method returns an **HRESULT**. Possible values include, but are not limited to, those in the following table.

Return code	Description
S_OK	The config info was successfully returned from the config store.
S_FALSE	The config info did not already exist.
E_ACCESSDENIED	Access denied.
E_INVALIDARG	Invalid argument.

Remarks

If the config info specified by the parameters does not already exist in the config store, this method will return S_FALSE.

If the *bstrSSOServer* parameter is NULL, the Single Sign-On (SSO) server location is obtained from the registry. If the server location is not available in the registry, the local computer is used.

Example

```
        ConfigStore

        bstrApplication
```

```
        bstrIdentifier
```

Concepts

ISSOConfigStore Interface (COM)

Other Resources

Programming with Enterprise Single Sign-On

ISSOConfigStore::GetConfigInfo

The **GetConfigInfo** method gets the configuration information from the config store.

Syntax
C++

```
HRESULT GetConfigInfo(
BSTR bstrApplication,
BSTR bstrIdentifier,
LONG lFlags,
IPropertyBag* ppbConfigInfo
);
```

VB

```
GetConfigInfo(
bstrApplication As BSTR,
bstrIdentifier As BSTR,
lFlags As LONG,
ppbConfigInfo As IPropertyBag
)
```

Parameters
bstrApplication

[in] String containing the Single Sign-On (SSO) server. This property is optional.

bstrApplication

[in] String containing the SSO server. This property is optional.

bstrIdentifier

[in] String containing the identifier for the config info. This string is typically a GUID string.

bstrIdentifier

[in] String containing the identifier for the config info. This string is typically a GUID string.

lFlags

[in] Long integer containing the flags.

lFlags

[in] Long integer containing the flags.

ppbConfigInfo

[in] Pointer to an empty property bag that is populated with the config info as name/value pairs.

ppbConfigInfo

[in] Pointer to an empty property bag that is populated with the config info as name/value pairs.

Return Value

This method does not return a value.

The method returns an **HRESULT**. Possible values include, but are not limited to, those in the following table.

Return code	**Description**
S_OK	The config info was successfully returned from the config store.
E_ACCESSDENIED	Access denied.

E_INVALIDARG	Invalid argument.

Remarks

This method can be executed either in admin or run-time (lookup) mode. The caller specifies SSO_FLAG_LOOKUP if the run-time (lookup) mode is required. The default mode is admin mode.

In admin mode, masked properties are not returned. Instead, the property is missing. Unmasked properties are returned. Admin mode can specify any SSO server, not just the local computer.

In run-time mode, all properties, including masked properties, are returned. Because run-time mode only uses the SSO server on the current computer, the *bstrSSOServer* parameter will be ignored.

If the *bstrSSOServer* parameter is NULL, the SSO server location is obtained from the registry. (This applies to admin mode only. Run-time mode always uses the local computer.) If the server location is not available in the registry, the local computer is used.

To get the config info, this method is provided with an empty property bag that is populated with the properties. This allows the BizTalk Server 2006 implementation of the property bag to be used, which can handle the type conversion from BSTRs to the actual variant types based on a format convention specific to BizTalk Server 2006. The property values will be XML tags for Host Integration Server.

Example Code

```
        ConfigStore

        bstrApplication

        bstrIdentifier

        lFlags

        ppbConfigInfo
```

See Also

Concepts

ISSOConfigStore Interface (COM)

Other Resources

Programming with Enterprise Single Sign-On

ISSOConfigStore::SetConfigInfo

The **SetConfigInf**o method sets the configuration information in the config store.

Syntax
C++

```
HRESULT SetConfigInfo(
BSTR bstrApplication,
BSTR bstrIdentifier,
IPropertyBag* ppbConfigInfo
);
```

VB

```
SetConfigInfo(
bstrApplication As BSTR,
bstrIdentifier As BSTR,
ppbConfigInfo As IPropertyBag
)
```

Remarks
bstrApplication

[in] String containing the external application name.

bstrApplication

[in] String containing the external application name.

bstrIdentifier

[in] String containing the identifier for the config info. This string will typically be a GUID.

bstrIdentifier

[in] String containing the identifier for the config info. This string will typically be a GUID.

ppbConfigInfo

[in] Contains a pointer to a property bag containing the config info as name/value pairs.

ppbConfigInfo

[in] Contains a pointer to a property bag containing the config info as name/value pairs.

Return Values

This method does not return a value.

The method returns an **HRESULT**. Possible values include, but are not limited to, those in the following table.

Return code	Description
S_OK	The config info was successfully stored in the config store.
E_ACCESSDENIED	Access denied.
E_INVALIDARG	Invalid argument.

Remarks

This method can be used for originally creating the config info or for updating the config info.

If the config info does not already exist, all properties of the config info, as defined by the field info for the specified application, must be provided.

If the config info does already exist, a property within the config info can be missing. Only properties that are provided will be updated. At least one property must be provided.

Note that due to the use of the Single Sign-On (SSO) store, the first property cannot be masked.

If the ***bstrSSOServer*** parameter is NULL, the SSO server location is obtained from the registry. If not available in the registry, the local computer will be used.

Example

```
        ConfigStore

        bstrApplication

        bstrIdentifier

        ppbConfigInfo
```

ISSOLookup1.GetCredentials Method

The **GetCredentials** method retrieves the user credentials for an application.

Syntax
C++

```
HRESULT GetCredentials(
BSTR bstrApplicationName,
LONG lFlags,
BSTR* pbstrExternalUserName,
SAFEARRAY credentials
);
```

VB

```
Function GetCredentials(
bstrApplicationName As String,
lFlags As Long,
pbstrExternalUserName As String
)
As String
```

Parameters
bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

lFlags

[in] Long integer that specifies the flags to set. Using the SSO_FLAG_REFRESH indicates that the credential cache should be bypassed.

lFlags

[in] Long that specifies the flags to set. Using the SSO_FLAG_REFRESH indicates that the credential cache should be bypassed.

pbstrExternalUserName

[out] Pointer to a string that receives the external user name.

pbstrExternalUserName

[out] String that receives the external user name.

credentials

[out] String array that receives the credentials.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

String array that receives the credentials.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the Number property of the global Err object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Remarks

To access this method, you must be an Application User. You can only retrieve your own credential.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOLookup2.GetCredentials Method

The **GetCredentials** method retrieves the user credentials for an application.

Syntax
C++

```
HRESULT GetCredentials(
BSTR bstrApplicationName,
LONG lFlags,
BSTR* pbstrExternalUserName,
SAFEARRAY credentials
);
```

VB

```
Function GetCredentials(
bstrApplicationName As String,
lFlags As Long,
pbstrExternalUserName As String
)
As String
```

Parameters
bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

lFlags

[in] Long integer that specifies the flags to set. Using the SSO_FLAG_REFRESH indicates that the credential cache should be bypassed.

lFlags

[in] Long that specifies the flags to set. Using the SSO_FLAG_REFRESH indicates that the credential cache should be bypassed.

pbstrExternalUserName

[out] Pointer to a string that receives the external user name.

pbstrExternalUserName

[out] String that receives the external user name.

credentials

[out] String array that receives the credentials.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

String array that receives the credentials.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the Number property of the global Err object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Remarks

To access this method, you must be an Application User. You can only retrieve your own credential.

ISSOLookup2.LogonExternalUser Method

The **LogonExternalUser** method logs on an external user.

Syntax
C++

```
Int GetCredentials(
BSTR bstrApplicationName,
BSTR bstrUserName,
LONG lFlags,
Array ppsaCredentials
);
```

VB

```
Function GetCredentials(
bstrApplicationName As String,
bstrUserName As String,
lFlags As Long,
ppsaCredentials As String
)
As Integer
```

Parameters
bstrApplicationName

[in] String that specified the name of the application to log on to.

bstrApplicationName

[in] String that specified the name of the application to log on to.

bstrUserName

[in] String that specified the name of the external user to log on.

bstrUserName

[in] String that specified the name of the external user to log on.

lFlags

[in] Long integer that specifies the flags to set.

lFlags

[in] Long integer that specifies the flags to set.

ppsaCredentials

Array that holds the credentials of the user.

ppsaCredentials

Array that holds the credentials of the user.

Return Value

A windows handle.

A windows handle.

ISSOMapper.GetApplications Method

The **GetApplications** method retrieves the available applications for a Microsoft Windows user.

Syntax

C++

```
HRESULT GetApplications(
SAFEARRAY applications,
SAFEARRAY descriptions,
SAFEARRAY contactInfo
)
```

VB

```
Sub GetApplications(
applications As String,
descriptions As String,
contactInfo As String
)
```

Parameters

applications

[out] String array that returns the application name.

applications

[out] String array that returns the application name.

descriptions

[out] String array that returns a description for the application.

descriptions

[out] String array that returns a description for the application.

contactInfo

[out] String array that returns the contact information for the application.

contactInfo

[out] String array that returns the contact information for the application.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the **Number** property of the global **Err** object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_INVALIDARG	An invalid parameter was detected.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOMapper.GetFieldInfo Method

The **GetFieldInfo** method retrieves the field information for an application.

Syntax
C++

```
HRESULT GetFieldInfo(
BSTR bstrApplicationName,
SAFEARRAY labels,
SAFEARRAY flags
);
```

VB

```
Sub GetFieldInfo(
bstrApplicationName As String,
labels As String
flags As Long
)
```

Parameters
bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

labels

[out] String array that returns the field labels.

labels

[out] String array that returns the field labels.

flags

[out] Long integer array that returns the field flags.

flags

[out] Long array that returns the field flags.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the **Number** property of the global **Err** object to one of the values in the following table.

Value	**Description**
S_OK	The method succeeded.

E_ACCESSDENIED	Access is denied to the caller.
E_FAIL	The application is disabled.
E_INVALIDARG	An invalid parameter was detected.

Remarks

The field information will only be returned if the application is currently enabled. An application cannot be enabled unless its field information is complete.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOMapper.GetMappingsForExternalUser Method

The **GetMappingsForExternalUser** method retrieves the mappings for an external user.

Syntax
C++

```
HRESULT GetMappingsForExternalUser(
BSTR bstrApplicationName,
BSTR bstrExternalUserName,
SAFEARRAY mappings
);
```

VB

```
Function GetMappingsForExternalUser(
bstrApplicationName As String,
bstrExternalUserName As String)
As Variant
```

Parameters
bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrExternalUserName

[in] String that specifies the external user name. This value can contain spaces. If a NULL value is specified for this parameter, all mappings are returned for the specified application.

bstrExternalUserName

[in] String that specifies the external user name. This value can contain spaces. If a NULL value is specified for this parameter, all mappings are returned for the specified application.

mappings

[out] Object array that contains the mappings as **ISSOMapping** objects.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Variant array that contains the mappings as **ISSOMapping** objects.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the **Number** property of the global **Err** object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.

E_INVALIDARG	An invalid parameter was detected.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOMapper.GetMappingsForWindowsUser Method

The **GetMappingsForWindowsUser** method retrieves the mappings for a Microsoft Windows user.

Syntax

C++

```
HRESULT GetMappingsForWindowsUser(
BSTR bstrWindowsDomainName,
BSTR bstrWindowsUserName,
BSTR bstrApplicationName,
SAFEARRAY mappings
);
```

VB

```
Function GetMappingsForWindowsUser(
bstrWindowsDomainName As String,
bstrWindowsUserName As String,
bstrApplicationName As String
)
As Variant
```

Parameters

bstrWindowsDomainName

[in] String that specifies the Microsoft Windows domain name. This parameter is optional, but if it is specified, the *windowsUserName* parameter must also be specified. If this parameter is not specified, the current user context is used.

bstrWindowsDomainName

[in] String that specifies the Microsoft Windows domain name. This parameter is optional, but if it is specified, the *windowsUserName* parameter must also be specified. If this parameter is not specified, the current user context is used.

bstrWindowsUserName

[in] String that specifies the Microsoft Windows domain name. This parameter is optional, but if it is specified, the *windowsUserName* parameter must also be specified. If this parameter is not specified, the current user context is used.

bstrWindowsUserName

[in] String that specifies the Microsoft Windows domain name. This parameter is optional, but if it is specified, the *windowsUserName* parameter must also be specified. If this parameter is not specified, the current user context is used.

bstrApplicationName

[in] String that specifies the external application name. If this parameter is specified, only one mapping is returned if it exists. If this parameter is NULL, all mappings for the specified user are returned. This parameter is optional.

bstrApplicationName

[in] String that specifies the external application name. If this parameter is specified, only one mapping is returned if it exists. If this parameter is NULL, all mappings for the specified user are returned. This parameter is optional.

mappings

[out] Object array that contains the mappings as **ISSOMapping** objects.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Variant array that contains the mappings as **ISSOMapping** objects.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the **Number** property of the global **Err** object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Remarks

An Application Administrator must specify the *bstrApplicationName* value.

Users described as Application User can only access their own mappings. They cannot access the mappings for another user.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOMapper.SetExternalCredentials Method

The **SetExternalCredentials** method stores a set of external credentials in the Enterprise Single Sign-On (SSO) server database.

Syntax
C++

```
HRESULT SetExternalCredentials(
BSTR bstrApplicationName,
BSTR bstrExternalUserName,
SAFEARRAY externalCredentials
);
```

```
[Visual Basic]
Sub SetExternalCredentials(
bstrApplicationName As String,
bstrExternalUserName As String,
externalCredentials As String
)
```

Parameters
bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrExternalUserName

[in] String that specifies the external user name.

bstrExternalUserName

[in] String that specifies the external user name.

externalCredentials

[in] String array that specifies the external credentials to be stored.

externalCredentials

[in] String array that specifies the external credentials to be stored.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the **Number** property of the global **Err** object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.

E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Remarks

Users described as Application User can only set their own credentials. Also, the number of external credentials provided must match the number of fields expected by the external application.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOMapper.SetWindowsPassword Method

The **SetWindowsPassword** method sets the Microsoft Windows password. This method is not currently implemented.

Syntax
C++

```
HRESULT SetWindowsPassword(
BSTR bstrWindowsPassword
);
```

VB

```
Sub SetWindowsPassword(
bstrWindowsPassword As String
)
```

Parameters
bstrWindowsPassword

[in] String that specifies the Windows password.

bstrWindowsPassword

[in] String that specifies the Windows password.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the **Number** property of the global **Err** object to one of the values in the following table.

Value	Description
E_NOTIMPL	The method is not implemented.

ISSOMapper2 Interface (COM)

The **ISSOMapper2** interface creates mappings between users and applications

Requirements

Type Library: SSOMapper 1.0 Type Library (SSOMapper.dll)

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOMapper2 Members

The following table shows the ISSOMapper2 methods.

Public Methods

ISSOMapper2.GetApplications2 Method	Retrieves the available applications for a Microsoft® Windows® user.
ISSOMapper.GetFieldInfo Method	Retrieves the field information for an application.
ISSOMapper.GetMappingsForExternalUser Method	Retrieves the mappings for an external user.
ISSOMapper.GetMappingsForWindowsUser Method	Retrieves the mappings for a Microsoft Windows user.
ISSOMapper.SetExternalCredentials Method	Stores a set of external credentials in the Single Sign-On database.
ISSOMapper.SetWindowsPassword Method	Sets the Microsoft Windows password. This method is not currently implemented.

ISSOMapper2 Methods

The following table shows the **ISSOMapper2** methods.

Public Methods

Method	Description
ISSOMapper2.GetApplications2 Method	Retrieves the available applications for a Microsoft® Windows® user.

ISSOMapper2.GetApplications2 Method

The GetApplications2 method retrieves the available applications for a Microsoft Windows user.

Syntax
VB

```
Sub GetApplications2(
applications As String,
descriptions As String,
contactInfo As String,
userAccounts As String,
adminAccounts As String,
flags As Long
);
```

C#

```
HRESULT GetApplications2(
SAFEARRAY applications,
SAFEARRAY descriptions,
SAFEARRAY contactInfo,
SAFEARRAY userAccounts,
SAFEARRAY adminAccounts,
SAFEARRAY flags
);
```

Parameters

Parameter	**Description**
applications	String array that returns the application name.
descriptions	String array that returns a description of the application.
contactInfo	String array that returns the contact information for the application.
userAccounts	String array that returns all user accounts for the application. GetApplications2 returns a null in this parameter when called by an application user.
adminAccounts	String array that returns all administration accounts for the application. GetApplications2 returns a null in this parameter when called by an application user.
flags	Integer array that returns the flags for the application.

Property Value/Return Value

[C++] This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

[Visual Basic] Not Applicable.

Exceptions

[C++] This method returns an HRESULT containing one of the values in the following table.

[Visual Basic] This method indicates errors by setting the Number property of the global Err object to one of the values in the following table.

Value	**Description**

S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDREG	An invalid parameter was detected.

ISSOMapping Interface (COM)

The **ISSOMapping** interface manages the state of a mapping instance.

Requirements

Type Library: SSOMapper 1.0 Type Library (SSOMapper.dll)

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOMapping.ApplicationName Property

The **ApplicationName** property specifies the name of the application.

Syntax
C++

```
HRESULT ISSOMapping::get_ApplicationName(
BSTR* ApplicationName
);
HRESULT ISSOMapping::put_ApplicationName(
BSTR ApplicationName
);
```

VB

```
Property ApplicationName() As String
```

Parameters
ApplicationName

[in] When putting the property, a string that contains the application name. [out, retval] When getting the property, a string used to return the application name.

None.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the **Number** property of the global **Err** object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOMapping.ExternalUserName Property

The **ExternalUserName** property specifies the external (non-Microsoft Windows) user name.

Syntax
C++

```
HRESULT ISSOMapping::get_ExternalUserName(BSTR* ExternalUserName);
HRESULT ISSOMapping::put_ExternalUserName(BSTR ExternalUserName);
```

VB

```
Property ExternalUserName() As String
```

Parameters
ExternalUserName

[in] When putting the property, a string that contains the external user name. [out, retval] When getting the property, a string used to return the external user name.

None.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the **Number** property of the global **Err** object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Requirements

ISSOMapping.Flags Property

The **Flags** property is reserved for internal use only.

Syntax
C++

```
HRESULT ISSOMapping::get_Flags(BSTR* Flags);
HRESULT ISSOMapping::put_Flags(BSTR Flags);
```

VB

```
Property Flags() As String
```

Parameters
Flags

[in] When putting the property, a string that contains the flag value. [out, retval] When getting the property, a string used to return the flag value.

None.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the **Number** property of the global **Err** object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

ISSOMapping.WindowsDomainName Property

The **WindowsDomainName** property specifies the Microsoft Windows domain name.

Syntax

C++

```
HRESULT ISSOMapping::get_WindowsDomainName(BSTR* WindowsDomainName);
HRESULT ISSOMapping::put_WindowsDomainName(BSTR WindowsDomainName);
```

VB

```
Property WindowsDomainName() As String
```

Parameters

WindowsDomainName

[in] When putting the property, a string that contains the Windows domain name. Maximum length is 15 characters.

[out, retval] When getting the property, a string used to return the Windows domain name.

None.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the **Number** property of the global **Err** object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

ISSOMapping.Create Method

The **Create** method creates the mapping.

Syntax
C++

```
HRESULT Create(
LONG lFlags
);
```

VB

```
Sub Create(
lFlags As Long
)
```

Parameters
lFlags

For the current release, *lFlags* can be set to SSO_FLAG_REFRESH only.

lFlags

For the current release, *lFlags* can be set to SSO_FLAG_REFRESH only.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the **Number** property of the global **Err** object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

ISSOMapping.Delete Method

The **Delete** method deletes the mapping.

Syntax

C++

```
HRESULT Delete();
```

VB

```
Sub Delete()
```

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the **Number** property of the global **Err** object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Remarks

After the mapping has been deleted, the mapping object can no longer be used and should be released.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOMapping.Enable Method

The **Enable** method enables the mapping.

Syntax
C++

```
HRESULT Enable(
LONG lFlags
);
```

VB

```
Sub Enable(
lFlags As Long
)
```

Parameters
lFlags

Not currently implemented.

lFlags

Not currently implemented.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Not applicable.

Error Values

This method returns an HRESULT containing one of the values in the following table.

This method indicates errors by setting the **Number** property of the global **Err** object to one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

ISSONotification.InitializeAdapter Method

Initializes the password sync adapter to the ENTSSO system.

Syntax
C++

```
HRESULT InitializeAdapter(
BSTR strAdapterName,
ULONG lFlags,
ULONGLONG* hNotifyEvent,
GUID* guidTrackingId);
```

Parameters
bstrAdapterName

[in] The unique adapter name.

ulFlags

[in] A bitwise combination of the SSO_NOTIFICATION_FLAG values.

phNotifyEvent

[out] When this method returns, contains an event handle created by PS Helper. You should cast the return value to a HANDLE on return, as MIDL does not support the HANDLE data type. This parameter can be NULL if the event handle is not required by the adapter.

pguidTrackingId

[out] When this method returns, contains the tracking ID generated by ENTSSO. The tracking ID is used for auditing purposes. This parameter can be NULL if the tracking ID is not required by the adapter.

Return Value

This method returns an HRESULT indicating whether it completed correctly. For more information, see the Error Values section.

Error Values

This method returns an HRESULT containing one of the values in the following table.

Value	Description
S_OK	The initialization was successful.
S_FALSE	The initialization was successful, but was a reconnect. For more information, see the Remarks section.
E_ACCESSDENIED	Access is denied.
ENTSSO_E_NO_SERVER	Could not contact the ENTSSO server. Check that the ENTSSO service is running.

Remarks

Before calling **InitializeAdapter**, you must have entered the relevant adapter name into ENTSSO.

InitializeAdapter should be the first method your adapter calls, because you cannot call any other **ISSONotification** methods before you call **InitializeAdapter**. You should not call **InitializeAdapter** again until after you call **ShutdownAdapter**. Once you shut down the adapter, however, you may call **InitializeAdapter** at any time to reconnect.

InitializeAdapter initiates communication between the PS Helper and the adapter. When your adapter calls **InitializeAdapter**, the PS Helper calls the Enterprise Single Sign-On (ENTSSO) service over encrypted LRPC. Using the adapter name, the ENTSSO service grants or denies access based on the access account that was defined for the current adapter.

You must have started the ENTSSO service before calling **InitializeAdapter**. PS Helper cannot automatically start ENTSSO because the adapter process might not be running with sufficient privileges to start a service. Therefore, your adapter must initiate all communication between the adapter and ENTSSO.

PS Helper first establishes a connection with the ENTSSO service, and then creates a named event. PS Helper then passes the named event to the ENTSSO service. ENTSSO uses the event signal to the PS Helper when a notification arrives for the adapter. ENTSSO returns the event to the adapter so that the adapter can wait on the event, or else ignore the event and allow PS Helper to wait instead. This gives more flexibility to the adapter for the adapter threading model. The event is valid for the adapter until ENTSSO completes the processing initiated by a call to **ShutdownAdapter**.

The ENTSSO service accepts the initial remote procedure call (RPC) call from the PS Helper if ENTSSO is running. ENTSSO then performs an access check. If ENTSSO is unable to access the database to obtain the adapter configuration information, then ENTSSO returns an E_ACCESSDENIED event. If ENTSSO has the adapter configuration information, but cannot currently contact the database, then ENTSSO continues to accept password change notifications and buffers the notifications locally and encrypt the notifications in a local temporary file.

InitializeAdapter also returns E_ACCESSDENIED if the adapter is deleted or disabled.

For all errors, more detailed information will be available in the Windows Event Log.

It is assumed that the adapter knows the appropriate name to use when communicating with ENTSSO.

InitializeAdapter is single-threaded. All other threads calling **InitializeAdapter** are blocked until **InitializeAdapter** has completed. It is also synchronized with the **ShutdownAdapter** method.

It is possible that the adapter process terminates before you can issue a **ShutdownAdapter**. In this case, and if ENTSSO receives another **InitializeAdapter** before ENTSSO receives a corresponding **ShutdownAdapter**, ENTSSO treats the second **ShutdownAdapter** call as a reconnect. In this case, ENTSSO cleans up and invalidates the existing event, and creates a new handle. ENTSSO also completes any pending **ReceiveNotifications** for the old event handle with a shutdown notification.

In the case of a reconnect, a new tracking ID is returned from the **InitializeAdapter**. ENTSSO returns a new tracking ID because the tracking ID returned from **InitializeAdapter** can be considered a session ID. Further, ENTSSO reissues any pending (but unconfirmed) notifications to the adapter.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSONotification Interface (COM)

ISSONotification Members

Other Resources

Programming with Enterprise Single Sign-On

ISSONotification.SendNotification Method

Sends a notification, such as a password change, from the adapter to the ENTSSO system.

Syntax
C++

```
HRESULT SendNotification(
SSendNotification SendNotification,
GUID* pguidTrackingId
);
```

Parameters
SendNotification

[in] The notification to send to ENTSSO from the adapter.

pguidTrackingId

[out] When this method returns, contains the tracking ID generated by ENTSSO. You can use the tracking ID for auditing purposes or to correlate request responses. May be NULL.

Return Value

This method returns an HRESULT indicating whether it completed correctly. For more information, see the Error Values section.

Error Values

This method returns an HRESULT containing one of the values in the following table.

Value	Description
S_OK	The method was successful.
E_ACCESSDENIED	Access is denied.
ENTSSO_E_NO_SERVER	Could not contact the ENTSSO server. Check that the ENTSSO service is running.
ENTSSO_E_WRONG_STATE	This method has been called in the wrong state.
ENTSSO_E_INVALID_NOTIFICATION	Invalid notification type.

Remarks

You can use **SendNotification** to send password changes and other notifications to the ENTSSO system.

If **SendNotification** returns S_OK, this does not mean that a password change was completed on the destination system. Instead, receiving an S_OK means ENTSSO has accepted and eventually will complete your request.

A password change from an external system can have several consequences:

- If a partial password sync is configured, then the SSO database might be updated, if a current mapping exists for the external account.
- If a full password sync is configured, then the password change might also be made to a Windows account.

If the external account has no current mapping in the SSO database, the password change might have no effect.

The password change complete notification is issued when the password change is considered complete from the ENTSSO point-of-view, which as discussed above, could mean different things. In some cases, it could mean no change was done, that only the SSO database was updated, or that the Windows password was changed.

Note that password change complete notifications sent back to the adapter are not completely reliable. Under some error conditions, Single Sign-On may never actually receives the requested notifications.

In ENTSSO, the definition of credentials, such as those sent by **SendNotification** for password updates, is more flexible than a simple password. When you define an SSO application, you also define the credential fields. The fields identify the labels to use for the UI fields, and whether those fields are masked or not. In addition, there is also a special flage which specifies whether the field should be synchronized or not. Field 0 is a special case and defines the label for the user ID. For more information, see the ISSOAdmin Interface.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

Other Resources

Programming with Enterprise Single Sign-On

ISSONotification.ReceiveNotification Method

Receives a notification from the ENTSSO system, such as password changes.

Syntax
C++

```
HRESULT ReceiveNotification(
ULONG ulNotificationFlagsIn,
SReceiveNotification* pReceiveNotification,
GUID* pguidTrackingId
);
```

Parameters
bstrAdapterName

[in] The unique adapter name.

ulNotificationFlagsIn

[in] The notification flags to control this notification, from the SSO_NOTIFICATION_FLAG enumeration.

pReceiveNotification

[in] Pointer for the received notification.

pguidTrackingId

[out] The tracking ID. The ENTSSO system will generate a tracking ID and return it to the caller. The tracking ID is used for auditing purposes and can also be used by the adapter to correlate responses to requests. This parameter can be NULL if the tracking ID is not required by the adapter.

Return Value

This method returns an HRESULT indicating whether it completed correctly. For more information, see the Error Values section.

Error Values

This method returns an HRESULT containing one of the values in the following table.

Value	Description
S_OK	The method was successful.
E_ACCESSDENIED	Access is denied.
ENTSSO_E_NO_SERVER	Could not contact the ENTSSO server. Check that the ENTSSO service is running.
ENTSSO_E_NO_NOTIFICATIONS	There are no notifications to be received.
ENTSSO_E_WRONG_STATE	This method has been called in the wrong state.

Remarks

You can use **ReceiveNotification** to receive both password changes and other notifications from the ENTSSO system.

You may call **ReceiveNotification** with or without a WAIT flag. If you specify the WAIT flag, **ReceiveNotification** blocks until a notification is available. Doing so enables you to determine if you want to dedicate a thread for receiving notifications from the ENTSSO service, or whether you want to use the event handle returned from **InitializeAdapter** to perform your own waits, shared with other events.

If **ReceiveNotification** is waiting when you call ShutdownAdapter, then **ReceiveNotification** returns a SHUTDOWN notification as the last notification. The SHUTDOWN notification preempts any other pending notifications.

It is possible that multiple threads could be calling **ReceiveNotification** for the same adapter name. In this case, the request is single-threaded at the ENTSSO service, and only one **ReceiveNotification** completes with valid information. The threads

complete with either the next notification or NONE. The reason is that each of these threads waits for the same event.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

See Also

Concepts

ISSONotification Interface (COM)

ISSONotification Members

Other Resources

Programming with Enterprise Single Sign-On

ISSONotification.ShutdownAdapter Method

Indicates that the password sync adapter is shutting down.

Syntax
C++

```
HRESULT ShutDownAdapter(
GUID* pguidTrackingId
);
```

Parameters
pguidTrackingId

[out] When this method returns, contains the tracking ID. The tracking ID is the same tracking ID that ENTSSO returns in the initialization process, which you can use for auditing purposes. May be NULL.

Return Value

This method returns an HRESULT indicating whether it completed correctly. For more information, see the Error Values section.

Error Values

This method returns an HRESULT containing one of the values in the following table.

Value	Description
S_OK	The shutdown was successful.
E_ACCESSDENIED	Access is denied.
ENTSSO_E_NO_SERVER	Could not contact the ENTSSO server. Check that the ENTSSO service is running.
ENTSSO_E_WRONG_STATE	This method has been called in the wrong state.

Remarks

ShutdownAdapter should be the last method you call. You may call neither SendNotification nor ReceiveNotification after you call **ShutdownAdapter.** The only method you may call afterward is InitializeAdapter, which initializes a new session.

Calls to **SendNotification** or **ReceiveNotification** that are in progress (on other threads) when you call **ShutdownAdapter** may receive ENTSSO_E_WRONG_STATE, although one thread calling **ReceiveNotification** receives the SHUTDOWN_COMPLETE notification.

ShutdownAdapter is single-threaded. ENTSSO blocks all other threads calling **ShutdownAdapter** until **ShutdownAdapter** has completed. **ShutdownAdapter** is also synchronized with the **InitializeAdapter** method.

ISSOTicket.IssueTicket Method

The **IssueTicket** method issues an Enterprise Single Sign-On (SSO) server ticket for authenticating a user on an application.

Syntax
C++

```
HRESULT IssueTicket(
LONG lFlags,
BSTR* pbstrTicket
);
```

Parameters
lFlags

[in] This parameter is ignored in the current release.

lFlags

[in] This parameter is ignored in the current release.

pbstrTicket

[out] Pointer to a string that receives the ticket. This is a Base64-encoded value for use in XML documents.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Error Values

This method returns an HRESULT containing one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Remarks

To access this method, you must be an Application User. You can only issue a ticket for yourself.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

Programming with Enterprise Single Sign-On

ISSOTicket.RedeemTicket Method

The **RedeemTicket** method redeems an Enterprise Single Sign-On (SSO) server ticket that was previously issued with the **IssueTicket** method.

Syntax

C++

```
HRESULT RedeemTicket(
BSTR bstrApplicationName,
BSTR bstrTicket,
LONG lFlags,
BSTR* pbstrExternalUserName,
SAFEARRAY BSTR
);
```

Parameters

bstrApplicationName

[in] String that specifies the application name. This parameter cannot be NULL, an empty string, or contain spaces. Application names are not case-sensitive, but case will be preserved. For example, ABC, abc, and AbC are considered to be the same application.

bstrTicket

[in] String that specifies the ticket value obtained from the **IssueTicket** method.

lFlags

[in] Long integer that specifies the flags to set. Use the flag SSO_FLAG_REFRESH to indicate that the credential cache should be bypassed.

pbstrExternalUserName

[out] Pointer to a string that receives the external user name associated with the ticket.

BSTR

[out] String that receives the external credentials associated with the ticket. If there are no credentials, the size of the returned array is zero.

Return Value

This method returns an HRESULT indicating whether it completed successfully. For more details, see the Error Values section.

Error Values

This method returns an HRESULT containing one of the values in the following table.

Value	Description
S_OK	The method succeeded.
E_ACCESSDENIED	Access is denied to the caller.
E_INVALIDARG	An invalid parameter was detected.

Remarks

Because the credentials are returned in plain text by this method, the caller should be careful to clear (overwrite) them as soon as possible after use.

To access this method, you must be an SSO Administrator, SSO Affiliate Administrator, or an Application Administrator.

Requirements

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

ISSOPSWrapper Interface (COM)

The ISSOPSWrapper interface allows developers to create password sync adapters in either managed or native code.

Requirements

Type Library: SSOPSHelper 1.0 Type Library (SSOPSHelper.dll)

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

Remarks

ISSOPSWrapper implements the same methods as ISSONotification but does not use structures.

Other Resources

Programming with Enterprise Single Sign-On

ISSOPSWrapper Members

The following table shows the ISSOPSWraper members.

Public Methods

ISSOWrapper.InitializeAdapter Method

Initializes the adapter.

ISSOWrapper.ReceiveNotification Method

Receives a notification to the adapter from the ENTSSO service.

ISSOWrapper.SendNotification Method

Sends a notification from the adapter to the ENTSSO service.

ISSOWrapper.ShutdownAdapter Method

Indicates to the ENTSSO service that the adapter is shutting down.

ISSOWrapper Methods

The following table describes the ISSOWrapper methods.

Public Methods

ISSOWrapper.InitializeAdapter Method

Initializes the adapter.

ISSOWrapper.ReceiveNotification Method

Receives a notification to the adapter from the ENTSSO service.

ISSOWrapper.SendNotification Method

Sends a notification from the adapter to the ENTSSO service.

ISSOWrapper.ShutdownAdapter Method

Indicates to the ENTSSO service that the adapter is shutting down.

ISSOWrapper.InitializeAdapter Method

Initializes the password sync adapter to the ENTSSO system.

Syntax
C++

```
HRESULT InitializeAdapter(
BSTR bstrAdapterName,
ULONG ulFlags,
ULONGLONG* phNotifyEvent,
GUID* pguidTrackingId
);
```

Parameters
bstrAdapterName

The unique adapter name.

ulFlags

A bitwise combination of the SSO_NOTIFICATION_FLAG values.

phNotifyEvent

When this method returns, contains an event handle created by PS Helper. You should cast the return value to a HANDLE on return, as MIDL does not support the HANDLE data type. This parameter can be NULL if the event handle is not required by the adapter.

pguidTrackingId

When this method returns, contains the tracking ID generated by ENTSSO. The tracking ID is used for auditing purposes. This parameter can be NULL if the tracking ID is not required by the adapter.

Return Value

This method returns an HRESULT indicating whether it completed correctly. For more information, see the Exceptions section.

Exceptions

This method returns an HRESULT containing one of the values in the following table.

Value	Description
S_OK	The initialization was successful.
S_FALSE	The initialization was successful, but was a reconnect. For more information, see the Remarks section.
E_ACCESSDENIED	Access is denied.
ENTSSO_E_NO_SERVER	Could not contact the ENTSSO server. Check that the ENTSSO service is running.

Remarks

InitializeAdapter acts in the same way as the ISSONotification.InitializeAdapter Method.

ISSOWrapper.SendNotification Method

Sends a notification from the adapter to the ENTSSO service.

Syntax
C++

```
HRESULT SendNotification(
ULONG ulNotificationType,
ULONG ulNotificationFlags,
Guid guidTrackingIdIn,
bstr bstrExternalAccount,
bstr bstrNewExternalPassword,
bstr bstrOldExternalPassword,
ulonglong ullTimestamp,
ulonglong ullErrorCode,
bstr bstrErrorMessage,
out Guid *pguidTrackingIdOut
);
```

Parameters

Parameter	Description
ulNotificationType	Notification type.
ulNotificationFlags	Notification flags.
guidTrackingIdIn	The tracking id of the password change to be confirmed.
bstrExternalAccount	The external account for which the password has changed.
bstrNewExternalPassword	The new password for the external account.
bstrOldExternalPassword	Optional. The old password for the external account.
ullTimestamp	The timestamp when the password change was made, or zero to use the current time.
ullErrorCode	If non-zero, the external password change failed. errorCode will be written to the event log. Zero for successful external password changes.
bstrErrorMessage	Optional. The message to write to the event log if the password change failed.
pguidTrackingIdOut	Optional. On return, contains a pointer to a GUID to receive the tracking id.

Property Value/Return Value
E_ACCESS_DENIED

Access is denied.

Exceptions

Remarks

SendNotification uses different parameters depending on the notificationType. The following table describes the necessary parameters for each type of notification.

notificationType	Parameters

SSO_NOTIFICATION_TYPE_PASSWORD_CHANGE	externalAccount newExternalPassword oldExternalPassword timestamp
SSO_NOTIFICATION_TYPE_PASSWORD_CHANGE_COMPLETE	trackingIdIn errorCode errorMessage
SSO_NOTIFICATION_TYPE_STATUS_OFFLINE	errorCode errorMessage
SSO_NOTIFICATION_TYPE_PASSWORD_EXPIRED	externalAccount
SSO_NOTIFICATION_TYPE_STATUS_REQUEST	None
SSO_NOTIFICATION_TYPE_STATUS_ONLINE	None

Requirements

ISSOWrapper.ReceiveNotification Method

Receives a notification to the adapter from the ENTSSO service.

Syntax
C++

```
void ReceiveNotification(
ULONG ulNotificationFlagsIn,
GUID guidTrackingIdIn,
out ULONG *pulNotificationType,
out ULONG *pulNotificationFlagsOut,
out BSTR *pbstrExternalAccount,
out BSTR *pbstrNewExternalPassword,
out BSTR *pbstrOldExternalPassword,
out ULONGLONG *pullTimestamp,
out ULONGLONG *pullErrorCode,
out BSTR *pbstrErrorMessage,
out SAFEARRAY(BSTR) *ppsaAdapters,
out BSTR *pbstrAdapterName,
out GUID *pguidTrackingIdOut
);
```

Parameters

Parameter	Description
ulNotificationFlagsIn	The notification flags. Specify SSO_NOTIFICATION_FLAG_WAIT if you want your call to block waiting for a notification, or SSO_NOTIFICATION_FLAG_NONE.
guidTrackingIdIn	The tracking ID.
pulNnotificationType	On return, contains a pointer to a ULONG that will receive the notification type.
pulNotificationFlagsOut	On return, contains a pointer to a ULONG that will receive the notification flags
pbstrExternalAccount	On return, contains the external account for which the password should be changed.
newExternalPassword	On return, contains the new password for the external account.
pbstrOldExternalPassword	Optional. On return, contains the old password for the external account.
pullTimestamp	On return, contains the timestamp when the password change was made.
pullErrorCode	On return, contains the error code.
pbstrErrorMessage	On return, contains an error message.
ppsaAdapters	On return, contains an array of adapter names.
pbstrAdapterName	On return, contains the adapter name.

pbuidTrackingIdOut	On return, contains the tracking ID.

Return Value

This method returns an HRESULT indicating whether it completed correctly. For more information, see the Exceptions section.

Exceptions

E_ACCESS_DENIED

Access is denied.

Remarks

ReceiveNotification uses different parameters to return information depending on the notificationType. The following table describes the relationship between the different parameters and types of notifications.

notificationType	**Parameters**
SSO_NOTIFICATION_TYPE_PASSWORD_CHANGE	externalAccount newExternalPassword oldExternalPassword timestamp
SSO_NOTIFICATION_TYPE_PASSWORD_CHANGE_COMPLETE	trackingIdIn errorCode errorMessage
SSO_NOTIFICATION_TYPE_STATUS_OFFLINE	errorCode errorMessage
SSO_NOTIFICATION_TYPE_PASSWORD_EXPIRED	externalAccount
SSO_NOTIFICATION_TYPE_STATUS_REQUEST	None
SSO_NOTIFICATION_TYPE_STATUS_ONLINE	None

ISSOWrapper.ShutdownAdapter Method

Indicates to the ENTSSO service that the adapter is shutting down.

Syntax
C++

```
HRESULT ShutDownAdapter(
GUID* pguidTrackingId
);
```

Parameters

Parameter	Description
pguidtrackingId	When this method returns, contains the tracking ID. The tracking ID is the same tracking ID that ENTSSO returns in the initialization process, which you can use for auditing purposes. May be NULL.

Return Value

This method returns an HRESULT indicating whether it completed correctly. For more information, see the Error Values section.

Exceptions

This method returns an HRESULT containing one of the values in the following table.

Value	Description
S_OK	The shutdown was successful.
E_ACCESSDENIED	Access is denied.
ENTSSO_E_NO_SERVER	Could not contact the ENTSSO server. Check that the ENTSSO service is running.
ENTSSO_E_WRONG_STATE	This method has been called in the wrong state.

Remarks

Example

This is the description for a Code Example.

Optional comments.

SSO_NOTIFICATION_TYPE Enumeration (COM)

Specifies the different notification types used for Enterprise Single Sign-On (SSO).

Syntax

VB

```
<Serializable>
Public Enum SSO_NOTIFICATION_FLAG
```

C#

```
[Serializable]
public enum SSO_NOTIFICATION_FLAG
```

C++

```
[Serializable]
__value public enum SSO_NOTIFICATION_FLAG
```

JScript

```
            public
   Serializable
enum SSO_NOTIFICATION_FLAG
```

Members

Member Name	Value	Direction	Description
SSO_NOTIFICATION_TYPE_NONE	0x00000000	ENTSSO to adapter	No notifications are pending. This notification type is supported by group adapters. It is not necessary to confirm this notification.
SSO_NOTIFICATION_TYPE_SHUTDOWN	0x00000001	ENTSSO to adapter	The ENTSSO service requires the adapter to shutdown. The adapter should respond by calling ISSONotification.ShutdownAdapter Method. This notification type is supported by group adapters. It indicates that the group adapter only should shut down. Each individual adapter that is part of the adapter group gets its own SHUTDOWN notification. It is not necessary to confirm this notification.

SSO_NOTIFICATION_TYPE_SHUTDOWN_COMPLETE	0x00000002	ENTSSO to adapter	The ENTSSO service has processed the **ShutdownAdapter** method. This is the last notification that is received by the adapter using the current event handle. This notification type is supported by group adapters. It is not necessary to confirm this notification.
SSO_NOTIFICATION_TYPE_PASSWORD_CHANGE	0x00000003	Both	A password has changed. When sending a password change from an adapter to ENTSSO, the password change is considered to be accepted, and durable, on return from the notification to ENTSSO through SendNotification. That does not indicate that the password change is complete, but rather that it has been accepted, is durable, and is likely to be accomplished. Under some error conditions queues could fill up, in which case older password changes could be discarded. In general, you should perform more recent password changes than older ones. An adapter should make password changes received through ReceiveNotification, The adapter should make that change durable or effect the change immediately. The adapter should then call **SendNotification** with PASSWORD_CHANGE_COMPLETE for that password change to delete it from the database queue. This notification type is not supported by group adapters. An adapter must confirm this notification. It is optional for ENTSSO to confirm this notification.
SSO_NOTIFICATION_TYPE_PASSWORD_CHANGE_COMPLETE	0x00000004	Both	The ENTSSO service completed the password change. Note that the definition of complete may vary depending on what is configured. For more information, see the Remarks section of ReceiveNotification. You can use the tracking ID to correlate the original request with the response. This notification type is not supported by group adapters. It is not necessary to confirm this notification.
SSO_NOTIFICATION_TYPE_PASSWORD_EXPIRED	0x00000005	Both	The password for an account has expired. For ENTSSO, this causes the stored password for this account to be flagged as **expired**. This notification type is not supported by group adapters. It is necessary for an adapter to confirm this notification. It is optional for ENTSSO to confirm this notification. Note that this notification is currently not implemented. ENTSSO will ignore any SSO_NOTIFICATION_TYPE_PASSWORD_EXPIRE messages, and will never send a message of this type to an adapter.
SSO_NOTIFICATION_TYPE_STATUS_REQUEST	0x00000006	Both	An inquiry regarding the status of the adapter or ENTSSO service, or as a response. If the ENTSSO service detects that a password sync adapter has not sent any password changes for some time, it may send a STATUS notification to that adapter as a "keep alive". The adapter should respond with a STATUS_ONLINE or STATUS_OFFLINE notification. This notification type is supported by group adapters. It applies only for the status of the group adapter, not for the adapters within the adapter group. It is not necessary to confirm this notification.

SSO_NOTIFICATION_TYPE_STATUS_ONLINE	0x00000007	Both	The status of an adapter or ENTSSO service is online. If the ENTSSO service detects that a password sync adapter has not sent any password changes for some time, it may send a STATUS notification to that adapter as a "keep alive". If online, the adapter should respond with a STATUS_ONLINE. If the adapter detects that it is offline, it can send these notifications unsolicited. This notification type is supported by group adapters. It applies only for the status of the group adapter, not for the adapters within the adapter group. It is not necessary to confirm this notification.
SSO_NOTIFICATION_TYPE_STATUS_OFFLINE	0x00000008	Both	The adapter or ENTSSO service is offline. If the ENTSSO service detects that a password sync adapter has not sent any password changes for some time, it may send a STATUS notification to that adapter as a "keep alive". If your adapter is offline, it should respond with a STATUS_OFFLINE notification. If the adapter detects that it is offline, it can send these notifications unsolicited. This notification type is supported by group adapters. It applies only for the status of the group adapter, not for the adapters within the adapter group. It is not necessary to confirm this notification.
SSO_NOTIFICATION_TYPE_ADAPTERS_IN_GROUP	0x00010000	ENTSSO to adapter	An adapter is contained within a specified adapter group. It is one of the first notifications received by a group adapter after initialization. The adapter names are contained within the "new external credentials array" parameter. If there are a very large number of adapters in this adapter group, it is possible that this notification is received by the group adapter more than once with the remaining adapter names. This notification type is only issued to group adapters. It is not necessary to confirm this notification.
SSO_NOTIFICATION_TYPE_ADD_ADAPTER	0x00010001	ENTSSO to adapter	An adapter has been added to the adapter group. The adapter name that has been added is contained within the "notification string" parameter. This notification type is only issued to group adapters. It is not necessary to confirm this notification.
SSO_NOTIFICATION_TYPE_DELETE_ADAPTER	0x00010002	ENTSSO to adapter	An adapter has been deleted from the adapter group. The adapter name that has been deleted is contained within the "notification string" parameter. This notification type is only issued to group adapters. It is not necessary to confirm this notification.

Remarks

There is no online or offline notification for adapters to the group adapter. This is because control of the individual adapters is handled by each adapter itself.

In general, the notifications that require confirmation are those that are durable in the database queue. The other notifications are control and status information which are transient. Notifications that require confirmation have one of the confirm flags set.

There is no notification to or from the adapter about enabled or disabled status. This is because the enable and disable is handled by the enable and disable of the underlying configuration store application. Thus, when the adapter is disabled by an administrator, the adapter receives access denied messages from all calls to ENTSSO.

Requirements

Type Library: SSOLookup 1.0 Type Library (SSOLookup.dll)

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

See Also

Programming with Enterprise Single Sign-On

SSO_NOTIFICATION_FLAG Enumeration (COM)

Specifies the different types of flags used for Enterprise Single Sign-On (SSO).

Syntax

VB

```
<Serializable>
Public Enum SSO_NOTIFICATION_FLAG
```

C#

```
[Serializable]
public enum SSO_NOTIFICATION_FLAG
```

C++

```
[Serializable]
__value public enum SSO_NOTIFICATION_FLAG
```

JScript

```
            public
   Serializable
enum SSO_NOTIFICATION_FLAG
```

Remarks

The following table describes the possible values for the notification flags.

Members

Member Name	Value	Direction	Description
SSO_NOTIFICATION_FLAG_NONE	0x00000000	Both	Null value.
SSO_NOTIFICATION_FLAG_ADMIN_CHANGE	0x00000001	Both	The password change was a result of an administrator action. Some systems will be able to distinguish between an administrator action, while some will not. ENTSSO will not set this flag. This flag is currently not used.
SSO_NOTIFICATION_FLAG_TEST	0x00000008	Both	The current notification is a test request. Your adapter can safely ignore this notification. You can use this notification for testing and diagnostics purposes. This flag is currently not used.
SSO_NOTIFICATION_FLAG_AUDIT	0x00000010	Both	The current request requires auditing. This flag is currently not used.

SSO_NOTIFICATION_FLAG_WINDOWS	0x00000020	Not applicable	Reserved for internal use.
SSO_NOTIFICATION_FLAG_WAIT	0x00000040	Adapter to ENTSSO	**ReceiveNotification** should block and wait until a notification is available. Best practice indicates you should set this flag and allow the PS Helper to wait for notifications.
SSO_NOTIFICATION_FLAG_SEND_ONLY	0x00000080	Adapter to ENTSSO	Indicates that this PS Helper should initialize for sending only. It assumes that another PS Helper will be initialized normally. You should use this flag when using one PS Helper for ReceiveNotification (for receiving password changes), and another fro SendNotification (for sending password changes).

Requirements

Type Library: SSOPSHelper 1.0 Type Library (SSOPSHelper.dll)

Platforms: Windows XP Professional, Windows Vista, Windows Server 2003, Windows Server 2008

Enterprise Single Sign-On Flags

The following flags are used with the Microsoft® Host Integration Server Enterprise Single Sign-On (SSO) methods.

Common flags

Member name	Value
SSO_FLAG_NONE	0x00000000
SSO_FLAG_REFRESH	0x00000001
SSO_FLAG_ENABLED	0x00000002
SSO_FLAG_RUNTIME	0x00000004
SSO_FLAG_SSO_EXTERNAL_TO_WINDOWS	0x00000008
SSO_FLAG_SSO_VERIFY_EXTERNAL_CREDS	0x00000010
SSO_FLAG_ALLOW_TICKETS	0x00000020
SSO_FLAG_VALIDATE_TICKETS	0x00000040
SSO_FLAG_ADMIN_ENABLED	0x80
SSO_FLAG_READ_MODIFY_WRITE	0x100
SSO_FLAG_REPLAY	0x100

Password synchronization flags

Member name	Value
SSO_FLAG_PARTIAL_SYNC_FROM_WINDOWS_TO_DB	0x00000100
SSO_FLAG_PARTIAL_SYNC_FROM_EXTERNAL_TO_DB	0x00000200
SSO_FLAG_FULL_SYNC_FROM_WINDOWS_TO_EXTERNAL	0x00000400
SSO_FLAG_FULL_SYNC_FROM_EXTERNAL_TO_WINDOWS	0x00000800
SSO_FLAG_SYNC_VERIFY_EXTERNAL_CREDS	0x00001000

Samples

Host Applications Samples

The HostApplications sample demonstrates the BizTalk Adapter for Host Applications.

Location in SDK

<installation directory>\Program Files\Microsoft Host Integration Server\SDK\Samples\Adapter\HostApplications

File Inventory

The following table shows the files in the sample and describes their purpose.

File(s)	Description
In the root directory	Contains detailed setup, configuration, deployment, and execution instructions.
In the \BtsMsiFiles directory	BizTalk Server installation files.
In the \CICSPrograms directory	The cobol files for the sample application.
In the \Documents directory	Contains the XML documents used by BizTalk.
In the \FiledropApplication directory	The Visual Studio files for creating a file drop application.
In the \HTTPApplication directory	The Visual Studio files for creating an http application.
In the \InputDocuments directory	The directory to drop input documents for the sample application.
In the \OutputDocuments directory	The directory for the application to drop documents to.
In the \TIConfiguration directory	Contains components used to configure TI.

Pipeline Component Sample

The Pipeline component sample describes the three components necessary to put messages into an MQSeries queue with the MQRFH2 header: a pipeline component project, a pipeline project that makes use of the pipeline component, and a test application that puts messages into the queue.

Location in the SDK

<Installation directory>\SDK\Samples\Adapters\MQSC\MQRFH2Sample

File Inventory

The following table shows the files in the sample and describes their purpose.

File(s)	Description
In the / BizTalk ServerMQRFH 2Pipeline folde r	Describes the BizTalk pipeline project that contains both receive and send pipeline.
In the / MQRF H2PipelineCo mponent folde r	Contains the pipeline component that reads MQRFH2 properties from the MQSeries message and promotes it into BizTalk context properties in the receive scenario. Similarly, on the send side, the component can set these MQRFH2 properties in the MQSeries message based on values provided through the context properties..
In the MQRFH 2TestDriver fol der	Contains an application that can send MQSeries messages to an MQSeries queue with the MQRFH2 header.

How to Use the Sample

Use the following instructions to build, deploy, configure, and run the sample.

To build and deploy the sample

1. Open MQRFH2TestDriver.cpp and specify the correct channelName, connectionName, qmgrName and qName to correct values that match what you have configured in your WebSphere MQ Server configuration.
2. Save the file.
3. Run <InstallPath>\SDK\Samples\Adapters\MQSC\MQRFH2Sample\setup.bat to build the projects and deploy the pipeline component and pipeline project in BizTalk.

To configure and run the sample

1. Create a BizTalk receive port and receive location using MQSC adapter to point to an MQ queue on a MQ Server (MQServer1\QM1\RECVQ).
2. Associate MQRFHReceivePipeline with this receive location.
3. Configure a send port using MQSC Adapter to point to an MQ queue on a MQ Server (MQServer1\QM2\SENDQ).
4. Create a subscription that uses the receive port created in step1.

   This will enable a round trip receive-send scenario between MQ->BizTalk->MQ. Associate MQRFHSendPipeline with this send port.
5. Enable the receive location and start the send port.
6. Start the host instance associated with these end-points.
7. Use MQRFH2TestDriver.exe to put an MQSeries message to MQServer1\QM1\RECVQ.
8. Check the MQSeries queue MQServer1\QM2\SENDQ to see the new message that was sent from BizTalk Server.

   You can view the message in MQSeries queue to see the MQRFH2 header.

MQSC Adapter Samples

BizTalk Correlation Sample

The BizTalk Correlation sample describes how to retrieve messages from an MQSeries queue and put the response messages into another MQSeries queue.

Location in the SDK

<Installation directory>\SDK\Samples\Adapters\MQSC\ MQSSolicitResponse

File Inventory

The following table shows the files in the sample and describes their purpose.

File(s)	Description
In the /MQSCorrelationSetOrchestrationWithSolicitResponse folder	The BizTalk Orchestration project that contains associations between file and MQSeries end-points along with the correlation sets.
In the / MQSSolicitResponseApp folder	The application that retrieves messages from an MQSeries queue and puts a response message to another MQSeries queue.

How to Use the Sample

Use the following procedures to build, deploy, configure, and run the sample.

To build and deploy the sample

1. On your BizTalk Server computer, open the orchestration project MQSCorrelationSetOrchestrationWithSolicitResponse\MQSCorrelationSolicitResponse.sln.
2. Open the orchestration MQSCorrelationSolicitResponse.odx.
3. Double-click on the message assignment shape MessageAssignment_1.
4. Adjust the assignment statements for the MQMD_ReplyToQ and MQMD_ReplyToQMgr context properties to point to MQServer1\QM1\QUEUEB.
5. Save the changes to this orchestration.
6. Run MQSCorrelationSetOrchestrationWithSolicitResponse\Setup.bat to build and deploy the orchestration to BizTalk.
7. Run MQSSolicitResponseApp\Setup.bat to build the test application.

To configure and run the sample

1. Create a solicit-response send port, point it at MQServer1\QM1\QUEUEA
2. Create a receive port and a receive location, point it at MQServer1\QM1\QUEUEB
3. Bind the orchestration you deployed earlier to the solicit-response send port and receive port.
4. Create three folders: c:\temp\pickup2, c:\temp\moveit, and c:\temp\dropit2
5. Start the receive locations, send ports and the orchestration.
6. Put an XML file in the pickup2 folder.

   For example, <test>This is a test</test>.
7. Observe the file disappear as it is picked up by BizTalk.
8. Observe the message arrive in MQServer1\QM1\QUEUEA.
9. Observe the MQSeries response message arrive in c:\temp\moveit.

   This message will be an XML file describing the message ID and correlation ID the MQSeries server assigned to the message.
10. Observe that there is one active orchestration instance in the BizTalk Administration Console.

    This is the long-running orchestration waiting for a message to correlate with the message that it already received.

11. Use the test application MQSSolicitResponseApp to read the message BizTalk sent and send a response message.

    You may also use the command line parameters to receive the message from MQServer1\QM1\QUEUEA.

12. Observe a message arrive in c:\temp\dropit2.

    This message is the response message from the test application.

CICS Sample

The CICS sample describes how to compile and access the Woodgrove Bank CICS using host-initiated processing.

Location in SDK

<installation directory>:\Program Files\Microsoft Host Integration Server\SDK\Samples\ApplicationIntegration\HostInitiated\CICS

File Inventory

The following table shows the files in the sample and describes their purpose.

File(s)	Description
In the /CICSBanking folder CICSBanking.csproj CICSBanking.sln CICSBanking.suo CICSBankingExceptions.cs Class1.cs Readme-01-VTAM-LU0-LU2-Setup.txt Readme-02-CICS-LU0-LU2-Setup.txt Readme-06-Configure-HIS.txt ReadMeSNA.txt REadMeTCPIP.txt	The files that contain the sample application. The readme files describe the different setup and support files necessary for the various configurations.
In the /CICSBanking/Properties folder AssemblyInfo.cs	Contains the assembly information for the sample application.

In the /CICSBanking/TIClientDefs folder MSHIPLNK.cbl MSHIPLNK.lkd TIClientDefs.tiproj WBCLKNPS.cbl WBCLKNPS.lkd WBCLKNPT.cbl WBCLNKNPT.lkd WBCUDPCS.cbl WBCUBPCS.lkd WBCUDPCT.cbl WBCUDPCT.lkd wgbmaps.bms wgmaps.lkd	Contains the files that describe the programs, transitions, and maps for the host application.
In the /CICSBanking/TIServerDefs CICSBanking.DLL CICSBanking.TIM TIServerDefs.tiproj	Contains the support files that describe the remote host application to the sample application.

OS400 Sample

The OS400 sample describes how to verify an installation of an application on a remote host.

Location in SDK

<installation directory>:\Program Files\Microsoft Host Integration Server\SDK\Samples\ApplicationIntegration\HostInt\OS400

File Inventory

The following table shows the files in the sample and describes their purpose.

File(s)	Description
In the /OS400/OS400Banking folder Class1.cs OS400Banking.csproj OS400Banking.sln OS400Banking.suo OS400BankingException.cs ReadMeTCPIP.txt	The files that contain the sample application. The readme files describe the different setup and support files necessary for the various configurations.
In the /OS400Banking/Properties folder AssemblyInfo.cs	Contains the assembly information for the sample application.
In the /OS400/TIClientDefs folder Mshiplnk.rpg qrpglesrc_ernno_h.txt qrpglesrc_socket_h.txt qrpglesrc_socketutil_h.txt qrpglesrc_socketutilr4.txt TIClientDefs.tiproj wbclknpt.rpg wgbmaps.scr	Contains the files that describe the remote host application.
In the /OS400/TIServerDefs folder OS400Banking.DLL OS400Banking.TIM TIServerDefs.tiproj	Contains the support files that describe the remote host application to the sample application.

Windows-Initiated Processing Samples

Bounded Recordsets Sample

The Bounded Recordsets sample demonstrates how to use Transaction Integrator (TI) with Microsoft Visual Basic bounded recordsets. This sample includes Visual Basic code and Customer Information Control System (CICS) COBOL code showing how to use bounded recordsets by calling into a CICS transaction program through LU 6.2 (Remote Environment CICS using LU 6.2).

Location in SDK

<Installation directory>\Program Files\Microsoft Host Integration Server\SDK\Samples\ApplicationIntegration\WindowsInitiated\BoundedRecordsets\

File Inventory

The following table shows the files in this sample and describes their purpose.

File(s)	Description
In the \BoundedRecordsets\COBOL-CICS folder RecordSetSample.cbl RecordSetSample.tlb	A TI type library (.tlb file) that can be used with this sample. The type library is set up for accessing a transaction named GETI on the host. This folder also contains sample COBOL code that can be compiled and linked on the mainframe side. The compiled code should be set up to run on the host as a transaction named GETI or the TI type library must be changed to reflect the name of the transaction if it is different.
In the \BoundedRecordsets\VB folder RecordSetSample.bas RecordSetSample.exe RecordSetSample.vbp RecordSetSample.vbw	A Visual Basic class file that illustrates the use of bounded recordsets. Note that additional Visual Basic code would need to be written to use this Visual Basic class file in a project. The code in the class file demonstrates how to create a recordset and populate it with data to send to the mainframe. Note that there is no code that actually displays the data that comes back from the mainframe. You can put in a breakpoint in the Visual Basic code using the debugger and use the immediate window to view the data or insert further code to examine the data that is returned.

Host Integration Server Designer Discriminated Union Tutorials

In This Section

Tutorial 1: Creating a Project that Uses Discriminated Unions

This tutorial provides a simple walkthrough on how to build a project that uses discriminated unions. This tutorial also sets up environmental parameters that you can use in the second tutorial.

In This Section

Import the Discriminated Union Tutorial into TI Manager

To follow the steps in Tutorial 1: Creating a Project that Uses Discriminated Unions, first, you must import the files necessary to run the tutorial.

To import the discriminated union tutorial

1. In TI Manager, expand the **Transaction Integrator** node.
2. Right-click the **Window-Initiated Processing** node, and then click **Import**.
3. On the **Welcome** page of the Import WIP Definitions Wizard, click **Next**.
4. On the **Define Import characteristics** page, confirm that the **Use Original Definitions** radio button is selected.
5. Use **Browse** to locate the TIHostApplicationDef folder, and then click **Next**.

   The TIHostApplicationDef folder contains all of the relevant files for describing the host environment for this tutorial. The folder is located in <*Installation directory*>\Program Files\Microsoft Host Integration Server\SDK\Samples\AppInt\DiscriminatedUnions\TIHostApplicationDef.
6. On the **Importing WIP Definitions** page, wait for the import to complete, and then click **Next**.
7. On the **Completing the Import WIP Definitions Wizard** page, click **Finish**.

Concepts

Start SimHost for the Discriminated Union Tutorial

Other Resources

Tutorial 1: Creating a Project that Uses Discriminated Unions

Start SimHost for the Discriminated Union Tutorial

The second step in Tutorial 1: Creating a Project that Uses Discriminated Unions turns on SimHost, which simulates a remove mainframe for the tutorial to connect to.

Procedures **To start SimHost for the discriminated union tutorial**

1. Right-click **Start**, and then click **Explore**.
2. Locate the SimHost folder.

   For this tutorial, the SimHost folder is located in <*Installation directory*>\Program Files\Microsoft Host Integration Server\System.
3. Double-click SimHost.exe.

   This starts the Microsoft Transaction Integrator Host Simulator. You can use the Host Simulator to simulate a Host Environment. For this tutorial, you will use it to act as a remote Host operating over a TCP/IP CICS connection.
4. Click **Start TCP**.

Concepts

Build and Execute the Discriminated Union Tutorial

Other Resources

Tutorial 1: Creating a Project that Uses Discriminated Unions

Build and Execute the Discriminated Union Tutorial

Finally, you can build and execute the discriminated union tutorial sample application. After you examine this application, you can create your own application in Tutorial 2: A Step-by-Step Guide to Creating a Simple Discriminated Union Application.

Procedures **To build and execute the discriminated union tutorial**

1. In Visual Studio, on the **File** menu, click **Open**, and then click **Project/Solution**.
2. In the **Open Project** dialog box, locate the folder that contains the tutorial solution file.

   For this tutorial, the tutorial solution file is located in <Installation directory>\Program Files\Microsoft Host Integration Server\SDK\Samples\AppInt\DiscriminatedUnions.
3. Click DiscriminatedUnions.sln, and then click **Open**.
4. Click **Build**, and then click **Build Solution**.
5. Click **Debug**, and then click **Start Debugging**.

   A console window appears and displays the output of the application.
6. End the debugging session by closing the console window.

Concepts
Code the C# Application for the Discriminated Union Tutorial

Code the C# Application for the Discriminated Union Tutorial

After you create the C# project to contain your code (in Create a Visual C# Project for the Discriminated Union Tutorial), you can write code for the C# application that uses the deployed interface to access the remote mainframe.

Follow these steps to write code for the application in
Tutorial 2: A Step-by-Step Guide to Creating a Simple Discriminated Union Application.

Procedure **To code the C# application for the discriminated union tutorial**

1. In Solution Explorer, expand the ConsoleApplication1 node.
2. Right-click **References**, and then click **Add Reference**.
3. In the **Add Reference** dialog box, select the **Browse** tab, and locate the DiscrUnionTutorial folder.

   For this tutorial, the DiscrUnionTutorial folder is located at <*Installation Directory*>\Program Files\Microsoft Host Integration Server\SDK\Samples\AppInt\DiscrUnionTutorial\DiscrUnionTutorial.
4. Click Banking.DLL, and then click **OK**.
5. Add the following code to your Program.cs file:

```
using System;
using System.Collections.Generic;
using System.Text;
using Banking;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            Banking.Accounts MyBankObj = new Banking.Accounts();
            Banking.ACCT_ARRAY[] accountInfoArray = new Banking.ACCT_ARRAY[2];
            Banking.SAVINGS MySavInfo = new Banking.SAVINGS();
            Banking.CHECKING MyChkInfo = new Banking.CHECKING();

            accountInfoArray[0].ACCT_NUM = "SAV1234567";
            accountInfoArray[0].ACCT_TYPE = "S";
            accountInfoArray[0].UNION1 = MySavInfo;

            accountInfoArray[1].ACCT_NUM = "CHK4566112";
            accountInfoArray[1].ACCT_TYPE = "C";
            accountInfoArray[1].UNION1 = MyChkInfo;

            MyBankObj.GetAInfo("11223333", ref accountInfoArray);

            foreach (ACCT_ARRAY aa in accountInfoArray)
            {
                switch (aa.ACCT_TYPE)
                {
                    case "C":
                        Banking.CHECKING ChkInfo = (Banking.CHECKING)aa.UNION1;
                        break;
                    case "S":
                        Banking.SAVINGS SavInfo = (Banking.SAVINGS)aa.UNION1;
                        break;
                }
            }
```

```
            }
        }
    }
```

6. On the **File** menu, click **Save All**.
7. Click **Build**, and then click **Build ConsoleApplication1**.
8. Click **Debug**, and then click **Start**.

Tutorial: Creating an RE Override

When your application uses a Transaction Integrator (TI) component, you can specify the remote environment (RE) used by the TI run-time environment. This tutorial describes how to create such an RE override, using the REOverride sample found in the Host Integration Server SDK. After you are finished with this tutorial, you will be able to:

- Set up SimHost
- Import a host application definition
- Create and deploy a host application interface
- Create an application that performs an RE override.

Compiling and Running the REOverride Sample

The following procedures describe how to compile and run the REOverride sample application. After you have run the application once, you can perform the tutorial to rebuild the sample in a step-by-step process.

To start the primary instance of SimHost for the REOverride tutorial

1. Right-click **Start**, and then click **Explore**.
2. Locate the **SimHost** folder.

   For this tutorial, the SimHost folder is located in <*Installation directory*>\Program Files\Microsoft Host Integration Server\System.
3. Double-click **SimHost.exe**.

   This starts the Microsoft Transaction Integrator Host Simulator. You can use the Host Simulator to simulate a host environment. For this tutorial, you will use it to act as a remote host operating over a TCP/IP CICS connection.
4. Click **Options**, and then click **Reset to default values**.
5. Click **Start TCP**.

To start the secondary instance of SimHost for the REOverride tutorial

1. Double-click **SimHost.exe**.
2. Click **Options**, and then click **Reset to default values**.
3. In the **TCP/IP CICS ELM** dialog box, in the **Link Port** field, enter **6511**.
4. Make sure there are no duplicate port numbers being used by the Host Simulator.
5. Click **Start TCP**.

To import the host application definitions for the REOverride tutorial

1. In TI Manager, expand the **Transaction Integrator** node.
2. Right-click the **Window-Initiated Processing** node, and then click **Import**.
3. On the **Welcome to the Import WIP Definitions Wizard** page, click **Next**.
4. On the **Define Import Characteristics** page, confirm that the **Use Original Definitions** option button is selected.
5. Use **Browse** to locate the **TIHostApplicationDef** folder, and then click **Next**.

   The TIHostApplicationDef folder contains all of the relevant files for describing the host environment for this tutorial. The folder is located in <*Installation directory*>\Program Files\Microsoft Host Integration Server\SDK\Samples\AppInt\REOverride\TIHostApplicationDef.
6. On the **Importing WIP Definitions** page, wait for the import to complete, and then click **Next**.

Note that the RE0Banking.Accounts.1 file is registered to the "SimHost ELM Link" host, and not to the "SimHost ELM Link Secondary" host.

7. On the **Completing the Import WIP Definitions Wizard** page, click **Finish**.

To build and execute the REOverride sample

1. In Visual Studio, on the **File** menu, click **Open**, and then click **Project/Solution**.
2. In the **Open Project** dialog box, locate the folder that contains the tutorial solution file.

   For this tutorial, the tutorial solution file is located in <*Installation directory*>\Program Files\Microsoft Host Integration Server\SDK\Samples\AppInt\REOverride.
3. Click **REOverride.sln**, and then click **Open**.
4. Click **Build**, and then click **Build Solution**.
5. Click **Debug**, and then click **Start Debugging**.

   A console window appears and displays the output of the application. You should see one message for the primary host simulator, and one for the secondary host simulator.
6. End the debugging session by closing the console window.

To cause the REOverride sample to fail

1. click **Stop TCP** on the secondary SimHost.
2. Build and execute the REOverride sample again.

   The call to the primary SimHost will succeed, while the call with the RE Override will fail.

A Step-by-Step Guide to the RE Override Tutorial

After you have set up and run the REOverride sample, you can go back and rebuild the solution manually by creating the TI project, adding a .NET client object, importing the host definition file, deploying the .hdf file, and then creating and coding the application.

Step 1: Create a Transaction Integrator Project

To create a new project for the RE Override tutorial

1. In Visual Studio, on the **File** menu, point to **New**, and then click **Project**.
2. In the **New Project** dialog box, in the **Project Types** pane, select **Host Integration Projects**.
3. In the **Templates** pane, select **Transaction Integrator Project**.
4. In the **Name** field, type **REOverrideTutorial**.
5. In the **Location** field, type the location where you want to save the tutorial, and then click **OK**.

   For this tutorial, the location of the project will be <*Installation directory*>\Program Files\Microsoft Host Integration Server\SDK\Samples\ApplicationIntegration.

Step 2: Add a .NET Client Object

To add a .NET client object

1. In Solution Explorer, right-click **REOverrideTutorial**, point to **Add**, and then click **Add .NET Client Library**.
2. In the **Add New Item** dialog box, confirm that **.NET Client Library** is selected in the **Templates** pane.
3. In the **Name** field, type **REOBanking**, and then click **Add**.
4. On the **.NET Client Library** page, click **Next**.
5. On the **Library** page, in the **Interface Name** field, type **GetBalance**, and then click **Next**.
6. On the **Remote Environment** page, in the **Programming Model** list, select **ELM Link**, and then click **Next**.
7. Click **Create**.

Step 3: Import the Host Definition File

To import the host definition file

1. On the menu bar in Visual Studio, click **View**, and then click **Properties Window**.
2. On the **REOBanking.dll** tab, right-click the **REOBanking** node, point to **Import**, and then click **Host Definition**.
3. On the **Welcome to the Import COBOL Wizard** page, click **Next**.
4. On the **Import COBOL Source File** page, click **Browse**, and then locate the **TIHostApplicationDef** folder.

   For this tutorial, the TIHostApplicationDef folder is located at <*Installation directory*>\Program Files\Microsoft Host Integration Server\SDK\Samples\ApplicationIntegration\REOBanking\TIHostApplicationDef.
5. Click the **GetBalance.cbl** file, click **Open**, and then click **Next**.
6. On the **Import Options** page, click **Next**.
7. On the **01 DFHCOMMAREA** page, select the check box next to the **DFHCOMMAREA** node, and then click **Next**.
8. Expand the **DFHCOMMAREA** node.
9. Click the arrows next to the **name** field, and then click **In**.
10. Click the arrows next to the **ACCNUM** field, and then click **In**.
11. Click the arrows next to the **ACCBAL** field, and then click **Out**.
12. Click **Next**.
13. On the **Data Tables, Structures and Unions** page, click **Next**.
14. On the **Completing the Import COBOL Wizard** page, click **Modify**.

Step 4: Save and Deploy the Interface

To save and deploy the GetAInfo interface

1. On the **REOBanking.dll** tab, click the **GetBalance** node.
2. In the **Properties** window, click the **Include Context Parameters** field, and then click **True** in the list.
3. On the **File** menu, click **Save All**.
4. On the **REOBanking.dll** tab, click the **REOBanking** node.
5. In the **Properties** window, click the **Remote Environment** field, and then select **SimHost using ELM Link**.
6. On the **REOBanking.dll** tab, right-click the **REOBanking** node, and then click **Deploy**.

Step 5: Create a Visual Studio Project

To create a Visual C# project for the tutorial

1. In Visual Studio, on the **File** menu, point to **Add**, and then click **New Project**.
2. In the **Add New Project** dialog box, in the **Project Types** pane, click **Visual C#**.
3. In the **Templates** pane, click **Console Application**, and then click **OK**.

Step 6: Code the Client Application

To code the C# application for the RE Override tutorial

1. In Solution Explorer, expand the **ConsoleApplication1** node.
2. Right-click **References**, and then click **Add Reference**.
3. In the **Add Reference** dialog box, click the **Browse** tab, and locate the **REOverride** folder.

   For this tutorial, the REOverride folder is located at <*Installation directory*>\Program Files\Microsoft Host Integration Server\SDK\Samples\ApplicationIntegration\WindowsInitiated\REOverride.
4. Click **REOBanking.dll**, and then click **OK**.
5. Add the following code to your Program.cs file:

```
using System;
using System.Collections.Generic;
using System.Text;
using Microsoft.HostIntegration.TI;
using REOBanking;

namespace REOverride
{
    class Program
    {
        static void Main(string[] args)
        {
            object[] contextArray = null;
            decimal Balance = 0.0m;
            ClientContext TIClientContext = new ClientContext();
            REOBanking.Accounts MyBankObj = new REOBanking.Accounts();
            try
            {
                MyBankObj.GetBalance("Kim Akers", "123456", out Balance, ref contextAr
ray);
                Console.WriteLine("Account balance from the primary RE {0,9:C2}\n", Ba
lance);
                TIClientContext.WriteContext("REOverride", "SimHost ELM Link Secondary
", ref contextArray);
                MyBankObj.GetBalance("Kim Akers", "123456", out Balance, ref contextAr
ray);
                Console.WriteLine("Account balance from the Secondary RE {0,9:C2}\n",
Balance);
            }

            catch (Microsoft.HostIntegration.TI.CustomTIException Ex)
            {
                Console.WriteLine("Exception: TI Runtime Error {0}", Ex.Message);
            }
            catch (Exception Ex)
            {
                Console.WriteLine("Exception: {0}", Ex.Message);
                if (Ex.Message.StartsWith("ClassFactory cannot supply requested class"
, StringComparison.CurrentCultureIgnoreCase))
                {
                    Console.WriteLine("Error: REOBanking object could not be created.
Use TI Manager to ensure it is registered");
                }
            }

            Console.WriteLine("\nPress any key to continue...");
            Console.Read();
        }
    }
```

6. }On the **File** menu, click **Save All**.
7. Click **Build**, and then click **Build ConsoleApplication1**.
8. Click **Debug**, and then click **Start**.

SampleMainframeCode Sample

The SampleMainframeCode sample contains sample code for a variety of mainframe environments.

Location in SDK

Samples

Sample Programs for MSMQ-MQSeries Bridge

The source code for several sample programs that illustrate using MSMQ-MQSeries Bridge are included in the Host Integration Server 2009 SDK. These files are copied to your hard drive during Host Integration Server software or Host Integration Client software installation when the Host Integration Server Software Development Kit option is selected. These samples are installed in the Samples\AppInt\Bridge subdirectory below where the Host Integration Server SDK software is installed (C:\Program Files\Microsoft Host Integration Server\SDK, by default).

These sample programs include the files in the subdirectories listed in the following table.

Subdirectory	Description
EPRecv	EPRecv Sample A sample program in C that uses the MSMQ-MQSeries Bridge Extensions API to display the MQMD structure in the Message Queuing (also known as MSMQ) extension property.
EPSend	EPSend Sample A sample program in C that uses the MSMQ-MQSeries Bridge Extensions API to override the default MSMQ-MQseries Bridge message property mapping MsgType, ReplyToQMgr, and ReplyToQ in the MQSeries MQMD structure.
MQSRRecv	MQSRRecv Sample A sample program in C that uses the MQSeries API to receive messages from a specified MQSeries queue.
MQSRSend	MQSRSend Sample A sample program in C that uses the MQSeries API to send ten test messages to a specified MQSeries queue.
MSMQRecv	MSMQRecv Sample A sample program in C that uses the Message Queuing API to receive messages from a specified Message Queuing queue.
MSMQSend	MSMQSend Sample A sample program in C that uses the Message Queuing API to sends ten test messages to a specified Message Queuing local or foreign queue.
WMI	WMI MSMQ-MQSeries Bridge Sample A collection of Windows Management Instrumentation (WMI) sample scripts written in Active Server Pages (ASP) that shows how to use WMI to configure the MSMQ-MQSeries Bridge.

Several sample programs with source code are provided with Host Integration Server 2009 that illustrate how to use the MSMQ-MQSeries Bridge and Bridge Extensions.

The MSMQ-MQSeries Bridge samples are designed to be built using Microsoft Visual Studio .NET 2003 or later. Most of these samples also require that the IBM MQSeries Client toolkit be installed, providing access to several MQSeries include and library files.

To build the MSMQ-MQSeries Bridge samples using the command-line compiler, set up your build environment as follows:

- Run VSVARS32.bat from the Visual Studio bin directory (by default, C:\Program Files\Microsoft Visual Studio .NET 2003\Common7\Tools.
- Set the MQS_INC environment variable so it points to the INCLUDE directory where MQSeries was installed. The default location for this variable is normally C:\Program Files\MQSeries Client\tools\c\include.
- Set the MQS_LIB environment variable so it points to the LIB directory where MQSeries was installed. The default location for this variable is normally C:\Program Files\MQSeries Client\tools\lib.

For example, set the following environment variables for building the MQS samples:

```
set MQS_INC=C:\Program Files\MQSeries Client\tools\c\include
set MQS_LIB=C:\Program Files\MQSeries Client\tools\lib
```

To build all the C/C++ samples (EPSend, EPRecv, MQSRRecv, MQSRSend, MSMQSend and MSMQRecv), open a Command Prompt window, navigate to the Bridge subdirectory, and invoke NMAKE. This recursively invokes NMAKE and builds all of the Bridge samples.

To build a specific sample (EPSend, for example), using the command-line compiler, open a Command Prompt window, navigate to the appropriate subdirectory (Bridge\EPSend, for example), and invoke NMAKE.

Note

To build a specific sample (EPSend, for example) using Visual Studio .NET 2003, open the appropriate Visual C++ project file (epsend.vcproj, for example) from the **File** menu. Select a configuration and build the sample from the **Build** menu. Each pro ject file has two configurations, one for a DEBUG build and one for a RETAIL build.

Note

Several of the MSMQ-MQSeries Bridge samples require access to the IBM MQSeries Client toolkit and library files.

The project files for these samples assume that the IBM MQSeries Client toolkit is installed in the default location at C:\Program Files\MQSeries Client\tools. You need to modify the project files if the IBM MQSeries Client toolkit is installed in a different location. For each C source file, you need to change the **Additional Include Directories** property under **C/C++/General**. For the target, you need to change the **Additional Dependencies** property under **Linker/Input**.

In This Section

EPSend Sample

MQSRRecv Sample

MQSRSend Sample

MSMQRecv Sample

MSMQSend Sample

WMI MSMQ-MQSeries Bridge Sample

EPRecv Sample

The MSMQ-MQSeries Bridge Extension API can be used to obtain the original MQSeries message properties for an MQSeries message sent using the MSMQ-MQSeries Bridge to Message Queuing (also known as MSMQ). The Bridge\EPRecv folder contains a sample program written in C that receives messages from a Message Queuing queue using the Message Queuing APIs and prints the original MQSeries message descriptor (MQMD) properties in the PROPID_M_EXTENSION, if they exist. The sample illustrates how to use MSMQ-MQSeries Bridge Extensions. You can use it for testing or troubleshooting the MSMQ-MQSeries Bridge and Bridge Extensions.

The usage for this command-line tool is as follows:

```
EPRecv <computer name>\<queue name>
```

The parameter *<computer name>\<queue name>* is the path name where messages are received. This is a Message Queuing queue name and is specified in UNC or DNS format.

Sample program usage and sample output are as follows:

```
eprecv MSBRIDGE\QUEUE
```

Queue opened.

Waiting for messages to arrive.

Use CTLR-C to stop.

-------> Message arrived:

Sample Programs for MSMQ-MQSeries Bridge

MSMQ-MQSeries Bridge Programmer's Guide

EPSend Sample

You can use the MSMQ-MQSeries Bridge Extension API to override the default MSMQ-MQSeries Bridge message property mapping.

The Bridge\EPSend folder contains a sample written in C that illustrates how to use the MSMQ-MQSeries Bridge Extension API to override the default MSMQ-MQSeries Bridge message property mapping for MsgType, ReplyToQMgr, and ReplyToQ in the MQSeries MQMD structure. This sample sends messages to the Message Queuing (also known as MSMQ) queue, overriding the default values for these MQMD extension fields.

This sample can be used for testing or troubleshooting the MSMQ-MQSeries Bridge and Bridge Extensions.

The usage for this command-line tool is as follows:

```
EPSend <computer name>\<queue name>
```

The parameter <*computer name*>\<*queue name*> is the path name of the specified Message Queuing queue name where messages are to be sent. This Message Queuing queue name can be specified in UNC or DNS format.

Sample program usage and sample output are as follows:

```
epsend IBMNT_QM\QUEUE
```

Queue opened.

Reply Q Manager Name : MSBRIDGE1

Reply Q Name : QUEUE

------> Sending message (Use CTRL-C to stop).Label: ABC

Body: ABC

MQSRRecv Sample

The Bridge\MQSRRecv folder contains a sample program written in C that uses the MQSeries API to receive messages from a specified MQSeries queue. This sample can be used to receive messages sent from MQSeries or sent from Message Queuing (also known as MSMQ) using the MSMQ-MQSeries Bridge. The sample can be used for testing or troubleshooting the MSMQ-MQSeries Bridge.

The usage for this command-line tool is as follows:

```
MQSRRecv <QM name> <queue name>
```

The first parameter, *QM name*, is the name of the MQSeries Queue Manager. The second parameter, *queue name*, is the queue name from which to receive the messages. Note that the program assumes that queue name is located on the *QM name* computer.

You can run the MQSRRecv program on a computer where the MQSeries Client is installed and configured. The environment variables used by the MQSeries client should point to the appropriate channel table file. The computer running the MSMQ-MQSeries Bridge is a good choice because it should already be properly configured.

Sample Programs for MSMQ-MQSeries Bridge

MSMQ-MQSeries Bridge Programmer's Guide

MQSRSend Sample

The Bridge\MQSRSend folder contains a sample written in C that uses the MQSeries API to send ten test messages to a specified MQSeries queue. This sample can be used to send messages to a specified MQSeries queue or to a specified Message Queuing (also known as MSMQ) queue using the MSMQ-MQSeries Bridge. The sample can be used for testing or troubleshooting the MSMQ-MQSeries Bridge.

The usage for this command-line tool is as follows:

```
MQSRSend <local QM name> <destination QM name>
        <queue name>
```

The first parameter, *local QM name*, is the name of the immediate MQSeries Queue Manager to connect to (the server side of the MQI channel). **MQSRSend** needs this information to establish the MQI channel connection.

The second parameter, *destination QM name*, is the destination queue manager for the messages. To send messages to Message Queuing, specify the queue manager alias for the destination QM name representing the Message Queuing queue.

The third parameter, *queue name*, is the name of the queue where the messages should be sent.

You can send MQSeries message to a Message Queuing queue with one of the following methods.

1. Specify the MSMQ-MQSeries Bridge computer name in the destination QM name and the Message Queuing format name in the queue name.

2. Define QREMOTE for the Message Queuing destination QM name in MQSeries.

You can run the MQSRSend program on a computer where the MQSeries Client is installed and configured. The environment variables used by the MQSeries client should point to the appropriate channel table file. The computer running the MSMQ-MQSeries Bridge is a good choice because it should already be properly configured.

Sample Programs for MSMQ-MQSeries Bridge

MSMQ-MQSeries Bridge Programmer's Guide

MSMQRecv Sample

The Bridge\MSMQRecv folder contains a sample written in C that uses the Message Queuing (also known as MSMQ) API to receive messages from a specified Message Queuing queue. This sample can be used to receive messages sent from Message Queuing or receive messages sent from MQSeries using the MSMQ-MQSeries Bridge. The sample illustrates how to receive messages using Message Queuing and can be used for testing or troubleshooting the MSMQ-MQSeries Bridge.

The usage for this command-line tool is as follows:

```
MSMQRecv <computer name>\<queue name>
```

The parameter <*computer name*>\<*queue name*> is the path name of the specified Message Queuing queue name where messages are received. This Message Queuing queue name can be specified in UNC or DNS format.

You can run the MSMQRecv program on any computer where Message Queuing is installed, not necessarily the computer running the MSMQ-MQSeries Bridge.

MSMQ-MQSeries Bridge Programmer's Guide

MSMQSend Sample

The SDK\Samples\Bridge\MSMQSend folder contains a sample written in C that sends ten test messages using the Message Queuing (also known as MSMQ) APIs. This sample can be used to send messages to a specified Message Queuing queue or a foreign MQSeries queue through the MSMQ-MQSeries Bridge. The sample illustrates how to send messages using Message Queuing and can be used for testing or troubleshooting the MSMQ-MQSeries Bridge.

The usage for this command-line tool is as follows:

```
MSMQSend <computer name>\<queue name>
```

The parameter <*computer name*>\<*queue name*> is the path name of the specified Message Queuing queue name where messages are to be sent. This Message Queuing queue name can be specified in UNC or DNS format.

You can run the MSMQSend program on any computer where Message Queuing is installed, not necessarily the computer running the MSMQ-MQSeries Bridge.

Sample Programs for MSMQ-MQSeries Bridge

MSMQ-MQSeries Bridge Programmer's Guide

WMI MSMQ-MQSeries Bridge Sample

The Bridge\WMI folder contains a collection of Active Server Pages (ASP) for use with a Web server application that enables you to view and make changes to the MSMQ-MQSeries Bridge configuration using Windows Management Instrumentation (WMI). These sample applications require Microsoft Internet Information Services (IIS) version 3.0 or greater with ASP installed. Host Integration Server 2009 and IIS must be installed and be running on the same computer.

The WMI ASP samples must be installed into the Web server's public directories below WWWRoot. Copy the contents of the entire WMI directory from the SDK\Samples\Bridge\WMI subdirectory to your WWWROOT directory on the Web server. After these files have been copied you should have a WWWROOT\WMI folder containing a number of ASP and GIF files.

The samples may then be run by opening Microsoft Internet Explorer or some other Web browser on the same computer or a different computer and entering the following URL in the address line:

```
http://<computer name>/WMI/WMI_Test_Main.asp
```

Substitute the network name of the computer hosting the Web server and the MSMQ-MQSeries Bridge for the computer name (in angle brackets in the URL above). This will open the main page of the Bridge WMI ASP application and enable you to select any of the other sample ASP pages. Information about each sample is provided on this Web page.

These ASP pages illustrate using WMI to view and make changes to the MSMQ-MQSeries Bridge configuration. The management functions supported by this application enable you to create a new instance, move to other instances (previous and next), delete an instance, and save an instance.

The WMI subdirectory below WWWROOT needs to have IIS security enabled (no anonymous access). Otherwise, the scripts in these subdirectories will fail since the anonymous user account by default does not have access rights that would allow it to start or stop services on Windows 2000 or make changes to the MSMQ-MQSeries Bridge on the Host Integration Server system.

It is possible to host these ASP pages on a computer running the Web server that is different from the computer running the MSMQ-MQSeries Bridge and Host Integration Server. However, this requires some changes to the ASP pages to handle connections to a different computer, security, and authentication issues.

Samples

Administration and Management Samples

The source code for several sample programs that illustrate using Windows Management Instrumentation (WMI) for administration and management of Host Integration Server 2009 are included in the Host Integration Server 2009 SDK. These files are copied to your hard drive during Host Integration Server software or Host Integration Server Client software installation when you select the **Host Integration Server Software Development Kit** option. These samples are installed in the Samples\NetworkIntegration\Administration subdirectory below where the Host Integration Server 2009 SDK is installed (C:\Program Files\Microsoft Host Integration Server\SDK, by default).

These sample programs include the files in the following subdirectories:

File or subdirectory	Description
\VBScript	A WMI sample script written in Microsoft Visual Basic Scripting Edition (VBScript) that illustrates how to import and export configuration information from Host Integration Server.
\Scripts	The main page of a WMI sample script written in Microsoft Active Server Pages (ASP) for retrieving configuration information from Host Integration Server using WMI.
\ASP-SNAWebAdmin	Subsidiary pages of WMI sample scripts written in Microsoft Active Server Pages (ASP) for retrieving configuration information from HIS using WMI. Each one of these subdirectories contains ASP sample scripts that illustrate how to retrieve information from Host Integration Server on a specific feature.

Several sample programs (with source code) that illustrate administration and management are provided with HIS.

Network Integration Samples

Active Server Pages SNAWebAdmin Sample

The Administration\ASP-SnaWebAdmin folder contains a collection of Active Server Pages (ASP) for use with a Web server application designed to access configuration, management, and status information from the SNA server component of Host Integration Server 2009. These sample applications require Microsoft Internet Information Services (IIS) version 5.0 or later with ASP installed. Host Integration Server 2009 and IIS must be installed and running on the same computer.

The Windows Management Instrumentation (WMI) ASP samples must be installed into the public directories of the Web server below WWWRoot. Copy the contents of the Admin directory from the SDK\Samples\NetworkIntegration\Administration subdirectory, including SNAWebAdmin subdirectory, to your WWWROOT directory on the Web server. After these files have been copied, you should have a copy of the SNAWMI.ASP, fphover.class, and fphoverx.class files in WWWROOT and a WWWROOT\SNAWebAdmin folder with a series of subdirectories containing several ASP and Graphics Interchange Format (GIF) files.

You can then run the samples by using Microsoft Internet Explorer, or some other Web browser on the same computer, or a different computer. Type **HTTP://<computer name>/SNAWMI.asp** in the **Address** box.

Substitute the network name of the computer hosting the Web server and HIS for the computer name in angle brackets in the URL above. This opens the main page of the SNAWebAdmin ASP application and enables you to select any of the other sample ASP pages. Information about each sample is provided on this Web page. Additional information is available at HTTP://<*computer name*>/admin/headers/welcome.htm.

These ASP pages illustrate using WMI to retrieve SNA management and configuration from Host Integration Server 2009.

The two Java class files, fphover.class and fphoverx.class, are redistributable files that are included with Microsoft FrontPage. These files are used in some of the WMI sample scripts instead of a **Submit** button to stop and start services.

Several subdirectories below SNAWebAdmin must have IIS security enabled (no anonymous access); otherwise the scripts in these subdirectories fail since the anonymous user account by default does not have permissions that would allow it to start or stop services on Microsoft Windows 2000 or make changes to the Host Integration Server 2009 system. The subdirectories that must have IIS security enabled are as follows:

- SNASebAdmin\Change
- SNASebAdmin\Connections
- SNASebAdmin\Services
- SNASebAdmin\Status

It is possible to host these ASP pages on a computer running the Web server that is different from the computer running Host Integration Server 2009. However, this requires some changes to the ASP pages to handle connections to a different computer, security, and authentication issues.

Other Resources

Administration and Management Samples

VBScript ImportExport Sample

The Administration\VBScript folder contains a sample written in Microsoft Visual Basic Scripting Edition (VBScript) that illustrates how to import and export SNA configuration information from Host Integration Server 2009 in managed object format (MOF) using Windows Management Instrumentation (WMI). This sample relies on the MOFCOMP.exe application supplied with Microsoft Windows for importing.

In the following examples, ImportExport.VBS has been renamed to HISCFG.vbs.

The usage for this command-line tool for exporting configuration information is as follows:

```
HISCFG [/S:server] [/N:namespace] [/C:class] [/O:outfile]
       [/U:username] [/W:password] [/Q]
```

The various command-line options are explained in the following table.

Note
Case is ignored for command-line options except for help and either the '/' or '-' character is interpreted as the leading chara cter for an option. The following table uses the '/' character for illustration.

Command-Line Switch	Comments
/?	This flag shows the usage for this command and exits.
/C	The name of the WMI parent class to be queried. This should be set to one of the WMI classes defined in the MOF files supplied with Host Integration Server 2009. This parameter defaults to *MsSna_Config* and exports all of the classes SNA classes and their associations.
/h	This flag shows the usage for this command and exits.
/N	The WMI namespace to be queried. This parameter defaults to "root\MicrosoftHIS" for Host Integration Server 2009.
/O	The name of the file used for output. This parameter has no default value.
/Q	This Boolean flag indicates whether this is query should be completed quietly without displaying any status or error messages. This parameter defaults to verbose option.
/S	The name of the computer running Host Integration Server 2009. This parameter has no default value.
/U	The user name of a user on the domain or active directory where Host Integration Server 2009 is running wit h administrative rights. This parameter has no default value.
/W	The password of a user on the domain or active directory where Host Integration Server 2009 is running with administrative rights. This parameter has no default value.

The usage for this command-line tool for importing SNA configuration information is as follows:

```
HISCFG [/I:inputfilename]
```

A potential problem using WMI can occur with duplicate logical unit (LU) pools that can be illustrated using this sample program. Normally, exporting and re-importing the MOF file would not create duplicates. However, the HIS WMI provider allows pool-to-workstation association instances to be duplicated because, by design, duplicates of this type of object are allowed. It is possible to associate the same pool to the same workstation or user multiple times. Emulators use this to create more sessions for clients. Therefore, it is not possible to identify one such association from another. The WMISNA Provider,

WMISNA.DLL, always create new associations of these types, even if an association with the same pair (Pool, Wks) already exists. Only in the case of this object type is this allowed. However, this can create a problem for applications developed using WMI (the Import/Export sample, for example) if the application does not know to not create the duplicates.

The following sequence illustrates this issue using the ImportExport sample:

1. Create a Pool-Workstation association by using Host Integration Server Manager or the Administration Manager client.
2. Export the SNA configuration to a MOF file using the ImportExport utility.
3. Import that same MOF file again using the ImportExport utility.
4. Duplicate Pool-Workstation associations will be created.

The result is that if a client uses the import/export sample or a similar application developed using WMI on a Host Integration Server 2009 configuration that has pool-to-workstation associations, then the number of associations will effectively double after running the sample. The workaround using the ImportExport sample would be as follows:

1. Export the configuration to a MOF file.
2. Remove the pool to workstation associations from the MOF file just created.
3. Import the MOF file back.

When importing the configuration from one domain to another using the ImportExport sample or a similar application developed using WMI, then step 2 should be ignored. Normally, WMI applications should copy an existing configuration to a blank configuration file so this condition does not arise.

Administration and Management Samples

APPC Samples

The Host Integration Server 2009 SDK includes the source code for several sample programs that illustrate using Advanced Program-to-Program Communications (APPC). These sample programs are copied to your hard drive during Host Integration Server software or Host Integration Client software installation when the **Host Integration Server Software Development Kit** option is selected. These samples are installed in the Samples\NetworkIntegration\APPC subdirectory below where the Host Integration Server SDK software is installed (C:\Program Files\Microsoft Host Integration Server\SDK, by default).

These APPC sample programs include the following:

APPC TP samples	Description
APPC Send and Receive TPs	Sample programs in C that represent simple APPC send and receive transaction programs (TPs) illustrating the use of asynchronous verb completion. The samples located in the SENDRECV subdirectory implement simple bulk data sending and receiving TPs (SENDTP and RECVTP). These samples are located in the \APPC\SendRecv subdirectory on the CD.
Multithreaded Send and Receive TPs	Sample programs in C that represent more advanced APPC send and receive TPs illustrating the use of multiple threads and multiple conversations per thread. The multithreaded receive TP samples illustrate using events or IO completion ports for notification These samples are located in the \APPC\msendrcv subdirectory on the CD.

In addition to these APPC sample programs, the following supplemental programs are included on the Host Integration Server CD-ROM.

Supplemental program	Description
TPSETUP	A sample installation program in C demonstrating an interface that assists in the configuration of autostarted invokable TPs. This sample is located in the \APPC\tpsetup subdirectory on the CD.
TPSTART	A sample program in C required for the automatic startup of invokable TPs that run as applications under Microsoft Windows 2000. TPSTART is not required if a TP is written as a Windows 2000 service. An executable binary of TPSTART is installed by Host Integration Server Setup in the SYSTEM subdirectory of the Host Integration Server root directory. This sample is located in the \APPC\tpstart subdirectory on the CD.

Network Integration Samples

Building the TPs

The APPC samples are designed to be built by using the command-line compiler or the interactive development environment (IDE) in Microsoft Visual Studio .NET 2003 or later.

To build the APPC samples installed from the Host Integration Server CD, set the following environment variables:

Variable	Specifies
ISVLIBS	Directory containing the Microsoft Host Integration Server LIB files for Microsoft Windows 2000
ISVINCS	Directory containing the WINSNA header files
SAMPLEROOT	Root directory of the sample code

For example, if you installed the Host Integration Server SDK directory to the default location (C:\Program Files\Microsoft Host Integration Server\SDK), use the following lines to set the variables (assuming that Intel binaries are being produced for Windows 2000):

```
ISVLIBS=C:\Program Files\Microsoft Host Integration Server\SDK\LIB
ISVINCS=C:\Program Files\ Microsoft Host Integration Server \SDK\Include
SAMPLEROOT=C:\Program Files\ Microsoft Host Integration Server \SDK\Samples\SNA
```

To build a specific sample (SendTp, for example) using the Visual Studio IDE, start Visual Studio and open the appropriate Microsoft Visual C++ project file (NetworkIntegration\appc\sendtp.vcproj, for example) from the **File** menu. Select a configuration and build the sample from the **Build** menu. Each Visual C++ project file has two configurations, one for a DEBUG build and one for a RETAIL build.

APPC Samples

TPSETUP

TPSETUP is a program that simplifies the setting of registry or environment variables needed by autostarted invokable TPs. Without an interface like that provided by TPSETUP, configuring such variables can be complicated and error prone. Therefore, it is recommended that you use code like TPSETUP in installation programs for autostarted invokable TPs.

Operation

INSTALL.C, the source code for TPSETUP, can be compiled to work in Microsoft® Windows® 2000.

It is recommended that autostarted invokable TPs be written as Windows 2000 services. To create the installation program for such TPs, study the code in INSTALL.C. For example, use the **CreateService** function or similar code when installing a TP that will run as a service under Windows 2000. (For important information about how services work under Windows 2000, see the documentation for Windows 2000.)

TPSTART

An autostarted TP that runs as an application under Microsoft® Windows® 2000 requires the support of the TPSTART program, which is installed with the Microsoft Host Integration Server software in the SYSTEM subdirectory of the Host Integration Server root directory. Therefore, the TPSTART program must be started on a Windows 2000-based client before an autostarted invokable TP can be started as an application. You can start TPSTART by using standard Windows 2000 methods, such as including TPSTART in the **Startup** group on the client.

TPSTART.ini

You can use TpStart.ini to specify custom tracing options when using TPSTART.exe.

The TpStart.ini file should be placed in the <snaroot> folder.

TpStart.ini sample

```
[TpStart]
HIDE=0
QSIZE=64
TRACE=1
FILE=C:\traces\tpstart.txt
LEVEL=0
FSIZE=2000000

Details for the entries are:

HIDE - 1: Hides the icon
            0: Shows the icon

QSIZE - Size of the pending queue, MIN=16,MAX=256
             Note, if QSIZE is not included in the ini file, a size of 16 is used

TRACE - 1: Enable tracing
               0: Disable tracing

FILE - The path and filename to be created for the trace, note the folder must already exis
t

LEVEL - The level of tracing (0 - 10):  0 - the most detailed tracing,  10 - no tracing

FSIZE - Maximum file size, MIN=10000, MAX=0xFFFFFFFF
             Note, if FSIZE is not included in the ini file, a size of 10000 is used.
```

For additional information about TpStart.exe, see KB article 137074 at http://support.microsoft.com/kb/137074.

APPC Send and Receive TPs

These are simple APPC send and receive TPs that illustrate the use of asynchronous verb completion. This sample implements simple bulk data sending and receiving TPs (SENDTP and RECVTP).

Setup

To set up these TPs, create an appropriate APPC LU-LU-mode triplet. The default is SENDLU-RECVLU-#INTER, but this can be configured (see the following sections).

Input and Output

The APPC send and receive TPs each use a configuration file for input. To name the file, use .CFG as the extension, and use the same base file name as the TP executable file (SENDTP.CFG, for example). Save this configuration file in the same directory location as the executable file (the TP itself).

For SENDTP, the configuration file (called SENDTP.CFG if the executable file is SENDTP.EXE) can contain the following items, one per line, in any order. If a variable is not found in the file or the file is not present at all, the default is used.

Line	Default value	Value to supply
ResultFile =	C:\SENDTP.OUT	File name to print timings to
LocalLUAlias =	SENDLU	Local LU alias
RemoteLUAlias =	RECVLU	Remote LU alias
ModeName =	#INTER	Mode name
LocalTPName =	SENDTP	Name of local TP
RemoteTPName =	RECVTP	Name of remote TP
NumConversations =	1	Number of conversations
NumSends =	2	Number of SEND_DATA verbs per conversation
SendSize =	1024	Size in bytes of data sent each time
ConfirmEvery =	1	Number of **SEND_DATA** verbs between CONFIRM verbs
SendConversation =	No	Yes or No: Use the SEND_CONVERSATION verb rather than the sequence of ALLOCATE, **SEND_DATA**, DEALLOCATE

RECVTP uses a RECVTP.CFG file in a similar way, but only to read the **LocalTPName** field.

The output from SENDTP and RECVTP consists of details of the configuration and the time taken for each conversation, and is sent to the result file specified in SENDTP.CFG.

Operation

RECVTP should be started first; it issues RECEIVE_ALLOCATE with the specified TP name. SENDTP is then started; it first issues MC_SEND_CONVERSATION to tell RECVTP how many conversations will be carried out. It then carries out the specified number of conversations.

For SENDTP, each conversation consists of an MC_ALLOCATE verb, followed by a given number of MC_SEND_DATA verbs of a given size, and interspersed with MC_CONFIRM verbs at a given interval, followed by an MC_DEALLOCATE.

RECVTP issues MC_RECEIVE_AND_WAIT when **RECEIVE_ALLOCATE** completes, and then issues either MC_RECEIVE_AND_WAIT or MC_CONFIRMED according to the return from the previous **MC_RECEIVE_AND_WAIT**.

At any stage, if the TPs encounter an error, they terminate. Use APPC API tracing to diagnose problems with the configuration.

At the end of the specified number of conversations, SENDTP sends timing information to a file.

Both TPs are built from a single source code file, SENDRECV.C. SENDTP is compiled only if **-DSENDTP** is used on the command line.

The TPs run as Microsoft® Windows® 2000 applications with a minimized window, the title bar of which displays the status. When the WndProc of this window, TPWndProc, receives the WM_CREATE message for the window, this triggers the issuing of the first verb. When TPWndProc receives an ASYNC_COMPLETE message from Windows APPC, this triggers the issuing of the next verb, dependent on what the previous verb was. When the window is closed, WinAPPCCleanup is issued to terminate any active conversations.

APPC Samples

Multithreaded Send and Receive TPs

These multithreaded send and receive TPs are more advanced than the single-threaded equivalents. The samples located in the MSENDRCV subdirectory all use the asynchronous interface of APPC, with verb completion signaled by events (WinAsyncAPPCEx) or IO completion ports (WinAsyncAPPCIOCP). These TPs show how to code multithreaded APPC applications with multiple conversations per thread. They are more complex than the single-threaded equivalents, but are also more realistic.

If you are unfamiliar with APPC, examine the single-threaded TPs first. If you are unfamiliar with methods of creating threads or processing events in Microsoft® Windows® 2000, see the Microsoft Platform SDK documentation along with the multithreaded TPs.

Setup

There are four multithreaded send and receive routines that illustrate using asynchronous APPC calls:

- MRCV for receiving using events for notification
- MRCVIO for receiving using IO completion ports for notification
- MSEND for sending using events for notification
- MSENDRCV for simultaneous sending and receiving using events for notification

To set up these TPs, create an appropriate APPC LU-LU-mode triplet. The default is SENDLU-RECVLU-#INTER, but this can be configured (see the sections that follow). To run a large number of simultaneous conversations, increase the session limits for #INTER or use another mode with large session limits.

One obvious way of configuring these programs is to configure MSEND to run with MRCV or MRCVIO; another way is to configure MSENDRCV to run with another copy of MSENDRCV. However, you can also configure MSEND to run with one or more copies of RECVTP (the single-threaded version) and MRCV or MRCVIO to run with one or more copies of SENDTP. You can also configure MSENDRCV to run with MSEND, MRCV, SENDTP or RECVTP. For more information, see the sections that follow.

One possible arrangement is to place SENDTP (single-threaded) on multiple client computers, and configure MRCV or MRCVIO (multithreaded) on a server so that it interacts with all the TPs on the clients. Many other arrangements are possible.

Configuration for MRCV, MSEND, and MSENDRCV

The MRCV, MSEND, and MSENDRCV TP samples use a configuration file for configuration and input. To name the file, use .CFG as the extension, and use the same base file name and directory location as the executable file (the TP itself).

The following table shows examples of CFG files that could be used with MSEND and MRCV.

Example of MSEND.CFG file	Example of MRCV.CFG file
ResultFile=MSEND.OUT	TraceFile=MRCV.TRC
TraceFile=MSEND.TRC	LocalTPName=MRCVTP
RemoteTPName=MRCVTP	NumRcvConvs=32
LocalLUAlias=LUA	NumRcvThreads=4
RemoteLUAlias=LUB	RcvSize=4096
ModeName=#INTER	
NumSendConvs=32	

NumSends=128	
ConfirmEvery=16	
SendSize=256	

For MSEND, the configuration file (MSEND.CFG) can contain the following items, one per line, in any order. If a variable is not found in the file or the file is not present, the default is used.

Line	Default value	Value to supply
ResultFile =	MSEND.OUT	File name to print timings to (located in default directory for MSEND)
TraceFile =	MSEND.TRC	Trace file name (located in default directory for MSEND)
LocalLUAlias =	SENDLU	Local LU alias
RemoteLUAlias =	RECVLU	Remote LU alias
ModeName =	#INTER	Mode name
RemoteTPName =	MRCVTP	Name of remote TP (for MC_ALLOCATE)
NumSendConvs =	4	Number of conversations to send
NumSends =	8	Number of MC_SEND_DATA verbs per conversation
SendSize =	256	Size in bytes of data sent each time
ConfirmEvery =	2	Number of **MC_SEND_DATA** verbs between MC_CONFIRM verbs

The following lines are for MRCV:

Line	Default value	Value to supply
TraceFile =	MRCV.TRC	Trace file name (located in default directory for MSEND)
LocalTPName =	MRCVTP	Name of local TP (for RECEIVE_ALLOCATE)
NumRcvConvs =	4	Number of conversations to receive
NumRcvThreads =	2	Number of threads to start for processing receive conversations
RcvSize =	4096	Size in bytes of receive buffer for MC_RECEIVE_AND_WAIT

The following table shows examples of configuration files (MSENDRCV.CFG) that could be used with MSENDRCV. Each row of the table (Example A and Example B) contains two files that work together on a pair of computers.

Example A of MSENDRCV.CFG	Example B of MSENDRCV.CFG
ResultFile=MSENDRCV.OUT	ResultFile=MSENDRCV.OUT
TraceFile=MSENDRCV.TRC	TraceFile=MSENDRCV.TRC
LocalTPName=TPA	LocalTPName=TPB
RemoteTPName=TPB	RemoteTPName=TPA

LocalLUAlias=LUA	LocalLUAlias=LUB
RemoteLUAlias=LUB	RemoteLUAlias=LUA
ModeName=#INTER	ModeName=#INTER
NumRcvConvs=50	NumRcvConvs=25
NumRcvThreads=4	NumRcvThreads=4
RcvSize=4096	RcvSize=4096
NumSendConvs=25	NumSendConvs=50
NumSends=100	NumSends=100
ConfirmEvery=10	ConfirmEvery=10
SendSize=256	SendSize=256

The following lines are for MSENDRCV:

Line	Default value	Value to supply
ResultFile =	MSENDRCV.OUT	File name to print timings to (located in default directory for the MSEND or MSENDRCV sending TP)
TraceFile =	MSENDRCV.TRC	Trace file name (located in default directory for the MSEND or MSENDRCV sending TP)
LocalLUAlias =	SENDLU	Local LU alias
RemoteLUAlias =	RECVLU	Remote LU alias
ModeName =	#INTER	Mode name
RemoteTPName =	MRCVTP	Name of remote TP (for MC_ALLOCATE)
NumSendConvs =	4	Number of conversations to send
NumSends =	8	Number of MC_SEND_DATA verbs per conversation
SendSize =	256	Size in bytes of data sent each time
ConfirmEvery =	2	Number of **MC_SEND_DATA** verbs between MC_CONFIRM verbs
LocalTPName =	MRCVTP	Name of local TP (for RECEIVE_ALLOCATE)
NumRcvConvs =	4	Number of conversations to receive
NumRcvThreads =	2	Number of threads to start for processing receive conversations

RcvSize =	4096	Size in bytes of receive buffer for MC_RECEIVE_AND_WAIT

The output from MSEND and MSENDRCV consists of details of the configuration and the time taken for each conversation, and is sent to the result file specified in MSEND.CFG or MSENDRCV.CFG.

Operation of MRCV, MSEND, and MSENDRCV

The MRCV, MSEND, and MSENDRCV TPs use multiple event processing in Windows 2000 to avoid creating an unnecessary number of threads.

These TPs also use Windows-based processing, but this is incidental. Its only purpose is to display beneath the icon on the screen a running count of threads, the number of conversations currently sending or receiving data, and the number of conversations completed. The Windows-based processing could easily be removed to create a completely batch-oriented program. To do this, termination would need to be signaled with an event rather than with WM_CLOSE.

The TP name used in TP_STARTED is the name of the executable file (MSEND, MRCV, or MSENDRCV). The TP names used in MC_ALLOCATE and RECEIVE_ALLOCATE can be configured, as shown in the preceding tables.

MSEND reads its configuration file (or uses defaults) to determine the number of send conversations to start. Each conversation reads the value of **NumSends** (or uses the default), issues that number of MC_SEND_DATA verbs, and then terminates. When all of the conversations for a thread have terminated, the thread itself terminates. When all of the send threads have terminated, the program terminates.

An MC_CONFIRM verb is issued before the first **MC_SEND_DATA** and then at the intervals specified by **ConfirmEvery**. The complete data flow for a conversation is as follows:

TP_STARTED

MC_ALLOCATE

MC_CONFIRM

MC_SEND_DATA (repeated the number of times specified by **ConfirmEvery**)

MC_CONFIRM

MC_SEND_DATA (repeated the number of times specified by **ConfirmEvery**)

MC_CONFIRM

(Pattern repeats until the number of **MC_SEND_DATA** verbs equals **NumSends**.)

MC_DEALLOCATE

TP_ENDED

MRCV starts up an initial thread for issuing RECEIVE_ALLOCATE verbs, and then reads its configuration file (or uses defaults) to determine the number of receive threads to start and the number of conversations to receive. The initial thread issues a **RECEIVE_ALLOCATE** and waits. When the **RECEIVE_ALLOCATE** completes, the initial thread turns the processing of the conversation over to the next available receive thread, and issues another **RECEIVE_ALLOCATE**. This process continues until the configured number of **RECEIVE_ALLOCATE** verbs (that is, **NumRcvConvs**) have completed.

There is a limit to the number of conversations that can be supported on a thread, because of the limit to the number of events that can be waited for with **WaitForMultipleObjects** (a function in the Win32® API). For send threads, the limit is 64 conversations per thread; for receive threads, the limit is 63 conversations per thread.

MSEND works with this limit by starting enough threads to support the configured number of conversations. For example, if **NumSendConvs** is set to 200, four send threads are started: three of them process 64 conversations each and one processes the remaining eight conversations.

MRCV works with this limit by comparing **NumRcvConvs** to **NumRcvThreads**. If **NumRcvConvs** is more than (63 * **NumRcvThreads**), **NumRcvThreads** is increased. If **NumRcvThreads** is greater than **NumRcvConvs**, **NumRcvThreads** is reduced to prevent creating unneeded threads.

With MRCV, to ensure that a receive thread correctly picks up the conversation, two special events are used per thread: *event1* and *event2*. The following table illustrates their use.

RECEIVE_ALLOCATE thread	**Receive thread**
Issue RECEIVE_ALLOCATE and wait	Wait for *event1*

(**RECEIVE_ALLOCATE** completes)	
Select next receive thread and set *event1* for that thread; then wait for *event2* for that thread	
	(*Event1* completes)
	Add conversation to list of conversations being processed
	Set *event2*
(*Event2* completes)	
REPEAT	REPEAT

The receive thread waits not only on the *event1* set for it, but also on one event for each conversation the thread is processing.

If **NumRcvConvs** is set to zero, the **RECEIVE_ALLOCATE** thread will never terminate. If **NumSends** is set to zero, the conversation will never terminate; this is useful for getting the maximum number of simultaneous conversations.

Tracing of MRCV, MSEND, and MSENDRCV

If you want to observe the detailed processing of the MRCV, MSEND, or MSENDRCV sample TPs, you can enable tracing. To do this, find the following line, commented out, near the top of the file:

```
#define SRTRC
```

Enable this line or define this value on the command-line option to the compiler, and trace statements will be written to the trace file(s) specified by the **TraceFile** variable in the configuration.

There are also some trace statements that have been commented out. If they are left commented out, only MC_CONFIRM and MC_CONFIRMED processing is traced while a conversation is running, to maintain a send or receive count without generating a large amount of trace information. You can activate the detailed tracing of events (such as the sending of data) by enabling one or more trace statements.

The Trace Initiator (snatrace.exe) tool provides APPC API tracing for Microsoft Host Integration Server applications. For more information about the Trace Initiator and Trace Viewer tools, see Microsoft Host Integration Server Help.

Configuration for MRCVIO

The MRCVIO TP sample is a multithreaded console application that uses command-line options for configuration and input. If an option is not provided on the command line, then the default is used. The following table lists the possible command-line options for MRCVIO.

Command-line option	**Description**
-?	Displays usage information for this sample and exits.
-c numRcvConvs	The maximum number of APPC conversations to support. The default value is 8 with a maximum value of 64.
-d duration	The number of seconds that the sample application should run. The default value is 60 seconds. A value of 0 for duration means run indefinitely.
-h	Displays usage information for this sample and exits.

-i IntTraceFile	The name of the internal trace file if tracing is required. When this command-line option is specified, internal tracing is enabled. This option has no default value and internal tracing is turned off.
-n numRcvThreads	The number of Completion Port threads to allocate. The default value is 4 with a maximum value of 32.
-r rcvSize	The size in bytes of the buffer supplied on each **RECEIVE_ALLOCATE**. The default value is 4096 with a maximum value of 65535.
-t TPName	The name supplied on the **RECEIVE_ALLOCATE** verbs. The default value is the "MRCVTP" string.

Operation of MRCVIO

The MRCVIO TP sample uses IO completion ports for notification and will only operate on Windows 2000. Using the IO completion port mechanism is the preferable method for writing scalable APPC server applications.

The MRCVIO TP sample contains the routines for a multithreaded console application that uses asynchronous APPC calls on a single I/O completion port to receive data. The MRCVIO sample creates a small pool of threads that will be used for processing RECEIVE requests. It operates in conjunction with one of the following:

- Single-threaded version of send(SENDTP)
- Multithreaded event-based versions of send (MSEND, MSENDRCV)

The MRCVIO sample uses a server model that continues to accept conversations via RECEIVE_ALLOCATE until the application is manually terminated, or a specified timer expires. The conversations do not belong to any particular RECEIVE thread. Each receive thread issues **GetQueuedCompletionStatus** calls to wait for completion of an APPC verb (on any conversation). Each conversation issues **MC_RECEIVE_AND_WAIT** verbs to receive data. If confirmation is requested, an **MC_CONFIRM** verb is issued.

The TP name used in MC_ALLOCATE and RECEIVE_ALLOCATE can be configured by using the command-line options as shown in the preceding table of options for the configuration of MRCVIO.

MRCVIO starts up and parses its command-line options (or uses defaults) to determine the number of receive threads to start, the number of conversations to receive, the buffer size for each **RECEIVE_ALLOCATE**, its TP name, how long the application should run, and whether internal tracing is enabled.

Once command-line options are parsed, the MRCVIO sample calls the **CreateCompletionPort** function to allocate the IO completion port. If this call is successful, then the specified number of threads are created with the thread start routine pointing to the MRCVIO **ReceiveThread** function and the thread priority for each thread is lowered. Then the specified number of APPC conversations are started.

The MRCVIO sample uses the IO completion port structure and the WinAsyncAPPCIOCP function as listed below.

```
/* IOCP - Structure and function prototype          */
typedef struct
{
    HANDLE       APPC_CompletionPort;
    DWORD        APPC_NumberOfBytesTransferred;
    DWORD        APPC_CompletionKey;
    LPOVERLAPPED APPC_pOverlapped;
} APPC_IOCP_INFO;
extern HANDLE WINAPI WinAsyncAPPCIOCP(
    APPC_IOCP_INFO* iocp_handle, // IO completion port information
    long lpVcb);                 // pointer to APPC verb control block
```

The APPC_CompletionPort must be a HANDLE returned by the **CreateIoCompletionPort** function issued by the application before using **WinAsyncAPPCIOCP**. The other three fields can be set to any value whatsoever. The APPC library does nothing with these other fields, except to return them unaltered on the **GetQueuedCompletionStatus** when the APPC verb

completes. Application developers can set these values to whatever they like, but assuming the server application is handling multiple concurrent APPC conversations, an application will need to use one of these three fields to correlate APPC verbs with their completions.

For example, the MRCVIO sample passes a pointer to a Conversation Control Block into the APPC_pOverlapped field when it issues an APPC verb. The same value is returned when the APPC verb completes on the **GetQueuedCompletionStatus**. This allows the sample MRCVIO TP to figure out which APPC verb has actually completed. APPC developers can use a different method (an index into an array of VCBs, for example) to provide the same effect.

Also, an application might use the APPC_CompletionKey field to distinguish between APPC events and other events posted to this IO Completion port. For example, the MRCVIO sample sets this value to a user-defined constant IOCP_VERB_COMPLETE so that the **GetQueuedCompletionStatus** function can distinguish APPC verb completions from the other events that are posted to this IO Completion port (IOCP_START_CONVERSATION, IOCP_END_CONVERSATION and IOCP_TERMINATE_THREAD). However, this is purely for the convenience of the application. An APPC developer could decide not to post any events to its IO Completion port (except implicitly for APPC completions). In such a case, it would be unnecessary to set any value in the APPC_CompletionKey.

APPC Samples

CPI-C Samples

Host Integration Server 2009 SDK includes the source code for several sample programs that illustrate using Common Programming Interface for Communications (CPI-C) for transaction programs (TPs).

These files are copied to your hard drive during Host Integration Server software or Host Integration Client software installation when the Host Integration Server Software Development Kit option is selected. These samples are installed in the Samples\NetworkIntegration\CPI-C subdirectory below where the Host Integration Server SDK software is installed (C:\Program Files\Microsoft Host Integration Server\SDK, by default).

These sample programs include the files listed in the following table.

Sample TP program	Description
APING and APINGD	Sample programs that provide a simple test for end-to-end connectivity. These samples are located in the \CPI-C\aping folder on the CD.
Multithreaded APINGD	A multithreaded connectivity test that illustrates nonqueued behavior in Microsoft Windows Server 2003 and Windows 2000. This sample is located in the \CPI-C\mping folder on the CD.
CPI-C Send and Receive TPs	A pair of simple CPI-C TPs that illustrate the use of asynchronous CPI-C calls. These samples are located in the \CPI-C\CpicSendRecv folder on the CD.
AREXEC and AREXECD	A pair of TPs that execute commands on a remote computer and send the output back across the connection. These samples are located in the \CPI-C\ArExec folder on the CD.
AREMOTE	A sample client and server program using APPC that enables you to invoke and control a text-mode program from another computer. This sample using APPC was based a Win32 sample program that originally used named pipes. These samples are located in the \CPI-C\ARemote folder on the CD.

In addition to these TPs, the following supplemental programs are included on the Host Integration Server 2009 CD.

Supplemental program	Description
TPSETUP	A sample installation program, demonstrating an interface that assists in configuring autostarted invokable TPs. This sample is located in the \NetworkIntegration\APPC\tpsetup folder on the CD.
TPSTART	A program required for the automatic startup of invokable TPs that run as applications under Windows Server 2003 or Windows 2000. TPSTART is not required if the TP has been written as a Windows Server 2003 or Windows 2000 service.TPSTART is installed by Host Integration Server Setup in the System folder of the Host Integration Server root directory. This sample is located in the \NetworkIntegration\APPC\tpstart folder on the CD.

Network Integration Samples

Building the TPs

The Common Programming Interface for Communications (CPI-C) samples are designed to be built using the command-line compiler or the IDE in Microsoft Visual Studio.

To build the CPI-C samples installed from the Host Integration Server CD, set the following environment variables listed in the following table.

Variable	Description
ISVLIBS	The directory containing the Host Integration Server 2009 LIB files for Microsoft Windows Server 2003 or Windows 2000.
ISVINCS	The directory containing the Host Integration Server 2009 header files.
SAMPLEROOT	The root directory where the sample code provided as part of the SDK has been installed on a local hard disk.

For example, if you installed the Host Integration Server SDK directory to the default location (C:\Program Files\Microsoft Host Integration Server\SDK), use the following lines to set the variables (assumes Intel binaries are being produced for Windows Server 2003 or Windows 2000.

```
ISVLIBS=C:\Program Files\Microsoft Host Integration Server\SDK\LIB
ISVINCS=C:\Program Files\Microsoft Host Integration Server\SDK\Include
SAMPLEROOT=C:\Program Files\Microsoft Host Integration Server\SDK\Samples\SNA
```

To build a specific sample (APING, for example) using Visual Studio .NET 2003, open the appropriate Microsoft Visual C++ project file (SNA\aping\aping.vcproj, for example) from the **File** menu. Select a configuration and build the sample from the **Build** menu. Each project file has two configurations, one for a DEBUG build and one for a RETAIL build.

CPI-C Samples

APING and APINGD

The sample code for APING and APINGD is ported from code on the IBM Advanced Program-to-Program Communications (APPC)/Common Programming Interface for Communications (CPI-C) disk. These samples are used to test end-to-end connectivity, and simply show that the configuration is correct by exchanging bytes of data across the link. APING is the client or invoking (local) half and attempts to contact APINGD (the APPC/CPI-C ping daemon or server), which is written here as a Microsoft Windows Server 2003 or Windows 2000 service so it can be installed as an invokable TP on the remote computer.

Setup

To use the APING and APINGD samples included in the Microsoft Host Integration Server 2009 SDK, follow these steps:.

To set up APING and APINGD

1. Create an appropriate APPC LU-LU-mode triplet (for example, LUPING-LUPINGD-#INTER).
2. Set up a CPI-C symbolic destination name that contains the configured remote LU and mode. (The TP name for APINGD is APINGD.)
3. Assign the local APPC LU to the APING TP, either by using a registry entry of APING:REG_SZ:*LocalLUAlias* in the **SnaBase\Parameters\Clients** key, or by assigning the local LU as the default local APPC LU for the user who will run APING.

Input and Output

APING is a console application. The syntax of its command line is

aping [**-s***size*] [**-i***iterations*] [**-c***packets*] [**-m***mode*] [**-t***tpname*] *PartnerLUName*

aping [**-s***size*] [**-i***iterations*] [**-c***packets*] *SymbolicDestinationName*

where

-s *size*

Specifies the size, in bytes, of the packet transmitted. The default is 100 bytes.

-i *iterations*

Specifies the number of iterations to carry out. The default is 2.

-c *packets*

Specifies the number of consecutive packets sent by each side. The default is 1.

-m *mode*

Specifies the mode name. The default is #INTER.

-t *tpname*

Specifies the TP name of the TP to start on the remote server. The default is APINGD.

PartnerLUName

Specifies the partner LU name of the destination.

SymbolicDestinationName

Specifies the symbolic destination name of the destination.

Output goes to **stdout** and **stderr**, and details the data rates and timings for each iteration.

Operation

Note that with APINGD, Specify_Local_TP_Name is used to set the local TP name, so Wait_For_Conversation must be used to wait for the Accept_Conversation call to complete, because it will return asynchronously.

The code at the end of APINGD.C is a stub for making any TP into a Windows Server 2003 or Windows 2000 service. There are three routines that are needed: **main**, **ServiceMain**, and **ControlHandler**. For details about how these work, see the comments in the file. The **TPStart** routine is the entry point of the TP proper.

In particular, note that in response to the SERVICE_CONTROL_STOP or SERVICE_CONTROL_SHUTDOWN messages in the **ControlHandler** routine, action should normally be taken to stop the service, but because each run does not last long with these samples, no code is included to take such an action.

CPI-C Samples

Multithreaded APINGD

The version of MPINGD provided in the sample code illustrates how to achieve nonqueued behavior from an invokable TP in Microsoft® Windows Server™ 2003 and Windows® 2000. This means that multiple copies of APING can talk to the same copy of MPINGD at the same time. However, you cannot run multiple copies of a Windows Server 2003 or Windows 2000 service. The features are achieved by always having a thread with an Accept_Conversation outstanding, so that any incoming attach for MPINGD will always be satisfied immediately.

Setup

Setup requirements for MPINGD are the same as for the single-threaded version, APINGD. The remote LU and mode that you use should support parallel sessions so that more than one conversation at a time is possible.

Input and Output

The input and output for MPINGD are the same as for the single-threaded version, APINGD.

Operation

The operation of MPINGD is similar to that of the single-threaded version, APINGD. The same three routines are used (**main**, **ServiceMain** and **ControlHandler**). **ServiceMain** calls the **TPStart** routine. This routine must not return until the service is ready to terminate.

The **TPStart** routine does some initialization, creates the first conversation thread, and then waits on an event created by the **ServiceMain** routine. This event is set when the service control manager issues an order to STOP or SHUTDOWN. When the event is set, it calls WinCPICCleanup, which will cancel any active conversations and return outstanding Accept_Conversation calls, thus making all conversation threads exit. It then marks the service as STOPPED.

The **ThreadStart** routine is the entry point for each of the conversation threads. It issues **Accept_Conversation** and Wait_For_Conversation, and when this completes, it creates another thread to wait for the next attach while the existing thread services the first attach.

CPI-C Samples

CPI-C Send and Receive TPs

These transaction programs (TPs) are Common Programming Interface for Communications (CPI-C) versions of the APPC send and receive TPs. The sample code illustrates the use of asynchronous CPI-C calls.

Setup

In order to use these TPs, follow these steps:

To set up the send and receive TPs

1. Create an appropriate APPC LU-LU-mode triplet.
2. Set up a CPI-C symbolic destination name that contains the configured remote LU and mode. (The default symbolic destination name is CPICRECV.)
3. Assign the local APPC LU to the CPICSEND TP, either by using a registry entry of CPICSEND:REG_SZ:*LocalLUAlias* in the **SnaBase\Parameters\Clients** key, or by assigning the local LU as the default local APPC LU for the user who will run CPICSEND.

For example, use SENDLU-RECVLU-#INTER as your LU-LU-mode triplet. Then, create a CPI-C symbolic destination name CPICRECV containing the application TP name CPICRECV, the partner LU alias RECVLU, and the mode name #INTER. Finally, add the intended user to the users list, and assign SENDLU as the users default local APPC LU.

Input and Output

CPICSEND and CPICRECV use the files Cpicsend.cfg and Cpicrecv.cfg for input. These files should be placed in the folder that contains the TP executable file. These files are similar to the input files for the APPC send and receive TPs.

The following entries are for CPICSEND only:

Line	Default Value	Description
ResultFile =	C:\Cpicsend.out	The file name where the timings results will be stored.
NumSends =	2	The number of Send_Data calls per conversation.
SendSize =	1024	The size of data sent each time in bytes .
ConfirmEvery =	1	The number of **Send_Data** calls between Confirm calls. If ConfirmEvery=0, CPICSEND will not issue CONFIRM verbs.
SymDestName =	CPICRECV	The symbolic destination name.
NumConversations =	1	The number of conversations. This setting must be the same for CPICSEND and CPICRECV. (They do not negotiate the number.) If this value is zero, the TPs will do an infinite number of conversations.

WaitMode=	No	Yes, No, or Block. If WaitMode=No, the verbs are completed through posted windows messages. The TPs issue Specify_Windows_Handle with a window handle so that Windows CPI-C will post completion messages to this window handle. If WaitMode=Yes, verbs are non-blocking and completed using asynchronous call completion. In this case, the TPs issue **Specify_Windows_Handle** with NULL so that the TPs must then issue a Wait_For_Conversation call to wait for the asynchronous call to complete. If WaitMode=Block, all verbs are blocking.

The following entries are for CPICRECV only:

Line	**Default value**	**Description**
ResultFile =	C:\Cpicrecv.out	The file name where the timings results will be stored.
LocalTP Name =	CPICRECV	The local TP name to use on the Specify_Local_TP_Name call.
NumConversations =	1	The number of conversations. This setting must be the same for CPICSEND and CPICRECV. (They do not negotiate the number.) If this value is zero, the TPs will do an infinite number of conversations.
WaitMode=	No	Yes, No, or Block. If WaitMode=No, the verbs are completed through posted windows messages. The TPs issue Specify_Windows_Handle with a window handle so that Windows CPI-C will post completion messages to this window handle. If WaitMode=Yes, verbs are non-blocking and completed using asynchronous call completion. In this case, the TPs issue **Specify_Windows_Handle** with NULL so that the TPs must then issue a Wait_For_Conversation call to wait for the asynchronous call to complete. If WaitMode=Block, all verbs are blocking.

As with CPICSEND, CPICRECV produces C:\Cpicrecv.out (by default) with timings of the conversations in it.

Operation

CPICRECV should be started first. CPICRECV issues Specify_Local_TP_Name to set its local TP name, and then Accept_Conversation to accept a conversation (note that because **Specify_Local_TP_Name** is issued, the **Accept_Conversation** will complete asynchronously).

Both TPs issue Specify_Windows_Handle during initialization to set either the window handle or NULL. CPICSEND calls Set_Processing_Mode after completion of Initialize_Conversation to set the processing mode to non-blocking for this conversation.

After each call is issued, the return code is checked. If the return code is not CM_OPERATION_INCOMPLETE, the call has already completed, so an ASYNC_COMPLETE message is posted to trigger the next call. If **WaitMode** is set to YES and the issued call did not complete immediately, a Wait_For_Conversation call is issued to wait for call completion, at which point an ASYNC_COMPLETE message is posted. If **WaitMode** is set to NO and the issued call did not complete immediately, Windows CPI-C detects call completion and posts an ASYNC_COMPLETE message. The receipt of the ASYNC_COMPLETE message triggers the next call to be issued.

For CPICSEND, each conversation consists of an Allocate call, followed by a given number of Send_Data calls of given size and interspersed with Confirm calls at a given interval, followed by a Deallocate.

CPICRECV issues Receive on completion of the Accept_Conversation, and then issues either **Receive** or Confirmed according to the return from the previous **Receive**.

At any stage, if the TPs encounter an error, they terminate. Use CPI-C API tracing to diagnose problems with the configuration.

Both TPs are built from a single source-code file, CPICSR.C. CPICSEND is compiled only if CPICSEND macro is #defined. This macro is normally defined using the -DCPICSEND option on the command line to the C compiler.

The TPs run as Microsoft® Windows Server™ 2003 or Windows® 2000 applications with a minimized window, the title of which displays the status. When the WndProc of this window, TPWndProc, receives the WM_CREATE message for the window, it triggers the issuing of the first call. When TPWndProc receives an ASYNC_COMPLETE message from Windows CPI-C, it triggers the issuing of the next call, dependent on what the previous call was. When the window is closed, WinCPICCleanupis issued to terminate any active conversations.

CPI-C Samples

AREXEC and AREXECD

The sample code for these two transaction programs (TPs) provides the ability to execute commands on a remote computer and to send the output back across the connection to the invoking TP.

Setup

In order to use the AREXEC and AREXECD samples provided with the Microsoft Host Integration Server 2009 SDK, follow these steps:

To set up AREXEC and AREXECD

1. Create an appropriate APPC LU-LU-mode triplet.
2. Set up a CPI-C symbolic destination name that contains the configured remote LU and mode. (The TP name for AREXECD is AREXECD.)
3. Assign the local APPC LU to the AREXEC TP, either by using a registry entry of AREXEC:REG_SZ:*LocalLUAlias* in the **SnaBase\Parameters\Clients** key, or by assigning the local LU as the default local APPC LU for the user who will run AREXEC.

Input and Output

AREXEC is a console application. The syntax of its command line is

arexec [**-m***mode*] [**-t***tpname*] *destination command*

where

-m *mode*

Specifies the mode name. The default is #INTER.

-t *tpname*

Specifies the TP name.

destination

Specifies the destination. Can be either a symbolic destination name or a partner LU name.

command

Specifies the command string to execute on the remote computer.

The **stdout** and **stderr** from the command executed at the remote end is sent across the link and printed to **stdout** on the invoking end.

Operation

The AREXECD program is a Microsoft Windows Server 2003 or Windows 2000 service, using the same routines in APING, APINGD, and multithreaded APINGD. The execution of the command and sending back of data are done in the routine **execute_and_send_output** in CPICPORT.C. This sample creates a named pipe and connects to the read end of the pipe. It then creates a process to run the command and gives that process a handle to the write end of the pipe as its **stdout** and **stderr**. Then, the data is read from the pipe, and Send_Data is used to send it across the link.

CPI-C Samples

AREMOTE

The sample code for this TP provides the ability to control a text-mode program on a remote computer. AREMOTE is a Win32 console application that implements a client and a server. The AREMOTE server is invoked with the name of the text-mode program that the client wishes to control remotely. The AREMOTE client redirects **stdin** (keyboard input) from the client to the AREMOTE server. In turn, the AREMOTE server redirects **stdin** and **stderr** from the program being controlled back to the AREMOTE client.

Setup

In order to use the AREMOTE sample provided with the Host Integration Server 2009 SDK, follow these steps:

To set up AREMOTE

1. Create an appropriate APPC LU-LU-mode triplet.
2. Set up a CPI-C symbolic destination name that contains the configured remote LU and mode. (The TP name for AREMOTE is AREMOTE.)
3. Assign the local APPC LU to the AREMOTE TP, either by using a registry entry of AREMOTE:REG_SZ:*LocalLUAlias* in the **SnaBase\Parameters\Clients** key, or by assigning the local LU as the default local APPC LU for the user who will run AREMOTE.

Starting the client

The syntax of the command line to start the client end of AREMOTE is as follows.

```
        ServerLU [TPName] [TPName] [LocalLU]
    [Modename] [Lines] [Color] [Color]
```

Parameters

/C

Specifies the client mode.

ServerLU

Specifies the SNA LU for connecting to the server.

/T TPName

Specifies the TP name that the server is using. The default is AREMOTE.

/P TPName

Specifies the TP name that the client is using. The default is AREMOTE

/L LocalLU

Specifies the LU name for the local TP to use. The default is AREMOTE.

/M Modename

Specifies the mode name. The default is #INTER.

/N Lines

Specifies the number of lines to get.

/F Color

Specifies the foreground color. Color options are black, blue, green, cyan, red, purple, yellow, white, lblack, lblue, lgreen, lcyan, lred, lpurple, lyellow, and lwhite.

/B Color

Specifies the background color. Color options are black, blue, green, cyan, red, purple, yellow, white, lblack, lblue, lgreen, lcyan, lred, lpurple, lyellow, and lwhite.

Starting the server

The syntax of the command line to start the server end of AREMOTE is as follows.

```
Cmd [TPName] [Modename] [Color] [Color]
```

Parameters

/S

Specifies the server mode.

Cmd

Specifies a text-mode program that you want to control from another computer.

/T TPName

Specifies the TP name that the server is using. The default is AREMOTE.

/M Modename

Specifies the mode name. The default is #INTER.

/F Color

Specifies the foreground color. Color options are black, blue, green, cyan, red, purple, yellow, white, lblack, lblue, lgreen, lcyan, lred, lpurple, lyellow, and lwhite.

/B Color

Specifies the background color. Color options are black, blue, green, cyan, red, purple, yellow, white, lblack, lblue, lgreen, lcyan, lred, lpurple, lyellow, and lwhite.

Output

The **stdout** and **stderr** from the command run at the remote end is sent across the link and printed to **stdout** on the client. The **stdin** from the client is sent across the link and becomes the **stdin** for the command run at the remote end.

The APPC remote installer (ARSETUP) included with this sample brings up a dialog box that prompts for TP configuration information. The information is then placed in the registry under Microsoft® Windows Server™ 2003 or Windows® 2000. The WIN32 compiler flag specifies that the Win32 version of ARSETUP should be built for use on Windows Server 2003 or Windows 2000.

Notes

The AREMOTE server can also be configured to run as a Windows Server 2003 or Windows 2000 service using the ARSETUP sample utility included in the same folder on the CD.

The AREMOTE client can exit by inputting the following character sequences:

%cQ : Quit but leave the AREMOTE server running.

%cK : Exit and stop the AREMOTE server.

Other special client commands include the following:

%cM : Send a message to the AREMOTE server.

%cP : Show a popup on the AREMOTE server.

%cS : Report the status of the AREMOTE server.

%cH : Provide help describing these special client commands.

CPI-C Samples

LUA Samples

The source code for several sample programs that illustrate using logical unit application (LUA) are included in the Host Integration Server 2009 SDK.

These files are copied to your hard drive during Host Integration Server software or Host Integration Client software installation when the Host Integration Server Software Development Kit option is selected. These samples are installed in the Samples\SNA subdirectory below where the Host Integration Server SDK software is installed (C:\Program Files\Microsoft Host Integration Server \SDK\Samples\NetworkIntegration\LUA, by default).

These sample programs include the following files.

Sample transaction program (TP)	Description
RUI3270	Sample code for a simple emulator based on using the Request Unit Interface (RUI) API. Sample code is provided for Win32 applications. This sample is located in the LUA\RUI3270 folder on the CD.
SLI3270	Sample code for a simple emulator based on using the Session Level Interface (SLI) API. Sample code is provided for Win32 applications. This sample is located in the LUA\SLI3270 folder on the CD.

These samples show how to build a simple 3270 emulator using either the RUI or SLI API. This emulator does not interpret the data it receives from the host, but does demonstrate how to use the APIs to establish a session with the host.

Building the LUA Samples

The logical unit application (LUA) samples are designed to be built using Microsoft Visual C++ 6.0 or later using the command-line compiler, or using Microsoft Visual Studio .NET 2003 or later.

To build the LUA samples, set the environment variables listed in the following table.

Variable	Description
ISVLIBS	The directory containing the Host Integration Server 2009 LIB files for Microsoft Windows Server 2003 or Windows 2000 Server.
ISVINCS	The directory containing the Host Integration Server 2009 header files.
SAMPLEROOT	The root directory where the sample code provided as part of the software development kit (SDK) has been installed on a local hard disk.

For example, if you installed the Host Integration Server SDK directory to the default location (C:\Program Files\Microsoft Host Integration Server\SDK), use the following lines to set the variables (assumes Intel binaries are being produced for Windows Server 2003 or Windows 2000):

```
ISVLIBS=C:\Program Files\Microsoft Host Integration Server \SDK\LIB
ISVINCS=C:\Program Files\Microsoft Host Integration Server \SDK\Include
SAMPLEROOT=C:\Program Files\Microsoft Host Integration Server \SDK\Samples\SNA
```

To build a specific sample (the Win32 version of RUI3270, for example) using Visual Studio, open the appropriate Visual C++ project file (SNA\RUI3270\Win32\NRUI3270.vcproj, for example) from the **File** menu. Select a configuration and build the sample from the **Build** menu. Each project file has two configurations, one for a DEBUG build and one for a RETAIL build.

LUA Samples

Specifying a File Name for Table G for Code Conversion

The sample emulators use a user-defined table referred to as Table G in Host Integration Server 2009 for converting between ASCII and EBCDIC characters. The sample applications require that the file name of this table be specified. Use the COMTBLG registry or create a COMTBLG environment variable to specify the file name. The registry entry is described in the sections on Host Integration Server Client Binary Setup.

A sample Table G file, COMTBLG.DAT, is installed with Host Integration Server in the SYSTEM subdirectory below the root directory where the product is installed. The default location where Host Integration Server is installed is the following:

C:\Program Files\Microsoft Host Integration Server

To use this COMTBLG.DAT file, copy it to the client computers where the sample programs will be run, and specify the file name using the COMTBLG environment variable or the registry entry.

SNA Print Server Data Filter Samples

The PrintServer sample illustrates features of the SNA Print Server Data Filter API. These features can be used to extend the capabilities of the Host Print Service in Host Integration Server 2009. The sample code illustrates how to write a print data filter dynamic-link library (DLL) that will be called by Host Print Service when a print job is initiated, when data is sent to the printer, and when the print job is completed.

Location in the SDK

<installation directory>\Program Files\<version>\SDK\Samples\NetworkIntegration\PrinServer

File Inventory

File(s)	Description
In the /PrintServer/PrintDefFile directory Hplj2.pdf	The sample file to print
In the /PrintServer/PrnFltr directory Makefile NTFilter.c NTFilter.Def NtFilter.h NTFilter.Mdp NTFilter.rc Prntfltr.sln Prntfltr.vcproj	The sample application an related files, The sample program written in C that illustrates use of the SNA Print Server Data Filter API. Also includes an include file with function defines, a resource file, a command-line makefile, and a project file.

How to Use the Sample

The PrnFltr sample is designed to be built using Visual Studio .NET 2003 or later.

To build the PrnFltr sample using the command-line compiler

1. Open a command prompt window
2. Run VSVARS32.bat from the Visual Studio bin directory

   by default, the location is C:\Program Files\Microsoft Visual Studio .NET 2003\Common7\Tools
3. Navigate to \PrintServer\PrnFlter subdirectory, and invoke NMAKE

To build the PrnFltr sample using Visual Studio

1. open the appropriate Visual C++ project file (PrintServer\PrnFltr\ntfilter.vcproj) from the **File** menu.
2. Select a configuration and build the sample from the **Build** menu.

   Each project file has two configurations, one for a DEBUG build and one for a RETAIL build.

Loopback Adapter Sample

Reference

Microsoft.EnterpriseSingleSignOn.Interop

Loopback Adapter Sample

The Loopback Adapter sample is a password sync adapter for Enterprise Single-Sign on (ENTSSO) implemented as a windows NT service written in C#. The sample demonstrates how to use the SSOPSHelper COM component and the ISSOPSWrapper interface to develop a password sync adapter in managed code.

Location in the SDK

<drive>\Program Files\Common Files\Enterprise Single Sign-On\SDK\Samples\LoopbackAdapter

File Inventory

The following table shows the files in the sample and describes their purpose.

File(s)	Description
AssemblyInfo.cs	Contains the assembly information for the project.
Createadapter_LoopbackAdapter.xml	Used with the ssops command-line tool to create the prototype adapter.
LoopbackAdapter.cs LoopbackAdapter.csproj LoopbackAdapter.Designer.cs LoopbackAdapter.resx	Contains the sample code for crating the Loopback adapter.
LoopbackAdapter.sln	Organizes all the projects, project items, and solution items into the Loopback Solution by providing the environment with references to their locations on disk. Use Visual Studio to view this file, or double-click the file to start Visual Studio 2005 and displays the solution in Solution Explorer.
LoopbackAdapter.suo	Records all of the options associated with the Loopback Adapter Solution so that each time you open it, it includes customizations that you have made.
ProjectInstaller.cs ProjectInstaller.Designer.cs ProjectInstaller.resx	Contains the sample code for the project installer.
Properties_LoopbackAdapter.xml	Property definitions for the Loopback Adapter.
Program.cs	Contains the basic framework of the application.
README.txt	Shows the steps to build and run the application.
